PLEN02_1 | How nature and nurture conspire to regulate brain development and plasticity

M. Greenberg
Harvard Medical School, Boston, MA, USA

Experience-dependent neuronal activity plays a critical role in shaping the connectivity and function of the central nervous system. These actions are mediated in part by the action of a program of neuronal activity-driven gene expression. Investigation of these gene expression programs has uncovered important roles in dendritic growth, the development of excitatory and inhibitory synapses, the composition of protein complexes at pre- and post-synaptic sites, and the production of neuropeptides that control neural circuit development. Moreover, defects in the activity-dependent gene program contribute to disorders of human cognition. Thus, study of this transcriptional response promises new insights into neuronal plasticity and disease.
Disclosure: Nothing to disclose.

PLEN02_2 | How the brain barriers ensure CNS immune privilege

B. Engelhardt
University of Bern, Theodor Kocher Institute, Switzerland

Proper communication of central nervous system (CNS) neurons requires a homeostatic environment, which does not tolerate uncontrolled entry of blood components including immune cells into the CNS parenchyma. The CNS has thus developed a unique relationship with the immune system known as CNS immune privilege. CNS immune privilege is established by endothelial, epithelial, glial and fibroblasts composed brain barriers. The brain barriers establish compartments in the CNS that differ with regard to their accessibility to immune cells and immune mediators. We have developed reporter mice allowing to image the brain barriers and immune cell and immune mediator movement in the CNS by in vivo live cell imaging. This allows to determine the barrier functions of the different brain barriers and how their disturbance affects CNS immunity during neuroinflammatory conditions. Based on our studies we propose that CNS immune privilege relies on the proper function of the brain barriers, which allow for CNS immune surveillance but prohibit activation of immune responses from the CNS parenchyma unless it is directly injured.
Disclosure: Nothing to disclose.

PLEN02_3 | How clinical observations challenge neuroscience

M. Vidailhet
Groupe Hospitalier de la Pitié Salpêtrière, Paris, France

PLEN02_4 | Myasthenia gravis; Individualized treatment based on a well-defined disease pathogenesis

N. E. Gilhus
Department of Neurology, Haukeland University Hospital and Department of Clinical Medicine, University of Bergen, Bergen, Norway

Background: Myasthenia gravis (MG) and MG subgroup is diagnosed by clinical history and examination, autoantibody testing, and electrophysiological tests.
Pathogenesis: Autoantibodies binding to the postsynaptic membrane at the neuromuscular junction cause MG. IgG antibodies to acetylcholine receptor (AChR), MuSK, or LRP4 impair AChRs by receptor cross-linking, complement activation, AChR blockade, or impaired AChR clustering. IgG subclass varies. Thymus hyperplasia and thymoma can both induce AChR autoantibody production and MG. Active synthesis of new AChRs is ongoing in MG, and the structural postsynaptic changes are reversible.
Treatment: MG treatment should be in accordance with international guidelines and at the same time adapted to the individual patient. Treatment decisions should be taken by neurologist and patient together. The treatment should be based on autoantibody status, MG generalization and severity, and thymus pathology. Symptomatic drug therapy with acetylcholine-esterase inhibition represents a primary therapy. Immunotherapy should be offered to all patients who have not met their treatment goals. The combination of prednisolone and azathioprine represents first-line immunotherapy. Rituximab is an alternative, especially in MuSK-MG and in newly-onset AChR-MG. Mycophenolate, tacrolimus, and methotrexate represent other commonly used immunosuppressants. Thymectomy should be undertaken with a thymoma and in generalized MG with AChR antibodies and debut below 50 (65) years. Complement inhibitors and

FcRn blockers have a proven and clinically meaningful effect in most MG patients. They improve symptoms already after 1-2 weeks. Due to very high drug costs their use is restricted to difficult-to-treat and severe MG, and depends on local availability, formal approval, and refunding policies. New and experimental therapies may be considered in refractory cases. Physical activity is safe and beneficial in MG. At least 150 minutes per week is recommended.

Conclusions: Successful MG treatment depends on the timely combination of interventions. Most patients do well, but there is room for further improvement.

Invasive neuromodulation: Hot topics and future directions

PLEN03_1 | Deep brain stimulation for the treatment of movement disorders

E. Moro
CHU de Grenoble, France

PLEN03_2 | Focused ultrasound for the treatment of tremor and Parkinson's disease

R. Martínez-Fernández
HM CINAC, University Hospital HM Puerta del Sur, Móstoles, Madrid, Spain

Over nearly a decade, MR-guided focused ultrasound technology has fully integrated into clinical practice. Utilized in its high-intensity modality for brain thermoablation, it has generated abundant high-quality scientific evidence and has become a standard treatment, particularly for Essential Tremor and Parkinson's Disease, its primary indications. While the number of sites offering the therapy and the yearly number of interventions increase exponentially, indications expand to other movement disorders such as dystonia or psychiatric conditions. Further broadening the tool's applications and unlocking its full potential will partially depend on advancements in the technology itself, along with increased clinical experience. In addition to its use for therapeutic brain ablation, focused ultrasound can also be applied in the low-intensity modality. In this mode, it enables focal and transient Blood-Brain Barrier opening, liquid biopsy, or neuromodulation. These approaches, which have already been preliminarily explored, may allow us to move beyond the symptomatic effects and impact disease pathogenesis, facilitate early and specific diagnosis, or achieve non-invasive modulation of brain activity. This presentation aims to provide an overview of the current state-of-the-art and future prospects for FUS technology in clinical neurology

Disclosure: I have received speaker honoraria form Insightec and Palex outside the context of this presentation.

PLEN03_3 | Vagal nerve and deep brain stimulation for the treatment of refractory epilepsy

P. Boon
Ghent University Hospital, Belgium

PLEN03_4 | Spinal cord stimulation for the treatment of chronic pain

C. de Vos
Center for Pain Medicine, Erasmus University Medical Center, Rotterdam, The Netherlands

Spinal Cord Stimulation is an innovative invasive therapy, which is applied in chronic pain patients who are otherwise therapy resistant. The very first implantation was already in 1967. Although over 50 years have passed, the quality of evidence of its efficacy is still debated. This is partly due to the fact that until recently no paresthesia-free stimulation modes were available, and therefore sham controlled studies were not possible. It is also partly a due to a lack of understanding of its mechanisms of action and a lack of more objective patient related outcome measures. Fortunately, times are changing rapidly. Since the introduction of paresthesia-free stimulation modes, sham controlled studies are conducted. In addition, are we starting to better understand the mechanisms of action of Spinal Cord Stimulation, based on both animal research and more objective measures to characterize physiological effects in chronic pain patients.

Highlights and breaking news

PLEN04_8 | EJoN: Long-term risk of recurrent vascular events and mortality in young stroke patients: Insights from a multicenter study

J. Broman[1]; S. Fandler-Höfler[2]
[1]*Department of Neurology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland;* [2]*Department of Neurology, Medical University of Graz, Graz, Austria*

Introduction: Although the incidence of stroke in the young is rising, data on long-term outcomes in these patients are scarce. We thus aimed to investigate the long-term risk of recurrent vascular events and mortality in a multicenter study.

Methods: We followed 396 consecutive patients aged 18–55 years with ischemic stroke (IS) or transient ischemic attack (TIA) enrolled in three European centers during the period 2007–2010. A detailed outpatient clinical follow-up assessment was performed between 2018 and 2020. When an in-person follow-up visit was not possible, outcome events were assessed using electronic records and registry data.

Results: During a median follow-up of 11.8 (IQR 10.4–12.7) years, 89 (22.5%) patients experienced any recurrent vascular event, 62 (15.7%) had any cerebrovascular event, 34 (8.6%) had other vascular events, and 27 (6.8%) patients died. Cumulative 10-year incidence rate per 1000 person-years was 21.6 (95% CI 17.1–26.9) for any recurrent vascular event and 14.9 (95% CI 11.3–19.3) for any cerebrovascular event (Table 1). The prevalence of cardiovascular risk factors increased over time, and 22 (13.5%) patients lacked any secondary preventive medication at the in-person follow-up. After adjustment for demographics and comorbidities, atrial fibrillation at baseline was found to be significantly associated with recurrent vascular events.

Conclusion: This multicenter study shows a considerable risk of recurrent vascular events in young IS and TIA patients. Further studies should investigate whether detailed individual risk assessment, modern secondary preventive strategies, and better patient adherence may reduce recurrence risk.

Disclosure: Nothing to disclose.

What will change the neurologist's care for persons of child-bearing age with epilepsy and migraine?

SYMP01_1 | Planning pregnancy in women with epilepsy and migraine using antiseizure medications

T. Tomson
Dept of Clinical Neuroscience, Karolinska Institutet, Solna, Sweden

Use of medication during pregnancy requires consideration of potential risks to the fetus due to medication exposure and risks to the fetus as well as the pregnant woman associated with sub-optimally treated condition. The outcome of such risk-benefit analyses will vary depending on the maternal condition under treatment. Poorly controlled epilepsy can cause serious harm to the mother and the fetus, which rarely is the case in migraine. In recent years new data have emerged on the risks to the fetus with exposure to different ASMs and on differences between ASMs in this regard. This has led regulators such as FDA and EMA to issue restrictions on the use of some ASMs (contraindications for valproic acid and topiramate, both also used in prophylactic treatment for migraine) in female patients of childbearing potential. In the case of active epilepsy, it is usually necessary to replace these medications with other ASMs. Finding a suitable alternative can take time, sometimes a year or more. Therefore, ideally young girls or women should not be started on these medications unless absolutely necessary. Recent data indicate that lamotrigine, levetiracetam and oxcarbazepine are among the safest ASMs. These have become preferred first-line medications for the treatment of epilepsy in patients of child-bearing potential. Pre-pregnancy optimization also includes establishing the lowest effective dose of the selected medication and documentation of the corresponding plasma concentration to serve as individual base-line for follow-up monitoring during pregnancy. Folate supplementation should also be initiated well in advance of conception.

Disclosure: Funding from Accord, Glenmark, GSK, UCB, Eisai, Ecu Pharma, Bial, Teva, Sanofi, SF Group, GW Pharma, Zentiva, and Angelini as donations to the EURAP pregnancy registry; Speaker honoraria from Eisai, Angelini, GSK and UCB.

SYMP01_2 | Care for persons with epilepsy and migraine in pregnancy, delivery and postpartum

B. Schmitz
Department of Neurology, Stroke Unit and Center for Epilepsy, Vivantes Humboldt-Klinikum Berlin, Germany

Both epilepsy (prevalence 1%) and migraine (prevalence 40%) are common disorders in women of childbearing age. Therefore, neurologists should be familiar with respect to 1. Interactions between prophylactic treatments and oral contraceptives 2. Pregnancy related changes with respect to disease severity 3. Safe acute and prophylactic treatments during pregnancy and lactation. The lecture will discuss praxis-relevant actual data with respect to pregnancy, delivery and the postpartum period in women with migraine and / or epilepsy. Clinical recommendations for counseling of patients are presented.

Disclosure: Bettina Schmitz received Honoraria Angelini / Arvelle, Bial, Desitin, Eisai, Precisis, Sanofi, UCB-Pharma Memberships and Commissions DGN, DGfE, DEGUM, DSG, BGPN Michael Foundation Chair of board of trustees EURAP Coordination Germany

SYMP01_3 | Antiseizure medication in men

M. Bjork
Haukeland University Hospital - Helse Vest, Bergen, Norway

SYMP01_4 | Clinical care of children exposed to antiseizure medications in utero

R. Bromley
University of Manchester/Royal Manchester Children's Hospital, UK

Prenatal exposure to certain antiseizure medications is associated with higher rates of congenital anomalies and altered neurodevelopmental outcomes. Offspring with such symptoms therefore become patients themselves, with a constellation of lifelong health conditions which require clinical review, diagnosis and care management plans. This talk will summarise current evidence regarding the physical and neurodevelopmental outcomes of children exposed to

antiseizure medications. It will demonstrate how, in some instances, these altered fetal and child outcomes fit together as a constellation of symptoms which form a diagnosable fetal exposure syndrome. Based on experience with fetal valproate syndrome/fetal valproate spectrum disorder (ICD 11 LD2F.03) current international guidelines suggest that clinical diagnosis for fetal exposure syndromes should be multidisciplinary in nature and include health, dysmorphology, speech therapy, physiotherapy, neuropsychological/ neurodevelopmental assessments and genetic investigations. Health service utilisation over the course of development can be high due to wide ranging physical and neurodevelopmental symptoms and key recommendations are made regarding multidisciplinary clinical care across the lifespan. The need to collaborate with educational and social services to reduce secondary impacts (e.g., poorer mental health) and to maximise educational and future occupational achievements is outlined. Finally, the role of an optimised healthcare service for children exposed to medications within the pharmacovigilance framework for antiseizure medications is discussed.

Disclosure: Dr Bromley's institution has received consultancy fees from UCB Pharma for her participation in a women's health initiative.

EAN/MDS-ES: Towards a biological classification of Parkinson's disease

SYMP02_1 | Genetic status defining Parkinson's disease

C. Klein
University of Lübeck, Germany

SYMP02_2 | Synuclein status defining Parkinson's disease

L. Parkkinen
Nuffield Department of Clinical Neurosciences, Oxford Parkinson's Disease Centre, University of Oxford, UK

Introduction: Technological advances have made it possible to define the presence of Parkinson's disease (PD) well before the onset of symptoms, and thus, we are moving away from the clinical to molecular diagnosis, similarly to Alzheimer's disease. This molecular definition of PD depends on alpha-synuclein (aSyn) seed amplification assay (SAA) that detects pathological aSyn in the CSF or other biosamples of PD and at risk-patients.

Methods: We examined the diagnostic value of the SAA quantitative parameters and whether they could be used to stratify between different synucleinopathies, monitor disease progression and predict disease conversion in patients with idiopathic REM sleep behaviour disorder (iRBD).

Results: aSyn SAA was performed in CSF samples from 74 PD, 24 multiple system atrophy (MSA) and 45 iRBD patients alongside 55 healthy controls. aSyn SAA showed 89% sensitivity and 96% specificity for PD; there was no correlation between SAA quantitative parameters and severity of clinical symptoms (e.g. UPDRS) but the different PD phenotype clusters differed in their SAA positivity. The sensitivity in MSA was 75%, and some SAA quantitative parameters were able to stratify between PD and MSA patients. Finally, we were able to detect CSF aSyn aggregation in 64% of RBD patients at baseline before they converted to synucleinopathy.

Conclusions: Our results show that aSyn SAA classifies people with PD with high sensitivity and specificity. It also provides information about molecular heterogeneity by stratifying between PD and MSA and different phenotypic clusters of PD. Importantly, aSyn SAA detects prodromal iRBD participants before diagnosis.

Disclosure: Nothing to disclose.

SYMP02_3 | Neurodegeneration and clinical status defining Parkinson's disease

J. Corvol
Sorbonne University, Pitié-Salpêtrière Hospital, Paris Brain Institute, Paris, France

Parkinson's disease is characterized by the presence of cardinal motor symptoms - akinesia, rigidity and rest tremor - related to the degeneration of dopaminergic neurons in the substantia nigra. Clinical diagnosis criteria currently rely on detecting these motor signs and excluding differential diagnosis. The denervation can be demonstrated through SPECT or PET imaging marking dopaminergic terminals. However, it is now clearly shown that denervation begins several years before the onset of motor symptoms, defining the premotor phase of the disease. In addition, the denervation also involves non-dopaminergic area responsible for non-motor symptoms, which may occur before the diagnosis during a prodromal phase in some patients. Novel imaging markers such as brain MRI neuromelanine, MIBG SPECT or FDG PET have shown good accuracy in detecting dopaminergic and non-dopaminergic denervation at the different stages of the disease. Future definitions and staging systems of Parkinson's disease must therefore incorporate both motor and non-motor features, along with dopaminergic and non-dopaminergic denervation, to comprehensively address the continuum of the disease, from its presymptomatic to its symptomatic stage.

Disclosure: J.C.C. has served in advisory boards for Alzprotect, Bayer, Biogen, Denali, Ferrer, Idorsia, iRegene, Prevail Therapeutic, Servier, Theranexus, UCB; and received grants from Sanofi and the Michael J Fox Foundation outside of this work.

SYMP02_4 | Integrative biological Parkinson's disease definitions

G. Höglinger
Ludwig-Maximilian University Hospital, Munich, Germany

EAN/EFAS: Through the looking glass: Towards autonomic markers, a raising awareness in common neurological diseases

SYMP03_1 | Autonomic dysfunction in stroke

M. Hilz
Depts. of Neurology, University of Erlangen-Nuremberg, Erlangen, Germany & Icahn School of Medicine at Mount Sinai, New York, NY, USA

Autonomic dysfunction increases the risk of stroke, e.g. in patients with diabetic autonomic neuropathy or any patient with cardiovascular autonomic dysfunction. Vice versa, stroke frequently causes autonomic nervous system dysfunction which adds to post-stroke mortality. Stroke-induced lesions of the central autonomic network cause multiple autonomic disorders, such as bladder dysfunction which is a common cause of post-stroke nursing home admission, but also post-stroke hyperglycemia, sleep disturbances, or cardiac events, including atrial fibrillation, congestive heart failure, myocardial infarctions, Takotsubo cardiomyopathy, and sudden death. Particularly insular lesions but also frontal, temporal, or parietal lobe lesions can be associated with autonomic dysregulation or increased mortality rates. Stroke severity seems to correlate with the degree of cardiovascular autonomic dysregulation. Increasing stroke severity is associated with a decrease in the overall autonomic cardiovascular modulation, particularly in cardiovagal modulation and baroreflex sensitivity, and results in a relative predominance of sympathetic activity. These changes worsen the prognosis of stroke patients and increase their risk of mortality. Psychological stress associated with the onset of stroke and the subsequent emergency situation very likely contributes to and worsens autonomic dysregulation and must be mitigated. Early initiation of cardiovascular and antihypertensive treatment might promote recovery of post-stroke cardiovascular autonomic dysregulation.

Disclosure: I received travel support and lecturing honoraria from Amicus Therapeutics and Sanofi and grant support from Sanofi. None of the support is related to my presentation.

SYMP03_2 | Autonomic manifestations of epilepsy

R. Thijs
Stichting Epilepsie Instellingen Nederland, Heemstede, The Netherlands

Autonomic manifestations of seizures are frequent; they are generally more prominent in focal seizures that originate from the temporal lobe and are particularly pronounced in focal- to- bilateral and generalized tonic–clonic seizures (TCSs). Ictal autonomic manifestations tend to be underreported because they might not be recognized as seizure- related, or might be too subtle or not remembered. Autonomic seizure manifestations can provide clues to the localization or lateralization of the ictal onset zone but should always be considered in the context of a complete diagnostic epilepsy evaluation. Ictal asystole is the most frequent clinically relevant seizure- related arrhythmia. The key clinical expressions include flaccid falls with injuries and other signs of syncope (for example, intense pallor, jerks, stiffening and gasping) during the course of a temporal lobe seizure. SUDEP contrasts with self- limiting autonomic features because it typically occurs in the aftermath of a TCS, whereas ictal apnoea and ictal asystole are associated with focal — mostly temporal lobe — seizures. SUDEP has a spectrum of heterogeneous causes but is predominantly attributable to TCS- triggered postictal apnoea–asystole.

Disclosure: RDT's s salary is supported by the Christelijke Vereniging voor de Verpleging van Lijders aan Epilepsie. RDT has received personal compensation for serving on the Advisory Boards or Speaker's Bureau for Xenon, Theravance, Novartis, Eisai, Angelini Pharma, LivAssured and UCB Pharma.

SYMP03_3 | Cardiovascular autonomic dysfunction in sleep disorders

G. Calandra-Buonaura
University of Bologna, Bologna, Italy

The autonomic nervous system and sleep are closely related. Neuronal populations involved in the transition from wakefulness to sleep and the subsequent development of sleep stages are located near central areas involved in autonomic functions, including cardiovascular autonomic control, and are mutually interconnected with them. Thus, it is not surprising that sleep dysfunction can result in altered cardiovascular autonomic control and that, similarly, several general medical and neurological disorders can cause both cardiovascular autonomic dysfunction and sleep disorders. The presentation describes the clinical features, presumed pathogenetic mechanisms, and diagnostic and prognostic implications of the impairment of cardiovascular autonomic control associated with sleep disorders such as primary insomnia, restless legs syndrome, obstructive sleep apnea, and REM sleep behavior disorder. Most of the available data suggest that the association between sleep disorders and altered autonomic control of the cardiovascular system needs to be systematically evaluated for its important clinical implications. Understanding the mechanism of this association may also provide insights into the interaction between the autonomic nervous system and sleep.

Disclosure: Nothing to disclose.

SYMP03_4 | Autonomic dysfunction in movement disorders

A. Fanciulli
Innsbruck Medical University Department of Neurology, Innsbruck, Austria

Dysautonomia is a frequent non-motor feature in both frequent and rare movement disorders and its occurrence has diagnostic,

therapeutic and prognostic implications. While autonomic referral centers are not widely available, there are several bedside screenings and first line therapeutic measures, which can be applied to improve the diagnostic accuracy and functional outcome of individuals living with movement disorders. This lecture will provide an overview on such measures for the most important autonomic domains and discuss the clinical red flags, when second line interventions and shared care approaches with allied specialties (i.e., urologists, gastroenterologists, ENT doctors) and healthcare professionals are recommended.

Disclosure: Nothing to disclose.

Stroke in women: Specific risk factors and optimal management

SYMP04_1 | Pathophysiological mechanisms of sex differences in stroke

A. Fonseca
Department of Neurology, Hospital de Santa Maria, Faculdade de Medicina, Universidade de Lisboa, Portugal

Differences in physiology between females and males underlie some of the differences between the sexes seen in stroke. Women go through specific development stages throughout their lives, which are associated with physiological and hormonal changes that can, at specific time points, influence the risk of cerebrovascular diseases. These life stages included the reproductive years, including pregnancy, and adulthood after menopause. Experimental studies conducted in recent years have also demonstrated intrinsic sex differences in animal models that may have relevance to our understanding of stroke in clinical populations.

Disclosure: Nothing to disclose.

SYMP04_2 | Stroke in pregnancy and puerperium

A. Arsovska
University Clinic of Neurology, University "Ss. Cyril and Methodius"- Faculty of Medicine, Skopje, North Macedonia

Introduction Most strokes in the general population are ischaemic (80–85%), but in pregnancy, ischaemia, haemorrhage and venous thrombosis have a similar contribution to aetiology. Pregnancy-associated stroke occurs in 18% of strokes in women younger than 35 years. The stroke incidence is 25–34 cases / 100,000 deliveries (which is three times the incidence in nonpregnant female individuals aged 15–44 years). Methods The risk is increased 9 times at the time of delivery and 3 times in the early postpartum period. During pregnancy, the female body undergoes significant physiological changes that may predispose women to thromboembolism and cardiovascular events. Associated risk factors are hematological disorders, preeclampsia and eclampsia, gestational diabetes, post-partum period, race, age older than 35 years and other. In pregnancy, imaging should be done promptly to allow early treatment and optimise outcomes. MRI is the preferred first-line imaging modality in pregnancy because it does not expose the pregnant woman to radiation. Results Regarding management of stroke during pregnancy and postpartum, the European Stroke Organization has recently published guidelines on stroke in women. Pregnant and postpartum women with acute disabling ischaemic stroke (occurring at least 10 days after delivery), who otherwise meet eligibility criteria, can be treated with intravenous thrombolysis or mechanical thrombectomy after appropriately assessing the benefit/risk profile on an individual basis. Conclusion Team approach is essential, planning is important, and management of these cases should be individualized.

Disclosure: Nothing to disclose.

SYMP04_3 | Migraine and risk of stroke in women

D. Mitsikostas
Aeginition Hospital, Athens, Greece

SYMP04_4 | Hormonal therapy and risk of stroke

H. Budinčević
Sveti Duh University Hospital, Department of Neurology, Zagreb, Croatia

Hormonal therapy is supplementing women with hormones lost during the menopausal transition to relieve symptoms associated with menopause. Conventional hormonal therapy includes estrogen alone or with a progesterone component to mimic hormones created by the human ovary. Women appear to be protected from stroke before menopause, which might be related to ovarian hormones (endogenous estrogen). The stroke risk factors specifically associated with women include oral contraceptive use and the use of exogenous hormonal therapy for menopausal symptoms. Recent European Stroke Organisation guidelines do not recommend the usage of hormonal therapy in postmenopausal women to reduce stroke risk. However, prior hormonal therapy has no impact on mortality in postmenopausal women with acute stroke. Similarly, American Heart Association guidelines recommend avoiding the use of oral contraceptive agents with exogenous estrogen in women with migraine with aura and prior ischemic stroke. Timing and route of administration may play an essential role in reducing stroke risk. The time of initiation of hormonal therapy, with initiation at <60 years of age or within ten years of menopause, appears to be associated with reduced cardiovascular risk (which includes stroke). Iatrogenically induced menopause during the premenopausal period is associated with higher cardiovascular risk, too.

Disclosure: Nothing to disclose.

Therapeutic advances in neuromuscular disorders

SYMP05_1 | From gene to RNA therapies: New treatment horizons for genetic neuromuscular disorders

S. Sacconi
CHU NICE PASTEUR 2, Nice, France

SYMP05_2 | Novel treatments in hereditary neuropathies

S. Peric
University of Belgrade – Faculty of Medicine, University Clinical Center of Serbia – Neurology Clinic, Belgrade, Serbia

Peripheral neuropathy may be the primary feature of inherited disease, or a part of the complex diseases. Only several drugs have been tested in humans for hereditary diseases where neuropathy is a primary feature. Phase 3 study was conducted to evaluate a combination of baclofen, naltrexone, and sorbitol in CMT1A. Clinical improvements were observed, but crystal formation in formulation caused a significant discontinuation. Aldose reductase inhibitor is temporarily investigated in patients with SORD neuropathy. Hereditary transthyretin amyloidosis (hATTR) is a disease where neuropathy is a part of the complex phenotype. Safety and efficacy of tafamidis, TTR stabilizer, in early-stage polyneuropathy have been demonstrated. Inotersen is an antisense oligonucleotide that proved its efficacy in a phase 3 trial conducted on patients hATTR polyneuropathy. Eplontersen is an antisense oligonucleotide conjugated to N-acetylgalactosamine which improves its distribution. Patisiran is an intravenous small interfering RNA (siRNA). Positive effects of the drug were registered in a phase 3 trial in adult patients with a hATTR polyneuropathy. Vutrisiran is a subcutaneous siRNA that was more efficacious than patisiran in a phase 3 open-label study. Another siRNA, givosiran, that silences the expression of the gene ALAS1, has been approved for the treatment of acute hepatic porphyrias. Givosiran treatment resulted in sustained reduction of annualized attack rate. Two approved enzyme replacement therapies for Fabry disease have shown favourable effects on peripheral neuropathy. Idebenone has been approved for treatment of Leber neuropathy. In conclusion, hereditary neuropathies have recently entered a therapeutic era.

Disclosure: Nothing to disclose related to this presentation.

SYMP05_3 | The landscape of new treatments in hereditary myopathies

A. Toscano
AOU G. Martino, Messina, Italy

SYMP05_4 | Advances of treatments in myasthenia gravis

K. Claeys[1,2]
[1]*Department of Neurology, University Hospitals Leuven, Leuven, Belgium;* [2]*Laboratory for Muscle Diseases and Neuropathies, Department of Neurosciences, KU Leuven, and Leuven Brain Institute (LBI), Leuven, Belgium*

Myasthenia gravis (MG) is a chronic autoimmune disease of the postsynaptic neuromuscular junction characterized by fluctuating muscle weakness and fatigability. Despite adequate dosing and longer duration of treatment, standard immunomodulatory treatment often does not achieve sufficient improvement of symptoms, leading to considerable morbidity in MG patients. Furthermore, conventional immunotherapy often is associated with severe and invalidating side effects and intolerance. This is a challenge for patients and treating neurologists, and clearly illustrates the need for new therapeutic possibilities. Newer immunotherapies more specifically address distinct targets of the main immunological pathways in MG. They include terminal complement C5 inhibitors, monoclonal antibodies against fragment crystallizable neonatal receptor (FcRn), B-cell depleting agents (anti-CD19 and 20, and B cell activating factor (BAFF) inhibitors), T-cells and cytokine-based therapies (chimeric antigen receptor T-cell (CART-T) therapy), and proteosome inhibitors. The new agents may have advantages over conventional immunosuppressive therapies for MG in terms of more favorable side effect profile, faster onset of action and the potential for a sustained and long-term remission. In my presentation, I will give an overview of the novel therapeutic agents that are already available or will become available in the following years. Also, the challenges associated with the new therapeutic options will be discussed.

Disclosure: KGC received speaker and/or advisory board honoraria from Alexion, Alnylam, Amicus Therapeutics, argenX, Biogen, Ipsen, Janssen Pharmaceuticals, Lupin, Pfizer, Roche, Sanofi-Genzyme, UCB. KGC is Chairholder of the Emil von Behring Chair for Neuromuscular and Neurodegenerative Disorders by CSL Behring.

EAN/ECTRIMS/EPNS: Paediatric- and late-onset multiple sclerosis: The extremes of the disease

SYMP06_1 | Clinical and neuroimaging features of paediatric multiple sclerosis

M. Rocca
Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; Vita-Salute San Raffaele University, Milan, Italy

Multiple sclerosis (MS) is a chronic, inflammatory, demyelinating, and neurodegenerative disease of the central nervous system (CNS), mostly affecting young adults. Approximately 3% to 10% of MS patients experience their first attack during childhood;

onset under 10 years old is probably less than 1% of all MS cases. Despite a relatively higher relapse rate and the tendency to form larger brain lesions compared to their adult counterparts, patients with paediatric-onset (PO) MS take longer to accrue similar levels of disability and to evolve to secondary progressive (SP) disease course, although they tend to reach a certain level of disability at a younger age. More than 30% of POMS patients experience cognitive impairment, with a prominent involvement of attention, memory, processing speed, expressive language, and visuomotor integration. Longitudinal clinical studies have shown that more than half of children with MS show cognitive impairment after 10 years of follow-up. Overall, these impairments may cause significant functional impact on daily life activities and may negatively influence the subject's academic achievements. Magnetic resonance imaging (MRI) plays a crucial role in the diagnosis of MS, monitoring disease progression and treatment response, both in children and adult patients with MS. Considering MRI findings, conceptually, there are many possible reasons why the MRI features (lesions, NAWM and GM damage) in children with MS may differ from that of adults: (1) the subclinical phase of the disease process is inherently brief in young patients by virtue of their young age; (2) although the majority of developmental modifications in myelin biochemistry take place during the first 24 months of life, full myelin maturation proceeds in a caudal-rostral pattern until early adulthood, and thus, myelin maturity may influence the regional proclivity for MS related damage, particularly in the very young MS patients; and (3) children may differ from adults in their innate capacity for myelin repair, leading to fundamental differences in the MRI aspects. All of these mechanisms may clearly contribute to explain differences of clinical and cognitive outcomes between paediatric and adult patients. In line with this, multiple studies have shown that MRI features in POMS patients are different from those of adults. Both POMS and adult-onset (AO) MS patients experience partial lesion recovery; however, the extent of lesional recovery is greater in POMS patients. On the other hand, maturation of the frontal lobe white matter during the second decade of life has been suggested as a possible mechanism which confers a sort of protection from MS-related damage in paediatric patients. Maturation effects might also influence a different functional reorganization in AOMS vs POMS, since the long-range connections between the posterior cingulate cortex and the anterior prefrontal cortex have been shown to mature with age and to be associated with the development of cognitive abilities. Juvenile MS patients have also an impaired age-expected brain growth, which results in abnormally small brain volumes. Additionally, a progressive loss of volume, consistent with brain atrophy, was detected in adolescent patients, likely to indicate a failure of the anticipated resiliency of the maturing CNS to the brain injury.

Disclosure: Nothing to disclose.

SYMP06_2 | Clinical and neuroimaging features of late-onset multiple sclerosis

C. Louapre
Hôpital Pitié Salpêtrière, Paris, France

SYMP06_3 | Escalation and de-escalation of treatments in pediatric multiple sclerosis

L. Kappos
Research Center for Clinical Neuroimmunology and Neuroscience Basel (RC2NB), Basel, Switzerland

With the increasing number of available approved and off-label treatments and the increasing experience with these treatments in pediatric MS populations the questions around their differential indication become more relevant. In addition to the known considerations in adult-onset MS, which most of us would consider as roughly applicable to pediatric MS, decisions in pediatric MS need to be based on the consideration of several questions more relevant or even specific to pediatric populations. On the side of efficacy, the more prominent role of acute inflammation, the part of MS pathogenesis best addressed by currently available treatments invites the use of the most effective treatments and not to escalate. On the side of adverse events, we need to address the concern about possible adverse impact on the immature / maturing immune system. Generally accepted and evidence-based criteria for escalation and de-escalation are not available yet. After a short review about comparable efficacy of DMTs in pediatric MS emerging – more "eminence based" – algorithms will be discussed as well as paths towards generating the necessary evidence with pragmatic trials based on well curated high quality pediatric MS cohorts.

Disclosure: No disclosure.

SYMP06_4 | Escalation and de-escalation of treatments in late-onset multiple sclerosis

F. Piehl
Department of Clinical Neuroscience, Karolinska Institutet, and Department of Neurology, Karolinska University Hospital, Stockholm, Sweden

Relapsing-remitting multiple sclerosis (RRMS), an inflammatory and neurodegenerative disease of the central nervous system, is usually diagnosed in early mid-life, but presentation at older ages is not uncommon. Large natural cohort studies demonstrate that while inflammatory disease manifestations with MS relapses decrease

with ageing, the risk of progressive worsening of disability instead increases. As the benefit of existing disease-modulatory therapies (DMTs) mainly concerns their capacity to suppress risk of MS relapse, the relative benefit may be different at higher ages. In fact, sub-group analyses from randomized controlled trials (RCTs) in RRMS generally indicate a reduced relative benefit regarding reducing risk of relapse and disability accrual in people aged above 40 years of age. Furthermore, there is only scarce information on if also safety aspects are impacted by age, especially since RCTs apply age limits and restrictions on comorbidities. However, the fact that comorbidities, including susceptibility to infections, increases at older ages may translate into greater treatment risks compared with younger individuals, at least regarding DMTs requiring continuous administration over extended periods of time. This also implies that treatment de-escalation or stopping should be considered in older individuals with stable disease, in particular if emerging comorbidities may impact the benefit-risk balance negatively. Until recently, the risk of disease reactivation upon stopping a DMT has been addressed only by observational studies, but recently a first RCT was completed. The evidence base for treatment decisions in people with late-onset MS will be discussed in this presentation.

Disclosure: FP has received research grants from Janssen, Merck KGaA and UCB, and fees for serving on DMC in clinical trials with Chugai, Lundbeck and Roche, and preparation of expert witness statement for Novartis.

Secondary prevention of cognitive impairment and dementia: Practical interventions to foster the European Brain Health Strategy

SYMP07_1 | Lifestyle and vascular multi-domain interventions: FINGERS in the era of monoclonal antibodies

M. Kivipelto
Karolinska Institutet, Solna, Sweden

SYMP07_2 | Multi-domain interventions in brain health services

G. Frisoni
Centre de la mémoire, Geneva University and University Hospitals, Geneva, Switzerland

The concepts of Brain Health, preventive neurology, and secondary prevention of neurological disorders are lately attracting great interest. However, a mismatch is evident in the literature and clinical practice, with sparse and mostly weakly effective prevention programs. A protocol for non-lifestyle non-vascular preventive interventions will be presented that might be integrated in Brain Health Services for dementia prevention. Its conceptual model will be that of the FINGER trial, which demonstrated a significant clinical impact in older persons at high vascular risk thanks to the additive effect of a number of small-impact individual interventions. The non-lifestyle non-vascular protocol will be a multi-domain intervention that will not require lifestyle changes ("biological interventions"), i.e. transcranial electrical stimulation, nutritional supplements with synaptogenetic and ketogenic efficacy, gamma sensory stimulation, and small molecules with anti-amyloid or anti-tau effects. The scenarios will be discussed of the positioning of biological multi-domain interventions in the era of anti-amyloid MABs.

Disclosure: Nothing to disclose.

SYMP07_3 | Pharmacological interventions

S. Tomic
University Hospital Center Osijek, Croatia

Secondary prevention in, at-risk persons for dementia, is among priority task of health care community due to deleterious consequence of dementia. Trials with antihypertensive drugs showed controversial results. Syst-Eur trial showed reduced risk for dementia, while SPRINT MIND study, besides its influence on overall morbidity and mortality, did not show positive effect on prevention of dementia. Same was with ramipril study or study with discontinuation of antihypertensive drugs. In the A4 study, solanezumab, which targets monomeric amyloid, did not manage to slow cognitive decline. Studies with BACE-1 inhibitor drug atabecestat was prematurely finished due to hepatic-related side effects while studies with umibecestat were stopped following an interim analysis showing worsening cognitive function with umibecestat treatment. SKYLINE study with gantenerumab was terminated following results of a pre-planned analysis of the safety and efficacy. Nonsteroid anti-inflammatory drugs (naproxen and aspirin) did not show improvement of cognition with severe side effects like major hemorrhage and all-cause mortality. Trials with hormone treatment (testosterone, estrogens or estradiol) fail to improve cognitive decline also. Hypoglicemic drugs pioglitazone and linagliptin fail to delay the onset of mild cognitive impairment or to influence on an incident accelerated cognitive decline. There was also no effect of a casein-derived angiotensin-converting enzyme inhibitory peptide (Met-Lys-Pro) on cognitive function. Still ongoing many trails that evaluate gene therapies targeting APOE4, APOE2, and NGF in addition to beta-amyloid and tau, anti-hypertensive treatment (IMPACTS-MIND and IPAT trial), semaglutid, SGLT2 inhibitors, DPP-4 inhibitors, metformin, intranasal insulin, lecanemab, donanemab, atorvastatin and lithium carbonate.

Disclosure: Svetlana Tomic has been sponsored from AbbVie and Medis Adria and received honoraria from AbbVie, Stada, Medis Adria and Pliva Teva.

EAN/ESRS: Lights off, brain still on: Sleep as a pillar of brain health

SYMP08_1 | Protein misfolding and aggregation in neurodegenerative disease: From why to how

T. Outeiro
University Medical Center Goettingen, Germany

The maintenance of the complex three-dimensional structure of all proteins is vital for their function. From the instant proteins are produced, they start facing tremendous challenges due to the highly crowded environment of the cellular milieu. Cells evolved sophisticated quality control systems that maintain protein homeostasis, and these include the protein folding and protein degradation systems. Oftentimes, as a consequence of environmental stress, genetic mutation, and/or infection, the folded structure of a protein gets altered rendering them sticky. In some instances, proteins escape the quality control systems, fall out of solution, and form protein aggregates which are pathological hallmarks in many diseases, known as protein aggregation diseases. When misfolded proteins accumulate, cells face serious problems, which may result in the activation of cell death pathways. This suicidal option is highly regulated and is, in many instances, associated with disease states, such as those found in cancer or neurodegenerative disorders, such as the prion diseases, Alzheimer's disease, Parkinson's disease, or Huntington's disease. The precise molecular mechanisms involved in protein folding and misfolding are still elusive, but it is highly likely that understanding why proteins misfold, and how we can interfere with their misfolding, and aggregation may lead to the identification of novel therapeutic targets in many of these disorders.
Disclosure: Nothing to disclose.

SYMP08_2 | How sleep maintains and improves brain health

A. Stefani
Medical University Innsbruck, Department of Neurology, Austria

Current data supporting a key role of sleep in maintaining and improving brain health will be presented and discussed.
The first talk will focus on mechanisms underlying proteins aggregation and amyloid formation in neurodegenerative diseases. Basic science studies showing a relationship between sleep and amyloid formation will be presented and discussed.
The second talk will provide the link between basic and clinical research, underlying how sleep can be a biomarker of brain health. Sleep is involved in regulation of processes like inflammation and brain waste clearance, which are fundamental in preserving brain health, and play a crucial role in the balance between healthy aging and development of neurodegeneration.
The third talk will highlight the bidirectional relationship between sleep and Alzheimer's disease. Potential mechanisms underlying the relationship between sleep changes and the development of Alzheimer's disease will be discussed. The last part of the talk will focus on future directions, e.g. novel methods to detect early sleep changes related to Alzheimer's disease, and the potential role of sleep improvement in Alzheimer's disease prevention and management.
The fourth talk will focus on the link between sleep and alpha-synucleinopathies. It is well recognized that isolated REM sleep behavior disorder is an early alpha-synucleinopathy, and more recently it has been hypothesized that isolated REM sleep without atonia may represent even an earlier stage of alpha-synucleinopathies. Current knowledge on this topic will be presented, as well as different hypothesis on spreading of alpha-synuclein pathology and their potential relation with different outcomes.
Disclosure: Nothing to disclose.

SYMP08_3 | Sleep changes and Alzheimer's disease: What comes first?

C. Liguori
2nd University of Rome Tor Vergata, Rome, Italy

SYMP08_4 | Detection of prodromal synucleinopathy through sleep

F. Dijkstra
Antwerp University Hospital, Belgium

This talk will focus on the link between sleep and alpha-synucleinopathies. It is well recognized that isolated REM sleep behavior disorder is an early alpha-synucleinopathy, and more recently it has been hypothesized that isolated REM sleep without atonia (the neurophysiological hallmark of REM sleep behavior disorder, in the absence of dream enactment behaviors) may represent even an earlier stage of alpha-synucleinopathies. Current knowledge on this topic will be presented, as well as different hypothesis on spreading of alpha-synuclein pathology and their potential relation with different outcomes (e.g. Parkinson's disease, Parkinson's dementia, dementia with Lewy bodies, or multiple system atrophy). The last part of the talk will focus on future directions, in particular addressing the role of isolated REM sleep behavior disorder and isolated REM sleep without atonia as early stages of alpha-synucleinopathies in the light of upcoming clinical trials of neuroprotection and neuromodulation. Related to this, novel methods to identify isolated REM sleep behavior disorder and isolated REM sleep without atonia, including wearables and nearables, will be discussed as potential screening or early diagnosis methods. In summary, this symposium on the basis of basic, translational and clinical neuroscience will position sleep as a window into brain health, and as an essential brain health pillar.
Disclosure: Nothing to disclose.

ABSTRACT

Focused Workshops

Saturday, June 29 2024

Non-invasive brain stimulation: Current state of the art

FW01_1 | Which techniques are available as diagnostic or therapeutic interventions?

J. Lefaucheur
Department of Clinical Neurophysiology, Henri Mondor Hospital, Créteil, France

Techniques of non-invasive brain stimulation mainly include transcranial magnetic stimulation (TMS) and transcranial direct current stimulation (tDCS). While the first technique includes diagnostic and therapeutic aspects, the second has purely therapeutic use. Most TMS measurements rely on stimulation of the motor cortex and recording of motor evoked potentials to study the pyramidal tract or radicular lesions. Advanced techniques, such as the triple stimulation technique, make it possible to detect the involvement of upper motor neurons, or, like TMS combined with an MRI-guided navigation system, make it possible to perform functional mapping of the motor cortex, for example during preoperative evaluation of brain tumor surgery. TMS can also be combined with electroencephalography to study cortical connectivity. Finally, various protocols based on single-pulse or paired-pulse TMS techniques can be applied to study various pathways or neurotransmitter systems involved in the modulation of cortical excitability under pathological conditions. From a therapeutic point of view, repetitive trains of TMS (rTMS) pulses applied during repeated daily sessions can provide clinical benefit in a number of neurological or psychiatric disorders. Various rTMS paradigms have demonstrated the ability to improve patients suffering from chronic pain or major depressive disorder, for example, with stimulation protocols delivered to various cortical targets (primary motor cortex or dorsolateral prefrontal cortex) with various parameters of frequency, pattern or duration of stimulation. Although it provides an entirely different type of stimulation (much lower current intensity delivered to the brain but of much longer duration and larger diffusion), tDCS has also shown evidence of being able to modulate clinical symptoms in various domains.
Disclosure: Nothing to disclose.

FW01_2 | Targeting deep brain structures for neurological disorders

F. Hummel
Swiss Federal Institute of Technology Lausanne (EPFL), Neuro-X Institute, Geneva, Switzerland

Deep brain structures like the basal ganglia, the thalamus or the hippocampus are core brain areas involved in the pathophysiology of neurological and psychiatric disorders, such as dementia, Parkinson's disease (PD), anxiety disorders, stroke or traumatic brain injury (TBI) as well as for transdiagnostic symptoms such as memory deficits, apathy or fatigue appearing in multiple neurological and psychiatric disorders despite the fact of their different underlying pathophysiology. Therefore, these brain areas are important and promising targets for interventional treatment strategies based on neuromodulation. However, due to their location deep in the brain they were so far only accessible by invasive deep brain stimulation (DBS). Novel non-invasive deep brain stimulation methods have the large potential to target deep brain structures with sufficient focal specificity and show particular promise for non-invasive neuromodulation-based treatment strategies for neuropsychiatric disorders in which deep brain structures play critical roles in the pathophysiology or in mediating recovery. An introduction in this novel field will be provided based on first human applications and the potential of them critically discussed.

EAN/MDS-ES: Tremor syndromes: From pathophysiology to diagnosis and treatment

FW02_1 | Essential tremor

M. Bologna
Department of Human Neurosciences, Sapienza University of Rome, Italy and Neuromed Institute IRCCS, Pozzilli (IS), Italy

Essential tremor (ET) is one of the most common syndromes in movement disorders. This presentation will initially discuss the pathophysiological mechanisms of tremor in patients with ET, with particular reference to the role of the cerebellum and interconnected brain areas as evidenced by neurophysiological and neuroimaging studies. The most relevant aspects concerning the diagnosis of essential tremor will then be discussed, with particular reference to areas overlapping with other pathological conditions, that is, parkinsonism, dystonia, and ataxia. In this regard, the significance of the ET plus concept will be discussed. In the final part of the presentation, the main therapeutic approaches in the field of ET will be mentioned, including the use of innovative medications, surgical options, that is, deep brain stimulation (DBS), Magnetic resonance-guided focused ultrasound (MRgFUS), as well as possible innovative interventions based on non-invasive brain stimulation techniques.
Disclosure: Nothing to disclose.

FW02_2 | Dystonic tremor

P. Schwingenschuh
Department of Neurology, Medical University of Graz, Graz, Austria

Dystonic tremor is defined as a tremor syndrome in which dystonia and tremor are the main neurological signs. The overall prevalence of tremor in dystonia is 53% and two subtypes of tremor are distinguished. Patients with dystonic tremor have a tremor in the dystonic body part, such as tremulous cervical dystonia, while patients with tremor associated with dystonia have dystonia and tremor elsewhere, such as upper limb tremor in cervical dystonia. Dystonic tremors are clinically characterized by coarse, jerky, irregular, directional, asymmetrical tremors, sometimes with sensory tricks, a null point, and overflow. A growing body of evidence suggests that the two subtypes of dystonic tremor also differ pathophysiologically. Dystonic tremor shares some mechanisms with nontremulous dystonia, while tremor associated with dystonia shows overlaps with essential tremor, which might imply different therapeutic strategies for the two subtypes of dystonic tremor.
Disclosure: Nothing to disclose.

FW02_3 | Parkinsonian tremor

R. Helmich
Radboud University Medical Centre, Donders Institute for Brain, Cognition and Behaviour, Neurology Department, Centre of Expertise for Parkinson & Movement Disorders, Nijmegen, The Netherlands

Parkinson's disease is a common neurodegenerative disorder characterized by bradykinesia, tremor, and rigidity. Parkinsonian tremor has unique clinical characteristics, as compared to other motor symptoms: it occurs early in the disease and may disappear with disease progression, in some patients it does not respond to even high doses of levodopa, it worsens considerably during stress, and tremor-dominant PD has been associated with a milder clinical course. The pathophysiology of parkinsonian tremor has been associated with abnormal activity in both the basal ganglia and the cerebello-thalamo-cortical circuit. According to the "dimmer-switch model", which is based on neuroimaging (fMRI) data, the basal ganglia trigger tremor (analogous to a light switch), while the cerebello-thalamo-cortical circuit amplifies the tremor (analogous to a light dimmer). In this lecture, I will discuss new research findings that may explain why parkinsonian tremor reduces over time, why it waxes and wanes spontaneously, why it responds variably to dopaminergic medication, and why different types of tremor (e.g. postural tremor and rest tremor) respond differently to treatment. I will also discuss, with videos, how to recognize parkinsonian tremor and how to treat it.
Disclosure: Nothing to disclose.

EAN/EFIC: Brain neurostimulation techniques to relieve pain

FW03_1 | How to treat pharmacoresistant pain. When should I recommend neuromodulation?

A. Truini
Department of Human Neuroscience, University of Rome "La Sapienza", Roma, Italy

FW03_2 | rTMS and tDCS for treating neuropathic pain

S. Jääskeläinen
Division for Medical Imaging, Turku University Hospital and University of Turku, Finland

Guidelines on therapeutic use of noninvasive brain stimulation (NIBS) with repetitive transcranial magnetic stimulation (rTMS) and transcranial direct current stimulation (tDCS) support their efficacy for chronic pain. There is level A (definite efficacy) recommendation for analgesic effect of high frequency (HF) rTMS at primary motor cortex (M1) contralateral to neuropathic pain distribution, and level B (probable efficacy) for HF-rTMS at left M1 or dorsolateral prefrontal cortex for improving quality of life or pain in fibromyalgia

(FM). tDCS with anodal stimulation of M1 contralateral to pain has been suggested to be probably effective (level B) for neuropathic pain with different aetiologies, and FM. The beneficial effects of NIBS techniques arise from either excitation (HF-rTMS, iTBS, anodal tDCS) or inhibition (LF-rTMS, cTBS, cathodal tDCS) of activity within targeted neural networks leading to neuroplastic alterations that outlast stimulation and accumulate with repeated sessions. NIBS induces the release of endogenous neurotransmitters, for example, dopamine and opioids, important in the analgesic actions in structures processing and modulating pain. The parietal opercular cortex ("S2"), and M1-S1 area near midline represent promising novel options for the treatment of neuropathic and post stroke pain. Multisite stimulation protocols illustrate a practical way to enhance treatment efficacy in pain patients with comorbid disorders (e.g. depression, anxiety). Clinically useful maintenance protocols include rTMS with decreasing, individually adjusted session frequency or tDCS treatment at home. Future studies should optimize therapeutic NIBS with properly controlled large trials, evaluating the best protocols for maintenance therapy, and searching novel targets to improve efficacy in clinical practice.

Disclosure: Nothing to disclose.

FW03_3 | Neuromodulation for (cluster) headache

S. Evers
University of Münster, Germany

Neuromodulation has become an additive procedure in the acute and the prophylactic treatment of cluster headache in the last decades. It started around the year 2000 when deep brain stimulation of the inferior hypothalamus was performed with initially very successful efficacy; however, the procedure is nowadays rarely performed due to the risk of the operation and probable recurrence of attacks. According to the recent EAN guideline, noninvasive vagal nerve stimulation was more effective than sham stimulation in the abortion of acute attacks in episodic but not in chronic cluster headache (difference: 27% of patients). The same procedure showed also efficacy in the prevention of cluster headache attacks as compared to standard of care. Greater occipital nerve stimulation showed some effect in the prevention of cluster headache, which however cannot be finally calculated due to poor data. Invasive neurostimulation of the sphenopalatine ganglion (SPG) showed a significant odds ratio of 2.6 for the abortion of acute attacks after 15 min. Also, prevention of cluster headache was successful by SPG in two studies. In summary, neurostimulation in cluster headache is possible both for acute (vagal nerve) and preventive (vagal nerve and SPG) in those patients not responding to drug treatment. In most patients, neurostimulation is used as add-on therapy. In migraine, neurostimulation procedures have been studied as well. In general, the treatment effects were lower than for cluster headaches. The published evidence for all neurostimulation procedures in all headache disorders studied is very low.

Precision diagnosis for rare neurological diseases

FW04_1 | Improving diagnosis rates in rare neurological disorders requires precision medicine and research: The Solve-RD project

H. Graessner
University Hospital Tübingen, Germany

FW04_2 | Ontology-based deep phenotyping: A starting point for accurate diagnosis and classification of rare neurological diseases

C. Lucano
Orphanet – INSERM US14, Paris, France

FW04_3 | European genome data sharing, enabling collaborative analysis and expert knowledge curation to diagnose and treat rare neurological diseases

S. Beltran
Centre Nacional d'Anàlisi Genòmica, Barcelona, Spain

Introduction Collaboration in rare disease (RD) research and diagnostics is essential since affected individuals, and hence experts and data relating to any specific rare disease, are sparse and patchy. While the adoption of NGS as a primary line of investigation over the last decade has proven invaluable in identifying the molecular basis of many rare diseases, leading to diagnosis in approximately 50% of individuals affected by a RD, the other half typically remain undiagnosed even after exome sequencing or genome sequencing analysis. A key objective of the H2020 Solve-RD project is to contribute to the diagnosis of thousands of patients affected by RDs across Europe, the majority of which have previously undergone exhaustive analysis of exome sequencing (ES) data, without resolution. Solve-RD relies on the expertise from 6 European Reference Networks (ERNs), including ERN-RND, and two Spanish and Italian undiagnosed disease programs. Their experts have shared pseudonymised data from unconclusive exomes and genomes and have submitted samples to conduct multi-omics experiments. Analysis and interpretation have been done in collaboration with the consortium. Methods Analysis and interpretation at this scale requires efficiency in terms of data generation, transfer, management, storage, analysis, interpretation, and communication. The Solve-RD data infrastructure relies on the European Genome Phenome Archive (EGA), the RD-Connect Genome-Phenome Analysis Platform (GPAP), the RD3 database

(powered by Molgenis), RD-Nexus (powered by Café Variome), and local and cloud computing resources. The data workflow has been organized in a two-level expert review framework, with a main Data Analysis Task Force (DATF), a Data Interpretation Tak Force (DITF) per ERN and several cross-cutting Working Groups (WGs). Results The Solve-RD consortium experts re-analysed and interpreted integrated phenotypic and genomic data from over 22,000 individuals from 12,800 families, who had previously been analysed at local and national centres of expertise without a diagnosis being reached. This resulted in a diagnostic uplift to date of 13% of these most challenging RD cases. Furthermore, 883 families underwent short-read genome sequencing (GS). Although clinical interpretation of identified variants is still ongoing, a further 4.5% of cases have already been confirmed resolved through the analysis of GS data versus that of the original ES data reanalysis. Finally, approximately 10% of the cases underwent analysis through some of the most recent omics technologies. These technologies include one or more of the following: long read GS, high coverage ES, Optical Genome Mapping, long and short read RNA-Seq, epigenetic and metabolomics. Some of these multi-omics approaches have already proved fruitful, resulting in the closure of further diagnostic odysseys. Conclusion Systematic analysis of short-read GS data, accompanied by detailed patient descriptions, and additional omics analyses can elevate the diagnostic rate in RD cases markedly, even where prior comprehensive analysis of genetic data proved inconclusive.

Disclosure: The Solve-RD project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 779257.

EAN/ISNI: Liquid biomarkers in autoimmune central nervous system diseases

FW05_1 | Serological correlations of disease progression in Multiple Sclerosis (MS)

M. Comabella

Servei de Neurologia, Centre d´Esclerosi Múltiple de Catalunya (Cemcat), Institut de Recerca Vall d´Hebron (VHIR), Hospital Universitari Vall d´Hebron, Universitat Autònoma de Barcelona, Barcelona, Spain

In patients with relapsing multiple sclerosis (MS), the prognostic role of biomarkers to predict disease activity and/or treatment response has been thoroughly investigated. However, in patients with progressive MS, the prognostic role of biomarkers to predict future disease progression remains more elusive. This talk will summarize the current evidence existing about the role of biomarkers to predict disease progression in MS. The presentation will mainly focus on studies measuring the serum levels of neurofilament light chain, GFAP, and chitinase 3-like 1 in patients with progressive MS. Other promising biomarkers with a potential role in disease progression will also be discussed.

Disclosure: I have received compensation for consulting services and speaking honoraria from Bayer Schering Pharma, Merk Serono, Biogen-Idec, Teva Pharmaceuticals, Sanofi-Aventis, Genzyme, BMS, ROCHE, and Novartis.

FW05_2 | Humoral signatures of myelin oligodendrocyte glycoprotein antibody associated disorder (MOGAD)

J. Lünemann

Department of Neurology with Institute of Translational Neurology, University Hospital Münster, Münster, Germany

Myelin oligodendrocyte glycoprotein (MOG)-antibody (Ab)-associated disease (MOGAD) is an inflammatory demyelinating disease of the CNS. Clinical manifestations and the course of MOGAD are heterogeneous. While the detection of MOG-IgG by cell-based assays is an essential criterion in MOGAD diagnosis, biomarkers that aid in disease prognostication, treatment monitoring, and the development of new interventions are lacking. Recent studies indicate that the combined analysis of functional MOG-Ab features can potentially provide clinically useful information on disease activity and future risk for relapse. MOG-Ab specificities for epitopes other than the immunodominant proline 42 epitope is reported to be associated with relapsing disease while enhanced MOG-Ab effector functions mediated by the IgG Fc-domain and increased serum levels of canonical biomarkers for neuro-axonal damage such as neurofilament light chain track with clinically active disease. Early identification and targeted management of patients with chronic disease and higher disease severity could improve long-term clinical outcomes for patients with MOGAD.

Disclosure: JDL received speaker fees, research support, travel support, and/or served on advisory boards by the EU Framework Programme Horizon Europe (BEHIND-MS), The German Research Foundation (LU 9001-1; LU 900-4; and the Collaborative Research Centre SFB-TRR128 'Initiating/Effector versus Regulatory Mechanisms in Multiple Sclerosis – Progress towards Tackling the Disease'), Abbvie, Alexion, Argenx, Biogen, Merck, Novartis, Roche, Sanofi, Takeda.

Targeting molecular pathways in gliomas: A promising approach

FW06_1 | Interactions between normal brain and tumor cells are leading to new treatment paradigms

W. Wick
Department of Neurooncology, Universitätsklinikum Heidelberg, Heidelberg, Germany

FW06_2 | Targeting IDH mutations: Biological rationale and clinical applications

R. Rudà
Division of Neuro-Oncology, Department of Neuroscience, University of Turin and City of Health and Science Hospital, Turin, Italy

Isocitrate dehydrogenase (IDH) 1 and 2 mutations are driver molecular alterations for glioma growth. IDH 1/2-mutant gliomas grade 2 and 3 (according to WHO Classification 2021) typically occur in a young, otherwise healthy population. In up to 80% of patients seizures, often pharmacoresistant, are the sole symptom. These tumors are slowly growing but with a high risk of malignant evolution over time and, overall, the majority is not curable. Standard of care consists of maximal safe resection, followed in grade 3 and high-risk grade 2 tumors by radiotherapy and chemotherapy with alkylating agents, while observation with MRI is reserved to young patients with grade 2 tumors after a large surgical resection. Importantly, although long-term tumor remissions can be obtained with available treatments, survivors carry a non-negligible risk of delayed treatment-induced adverse events. Vorasidenib, a brain-penetrant pan-IDH mutant inhibitor, has demonstrated in early clinical trials the ability to significantly reduce the concentration of D-2-hydroxyglutarate (2-HG), which is the product of mutant IDH enzyme and acts as an oncometabolite. Phase III INDIGO trial has shown that the inhibition of the mutant IDH neomorphic function with vorasidenib in the setting of residual or recurrent predominantly non-enhancing, chemo- and radiotherapy naive grade 2 gliomas after surgery, is able to significantly improve both imaging-based progression-free survival and time to next intervention as compared to placebo. Adverse effects were mild with only transitory elevation of liver enzymes. Trials are ongoing on novel IDH inhibitors, vaccination strategies and combinations of IDH inhibitors with other molecular compounds.
Disclosure: Bayer, Novocure, Servier, CureVac.

FW06_3 | How to best monitor molecular pathways with advanced neuroimaging

J. Heugenhauser
Department of Neurology, Medical University of Innsbruck, Austria

With the implementation of molecular information to histologic findings into the WHO classification in 2016 a new era in neuro-oncology was heralded. Some of these molecular markers are diagnostic, some provide predictive and prognostic information and more exciting some markers also hold therapeutic potential. Advanced neuroimaging by magnetic resonance imaging (MRI) or positron emission tomography (PET) has the potential to visualize molecular processes in tumors longitudinally and non-invasively by displaying pathophysiological processes in tumors. Neuroimaging may not only be used to visualize pathophysiological processes but also to monitor treatment response or predict response to new therapies. Since the discovery of the IDH (isocitrate dehydrogenase) mutation in lower grade gliomas, thrilling findings and investigations have been published culminating in a positive phase III clinical study in lower grade gliomas increasing progression-free survival. Magnetic resonance spectroscopy (MRS) has been shown to have the potential to visualize the oncogenic product of an IDH mutation (namely 2-HG). During therapy with IDH inhibitors reprogramming of tumor metabolism, change in glutathione, glutamine, glutamate, lactate and also significant decreases of 2-HG have been detected by MRS. Making it a good candidate to monitor treatment response in the future. Radiomics, the extraction of a large number of features from medical images using data-characterization algorithms, also has shown to have the potential to link molecular data to imaging data. In order to gain clinical validity these exciting findings have to be validated in larger patient cohorts and imaging protocols have to be harmonized across different centers.
Disclosure: Nothing to disclose.

Advancement of neuromodulation into new areas of neurology

FW07_1 | Invasive and non-invasive sensory feedback in upper limb prostheses

C. Antfolk
Department of Biomedical Engineering, Faculty of Engineering, Lund University, Sweden

The realm of upper limb prosthetics has witnessed substantial advancements, in terms of their mechanical construction, the methods to control them and way of providing the user with sensory feedback from them. The challenge to restore sensory feedback in prosthetic hands has provided several research solutions, but virtually none has reached clinical fruition. A prosthetic hand with sensory feedback that closely imitates an intact hand and provides the user with a natural perception of touch may induce the prosthetic hand to be included in the body image and also reinforces the control of the prosthesis. The addition of sensory feedback to upper limb prostheses has been shown to improve control, increase embodiment, and reduce phantom limb pain. This talk presents a review of

non-invasive sensory feedback systems such as mechanotactile, vibrotactile, electrotactile and combinational systems which combine the modalities; multi-haptic feedback and invasive methods using both extraneural and intraneural electrodes, such as cuff electrodes and transverse intrafascicular multichannel electrodes. The presentation aims to provide a comprehensive overview of current sensory feedback techniques, their impact on the quality of life for prosthesis users, and the future direction of prosthetic sensory feedback technology. This exploration is crucial for advancing prosthetic design, offering users a closer semblance to natural limb functionality and sensation.

Disclosure: Nothing to disclose.

EAN/EPNS: Challenges and opportunities in the management of status epilepticus across age groups

FW08_1 | A novel approach to status epilepticus in neonates

R. Cilio

Division of Pediatric Neurology, Department of Pediatrics, Saint-Luc University Hospital, Catholic University of Louvain, Brussels, Belgium

Neonatal status epilepticus differs from status epilepticus in older children and adults. Even in the context of status epilepticus, seizures in neonates are brief lasting mostly less than 2 min, even when highly recurrent. Therefore, status epilepticus it currently defined as the summed duration of seizures comprises >50% of an arbitrarily defined 1-h epoch. The recent implementation of neonatal neurocritical care including continuous video-EEG monitoring allowed for early detection of seizures in high-risk infants and accurate assessment of response to treatment. In addition, the advancements in neuroimaging, metabolic, and genetic testing have enabled the identification of a growing number of underlying causes in neonates with status epilepticus, paving the way for a targeted etiology-specific treatment, while moving away from the monolithic 'one-size-fits-all' approach. Phenobarbital is the most used ASM to treat neonatal status epilepticus. However, we should not use phenobarbital simply because it is the medication most used. Although, the most common etiologies for neonatal status epilepticus are acute symptomatic such as hypoxic-ischemic encephalopathy and stroke, for a significant minority seizures and status represent the first manifestation of epilepsy, a chronic disease. This presentation will focus on the early detection and electro-clinical characterization of neonates with status epilepticus, and etiology-specific treatment including phenobarbital for status epilepticus in the context of hypoxic-ischemic encephalopathy, sodium-channel blockers in the context of channelopathies, and levetiracetam and ketamine in neonates with congenital heart diseases.

Disclosure: Nothing to disclose.

FW08_2 | Revisiting evaluation and treatment of febrile illness-related epileptic syndrome (FIRES) and new-onset refractory status epilepticus (NORSE) in children

S. Buratti

Neonatal and Pediatric Intensive Care Unit, Emergency Department, IRCCS Istituto Giannina Gaslini, Genova, Italy

NORSE (new onset refractory status epilepticus) and its subset FIRES (febrile infection-related epilepsy syndrome) are rare and devastating conditions that challenge multidisciplinary care teams with diagnostic and therapeutic difficulties. Aetiologies are classified as autoimmune/inflammatory, genetic, infectious, and toxic. The diagnostic pathway is complex and in 50% of the cases, despite an extensive work up, the cause remains undetermined (cryptogenic NORSE). Clinical history, neuroimaging, continuous EEG, genetic and CSF analyses are critical to draw diagnostic hypotheses and frame the therapeutic strategies. Steroids, immunoglobulins, and immunomodulators are the mainstay of autoimmune and cryoptogenic NORSE. Novel approaches are based on timely analysis of serum and CSF cytokine levels and early cytokine-modulating therapy, mainly anakinra and tocilizumab (IL1 and IL6 receptor antagonists). International consensus recommendations based on best available evidence and expert opinion have been recently published and represent a practical framework for the clinicians. Though, lack of randomized controlled trials and scarse evidence on specific treatments represent future challenges for the scientific community. Future research developments should focus on the role of cytokines and inflammation, explore in vitro and in vivo models of NORSE, plan clinical trials, promote international biorepositories and establish studies on long-term outcomes. Despite severe sequelae and mortality (12% in children), improvement of patient management is a realistic objective to pursue. Aiming to the best outcome each patient

should be referred to a tertiary care center where structured and timely diagnostic and therapeutic pathways are implemented.
Disclosure: I have no conflicts of interest to declare.

FW08_3 | What to do when first and second-line treatment fails in adults?

C. Cornwall
Department of Neurology, Odense University Hospital, Denmark

Status epilepticus (SE), the second most common neurological emergency, is a severe and potentially life-threatening complication of epilepsy and acute brain diseases with high morbidity and mortality. Refractory SE (RSE) is defined as failure to appropriate first-line treatment with benzodiazepine and failure of second-line treatment with anti-seizure medication (typically levetiracetam, valproate, or (fos-)phenytoin). Super-refractory status epilepticus (SRSE) further delineates cases where SE continues or recurs 24 h or more after the onset of anesthetic therapy, including those cases where SE recurs on the reduction or withdrawal of anesthesia. Due to increased risk of significant neuronal damage with persistent seizure activity, international guidelines emphasize early and aggressive treatment. While we have made substantial progress in understanding and treating non-refractory SE, RSE, and especially SRSE, remains a highly challenging medical condition with primarily low-evidence literature available. Diagnostic evaluation includes electroencephalography monitoring, neuroimaging, and laboratory investigations to identify possible reversible causes and guide treatment decisions. Effective management requires a multidisciplinary approach involving neurologists, and intensivists to tailor treatment strategies to individual patient needs. Continued efforts in understanding the underlying mechanisms and refining therapeutic approaches are essential to improve outcomes for patients with RSE and SRSE. Recently, there has been an increased focus on whether treatments such as ketamine, barbiturates, ketogenic diet, or hypothermia may have a beneficial effect on seizure cessation in patients with RSE and SRSE. This talk will present the available evidence on epidemiology and etiology, but also possible treatment options and prognosis in this challenging patient group.
Disclosure: C.D. Cornwall has received travel support from Jazz Pharma. There are no conflicts of interest related to this talk.

FW08_4 | End-of-life considerations in status epilepticus

M. Horn
Department of Neurology, Oslo University Hospital, Oslo, Norway

The management of super-refractory status epilepticus (SRSE) is challenging, medically and ethically. Generally speaking, patients with SRSE will either succumb to epilepsy or underlying disease and die, or they will survive with significant neurologic sequelae, or survive with good functional outcomes. However, there is a lack of robust prognostic markers that allow caregivers to predict the outcome of individual patients with a degree of certainty. Therefore, a "maximalist" approach to treatment of SRSE will necessarily often lead to patients either dying or surviving but with poor outcomes. In hindsight, treatment may appear to have been futile, exposing the patient to unnecessary burdens, and wasting scarce resources in the intensive care unit. Conversely, a "minimalist" approach may lead to patients being denied a chance to survive with meaningful recovery. A "middle of the road" approach might be ideal, but without precise prognostic markers, might just lead to just as much futility and under-treatment. Clinicians caring for SRSE patients have to navigate these challenges, knowing that some risk of unwanted outcomes is probably unavoidable. This lecture will not provide the solution to how to select which patients should be offered maximal treatment – possibly for months – and which patients ought to be allowed to die, through non-treatment decisions (NTDs) and withdrawal of life-sustaining treatment (WLST). Rather, I will try to delineate a framework for ethical considerations of end-of-life issues in SRSE, primarily using the 6-step model for ethical analysis developed by the Centre for Medical Ethics at the University of Oslo.

Anti-amyloid antibodies in Alzheimer's disease: New treatments on the horizon

FW09_1 | Current status on the development of anti-amyloid antibodies: Evidence and gaps

K. Frederiksen
Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark

The amyloid cascade hypothesis has been the predominant disease model of Alzheimer´s disease and has served to provide possible drug targets for disease-modifying therapies. Research efforts have led to the development of anti-bodies targeting beta-amyloid. Therapies have demonstrated efficacy on disease progression both in terms of effects on symptoms as well as biomarkers. While evidence is mounting, there are still many unanswered questions regarding the therapies such as effects and side-effects in sub-groups, long-term effects, and understanding more detailed the mechanisms of action of drugs. These questions may be answered in future trials, but real-world evidence for example, from registries will likely also play a pivotal role.
Disclosure: Serves on an advisory board for Novo Nordisk.

Medical and non-medical neurostimulation in the ICU: Facts and fictions

FW10_1 | Medical and non-medical neurostimulation in coma

D. Kondziella
Copenhagen University Hospital – Rigshospitalet, Denmark

FW10_2 | Neurostimulation in refractory and super-refractory status epilepticus (SE)

L. Imbach
Swiss Epilepsy Center, Klinik Lengg, Zurich, Switzerland

Refractory status epilepticus is a neurological emergency with a high mortality rate. In particular, survivors are expected to have a poor functional clinical outcome after failure of first- and second-line treatments such as intravenous anaesthetics and combined anti-seizure medications. In this situation, neuromodulation approaches offer an alternative treatment option to resolve ongoing epileptic network dynamics. Several pilot studies and case series have shown efficacy of vagal nerve stimulation, deep brain stimulation or transcranial stimulation in super-refractory status epilepticus. This lecture provides an overview of acute neurostimulation in SE and discusses efficacy, indication, patient selection and clinical outcome. Novel approaches to optimize treatment response to neurostimulation based on personalized identification and entrainment of neural oscillations in EEG network models will also be presented.
Disclosure: Nothing to disclose.

FW10_3 | Neurostimulation in neuromuscular complications of critical illness

W. Z'Graggen
Departments of Neurology and Neurosurgery, Inselspital, University Hospital Bern, University of Bern, Bern, Switzerland

Muscle weakness is a well-known complication of critical illness. The condition was first described in 1892 by Sir William Osler as “rapid loss of flesh”. About one century later, an acquired neuromuscular dysfunction, also called “intensive care unit acquired weakness (ICUAW)” was identified as the underlying cause. This term is used for patients in whom there is clinically detected weakness without any etiology other than critical illness. Critical illness myopathy and polyneuropathy are the most common causes. ICUAW is associated with delayed recovery, prolonged hospitalization, increased mortality and morbidity. During the COVID-19 pandemic, the impact of ICUAW has become even more important and frequencies of >50% have been reported. The etiology is still unclear, but various risk factors have been identified. Beside the duration of intensive care treatment/mechanical ventilation and the severity of the acute disease, immobilization was reported as a consistent risk factor for ICUAW. This led to the hypothesis that ICUAW may be prevented by early muscle activation. The two concepts derived from this assumption are early mobilization and electrical muscle stimulation. While several smaller studies showed a positive effect of early mobilization on the incidence of ICUAW, one large, randomized trial reported a higher risk of adverse events. The effect of electric muscle stimulation on development of ICUAW was evaluated in several, mostly smaller studies using different outcome measurements. While some studies reported a beneficial effect, other trials failed to show a positive effect. Treatment duration, stimulation sites and net stimulation time are still unknown.
Disclosure: Nothing to disclose.

Cognitive reserve: Impact on intervention in neurological diseases

FW11_1 | The concepts of brain and cognitive reserve

M. Amato
University of Florence, Italy

The concepts of “brain” and “cognitive” reserve have been proposed to account for the disjunction between the degree of brain pathology and its clinical manifestations. The brain reserve model defines reserve as a physical trait: having larger brains, with more neurons and synapses, may allow brains to absorb more injury before cognitive function is affected. Brain reserve may be thought of as individual differences in the hardware of the brain. It can be conceived as a passive entity, which reflects an overt expression of impairment only after an individual's capacity falls below a critical threshold of brain damage. The cognitive reserve model posits flexibility and adaptability of cognitive/brain networks that allow the brain to actively resist the effects of age- or disease-related changes. Cognitive reserve focuses on functionality, plasticity and adaptability and may be thought of as a software that carries out the calculations in the brain, which is influenced by all aspects of life experience. Thus, the cognitive reserve model can be considered active. Given the same amount of brain reserve, some people can better cope with age- or

pathology-related brain changes than others, depending on their cognitive reserve capabilities. A plethora of studies have discussed different proxies to quantify reserve and future directions for the uniformity and reliability of these proxies are pertinent. Recently, empirical evidence pointed to the importance of studying the functional connectome as a compensatory mechanism utilized in patients with better cognitive results, which may pave the way to tailored rehabilitation strategies.

FW11_2 | Does cognitive reserve moderate effects of therapeutic intervention? Studies in healthy and pathological aging

K. Mitterova

Applied Neuroscience Research Group, Central European Institute of Technology, Masaryk University, Brno, Czechia

Cognitive reserve is the brain's ability to compensate for the effect of accumulating senescent or pathological load to maintain cognitive functions. Understanding cognitive reserve in the context of interventions is vital for promoting cognitive health through integrating both neurodegenerative and compensatory aspects of the brain. However, these compensatory mechanisms have not received much attention in terms of their potential role as moderators with therapeutic value. Our team studied the influence of a 6-month dance intervention on cognitive and fitness aspects in seniors without dementia as moderated by different cognitive reserve proxies. The results of this work will be presented with implications of estimating the reserve using dynamic scores which better represent the actual capacity against pathological load. Recent studies have observed that cognitive reserve may manifest as altered (from optimized to hyperconnected) brain functional connectome to preserve essential cognitive functions. We will discuss how these network changes pertain to cognitive interventions and whether they can moderate the benefits of tACS stimulation on working memory in cognitively healthy seniors and elderly with mild cognitive impairment with Lewy bodies. Each of our studies utilized neuropsychological testing and fMRI before and after intervention to evaluate both behavioral and functional network changes as outcomes. Intelligence and education are known determinants of successful aging, however, the search for more dynamic markers of CR, such as (mal)adaptive network changes is pertinent for aiding the selection of the intervention candidates and evaluation of outcomes.

Disclosure: Nothing to disclose.

FW11_3 | Cognitive reserve in stroke: Enhance understanding to improve treatment

R. Umarova

Department of Neurology, University Hospital Bern, University of Bern, Bern, Switzerland

To personalize stroke treatment, we need a reliable model to predict stroke outcome and recovery trajectories for the most prevalent stroke deficits, including cognitive impairment. Lesion characteristics explain far less than half of inter-individual variability of stroke-induced symptoms. Thus, an understanding of lesion-independent factors influencing stroke outcome is urgently needed. For neurodegenerative diseases, the concept of cognitive reserve was introduced to explain the interindividual variability in manifestation of cognitive deficits in response to brain pathology. In that context, cognitive reserve (CR) is suggested to reflect the brain's ability to moderate and compensate for injury, with CR being boosted by cognitively stimulating activities across the lifespan. There is increasing evidence that the underlying concept can also be applied to stroke. In my presentation, I will report on that evidence and exemplify association between CR and both cognitive and non-cognitive stroke outcome. In addition, I will discuss future perspectives of the concept of CR in the context of stroke and particularly its potential to understand the individual recovery trajectories, improve stroke prognosis, and finally establish individualized rehabilitation approaches.

EAN/IFCN-EMEAC: Clinical neurophysiology: New developments in diagnostics and non-invasive therapy

FW14_1 | Maximising VEP validity through differentiating axonal loss and demyelination

L. Leocani

University Vita-Salute San Raffaele, Milan, Italy

Although visual evoked potentials (VEPs) are routinely used for the assessment of visual disturbances, particularly monocular within the diagnostic workup of optic neuritis, their role is being currently reduced by the use of retinal and neuroimaging techniques—for example, optical coherence tomography, magnetic resonance imaging. Nevertheless, their unique property of detecting conduction delays should not be neglected, as these are the hallmark of demyelination. Studies have shown that VEP delays may be aspecific, being encountered also in inflammatory, non-demyelinating diseases such as neuromyelitis optica spectrum disorder (NMO), retinal and macular diseases and even myopia or deliberate or unintentional poor

visual fixation of the stimulus. However, the latter conditions are not associated with severe delay, which entity should be taken into account in the differential diagnosis, together with the other clinical and neuroimaging features. Among the latter, optical coherence tomography is the ideal candidate for allowing a helpful structural and functional combination of information. Finally, VEPs allow the possibility of monitoring remyelination and recovery of conduction, which is essential in testing the efficacy of remyelination strategies.
Disclosure: Nothing to disclose.

FW14_2 | tACS for delayed progression of cognitive decline

A. Antal
Department of Neurology, University Medical Center Göttingen, Göttingen, Germany

Transcranial Alternating Current Stimulation (tACS) for delayed progression of cognitive decline Andrea Antal, Lukas Diedrich Department of Neurology, University Medical Center Göttingen, Germany Non-invasive Brain Stimulation (NiBS) techniques such as repetitive Transcranial Magnetic Stimulation (rTMS) and transcranial Electrical Stimulation (tES), including Direct Current and Alternating Current Stimulation (tDCS, tACS), allow to modulate neuronal excitability, oscillatory activity and to boost cortical functions, hereby possibly offering a therapeutic potential to slow down cognitive decline. Cognitive decline reaches medical attention for about 8%–25% of individuals aged over 65, when suffering from Mild Cognitive Impairment (MCI). Around 15% of MCI patients develop dementia within two years, supporting a medical need for early diagnosis and treatment. Recent investigations propose tACS as a potential therapeutic tool to improve network activity and cognitive functions in older individuals and those with cognitive impairments. The most frequently used stimulation frequencies are theta and gamma, including the combination of the two waveforms (i.e. theta—gamma phase—amplitude coupling). There are promising results using tACS, mainly related to the improvement of working memory or declarative memory performance, two domains that are primarily affected by cognitive decline. However, several subject-specific factors, for example, anatomical and physiological differences, age, gender, brain state before and during stimulation, and also methodological factors, such as the type of the task applied in combination with the stimulation, can confound the effects of stimulation. This talk aims to provide an overview of the commonly utilized tACS protocols, elucidating their individual merits and drawbacks.
Disclosure: Andrea Antal and Lukas Diedrich: no direct COI AA is the Vice President of the European Society of Brain Stimulation; Member-at-Large at the EMEAC – IFCN; payed consultant by NeuroConn (Ilmenau), Germany and by Electromedical Products International (Pulvinar), USA. FW14_3 | Improving diagnostics by threshold tracking TMS

H. Tankisi
Aarhus University Hospital, Denmark

Paired-pulse TMS using a threshold-tracking technique measures the stimulus intensity required to obtain an MEP of or above a certain size instead of relying on the MEP amplitude as a response to a constant stimulus intensity. The first application of threshold-tracking TMS was performed for short-interval intracortical inhibition (SICI) measurements (Fisher et al., 2002). The clinical utility of threshold-tracking SICI in ALS has been shown in several studies and the method has been proposed as a potential biomarker (Vucic & Kiernan, 2013). Decreased SICI in ALS using conventional amplitude measurements was demonstrated already in 1999 (Ziemann et al., 1999). However, the advantages of threshold-tracking SICI over conventional SICI have not been investigated until recently (Tankisi et al., 2021, 2023). Beyond SICI, threshold tracking TMS has moved into short-internal intracortical facilitation, long-interval intracortical inhibition, and short and long-afferent inhibition. In this lecture, the utility of these methods in the diagnostics of various neurological disorders will be addressed. References: Fisher et al. *Exp Brain Res*. 2002;143:240.e8. EAN/MDS-ES: Movement disorders in autoimmune encephalopathies

FW12_1 | General considerations on the pathophysiology of autoimmune encephalopathies

M. Titulaer
Department of Neurology, Erasmus Medical Centre – University of Rotterdam, The Netherlands

FW12_2 | Hyperkinetic, hypokinetic and ataxic disorders in autoimmune encephalopathies

C. Colosimo
Department of Neurology, Santa Maria University Hospital, Terni, Italy

Movement disorders in autoimmune encephalopathies are a heterogeneous group of syndromes encompassing both hyperkinetic, hypokinetic, and ataxic conditions, usually characterized by acute/sub-acute onset, rapidly progressive evolution, and multifocal

localizations with several overlapping features. These movement disorders are immune-mediated, as shown by the presence of antineuronal antibodies in patients' biological samples, crucial for the diagnosis, and the potential response to immunotherapies. Clinicians should have a high index of suspicion when observing acute/subacute symptoms to achieve a prompt diagnosis and treatment. It is initially mandatory to exclude a paraneoplastic disorder. There is indeed a range of overlapping "high-risk" clinical syndromes, including but not limited to latent and overt rapidly progressive cerebellar syndrome, opsoclonus-myoclonus-ataxia syndrome, limbic encephalitis/encephalomyelitis, and stiff-person spectrum disorders. The field of movement disorders in autoimmune encephalopathies is constantly expanding with newly discovered clinical syndromes and related antibodies. Standardized diagnostic criteria and disease biomarkers are fundamental to recognize these disorders quickly, and to allow prompt treatment initiation, thus improving the long-term outcome of these conditions. Response to first and second-line immunotherapies is variable according to associated tumors and antibodies, whereas response to symptomatic treatment is usually poor. This presentation will critically reappraise the clinical features and pathophysiological mechanisms of autoimmune movement disorders, focusing on the most recent diagnostic and therapeutic strategies. The main aim is to make clinicians aware of these movement disorders and provide early diagnosing and managing these rare but potentially life-threatening conditions.

Disclosure: Nothing to disclose.

FW12_3 | Movement disorders complications of immunomodulatory therapies and checkpoint inhibitors

J. Honnorat

University Claude Bernard Lyon 1, Villeurbanne, France

Immune checkpoint inhibitors (ICI) are a class of efficient oncological treatments that enhance antitumour immunity. The use of ICI has represented a major advance in cancer treatment. By enhancing endogenous immune responses to destroy cancer cells, ICI can cause immune-related adverse events (irAEs), with possible involvement of any organ system. IrAEs are frequent, particularly those involving the skin or the endocrine system, and are usually completely reversible after temporary immunosuppression. On the opposite, neurological irAEs (n-irAEs) are relatively rare (less than 2% of all irAEs), often severe, and they carry a considerable risk of mortality and long-term disability. They can affect the peripheral nervous system (myositis, polyradiculoneuropathy, or cranial neuropathy) and, less frequently the CNS, causing encephalitis, meningitis, myelitis or abnormal movements. Although somehow reminiscent of the disorders that neurologists are familiar to deal with in their daily practice, n-irAEs are characterized by distinctive features. Several associations between the neurological phenotype and the type of ICI or the type of cancer have emerged in the last few years, and the growing administration of ICI in patients with neuroendocrine cancers has led to an increased number of reports of patients mimicking paraneoplastic neurological syndromes (PNS). Early diagnosis and initiation of immunosuppressive therapy are likely to be crucial in preventing the accumulation of neurological disability. This review aims to update current knowledge regarding the clinical presentation of n-irAEs and particularly the movement disorders. We will also discuss the essential parts of the diagnostic approach, and general recommendations for the patients' management.

Disclosure: Nothing to disclose.

EAN/ILAE: Current challenges in the management of rare and complex epilepsies, and epileptic encephalopathies

FW13_1 | Precision medicine in rare and complex epilepsies: Is it real?

A. McTague

Developmental Neurosciences, UCL Great Ormond Street Institute of Child Health, London, UK

FW13_2 | Epilepsy surgery: Towards more tailored approaches

F. Pizzo

Cerebral Rhythmology and Epilepsy Unit, La Timone, Marseille, France

FW13_3 | Palliative care in complex epilepsies: Are we ready for this?

R. Kälviäinen

University of Eastern Finland, Kuopio, Finland

Subgroup of drug-resistant complex epilepsies are progressive and management should be guided by the principles of palliative care and by relief of symptoms. End of life care (EOL) refers to patients, whose goals of care are consistent with a comfort-based approach and who are likely to die within days to weeks. Advance Care Planning (ACP) enables patients to define their preferences and expectations from therapeutic options. Advance directives (ADs) are an essential part of ACP; ADs include the presence of a living will, do-not-resuscitate order, do-not-hospitalize order, medication restriction, or feeding/hydration restriction. It is not possible to fully predict acute exacerbations, making ADs difficult to adopt and sometimes misleading. ACPs should be reviewed and discussed periodically and whenever the patient has a change in health status. Unfortunately, even the best and most updated severity-of-illness scores and risk cannot predict with certainty the fate of an individual patient. Multimodal neuro-prognostication will hopefully allow more accurate and personalized prognosis in future. Regarding status epilepticus (SE)

timely recognition and effective, early treatment with first- and second-line ASMs may prevent unnecessary hospitalizations. Rapid Epileptic Seizure Termination (REST) in outpatient setting is also useful, especially if known to be at risk for SE. Aggressive unlimited ICU treatment of refractory SE in palliative patients is not indicated and can be futile. In EOL care of complex epilepsy patients, consideration of withholding intensive care is not withholding effective treatment, but allowing patient to have a natural death in peaceful environment without prolonging their suffering unnecessarily.

EAN/EHF: Headaches with heavy burden

FW15_1 | Medication-overuse headache (MOH): Burden and management

G. Terwindt
Department of Neurology, Leiden University Medical Center, The Netherlands

Medication Overuse Headache (MOH) emerges from excessive consumption of acute headache medication, occurring in individuals enduring ≥15 headache days monthly. Despite its significant impact on quality of life, MOH often goes unnoticed. Typically, MOH patients harbour underlying migraine or tension-type headaches, commonly exhibiting frequent headaches alongside migraine symptoms like nausea, vomiting, light sensitivity, and sound sensitivity. However, manifestations can vary; overuse of analgesics may induce a diffuse, all-encompassing dull pressure in the head, while excessive triptan intake might result in daily migraine-like headaches that momentarily subside post-medication but swiftly return. Animal studies indicate that prolonged and repetitive use of analgesics and triptans can heighten susceptibility to evoked cortical spreading depression (CSD), modify pain regulation, and foster central sensitization. Individuals with episodic migraines who encounter allodynia during attacks are predisposed to migraine chronification, particularly women experiencing menstrual-related episodes. Treatment comprises a blend of preventive measures and curtailing acute medication usage, with the goal of lessening headache frequency and medication intake. Establishing a causal link between medication overuse and exacerbated headaches can be daunting; however, discontinuation often serves as indicative, though not obligatory, for diagnosing MOH, while thresholds defining medication overuse lack absolute parameters. Behavioral and educational interventions coupled with withdrawal therapy prove beneficial for MOH. A debate ensues over the superior approach: withdrawal from acute medication overuse or incorporating preventive medications targeting the underlying primary headache subtype. Interestingly, findings from preclinical models suggest that small-molecule CGRP receptor antagonists (gepants) are improbable contributors to MOH.

FW15_2 | From chronic migraine pathophysiology to novel treatments

A. Maassen van den Brink
Erasmus University Medical Center, Rotterdam, The Netherlands

FW15_3 | Pharmacological treatment of cluster headache

P. Irimia
Department of Neurology, Clínica Universidad de Navarra, Pamplona, Spain

Cluster headache management requires a tailored treatment approach encompassing both acute and preventive strategies. Acute therapy is useful for aborting individual attacks of cluster headache and primarily involves oxygen inhalation, subcutaneous sumatriptan, or intranasal sumatriptan/zolmitriptan. The primary goal of preventive therapy is to produce a suppression of attacks and to maintain remission over the expected duration of the cluster period. Verapamil is the medication of choice for the prevention of episodic and chronic cluster headache. Glucocorticoids or occipital nerve block are often used as a bridging therapy to provide more rapid benefit during the initial titration of verapamil. Alternative agents such as lithium, topiramate, or melatonin may also be beneficial. Galcanezumab has recently emerged as an additional option for episodic cases. Noninvasive neurostimulation techniques and deep brain stimulation offer potential avenues for medically refractory cases. This presentation will comprehensively review cluster headache treatment options, ensuring an evidence-based and up-to-date approach to patient care.

What's new on EAN guidelines?

SPS02_1 | GPG Strategy 2024–2028

J. Costa
Guideline Production Group, EAN

Guideline Production Group (GPG) aims to fulfil EAN's mission to reduce the burden of neurological diseases, realizing its vision to be the home of neurology and advance high-quality patient care, as well as upholding its values. Following this and the past GPG Strategy (2021–2023), whose goals have been successfully achieved, the GPG believes that a long-term plan is needed. One of its main objectives of the new GPG Strategy for 2024–2028 is to further strengthen the internal foundations of its guideline production system, which is rooted in its robust membership. Guidelines quality highly depends on the skills, competencies, and motivation of the EAN members comprising the Guideline Taskforces. To maintain the efficient production of high-quality guidelines, GPG plans to establish infrastructures to expand the available support and resources and open opportunities to develop skills and know-how. Plans of action have been developed for this purpose and will be executed. One of the projects, which will be launched in 2024 and will be presented in this session, is an SOP for Guideline Manuscripts aiming to standardize the format of EAN guidelines and support guideline developers. Secondly, the GPG intends to establish the external presence of the EAN guidelines. The final purpose of any guideline is to improve healthcare and patient-important outcomes. The end goal is not just to publish these papers, but to use them in practice. To achieve this, the GPG plans to study the breadth of the reach of EAN guidelines and develop strategies for awareness, dissemination, and implementation.

SPS02_4 | EAN CoCoCare graduation 2023

M. Leone[1]; M. Majoie[2]
[1]*Scientific Direction, IRCCS Casa Sollievo della Sofferenza, S. Giovanni Rotondo, Italy*; [2]*Department of Neurology, Academic Centre for Epileptology, Epilepsy Centre Kempenhaeghe & Maastricht University Medical Centre, Netherlands*

Clinical practice guidelines can play a crucial role in achieving more cost-efficient healthcare as they support the healthcare professional in deciding upon best efficient treatment. The Cost-Conscious Healthcare (CoCoCare) training is a training project for residents in neurology, developed in 2018 at Maastricht University, Netherlands, to equip them with competencies to make cost-conscious high-quality choices in their future work. The European Academy of Neurology (EAN) was brought into the project as part of the Consortium and collaborated to its conduction in 2019–2020. Recognizing its high value, the EAN Guideline Production Group decided to take over the programme and its first iteration was launched in early 2023, aiming to

teach 20 neurology residents and early career neurologists who wish to boost their knowledge and skills in guideline development and implementation. The course is structured as an integrated learning programme that combines e-learning as preparation of an introductory in-person kick-off meeting, and an on-the-job training. Monthly plenary webinar discussions with dedicated and experienced trainers are provided. Ninety-one participants from 21 European Countries participated in the training. Participants felt that they had learned a lot, were stimulated to apply guidelines and to reflect on their own (future) role in developing guidelines and providing cost-conscious care. The graduates of the first EAN CoCoCare programme will receive their certificates at the EAN Congress 2024 in Helsinki.

EAN/ESC: Heart & brain interactions: Cognition and gender

SPS03_1 | The role of heart disease for cognitive impairment – The cardiologist' perspective

W. Doehner
Charite Universitätsmedizin Berlin, Germany

SPS03_2 | Cognitive impairment and heart disease – The neurologist' perspective

G. Tsivgoulis
Second Department of Neurology, National and Kapostrian University of Athens, Greece

Introduction: Cognitive impairment and heart disease pose increasing challenges in an aging population, significantly impacting patient well-being. Their intricate connection has been extensively studied, revealing mutual influences on progression.
Methods: This lecture delves into the neurologist's perspective on the dynamic interplay between cognitive impairment and heart disease, aiming to illuminate underlying factors.
Results: Vascular disease plays a pivotal role in influencing both heart disease and cognitive impairment. Hypertension, atherosclerosis, and diabetes affect cerebral perfusion, leading to cerebral small-vessel disease and cognitive decline. Additionally, heart failure and valvular disease exacerbate cerebral hypoperfusion, while coronary artery disease correlates with carotid artery disease and intracranial atherosclerosis. Apart from small-vessel disease, heart disease, particularly conditions such as atrial fibrillation, can increase the risk of stroke, which, in turn, can cause cognitive impairment, depending on the severity and location of the brain injury. Furthermore, chronic inflammation, prevalent in both heart disease and neurodegenerative disorders, may further contribute to cognitive decline. Finally, lifestyle factors are of outmost importance in the relationship between heart disease and cognitive impairment. Adopting a heart-healthy lifestyle, including regular exercise, a balanced diet, and smoking cessation, can benefit both cardiovascular health and cognitive function. Effective screening strategies tailored to detect cognitive impairment in cardiac patients, while considering sex-specific disparities, are essential.
Conclusion: Addressing the intricate relationship between heart disease and cognitive impairment necessitates a collaborative, multidisciplinary approach between cardiologists and neurologists, aiming to optimize patient outcomes and enhance quality of life.
Disclosure: Nothing to disclose.

SPS03_3 | Sex differences in heart-brain interaction – The cardiologist' perspective

C. Gebhard
University Hospital Inselspital Bern, Switzerland

SPS03_4 | Sex differences in brain-heart interaction – The neurologist' perspective

M. Endres
Klinik für Neurologie, Charité-Universitätsmedizin Berlin, Germany

Sex and gender play an important role in cardiovascular disease and stroke. This review lecture will summarize important aspects of sex and gender in the pathophysiology and clinical course of these diseases from a neurological perspective. Diseases of both the heart and the brain share the same risk factors such as hypertension, diabetes, smoking and dyslipidemia and are also affected by inflammation, atherosclerosis and neuroendocrine changes, where sex and gender play an important role. A special focus of the lecture will be direct heart-brain interactions, in particular the so-called stroke-heart syndrome and also neurological causes of Takotsubo syndrome. For example, it has recently been shown that post-stroke myocardial injury occurs more frequently in women and also leads to greater disability.

Pregnancy in women with neurological diseases

SPS05_1 | Multiple sclerosis

A. Chan

Neurology Department, Inselspital Bern, Bern, Switzerland

Multiple sclerosis (MS) has a strong female gender preponderance and predominantly affects persons with MS (pwMS) at younger age. Thus, family planning and pregnancy are core aspects in patient management, with increasing complexity due to the growing number of disease-modifying immunotherapies (DMTs). Many DMTs have scarce or no safety data in pregnancy and breastfeeding and are thus labeled as contraindicated during these periods. In addition, often very long wash out intervals between DMT cessation and conception are stipulated. In view of relevant biological determinants (e.g. terminal half-life, penetration through placenta, bioavailability) this is in many instances an overly conservative approach. This is especially true in situations where non-treatment poses a considerable risk for the pwMS with pregnancy wish. Thus, in selected situations and if clinically necessary, shorter wash out intervals or even the continuation of immunotherapy can be considered for some substances. Currently, there are heterogeneous recommendations and guidelines active across different regions, also reflecting separate approval/reimbursement situations. Individualized approaches with careful consideration of the benefit-risk profile and interprofessional cooperation between the treating neurologist, obstetrician-gynecologist and pharmacist/pharmacologist ideally with involvement of experienced centers are necessary.

Disclosure: No disclosure.

SPS05_2 | Neuromuscular diseases

C. Sommer

Department of Neurology, University Hospital of Würzburg, Germany

Pregnancy in women with neuromuscular diseases presents unique challenges due to the impact of these conditions on function, mobility, overall health, and restrictions in treatment options. Whereas some neuromuscular diseases affect mostly men, others are more prevalent in women, including those of childbearing age. Examples are spinal muscular atrophy, myasthenia gravis, and Charcot-Marie-Tooth disease. Women with neuromuscular diseases may face higher risks during pregnancy, including respiratory complications and increased fatigue. Pregnancy can exacerbate existing muscle weakness in myasthenia gravis, in particular in the first trimester or in the puerperium. Cardiorespiratory function may be further impaired in pregnancy in mitochondrial diseases. Many drugs are contraindicated in pregnancy, and treatment needs to be adapted. Depending on the severity of the neuromuscular disease and associated complications, women may require specialized care during labor and delivery; for example, in spinal muscular atrophy, delivery is mostly by cesarian section. A multidisciplinary approach is needed in most cases to optimize maternal and fetal health while minimizing risks associated with the underlying neuromuscular condition.

Disclosure: CS has been a consultant for Algiax, Bayer, Grifols, Nevro and Takeda. She has given educational talks for CSL Behring, GSK, Grifols, Kedrion, Pfizer, and TEVA.

SPS05_3 | Cerebrovascular diseases

D. Leys
University of Lille, France

Background: As approximately 10% of strokes occur before the age of 45 years, it is important to inform women who have had a stroke about risks associated with a future pregnancy.
Objective: To determine what are the risks of recurrent stroke, other vascular events, and complication of pregnancy in case of pregnancy occurring after an ischaemic stroke or a cerebral venous thrombosis.
Method: Literature review.
Results: In women who have history of ischaemic stroke: (i) the risks of recurrent stroke and of new vascular events are increased compared to women who never had a stroke, but not increased compared to non-pregnant periods; (ii) the risks of serious complications of pregnancy (miscarriages, stillbirth, premature delivery, eclampsia) is increased. Women who have history of cerebral venous thrombosis have an increased risk of recurrence, but this risk seems lower if they receive anticoagulant therapy. In women who need anticoagulation during pregnancy, low molecular weight heparin is the treatment of choice. Vitamin K antagonists can safely be given after 13 weeks of pregnancy and should be stopped 1 month before delivery. Oral direct anticoagulants are not recommended.
Conclusion: After an ischaemic stroke the risk of recurrent ischaemic event (cerebral or of other location) is not increased by the pregnancy, but the risk is mainly that of obstetrical complications. In women with history of cerebral venous thrombosis, the risk of recurrence is higher but limited with appropriate anticoagulation.
Disclosure: Nothing to disclose.

SPS05_4 | Epilepsy

K. Vonck, V. De Herdt
Ghent University Hospital, 4Brain, Belgium

Epilepsy is one of the most common chronic neurological disorders affecting women of childbearing age. Treating and counseling women with epilepsy (WWE) at childbearing age is a specific challenge, especially with many new ASMs becoming available. Information prior to conception and pregnancy is of paramount importance as both the epilepsy and the treatment may affect the fetus. Neurologists should be involved as early as possible to discuss anticonception and pregnancy planning in WWE, risk of seizures during pregnancy, risk of fetal complications due to ASM intake, delivery and breastfeeding. During pregnancy there is a risk of a higher seizure frequency related to hormone changes, water and sodium retention, stress, and decreasing blood levels of ASMs. In WWE there is a higher percentage of congenital malformation and risk of cognitive and behavioral disturbances in offspring associated with certain ASM intake. Drug level monitoring throughout pregnancy and following delivery is advised. Due to its well-established advantages breastfeeding should be considered but all drugs transfer into breastmilk to some extent by simple diffusion. Infants should be observed for signs of sedation. Pregnancy in WWE can be managed on an individual basis and is therefore safe and should not be discouraged.

EAN/EPA: Non-invasive therapeutic neuromodulation in Parkinson's Disease and neuropsychiatric disorders

SPS06_1 | Non-invasive neurophysiological tools in humans

A. Suppa
Sapienza University of Rome, Italy

SPS06_2 | Therapeutic neuromodulation in Parkinson's disease

A. Macerollo
The Walton Centre NHS Foundation Trust for Neurology and Neurosurgery, Liverpool, UK

Therapeutic neuromodulation represents an umbrella term including different non-invasive brain stimulation techniques such as repetitive transcranial magnetic stimulation (rTMS) and transcranial direct current stimulation (tDCS). rTMS is a treatment that uses pulsing magnetic fields to activate or suppress the brain centres associated with a number of medical and psychiatric disorders. tDCS passes current through the scalp, skull, and meninges in order to stimulate the brain. A small electric current (1–2 mA) is delivered to the scalp by a battery-driven device connected to two saline-soaked surface electrodes. Both techniques as showed potential benefit for Parkinson's disease (PD), particularly in patients with pharmacorefractory motor symptoms or who are not candidates for surgical interventions such as deep brain stimulation (DBS). The main limitations in PD are low spatial resolution and superficial targeting. In the last few years a different therapeutic neuromodulation technique labelled transcranial-focused ultrasound stimulation (TUS) has attracted the attention of several neurologists and neuroscientists. Since the first medical application of ultrasounds in 1950s, the use of this procedure has evolved and is currently investigated as a new therapeutic role. Alongside with rTMS and tDCS, it has been demonstrated to be safe and promising in initial studies on patients with Parkinson's disease. The main benefit compared to the other two neuromodulations intervention is the possibility to reach superficial as well as deep cerebral targets with high spatial resolution. If rTMS can have a target of TMS of a few centimeters squares, TUS can reach targets of millimeters. It is possible to reach the basal ganglia with TUS but not with rTMS or tDCS.
Disclosure: Nothing to disclose.

SPS06_3 | Deep brain stimulation with transcranial focused ultrasound: Application to movement disorders and psychiatric disorders

J. Aubry
Physics for Medicine Paris, Paris, France

Since the late 1920s, less than 10 years after Paul Langevin filed the first patent on the development of an ultrasound transducer, intense research has focused on the medical applications of high-intensity focused ultrasound, particularly for cerebral applications. Unfortunately, for a long time, the skull constituted an impenetrable barrier to ultrasound. In the late 1990s, the use of multi-element arrays and the development of new aberration correction techniques laid the theoretical and technological foundations for transcranial ultrasound focusing. After introducing the most recent transcranial focusing techniques, we will show that world-first clinical results provide evidence that ultrasound neurostimulation is a revolutionary tool enabling, for the first time, to achieve deep brain stimulation in a non-invasive way. Clinical results will be presented on essential tremor, addiction and depression.

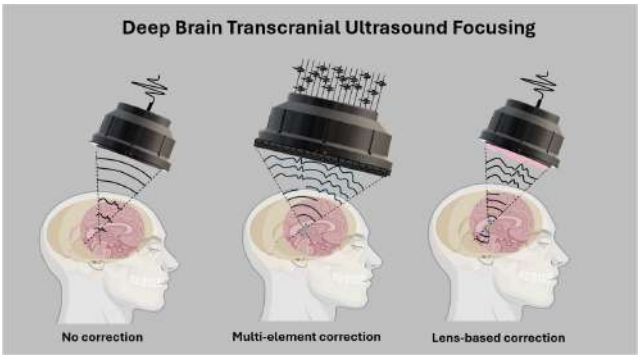

FIGURE 1 Defocusing effect of the skull bone and latest techniques for precise ultrasound transcranial focusing.

Disclosure: Jean-Francois Aubry holds five patents on transcranial ultrasound.

Ageing and dementia 1

OPR-001 | **Distressing dreams, cognitive decline, and risk of dementia: A prospective study of three population-based cohorts**

A. Otaiku
UK Dementia Research Institute, Imperial College London, London, UK

Background and aims: Distressing dreams are associated with faster cognitive decline and increased dementia risk in people with Parkinson's disease (PD). Whether distressing dreams are associated with cognitive decline and dementia in people without PD is unknown. This study investigated the association between self-reported distressing dream frequency and the risk of cognitive decline and incident dementia in community-dwelling men and women in the general population.

Methods: Risk of cognitive decline was evaluated in 605 middle-aged adults from the Midlife in the United States (MIDUS) study who were followed-up over 13 years. Cognitive decline was defined as having an annual rate of decline in global cognitive function ≥1 standard deviation faster than the mean decline rate. Risk of incident all-cause dementia was evaluated in 2600 older adults from the Osteoporotic Fractures in Men Study (MrOS) and the Study of Osteoporotic Fractures (SOF), who were followed-up over 7 years. Distressing dream frequency was assessed in all cohorts at baseline using item 5 h of the Pittsburgh Sleep Quality Index. The association between self-reported distressing dream frequency and later cognitive outcomes was evaluated using multivariable logistic regression.

Results: Compared with middle-aged adults who reported having no distressing dreams at baseline, those who reported having weekly distressing dreams had a 4-fold risk of experiencing cognitive decline (adjusted odds ratio [aOR] = 3.99; 95% CI: 1.07, 14.85). Amongst older adults, the difference in dementia risk was 2.2-fold (aOR = 2.21; 95% CI: 1.35, 3.62).

Conclusion: Distressing dreams predict cognitive decline and all-cause dementia in middle-aged and older adults in the general population.

Disclosure: Nothing to disclose.

OPR-002 | **Exploring family history in Alzheimer's disease: Evidence for X-chromosome linked and recessively inherited risk factors**

C. Bernardes[1]; R. Guerreiro[2]; J. Brás[2]; J. Durães[1]; I. Baldeiras[3]; M. Lima[1]; M. Almeida[3]; I. Santana[1]; M. Tábuas-Pereira[1]
[1]*Neurology Department, Coimbra University Hospital Centre, Coimbra, Portugal;* [2]*Department of Neurodegenerative Science, Van Andel Institute, Grand Rapids, MI, USA;* [3]*Center for Neuroscience and Cell Biology, Coimbra, Portugal*

Background and aims: Alzheimer's Disease (AD) heritability is estimated to be around 70–80%. Yet, much of it is yet to be explained. Studying transmission patterns in different populations may help to understand factors contributing to the development of AD. In this study, we aimed to analyse family history patterns in a large cohort of Portuguese AD patients.

Methods: We collected family history from patients with AD and cognitively healthy controls over 75. We compared the proportion of subjects with AD depending on their family history (to assess X-linked and Y-linked associated inheritance patterns) and on the parents' birthplace (as a proxy of remote consanguinity). Linear regressions to study the association of these variables with different endophenotypes were performed.

Results: We included 3073 participants, 2183 cognitively healthy controls and 890 patients with AD. Men with a mother with dementia develop AD more frequently than women with a mother with dementia. In female patients with a CSF-supported diagnosis of AD, paternal history of dementia is associated with lower CSF total Tau, but increased CSF phosphorylated Tau. People whose parents are from the same town have higher risk of dementia. In multivariate analysis, this proxy is associated with a lower age of onset and higher CSF phosphorylated Tau, but higher CSF amyloid-beta42.

Conclusion: Our study gives evidence, at a population level, of X-linked risk factors for AD. We also add evidence to remote consanguinity as a risk factor for AD.

Disclosure: Nothing to disclose.

OPR-003 | Regulation of conditioned fear memory extinction by the orexin system in the medial prefrontal cortex

P. Yi[1]; M. Lin[2]; F. Chang[3]
[1]*Department of Sport Management/Aletheia University, Taiwan, China;* [2]*Graduate Institute of Brain and Mind Sciences/National Taiwan University, Taiwan, China;* [3]*Graduate Institute of Veterinary Medicine/National Taiwan University, Taiwan, China*

Background and aims: Post-traumatic stress disorder (PTSD) disrupts discernment of trauma-related fear memories, causing emotional distress and sleep disruptions. The orexin system, originating from the lateral hypothalamus (LH), is implicated in fear memory recall post-extinction. Lesions in the medial prefrontal cortex (mPFC), a LH downstream projection, hinder fear memory extinction. We proposed that the LH-mPFC pathway crucially contributes to conditioned fear memory extinction and modulates rapid eye movement (REM) sleep, impacting memory processing.
Methods: Using chemogenetic technique, we selectively manipulated the LH-mPFC pathway by activating or inhibiting it during extinction learning, and behavior tasks were assessed. Concurrently, electrocorticography (EEG) measured sleep–wake states under these manipulations.
Results: Extinction acquisition heightened activity in both the mPFC and LH. Activating the LH-to-mPFC pathway maintained elevated freezing levels during fear memory extinction, while silencing initially lowered freezing levels, decreasing rapidly. This manipulation not only affected freezing expression but also influenced the formation of the extinction engram, impacting fear memory retrieval and anxiety tasks. These findings underscore the pivotal role of the LH-to-mPFC pathway in extinction acquisition. Pathway augmentation induced insomnia-like features, particularly during the light period.
Conclusion: Our results suggest that the LH-to-mPFC orexinergic projection regulates conditioned fear memory extinction and may disrupt REM sleep, providing insights into the intricate interplay between fear regulation, memory processing, and sleep disturbances in PTSD.
Disclosure: Nothing to disclose.

OPR-004 | Significance of plasma p-tau217 in predicting long-term dementia risk: Insights from machine learning approaches

Z. Xiao[1]; X. Zhou[1]; Q. Zhao[1]; Y. Cao[2]; D. Ding[1]
[1]*Institute of Neurology, Huashan Hospital, Fudan University, Shanghai, China;* [2]*Clinical Epidemiology and Biostatistics, Department of Medical Sciences, Faculty of Medicine and Health, Örebro University, Örebro, Sweden*

Background and aims: The role of plasma biomarkers for predicting incident dementia in the general population is still undetermined.
Methods: A total of 1857 baseline non-demented older adults with follow-ups within 10 years were included from a community-based cohort. Consensus diagnoses of dementia and Alzheimer's disease (AD) were based on clinical criteria. The Recursive Feature Elimination algorithm was used to select the important features from 90 baseline candidate predictors for developing dementia and AD prediction models. Area Under the Receiver Operating Characteristic Curve (AUC) was used to evaluate models' performance. Models were validated in the testing sets and subsets.

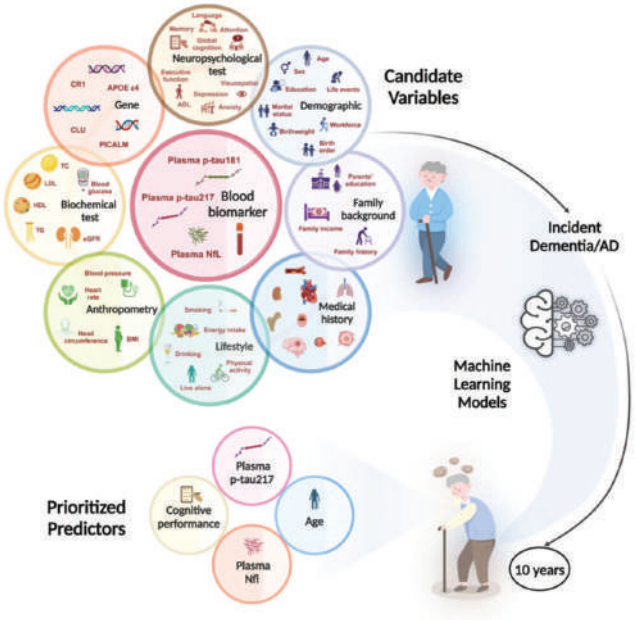

FIGURE 1 Illustration of the candidate variables and research process.

Results: During the follow-up of 12,716 person-years, 207 participants developed dementia (including 145 AD). The constructed Logistic Regression, Naive Bayes, Bagged Trees, and Random Forest models showed moderate-to-high AUCs predicting future dementia (AUCs = 0.709–0.808) in the testing sets. Age, neuropsychological tests, and plasma p-tau217 were the prioritized variables in all models. The models also showed robustness in diverse subgroups.

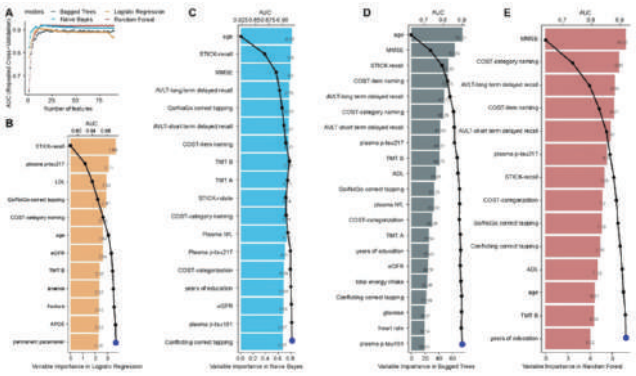

FIGURE 2 The selected models and variable importance for predicting dementia.

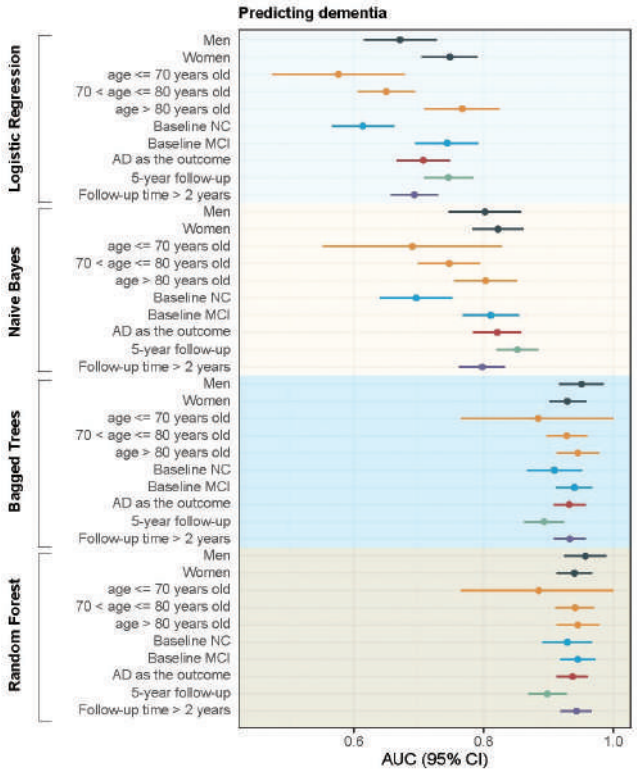

FIGURE 3 Subgroup analyses of the models for predicting dementia.

Conclusion: Plasma p-tau217, combined with age and cognitive performance, showed important values in predicting incident dementia among community older adults. In the resource-limited settings, using these variables may be convenient and cost-effective to identify participants with high risk of dementia in the general population.
Disclosure: Nothing to disclose.

OPR-005 | Autonomic dysfunction in REM sleep behavior disorder: Heart rate variability analysis to explore neurodegeneration

M. Figorilli[1]; P. Sattar[3]; E. Casaglia[1]; M. Mascia[1]; E. Facchini[2]; G. Baldazzi[3]; N. Mandas[4]; D. Pani[3]; P. Mattioli[6]; L. Giorgetti[5]; D. Arnaldi[6]; M. Puligheddu[1]
[1]*Department of Medical Sciences and Public Health, Sleep Disorder Research Center, University of Cagliari, Cagliari, Italy;* [2]*MeDSP Lab, Department of Electrical and Electronic Engineering, University of Cagliari, Cagliari, Italy;* [3]*MeDSP Lab, Department of Electrical and Electronic Engineering, University of Cagliari, Cagliari, Italy; Department of Medical Sciences and Public Health, Sleep Disorder Research Center, University of Cagliari, Cagliari, Italy;* [4]*MeDSP Lab, Department of Electrical and Electronic Engineering, University of Cagliari, Cagliari, Italy; The Hadron Academy, Istituto Universitario di Studi Superiori IUSS, Pavia, Italy;* [5]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DI-NOGMI),Clinical Neurology, University of Genoa, Genoa, Italy;* [6]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DI-NOGMI), Clinical Neurology, University of Genoa, Genoa, Italy; Neurophysiopathology Unit, IRCCS Ospedale Policlinico San Martino, Genoa, Italy*

Background and aims: Autonomic dysfunction is common along the alpha-synucleinopathy continuum from prodromal stage (isolated REM sleep behavior disorder, iRBD) to overt Parkinson's disease (PD). This study aims to investigate autonomic dysregulation in iRBD, RBD-PD and PD patients by examining sleep-related Heart Rate Variability (HRV) parameters.
Methods: 40 iRBD (67 ± 8 y.o., 73% males), 16 PD (67 ± 10 y.o., 50% males), 30 PD-RBD (71 ± 8 y.o., 66% males) and 24 controls (CG, 59 ± 10 y.o., 46% males) subjects were enrolled from two Italian sleep centers. A 5-min artifact-free ECG signal from N2, N3, and REM phases was investigated for time-domain HRV analysis. Intergroup significant differences have been assessed by nonparametric statistical analysis, for each sleep phase separately.
Results: When comparing iRBD and CG subjects, lower HRV parameters were observed in N2 ($p < 0.025$ for all) and REM ($p < 0.04$ for STDNN and R20) phases. iRBD showed lower HRV also when compared to PD-RBD in N2 ($p < 0.006$, for STDNN, SDSD, RMSSD), and PD in N2 ($p < 0.025$, for STDNN, SDSD, RMSSD, pR50) and in N3 ($p < 0.05$, for STDNN, SDSD, RMSSD). Conversely, the PD group showed significant reduction when compared to the CG ($p < 0.03$), as well as a significant increase when compared to the PD-RBD group ($p < 0.05$, R20 and pR20 in REM).
Conclusion: These findings suggest that the disrupted autonomic regulation is evident in the early alpha-synucleinopathy stage during N2 and REM sleep, even more than in overt PD. Longitudinal studies are warranted to determine whether autonomic dysfunction in iRBD could serve as a prognostic biomarker, aiding in the prediction of alpha-synucleinopathy subtypes development.
Disclosure: Nothing to disclose.

Cerebrovascular diseases 1

OPR-006 | NLRP3-inflammasome inhibition reduces stroke induced inflammation and delays infarct growth before recanalization

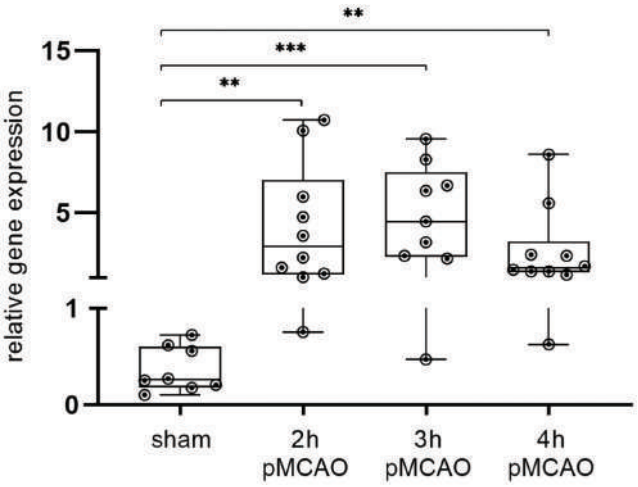
M. Bellut
Department of Neurology, University Hospital Würzburg, Würzburg, Germany

Background and aims: The NLRP3-inflammasome is a multiprotein complex regulating the activation of the innate immune system. NLRP3-dysregulation has been implicated in various inflammatory and autoimmune diseases. In experimental ischemic stroke, NLRP3-inhibition mitigated ischemia/reperfusion-injury and secondary infarct growth after recanalization. In the present study, we examined

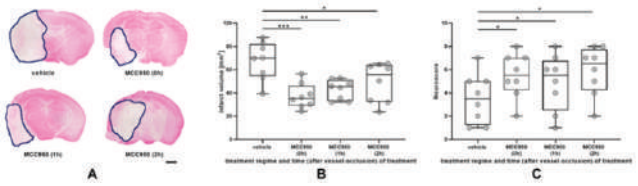
whether NLRP3-inhibition might alleviate stroke progression already under large vessel occlusion (LVO) before recanalization.

Methods: We occluded the middle cerebral artery in C57Bl/6-mice for up to 4 hours and examined the NLRP3-mRNA expression under LVO. In a subsequent experiment, C57Bl/6-mice were prophylactically or therapeutically (after 1 h and 2 h of vessel occlusion) treated with the NLRP3-inflammasome inhibitor MCC950. We then assessed stroke volumes, the NeuroScore, IL1b-levels (immunoblot) and blood–brain-barrier (BBB) integrity (albumin extravasation).

Results: We detected a 5–10-fold upregulation of NLRP3-mRNA expression already under LVO ($n = 10$/group). Its inhibition reduced stroke sizes significantly [vehicle/prophylactic/MCC950(1 h)/MCC950(2 h)-treatment: 67.4 ± 16.4 mL/37.2 ± 10.2 mL/42.9 ± 8.4 mL/49.1 mL ± 12.1 mL] ($n = 9$/group). Consequently, the IL1b-release decreased cortically by 20% ($n = 9$/group) while the integrity of the BBB and the NeuroScore ($n = 9$/group) improved significantly. We observed these improvements in both the prophylactic and therapeutic settings.



NLRP3 gene expression levels increase during pMCAO.



NLRP3 inhibition reduces infarct volume after prophylactic (MCC950 0 h) and delayed treatment, 1 h (MCC950 1 h) and 2 h (MCC950 2 h) post stroke onset.

Conclusion: As main finding we show that blocking of NLRP3 mitigates cerebral inflammation and infarct growth already under LVO and partly preserves the ischaemic penumbra, "buying time" before recanalization. This may have a major clinical impact in the future since infarct progression under LVO is a major caveat for an unfavourable clinical outcome despite successful recanalization.

Disclosure: Nothing to disclose.

OPR-007 | Antiplatelets in emergent carotid stenting after intravenous thrombolysis: A multicenter retrospective matched analysis

F. Colò[1]; A. Alexandre[1]; F. Arba[2]; L. Scarcia[3]; A. Falcou[4]; M. Ruggiero[5]; M. Piano[6]; A. Zini[7]; G. Bigliardi[8]; A. Broccolini[1]

[1]Policlinico Universitario Agostino Gemelli, Rome, Italy; [2]Careggi University Hospital, Firenze, Italy; [3]Henri-Mondor University Hospital, Créteil, France; [4]Clinica ospedaliero-universitaria Policlinico Umberto I, Rome, Italy; [5]AUSL Romagna - Sede Cesena, Neurology, Cesena, Italy; [6]Niguarda, Neurology, Milan, Italy; [7]Ospedale MAGGIORE Bologna, Bologna, Italy; [8]Stroke Unit, Ospedale Civile di Baggiovara, Modena, Italy

Background and aims: Mechanical thrombectomy (MT) with emergent carotid stenting (eCAS) is beneficial in patients with tandem occlusion (TO). Our aim was to address safety and efficacy of different intra-procedural antiplatelet regimens in patients undergoing eCAS after intravenous thrombolysis (IVT) and define predictors of parenchymal hemorrhage (PH).

Methods: The databases of 17 European stroke centers were screened for consecutive patients with TO who received MT with eCAS. Intra-procedural antiplatelet therapy was categorized in: (1) low intensity regimen, (2) high intensity regimen, and (3) high intensity regimen followed by i.v. Glycoprotein IIb/IIIa inhibitors (GPI) infusion. Propensity score matching (PSM) was used to estimate differences in outcome between treatment groups. Outcome measure included the occurrence of PH type 2 and type 1 and the 90-day mRS score 0–2.

Results: 621 patients were collected, 48.5% received IVT. After PSM there was no significant difference between IVT and non-IVT patients under different antiplatelet regimens concerning rates of PH type 2 and type 1. Subgroup analysis showed increased rate of PH type 2 in IVT patients receiving high intensity regimen plus GPI maintenance, but without difference in clinical outcome. In multivariate analysis, presence of atrial fibrillation (OR 4.089, 95% CI 1.759–9.508), high intensity antiplatelet regimen with GPI maintenance (OR 2.364, 95% CI 1.086–5.147) and stent thrombosis (OR 2.631, 95% CI 1.160–5.970) were predictors of PH type 2.

Table 1: Effect of IVT on outcome measures after PSM of patients from the entire cohort

	IVT (n=222)	Non-IVT (n=222)	p value *
Parenchymal hemorrhage type 2, number/total (%)	15/222 (6.76%)	18/222 (8.11%)	0.718
Parenchymal hemorrhage type 1, number/total (%)	53/222 (23.87%)	51/222 (22.97%)	0.911
Extracranial bleeding, number/total (%)	12/222 (5.41%)	5/222 (2.25%)	0.136
Stent thrombosis, number/total (%)	20/222 (9.01%)	25/222 (11.26%)	0.530
mTICI score 2b-3, number/total (%)	187/217 (86.18%)	194/219 (88.58%)	0.474
mRS score 0-2, number/total (%)	131/201 (65.17%)	104/188 (55.31%)	**0.049**
90-day mortality, number/total (%)	22/201 (10.95%)	25/188 (13.30%)	0.535

IVT = intravenous thrombolysis; PSM = propensity score matching; mTICI = modified Treatment In Cerebral Infarction; mRS = modified Rankin Scale; * statistical significance was considered at $p < 0.05$.

Table 2: Outcome measures after PSM of IVT and non-IVT patients under different intra-procedural antiplatelet regimens.

	Low APT regimen			High APT regimen			High APT regimen plus GPI maintenance

PSM = propensity score matching; IVT = intravenous thrombolysis; APT = antiplatelet; mTICI = modified Treatment In Cerebral Infarction; mRS = modified Rankin Scale; * Statistical significance was considered at $p < 0.05$.

Table 3. Multivariate logistic regression analysis for predictors of PH type 2

	OR	95% CI	p value*
Hypertension	1.588	0.787 - 3.203	0.196
Atrial fibrillation	**4.089**	**1.759 - 9.508**	**0.001**
Diabetes	1.300	0.570 - 2.016	0.533
Antiplatelet regimen for eCAS **			
High intensity	1.938	0.773 - 4.862	0.283
High intensity + GPI maintenance	**2.364**	**1.086 - 5.147**	**0.030**
Antiplatelet regimen after eCAS ***			
SAPT	0.428	0.091 - 2.016	0.283
DAPT	**0.217**	**0.061 - 0.770**	**0.018**
Stent thrombosis	**2.631**	**1.160 - 5.970**	**0.021**

PH = parenchymal hemorrhage; OR = odds ratio; CI = confidence interval; eCAS = emergent carotid stenting; GPI = Glycoprotein IIb/IIIa inhibitors; SAPT = single antiplatelet therapy; DAPT = dual antiplatelet therapy; * Statistical significance was considered at $p < 0.05$; ** = Coefficients are relative to low intensity regimen; *** = Coefficients are relative to no antiplatelet therapy.

Conclusion: Different intra-procedural antiplatelet regimens for eCAS are safe after IVT. Increased risk of PH type 2 is associated with use of intra-procedural GPI maintenance in IVT patients and presence of atrial fibrillation.

Disclosure: Nothing to disclose.

OPR-008 | Stroke recurrence and overall mortality in CPAP treated post-stroke obstructive sleep apnea patients

J. Suusgaard[1]; A. West[2]; L. Ponsaing[1]; H. Iversen[2]; P. Jennum[1]
[1]*Danish Center for Sleep Medicine, Department of Clinical Neurophysiology, Copenhagen University Hospital, Rigshospitalet, Denmark;* [2]*Department of Neurology, Cerebrovascular Research Center Rigshospitalet, Copenhagen University Hospital, Rigshospitalet, Denmark*

Background and aims: Obstructive sleep apnea (OSA) is strongly associated with stroke development and is identified in up to 70% of stroke patients. It is unclear whether treatment with continuous positive airway pressure (CPAP) reduces re-stroke risk or mortality among post-stroke patients. Previous studies examining the impact of CPAP on mortality in post-stroke patients have either had limited follow-up periods or involved small sample sizes.

Methods: We conducted a retrospective cohort study using data from the Danish National Patient Registry covering the period from 2003 to 2016, involving 1821 patients diagnosed with sleep-disordered breathing (SDB) and a prior ischemic stroke or transient ischemic attack (TIA). Patients were categorized into three groups: CPAP adherent, CPAP non-adherent and no CPAP treatment. By utilizing Cox hazard regression, we assessed the risk of recurrent stroke or TIA and overall mortality among these groups over a 5-year follow-up period.

Results: CPAP treatment improved survival rate in patients categorized as adherent compared to patients with no CPAP treatment (hazard ratio: 0.62; 95% CI: 0.50–0.76; $p < 0.001$). This effect persisted after adjusting for age, sex, and pre-existing comorbidities within 3 years (the Quan updated Charlson Comorbidity Index). There was no observed reduction in the risk of recurrent stroke/TIA between the CPAP groups.

Conclusion: In this large, registry-based study, we found that CPAP-adherence reduced the overall mortality in post-stroke/TIA patients with SDB. CPAP treatment did not seem to affect the risk of re-stroke/TIA during the 5 years of follow-up.

Disclosure: Nothing to disclose.

OPR-009 | Argatroban for ischemic stroke with early neurological deterioration: A meta-analysis of randomized controlled trials

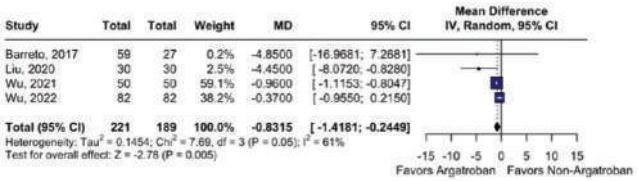
I. Barros Andrade[1]; V. Morbach[2]; V. Kendi Tsuchiya Sano[3]; V. Maia Arca[4]; A. de Oliveira Macena Lôbo[5]; A. Menegaz de Almeida[6]; F. Cezar Aquino de Moraes[7]; L. Henrique Geraldo[8]
[1]*Faculdade Santo Agostinho De Vitória Da Conquista, Bahia, Brazil;* [2]*Feevale University, Novo Hamburgo, Brazil;* [3]*Federal University of Acre, Rio Branco, Brazil;* [4]*Neurology Department – Hospital da Clínicas UFPE, Recife, Brazil;* [5]*Federal University of Pernambuco, Recife, Brazil;* [6]*Federal University of Mato Grosso, Sinop, Brazil;* [7]*Federal University of Para, Belém, Brazil;* [8]*Department of Neurology, New York University Grossman School of Medicine, New York, USA*

Background and aims: The presence of early neurological deterioration in acute ischemic stroke (AIS) underscores the urgent and intricate nature of managing this medical condition. Currently, argatroban is under investigation as a potential combination treatment, but there still a lack of evidence for its efficacy. Consequently, it becomes imperative to ascertain whether this compound contributes to improvement in neurological function following AIS.

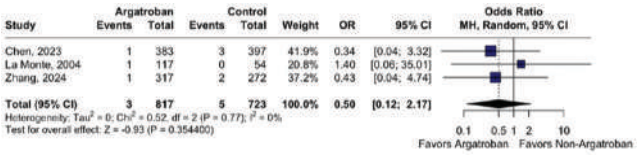
Methods: We systematically searched databases (PubMed, Embase, Web of Science, and Cochrane) until January 10, 2024. Odds ratio (OR) and mean differences (MDs) with 95% confidence intervals (CIs) were calculated using a random-effects model. Heterogeneity was assessed using I^2 statistics. The statistical analysis was performed using R software, version 4.3.1.

Results: A total of 9 studies and 2043 patients were included. As compared to the control group, Argatroban treated patients exhibited significantly improved NIHSS score at 7- and 90-days post stroke (MD −0.8315, 95% CI −1.418 to −0.2449, $p = 0.005$; MD −0.3903, 95% CI −1.9313 to 1.1506, $p = 0.62$) respectively. Argatroban treatment reduced the occurrence of parenchymal hematoma (PH). There

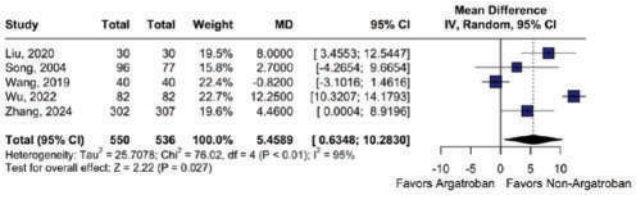
were no significant changes in the Modified Rankin Score (mRS) and symptomatic intracranial hemorrhage (sICH) occurrence in patients treated with Argatroban when compared to placebo group. Finally, patients on the placebo group had a significantly improved modified Barthel Index (mBI).



A forest plot of the change in the National Institutes of Health Stroke Scale (NIHSS) outcome of 7 days.



A forest plot of the change in the Parenchymal Hematoma (PH) outcome.



A forest plot of the modified Barthel Index (mBI) outcome.

Conclusion: Among these patients, treatment with argatroban plus drug improve NIHSS scores, most prominently at 7 days. These results demonstrate a benefit of Argatroban on reducing neurological deficits on AIS patients subject to thrombolytic therapy without increasing the risk of sICH.

Disclosure: The authors declare that they have no disclosure.

OPR-010 | Increased apnea-hypopnea index and elevated hypoxic burden are associated with atrial fibrillation in ischemic stroke

X. Yang[1]; J. Lippert[1]; I. Filchenko[1]; S. Baillieul[2]; C. Bernasconi[1]; S. Bauer-Gambelli[1]; A. Brill[3]; D. Seiffge[1]; T. Reichlin[4]; M. Arnold[1]; M. Schmidt[1]; C. Bassetti[1]

[1]Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [2]Grenoble Alpes University, HP2 Laboratory, INSERM U1300 and Grenoble Alpes University Hospital, Grenoble, France; [3]Department of Pulmonary Medicine, Allergology and Clinical Immunology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [4]Department of Cardiology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland

Background and aims: Sleep apnea (SA) increases the risk of cardiovascular disorders (CVD). SA is highly prevalent in stroke and is associated with an increased prevalence of atrial fibrillation (AF). Which markers of SA, the apnea-hypopnea index (AHI) or the hypoxic burden (HB), better predict AF in stroke, remains unknown.

Methods: This cross-sectional analysis utilized data from the Bernese Sleep & Stroke Cohort, an integral component of the Swiss Stroke Registry. During acute hospitalization, patients underwent respiratory polygraphy, leading to dichotomization into AHI+/ AHI- groups using a 20/h threshold. Further classification into HB+/HB- groups occurred with the 75% percentile as the threshold. Multivariate logistic regression assessed the associations between distinct combinations of HB and AHI (HB+/AHI+, AHI+/HB-, and HB+/AHI-) in comparison to HB-/AHI- on prevalent AF, adjusting for various confounders.

Results: In the analysis of 1010 patients (mean age 66y, 62% males), AF was diagnosed in 197 (20%) patients. HB+ was present in 254 (25%) patients, and AHI+ was present in 360 (36%) patients. The HB+/AHI+, AHI+/HB−, HB+/AHI−, and HB−/AHI− groups constituted 20%, 16%, 5%, and 59% of the total, respectively. Compared to the HB−/AHI− group, the HB+/AHI+ group was independently associated with prevalent AF (adjusted OR: 1.68; 95% CI: 1.10–2.55). No significant difference was observed in AHI+/HB− and HB+/AHI- groups.

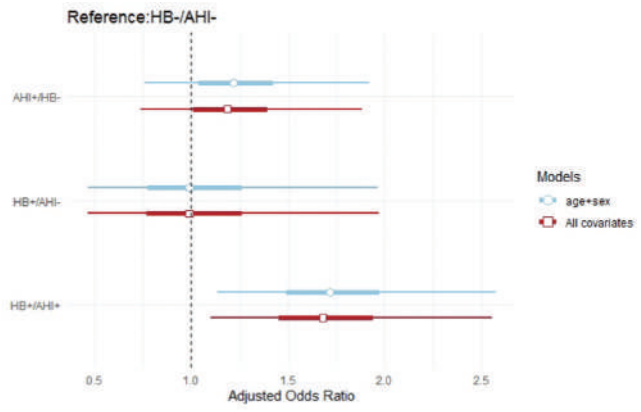


FIGURE 1 Adjusted Odds Ratios for prevalent AF across distinct combinations of HB and AHI (HB+/AHI+, HB+/AHI−, and AHI+/HB−), in comparison to the baseline group HB−/AHI−

TABLE 1 Baseline characteristics between HB−/AHI−, AHI+/HB−, HB+/AHI−, AHI+/HB+ groups.

Conclusion: In stroke, an elevated HB with an increased AHI, rather than either SA measures in isolation, is associated with a higher prevalent of AF. These findings underscore the potential of both markers in enhancing risk stratification for CVD.

OPR-011 | Compensated hypogonadism identified in males with cluster headache: A prospective case-controlled study

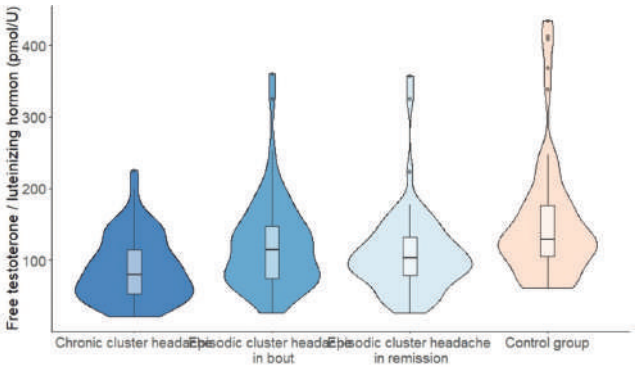
A. Petersen[1]; D. Kristensen[2]; C. Westgate[1]; T. Folkmann-Hansen[1]; N. Lund[1]; M. Barloese[3]; M. Søborg[1]; A. Snoer[1]; T. Johannsen[4]; H. Frederiksen[4]; A. Juul[4]; R. Jensen[1]

[1]*Department of Neurology, Danish Headache Center, University of Copenhagen, Rigshospitalet-Glostrup, Glostrup, Denmark;* [2]*Department of Science and Environment, Roskilde University, Denmark;* [3]*Department of Clinical Physiology and Nuclear Medicine, Centre for Functional and Diagnostic Imaging and Research, University of Copenhagen, Hvidovre Hospital, Hvidovre, Denmark;* [4]*Department of Growth and Reproduction, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark*

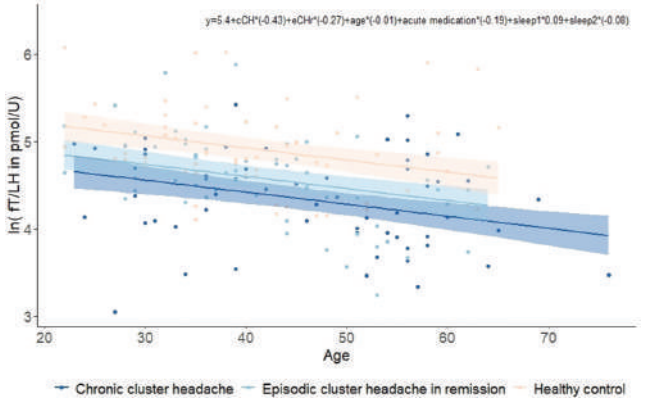
Background and aims: Androgens have been hypothesized to be involved in the pathophysiology of cluster headache due to the male predominance, but whether androgens are altered in patients with cluster headache remains unclear.

Methods: We performed a prospective, case-controlled study in adult males with cluster headache. Sera were measured for hormones including testosterone, luteinizing hormone (LH), and sex hormone-binding globulin in 60 participants with episodic cluster headache (during a bout and in remission), 60 participants with chronic cluster headache, and 60 age- and sex-matched healthy controls. Free testosterone (fT) was calculated according to the Vermeulen equation. Shared genetic risk variants were assessed between cluster headache and testosterone concentrations.

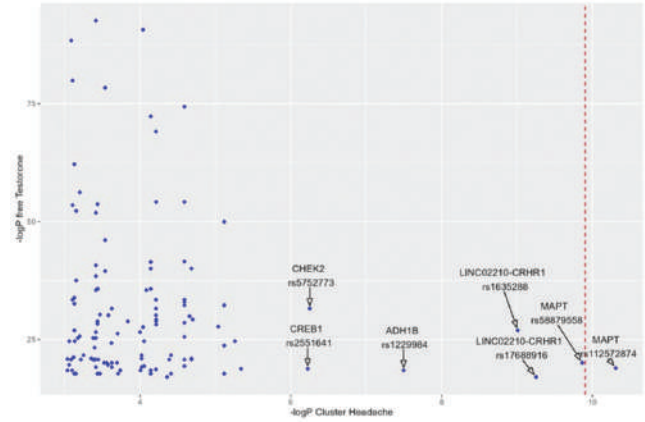
Results: The mean fT/LH ratio was reduced by 35% (95% CI: 21%–47%, $p<0.0001$) in patients with chronic cluster headache and by 24% (95% CI: 9%–37%, $p=0.004$) in patients with episodic cluster headache compared to controls after adjusting for age, sleep duration, and use of acute medication. Androgen concentrations did not differ between bouts and remissions. Furthermore, a shared genetic risk allele, rs112572874 (located in the intron of the microtubule associated protein tau (MAPT)), between fT and cluster headache was identified.



Violin plot of free testosterone/luteinizing hormone (fT/LH) -ratio in serum in participants with different types of cluster headache and in healthy, sex- and age- matched controls.



Linear regression of the free testosterone/luteinizing hormone (fT/LH) -ratio in serum as a function of age.



Shared genetic risk variants of cluster headache and serum free testosterone concentration.

Conclusion: Our results demonstrate that the male endocrine system is altered in patients with cluster headache to a state of compensated hypogonadism, and this is not an epiphenomenon associated with sleep or the use of acute medication. Together with the identified shared genetic risk allele, this may suggest a pathophysiological link between cluster headache and fT.

Disclosure: Nothing to disclose.

OPR-012 | Cluster tics in cluster headache: A cross-sectional and controlled study

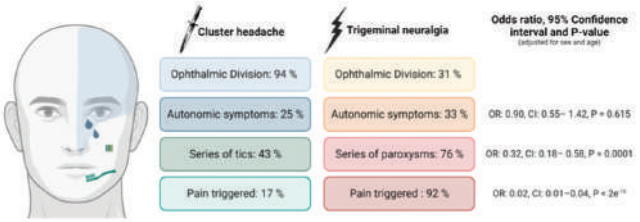
M. Carney[1]; S. Maarbjerg[1]; M. Søborg[1]; N. Lund[1]; J. Worm[1]; L. Bendtsen[1]; R. Jensen[1]; A. Petersen

Department of Neurology, Danish Headache Center, University of Copenhagen, Rigshospitalet-Glostrup, Glostrup, Denmark

Background and aims: This explorative study aimed to investigate the lifetime prevalence of cluster tics in patients with cluster headache, characterize cluster tics, including identifying possible associations to different clinical characteristics, and further investigate specific traits associated with cluster tics compared to trigeminal neuralgia.

Methods: A total of 424 patients with cluster headache were included in this controlled cross-sectional cohort study based on a semi-structured interview. The comparator cohort consisted of 576 patients diagnosed with trigeminal neuralgia, who had previously participated in a standardized, purpose-built, semi-structured interview.

Results: Cluster tics were reported in 200 out of 424 (47%) of patients with cluster headache. The odds of experiencing cluster tics were higher for males compared to females (OR: 1.93, 95% CI: 1.27–2.96, $p=0.002$), and for patients with chronic cluster headache compared to patients with episodic cluster headache (OR: 1.74, 95% CI: 1.15–2.62, $p=0.008$). We found that cluster tics presented as orbital pain in 70% of patients, and that, in comparison to trigeminal neuralgia paroxysms, the odds of a paroxysm being a cluster tic was low if the attack was triggerable (OR: 0.02, 95% CI: 0.01–0.04, $p<2e\text{-}16$).



Odds ratios (OR) for having been diagnosed with trigeminal neuralgia (TN) prior to interview when presenting with specific attack traits, adjusted for age and sex.

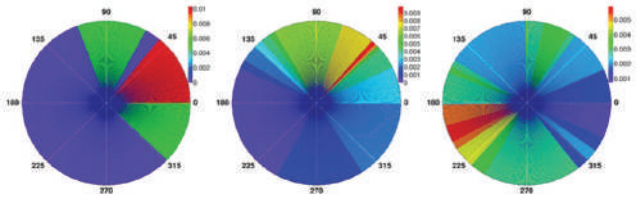
Conclusion: The lifetime prevalence of cluster tics in patients with cluster headache was 47%. The cluster tics were associated with the chronic cluster headache, and in contrast to the paroxysms in TN, cluster tics were associated to male sex, often had an orbital location of pain and were non-serial and non-triggerable.

Disclosure: Nothing to disclose.

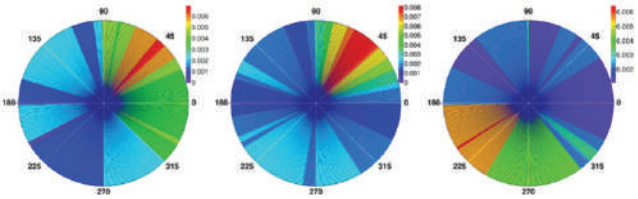
OPR-013 | Vascular compression in trigeminal neuralgia discloses trigeminal root somatotopic organization

G. De Stefano[1]; D. Litewczuk[1]; E. Ripiccini[2]; S. Maarbjerg[3]; G. Di Pietro[1]; P. Falco[1]; C. Leone[1]; E. Galosi[1]; A. Truini[1]; G. Di Stefano[1]
[1]*Department of Human Neuroscience, Sapienza University of Rome, Italy*; [2]*Advanced Quantum Architecture Laboratory, Swiss Federal Institute of Technology of Lausanne, Switzerland*; [3]*Danish Headache Center, Rigshospitalet, Glostrup, Denmark*

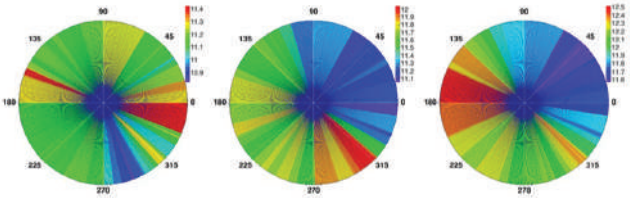
Background and aims: In Trigeminal Neuralgia pain is localized in the distribution of one or more branches of the trigeminal nerve. A hallmark of TN is the presence of discrete skin areas able to trigger pain attacks when touched. In classical TN, trigeminal reflexes are normal but it is possible to recognize a vascular compression with morphological changes of trigeminal nerve root.
Methods: We enrolled 53 patients with clinically defined TN, normal trigeminal reflexes testing, and evidence of neurovascular compression at 3-Tesla MRI. From MRI images we measured the polar coordinates of the impacting vessel on the trigeminal root circumference and then correlate it with pain distribution, trigger zones and latencies of the early components of the trigeminal reflexes.
Results: Pain in V1, V2 and V3 is associated, respectively, with vascular compression in the medial, superior and lateral aspect of the nerve ($p < 0.05$). Cutaneous trigger zones are associated with corresponding region of the circumference ($p < 0.05$). Increased latency of the R1 component of the blink reflex is associated with medial compression, while increased latency of the SP1 component of the masseter inhibitory reflex is associated with inferomedial compression when the reflex is evoked from the infraorbital nerve, and with lateral compression when it is evoked from the mental nerve ($p < 0.05$).



Relative frequency of location of neurovascular compression along the root circumference as derived by MRI data of TN patients with pain limited to one trigeminal division, V1 (left), V2 (middle) or V3 (right).



Relative frequency of location of neurovascular compression along the root circumference as derived by MRI data of TN patients reporting as trigger zones the forehead (left), the cheek (middle) or the jaw (right).



Mean latency of the early component of the trigeminal reflexes in patients with MRI evidence of neurovascular compression along a given zone of the trigeminal root. Reflexes were evoked from V1 (left), V2 (middle) and V3 (right).

Conclusion: Our study showing that pain distribution, trigger zones and increased latencies of the early components of the trigeminal reflexes are correlated with specific sites of neurovascular compression along trigeminal root circumference discloses its somatotopic organization.
Disclosure: Nothing to disclose.

OPR-014 | Endogenous pain control mechanisms during the migraine cycle and in chronic migraine with/without medication overuse

G. Cosentino[1]; E. Antoniazzi[2]; C. Cavigioli[2]; E. Guaschino[2]; N. Ghiotto[2]; G. Sances[3]; R. De Icco[1]; M. Todisco[2]; C. Tassorelli[1]
[1]*IRCCS Mondino Foundation, University of Pavia, Italy*; [2]*IRCCS Mondino Foundation, Pavia, Italy*; [3]*Headache Science & Neurorehabilitation Center, Pavia, Italy*

Background and aims: The offset analgesia (OA) phenomenon refers to the disproportionately large decrease in the perceived pain following a slight decrease in intensity of a noxious warm stimulus. This is considered as expression of activation of the endogenous pain-modulation system, whose dysfunction is could be involved in the pathophysiology of episodic migraine (EM) and chronic migraine (CM) with or without medication overuse (MO).
Methods: We enrolled 67 subjects with EM (in different phases of the migraine cycle), 30 patients with CM with/without MO, and 30 healthy controls. All subjects underwent an experimental paradigm consisting of 3 stimulus offset trials (OT) and 3 constant temperature trials (CT) at the level of the supraorbital region. Visual analogue scale (VAS) values were recorded during the OT and CT.
Results: Interictal EM patients and CM patients with MO did not show the OA phenomenon. A paradoxical pronociceptive facilitation during the offset trial was observed in the CM group without MO and in the preictal and ictal EM subjects. The OA phenomenon was restored in in the postictal phase. Only in patients with CM with MO we observed lack of adaptation to pain during the CT. The magnitude

of VAS changes during the offset trials negatively correlated with scores at 12-item Allodynia Symptom Checklist, migraine disability assessment (MIDAS), and depression section of the Hospital Anxiety and Depression Scale (HADS).

Conclusion: A dysfunction in the endogenous pain-modulation system may play a role in the recurrence of migraine attacks and in the process of migraine transformation from episodic to chronic pattern.

Disclosure: none.

OPR-015 | Cortical inflammation in migraine measured with quantitative magnetic resonance imaging: A REFORM study

R. Christensen[1]; H. Ashina[1]; H. Al-Khazali[1]; M. Pineda[2]; R. Rahmanzadeh[2]; N. Hadjikhani[3]; C. Granziera[2]; F. Amin[1]; M. Ashina[1]

[1]*Department of Neurology, Danish Headache Center, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark;* [2]*Translational Imaging in Neurology (ThINk) Basel, Department of Biomedical Engineering, Faculty of Medicine, University Hospital Basel and University of Basel, Basel, Switzerland;* [3]*Gillberg Neuropsychiatry Centre, Institute of Neuroscience and Physiology, Sahlgrenska Academy, Gothenburg, Sweden*

Background and aims: We aimed to investigate cortical inflammation using a novel quantitative, multimodal magnetic resonance imaging (MRI) technique in adult participants with migraine compared to age- and gender-matched healthy controls.

Methods: Participants underwent a single MRI session. Cortical quantitative T2 (qT2), quantitative T1 (qT1), and ADC values, considered surrogate markers of neuroinflammation, were measured in the cortical ribbon and compared between participants with migraine (with and without aura) and healthy controls. A general linear model was used with a vertex-wise threshold of $p<0.05$ and a cluster-wise threshold of $p<0.05$, adjusted for age and gender.

Results: A total of 296 participants with migraine (103 with aura and 180 with chronic migraine) and 155 age and gender matched healthy controls were included in the analysis. Participants with migraine had increased qT2 in the left occipital cortex compared to healthy controls ($p<0.0001$). In participants with migraine with aura, the increased qT2 was more widespread and located bilaterally in the occipital cortices compared to healthy controls (left, $p<0.0001$; right, $p=0.004$). Exploratory analysis revealed higher ADC values within the qT2 clusters in participants with migraine with aura than in controls ($p=0.01$). No significant differences were observed in qT1 values between the two groups.

Conclusion: Cortical inflammation is more prevalent in migraine with aura than in migraine without aura. The increased qT2 values in the occipital cortices of participants with migraine with aura are likely extracellular edema, as suggested by the concomitant ADC increase. These results support the importance of cortical inflammation in migraine pathogenesis, particularly in migraine with aura.

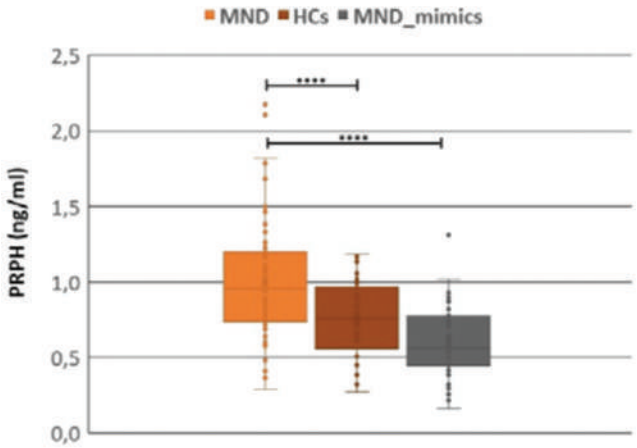
Motor neurone diseases 1

OPR-016 | Peripherin: A novel early diagnostic and prognostic biomarker in Amyotrophic Lateral Sclerosis

A. Bombaci; G. De Marco; F. Casale; G. Fuda; P. Salamone; G. Marchese; A. Calvo; A. Chiò
"Rita Levi Montalcini" Department of Neuroscience, University of Turin, Turin, Italy

Background and aims: motor neuron diseases (MND) are complex and heterogeneous neurodegenerative diseases. Biomarkers could help in early diagnosis, in defining patients' prognosis, and stratification. The most studied and promising biomarkers are neurofilaments (Nfs). A particular type of Nfs is peripherin, mainly expressed in neurons of the peripheral nervous system. There are no studies in literature led in humans evaluating peripherin in plasma.
Methods: sandwich-ELISA was used to quantify plasma peripherin from 120 ALS MND (including 12 ALS/FTD and 10 PLS), 9 HSP, 46 MND-mimics (including myelopathy, radiculopathy, axonal neuropathies, Hirayama disease, IBM, benign fasciculation syndrome, functional syndrome, myasthenia, post-polio syndrome) and 38 healthy-controls (HCs). Plasma was collected at the time of diagnosis or some months earlier. 46 ALS were evaluated longitudinally. ALSFRSr, MRC, spirometry, genetic tests, disease progression rate (PR), blood examinations, neuropsychological tests were performed. We analysed data using Kruskal–Wallis, ANCOVA and Cox regression analysis.
Results: peripherin plasma levels is different between groups ($p < 0.0001$); Bonferroni's correction shows higher levels of peripherin in MND compared to MND-mimics and HCs. Comparing ALS with PLS and HSP peripherin resulted to be higher ($p < 0.001$). Differences are confirmed co-variating for age and sex. ROC curve shows a good capability of peripherin to discriminate MND from MND mimics (AUC = 0.79).



Peripherin levels in MND, MND-mimics and healthy controls.

Conclusion: peripherin plasma levels result to be increased in MND (in particular in classic ALS) compared to MND mimics since the early phases of the disease. Further multicentre studies, testing together other fluid biomarkers, are needed to better explain role of peripherin in diagnosis and prognosis in MND.
Disclosure: Nothing to disclose.

OPR-017 | Rate of change in upper and lower motor neuron burden is associated with survival and in amyotrophic lateral sclerosis

A. Maranzano[1]; F. Gentile[2]; A. Doretti[1]; E. Colombo[1]; A. Wall[1]; V. Patisso[3]; A. De Lorenzo[3]; C. Gendarini[3]; C. Cinnante[4]; C. Morelli[1]; S. Messina[1]; M. Treddenti[3]; V. Silani[1]; F. Verde[1]; N. Ticozzi[1]

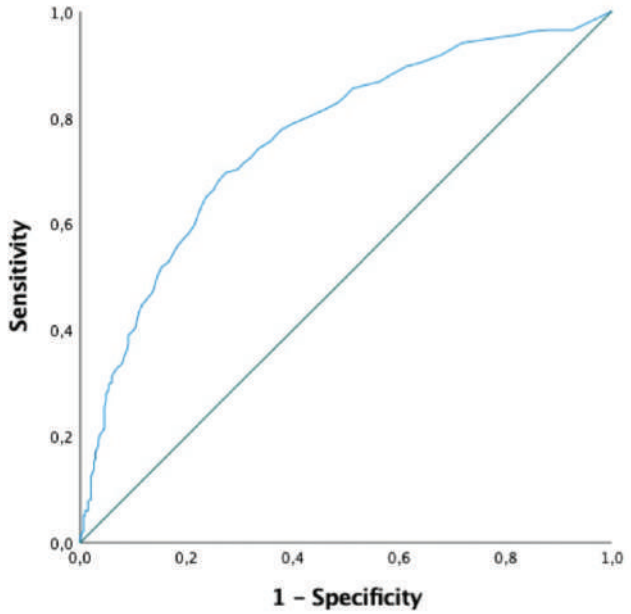
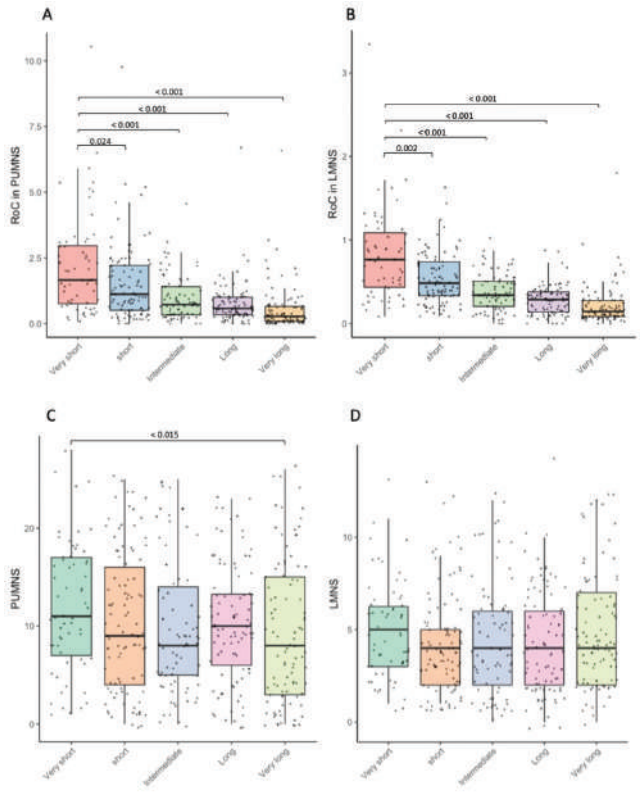
Background and aims: The role of upper (UMN) and lower motor neuron (LMN) involvement in amyotrophic lateral sclerosis (ALS) has been extensively studied in relation to clinical phenotype and survival. Conversely, it is not known whether the rate of change in UMN (ΔUMN) and LMN (ΔLMN) signs provides useful information on ALS evolution.
Methods: A retrospective inpatient cohort of 1000 ALS patients was evaluated. Burden of UMN and LMN signs was assessed using the Penn Upper Motor Neuron Score and Lower Motor Neuron Score, respectively. The time interval between symptom onset and first evaluation was used to quantify ΔUMN and ΔLMN values. Survival, time from symptom onset to percutaneous endoscopic gastrostomy (PEG), and to non-invasive ventilation (NIV) were used as outcome measures. For a subset of patients, we compute the ENCALS survival model.
Results: ΔUMN and ΔLMN values are negatively associated with survival (ΔUMN: HR = 1.30; ΔLMN: HR = 4.22) time to PEG (ΔUMN: HR = 1.34; ΔLMN: HR = 4.46) and time to NIV (ΔUMN: HR = 1.23; ΔLMN: HR = 5.0). A cut-off value of 0.195 for ΔLMN was identified to predict patients with estimated short vs. prolonged survival. ENCALS groups characterized by shorter survival were significantly associated with higher ΔUMN and ΔLMN scores when compared to those with longer survival.

	Exp(B)	95,0% inferior CI	95,0% superior CI	p value
Age at onset	1,039	1,028	1,05	<,001
Site of onset	1,136	0,871	1,482	0,348
ΔFS	1,43	1,221	1,675	<,001
C9orf72 hexanucleotide expansion	0,374	0,247	0,567	<,001
RoC in PUMNS	1,016	0,936	1,102	0,707
RoC in LMNS	2,537	1,791	3,594	<,001

Multivariate Cox regression investigating the effect of RoC in LMNS and PUMNS after adjusting for variables that are known to be associated with survival in ALS.



ROC curve illustrating the reliability of variable RoC in LMNS in predicting patients with short (survival <36 months) vs. prolonged (survival >36 months) survival.



Distribution of RoC in PUMNS (A), RoC in LMNS (B), PUMNS (C) and LMNS (D) among different ENCALS survival groups.

Conclusion: ΔUMN and ΔLMN might represent reliable clinical indexes to estimate disease evolution and survival in ALS patients. Indeed, these two measures provide distinct clinical information in addition to that derived from the total burden of UMN and LMN signs at first evaluation.

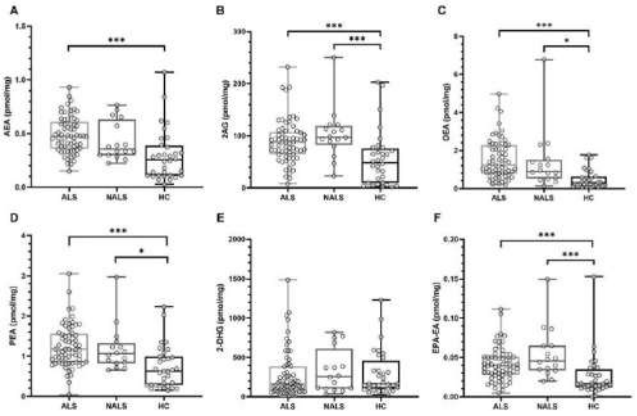
OPR-018 | Circulating endocannabinoid signatures of disease activity in amyotrophic lateral sclerosis

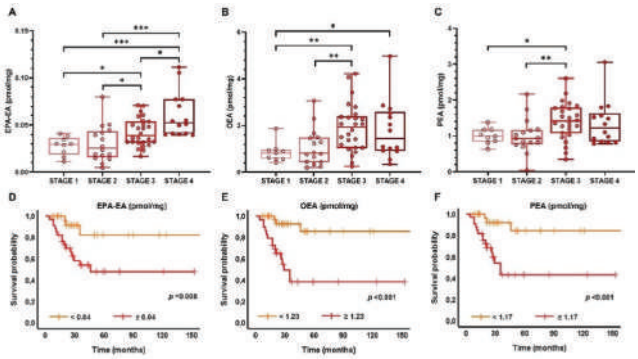
G. Senerchia[1]; F. Piscitelli[2]; R. Dubbioso[1]
[1]*Department of Neurosciences, Reproductive Sciences and Odontostomatology, Federico II University, Naples, Italy;*
[2]*Endocannabinoid Research Group, Institute of Biomolecular Chemistry (ICB), National Research Council (CNR), Pozzuoli, Italy*

Background and aims: Evidence from the preclinical model of amyotrophic lateral sclerosis (ALS) has consistently demonstrated altered levels of circulating endocannabinoids (eCBs) that may contribute to disease activity and course. Results from human studies are sparse and inconclusive. Main aim of this study was to determine the association between eCB levels and disease activity in patients with ALS.
Methods: Serum concentrations of the eCBs 2-arachidonoylglycerol (2-AG) and N-arachidonoylethanolamine (AEA), and related lipids palmitoylethanolamine (PEA), oleoylethanolamine (OEA), eicosapentaenoyl-ethanolamide (EPA-EA), 2-docosahexaenoyl-glycerol (2-DHG) and docosahexaenoyl-ethanolamide (DHA-EA) were measured in samples from 65 ALS patients, 32 healthy controls (HC) and 16 neurological disease controls (NALS). Moreover, 46 ALS patients underwent a longitudinal study. Disease activity and progression were correlated with eCBs levels.
Results: Circulating eCBs were higher in ALS than in HC ($p < 0.001$), but not compared to NALS. Across clinical stages, ALS patients showed increased levels of PEA, OEA, and EPA-EA ($p < 0.02$), which were confirmed by the longitudinal study ($p < 0.03$). Serum PEA and OEA levels were independent predictors of survival and OEA was higher in patients complaining of appetite loss. Cluster analysis revealed two distinct profiles of circulating eCBs associated with two

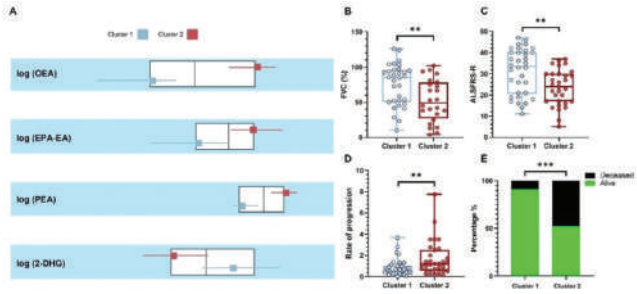
patterns of disease activity (severe vs. mild). Patients belonging to the "severe" cluster showed significantly higher levels of OEA and lower levels of 2-DHG compared to NALS and HC.



Comparison of circulating eCBs levels among the three groups: ALS, NALS and HC.



Circulating eCBs levels across ALS clinical stages and their association with survival.



Cluster analysis of circulating eCBs and clinical correlates of cluster membership.

Conclusion: Specific circulating eCBs profiles are indicative of different disease activities. This study paves the way for an individually-designed rather than a "one-fit-all" targeting the eCB system for therapeutic purposes.

Disclosure: Nothing to disclose.

OPR-019 | Skin innervation across ALS clinical stages: New biomarkers of disease progression and survival

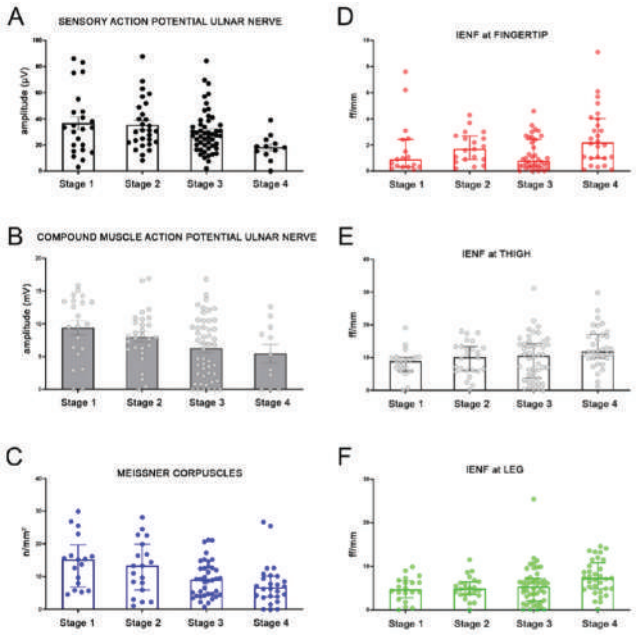
R. Dubbioso[1]; V. Provitera[2]; V. Iuzzolino[1]; G. Senerchia[1]; F. Manganelli[1]; M. Nolano[2]

[1]*Department of Neurosciences, Reproductive Sciences and Odontostomatology, University of Naples Federico II, Naples, Italy;* [2]*Istituti Clinici Scientifici Maugeri IRCCS, Skin biopsy lab, Neurological Rehabilitation Unit of Telese Terme Institute, Telese Terme, Italy*

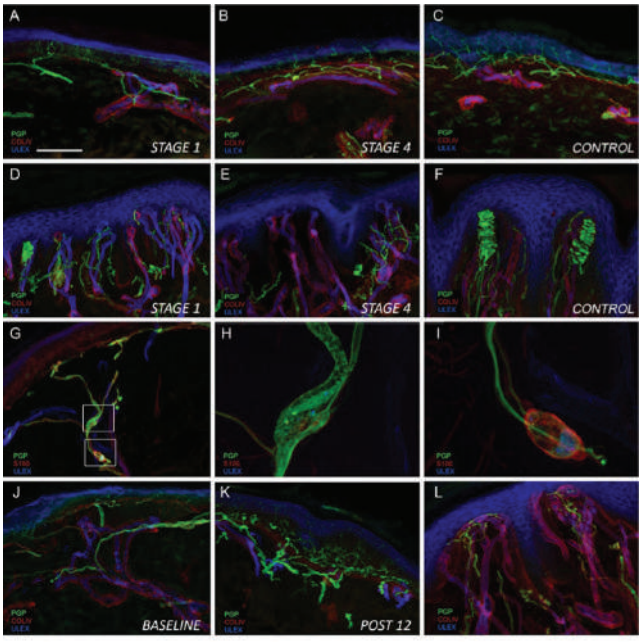
Background and aims: Aims of this study were to assess sensory involvement by applying a morpho-functional approach on a large population of ALS patients stratified according to King's stages and to correlate these findings with the severity and prognosis of the disease.

Methods: We recruited 149 ALS patients and 41 healthy controls (HC). Patients underwent clinical questionnaires, nerve conductions studies (NCS) and 3 mm-punch skin biopsy from leg, thigh and fingertip. We assessed intraepidermal nerve fibers (IENF) and Meissner corpuscles (MC) density by applying indirect immunofluorescence technique. Moreover, a subset of 65 ALS patients underwent a longitudinal study with repeated skin biopsies. Serum Neurofilament light chain (NfL) levels were measured in 40 patients.

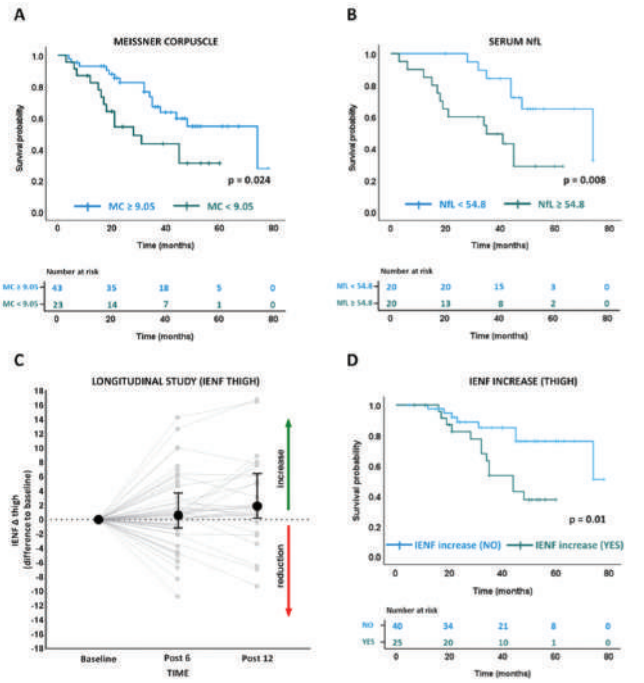
Results: Sensory symptoms and sensory NCS abnormalities were present in 32.2% and 24% of patients, respectively, and increased across clinical stages. Skin biopsy showed a significant loss of IENF and MC in ALS compared with HC (all $p<0.001$). Across the clinical stages, we found a progressive reduction in MC ($p=0.004$) and an increase in IENF (all $p<0.027$). Interestingly, the MC density inversely correlated with NfL level ($r=-0.424$, $p=0.012$), and survival analysis revealed that low MC density, higher NfL levels, and increasing IENF over time were associated with a poorer prognosis (all $p<0.024$).



Morpho-functional assessment of peripheral nerve fibers across ALS clinical stages Bar dot plots showing (A) a significant reduction from King's stage 1 to stage 4 in the sensory nerve action potential (SNAP) recorded from the fifth finger ($p = 0.034$)



Cutaneous innervation across King's ALS clinical staging and in the longitudinal study. Confocal images of punch biopsies from hairy and glabrous skin in ALS patients (A, B, D, E, G, H, J, K, L) versus controls (C and F). Green, nerve fibres; blue, epide.



Kaplan–Meier survival curves based on morphological and NfL data, and skin biopsy longitudinal study Kaplan–Meier curves of survival probability among ALS patients stratified by median value of (A) Meissner corpuscles (MC) density (*n*/mm2), (B) serum neuro.

Conclusion: In patients with ALS, peripheral sensory involvement worsens in parallel with motor disability. Furthermore, the correlation between skin innervation and disease activity may suggest the use of skin innervation as a putative prognostic biomarker.
Disclosure: Nothing to disclose.

Background and aims: Despite the existence of therapeutic recommendations in the 2010 EFNS/PNS and 2021 EAN/PNS guidelines for managing Chronic Inflammatory Demyelinating Polyradiculoneuropathy (CIDP), the sequence of therapy to be used remains unsettled.

Methods: A comparative analysis was conducted, examining therapeutic strategies and responses in 524 CIDP patients from tertiary referral centers included in a large national database.

Results: Intravenous immunoglobulins (IVIg) emerged as the most commonly used first-line therapy (53%), followed by steroids (33%) and plasmapheresis (3%). A consistent proportion of patients (8%) received combined first-line therapy with IVIg and steroids or (3%) monotherapy with immune suppressants. In acute-onset CIDP, IVIg and plasmapheresis were often used. There were also differences in relation to the early or late age at onset and to CIDP variants. Immune suppressants were often used as maintenance monotherapy (10%). There was a substantial variability among different centers in the choice of first- and second-line therapy, number of therapies performed, use of immunosuppressants and subcutaneous immunoglobulin (SCIg). A consistent proportion of patients responded to IVIg (86%) or steroid (85%) when used as second line therapy and only 7% of the patients failed to respond to two first-line therapies. There was no distinctive features between responder and not responder patients beside a more frequent ataxia at onset and greater disability at enrollment.

Conclusion: The absence of specific indications from guidelines may explain the notable heterogeneity in the therapeutic choice in CIDP patients. Therapeutic response significantly decreases after two failed attempts, but the identification of non-responders remains challenging.

Disclosure: Nothing to disclose.

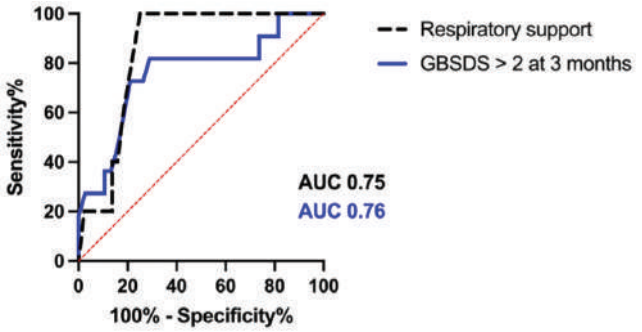
OPR-021 | Serum neurofilament light chain as a biomarker in Guillain-Barré syndrome: Origin and prognostic value

B. Hafsteinsdóttir[1]; H. Zetterberg[2]; M. Axelsson[1]; J. Lycke[1]
[1]Department of Clinical Neuroscience, Institute of Neuroscience and Physiology, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [2]Department of Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, The Sahlgrenska Academy, The University of Gothenburg, Mölndal, Sweden

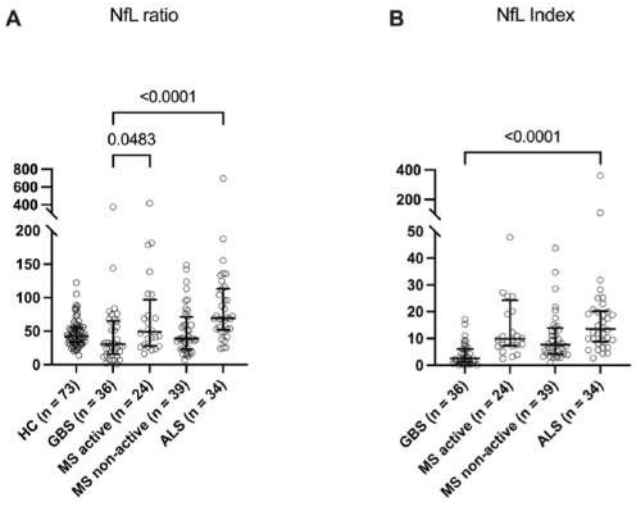
Background and aims: Our objective was to determine the origin serum neurofilament light chain (sNfL) and the utility of the sNfL Z-score, NfL ratio and NfL index as prognostic biomarkers in Guillain-Barré syndrome (GBS).

Methods: We included 96 patients with GBS between 1989 and 2014 in Western Sweden. Outcome measures were GBS disability scale (GBSDS) at 3 and 12 months and the need of respiratory support. Receiver operator characteristics curves were calculated for sNfL Z-score for the risk of respiratory support and GBSDS >2 at 3 months. NfL ratio and NfL index were compared with healthy controls (HC), multiple sclerosis (MS), and amyotrophic lateral sclerosis (ALS).

Results: The sNfL Z-score was higher for respiratory support (median 3.7, IQR 3.2–4.0 vs. median 2.7, IQR 1.6–3.5), GBSDS >2 at 3 months (median 3.5, IQR 3.2–4.0, vs. median 2.6, IQR 1.7–3.4) and 12 months (median 3.6, IQR 3.5–3.8, vs. median 2.6, IQR 1.8–3.5). No association was seen between NfL ratio or index and outcome. The area under the curve for the sNfL Z-score was 0.75 (95% CI 0.61–0.89) for respiratory support and 0.76 (95% CI 0.58–0.93) for GBSDS >2 at 3 months. The NfL ratio and index were lower in GBS than HC, MS, and ALS.



ROC curves for sNfL Z-score. AUC for GBSDS >2 at 3 months was 0.76 (95% CI 0.59–0.93, $p = 0.009$). AUC for respiratory support 0.75 (95% CI 0.61–0.89, $p = 0.004$). ROC = receiver operator characteristics; AUC = area under curve.



(A) NfL ratio in healthy controls (HC), Guillain-Barré syndrome (GBS), multiple sclerosis (MS) and amyotrophic lateral sclerosis (ALS). (B) NfL index in GBS, MS and ALS presented as median, interquartile range and individual values. The columns represent.

Conclusion: The sNfL Z-score at onset is a promising predictive biomarker for prognosis in GBS. Our results suggest that peripheral nerves are a significant contributor to sNfL in GBS.

OPR-022 | Activin-IIB-receptor inhibition prevents muscle atrophy and hastens motor recovery in experimental autoimmune neuritis

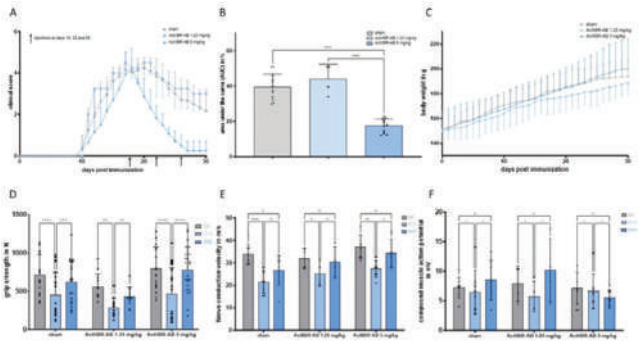
F. Kohle[1]; I. Gerlach[1]; M. Koch[2]; I. Klein[1]; G. R Fink[1]; G. Gatto[1]; M. Schroeter[1]; H. C Lehmann[3]

[1]Department of Neurology, Faculty of Medicine, University of Cologne and University Hospital Cologne, Cologne, Germany; [2]Center for Biochemistry, Institute for Dental Research and Oral Musculoskeletal Research, Faculty of Medicine and University Hospital Cologne, University of Cologne, Cologne, Germany; [3]Department of Neurology, Hospital Leverkusen, Leverkusen, Germany

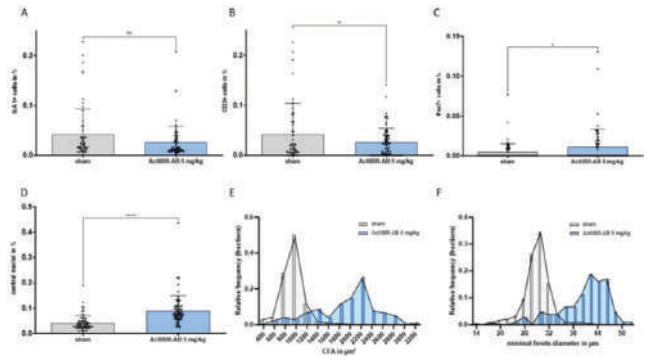
Background and aims: Muscle atrophy due to neuronal denervation is a significant determinant of the functional outcome in immune-mediated neuropathies after cessation of autoinflammation. Activin-IIB receptors (ActIIBR) are critically involved, and the blockade of these receptors has recently been explored in primarily degenerative muscular diseases. We examined the potential of ActIIBR blockade on motor recovery in the experimental autoimmune neuritis (EAN) animal model.

Methods: EAN was induced using myelin P253-78 protein in female Lewis rats. With the beginning of the recovery phase at day 18 post immunization, rats were treated with either sham, 1.25 mg/kg body weight, or 5 mg/kg body weight of a synthesized ActIIBR antibody subcutaneously every fourth day. Functional motor outcome was assessed using a neuritis score, grip strength, and balance beam paired with cinematic tracing until day 30. Nerve conduction studies, histological analyses of the sciatic nerve and the tibialis anterior muscle, real-time PCR, and muscle proteomics were performed.

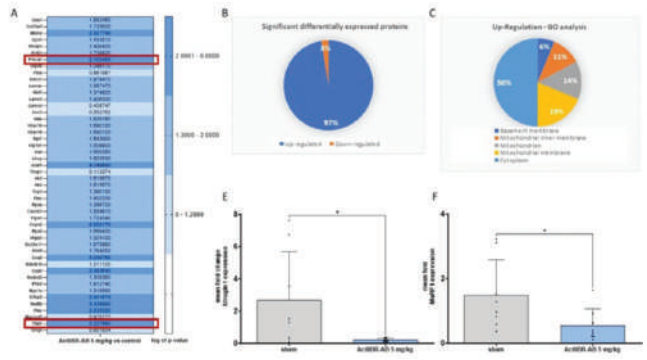
Results: Treatment with 5 mg/kg ActIIBR-antibody ameliorated EAN severity at day 30 (p-value: <0.0001). The grip strength nearly returned to baseline. No group differences were seen for nerve conduction studies and cellular inflammation in the sciatic nerve. Histologically, an increased cross-sectional area and ferret's diameter were observed. Muscle proteomics indicated alteration of the pAKT pathway, leading to a reduced expression of Atrogin1- and MuRF1 (p-values: 0.014 and 0.038).



Treatment with 5 mg/kg of the ActIIBR antibody enhances functional recovery after EAN.



ActIIBR inhibition prevents muscle atrophy and induces muscle hypertrophy without affecting cellular inflammation of the sciatic nerve.



Proteomics and real-time PCR analysis of the tibialis anterior muscles revealing reduced muscle degradation by downregulation of Atrogin-1 and MuRF-1 via ActIIBR-inhibition.

Conclusion: Blockade of the ActIIBR prevents muscle atrophy via Atrogin-1 and MuRF-1 downregulation, thereby hastening motor recovery in EAN. Further studies are warranted to investigate the role of ActIIBR blockade in autoimmune neuropathy.

Disclosure: FK was supported by the Cologne Clinician Scientist Program (CCSP), Project No. 413543196. I. Gerlach, I. Klein, M. Koch, G. R. Fink, G. Gatto, H.C. Lehmann and M. Schroeter reported no disclosures related to this study.

OPR-023 | Intracutaneous amyloid deposition predicts ulterior nerve conduction studies deterioration in ATTRv carriers

N. Schulz[1]; D. Beauvais[2]; C. Cauquil[1]; C. Labeyrie[1]; C. Adam[3]; V. Algalarrondo[4]; D. Adams[1]; G. Beaudonnet[1]

[1]*Department of Neurology, CHU Bicêtre, Le Kremlin-Bicêtre, France;*
[2]*Department of Neurology, CHU Bordeaux, Bordeaux, France;*
[3]*Department of Pathology, CHU Bicêtre, Le Kremlin-Bicêtre, France;*
[4]*Department of Cardiology, CHU Bichat, Paris, France*

Background and aims: Hereditary transthyretin amyloidosis (ATTRv) is an autosomal dominant systemic disease, leading to harmful tissue protein deposition, mainly in the heart and nerves, with an overall poor prognosis. While new disease-modifying treatments are being developed, it appears crucial to find markers of disease onset and progression for optimal timing in treatment initiation. Nerve conduction studies offer an objective, reproducible and non-invasive although late mean of following large nerve disease.

Methods: We studied 107 ATTRv carriers with normal nerve conduction studies (NCS) and sought to find elements predictive of ulterior NCS decline, defined as a 20% decrease of the average of the bilateral sural and fibular sensory nerve action potential (SNAPs).

Results: During a median follow-up of 5 years, 15/107 (14%) carriers presented a NCS deterioration. On univariate analysis, intracutaneous amyloid deposition (ICAD) (HR = 10.8, 95% CI(3.1 to 34.5), $p < 0.0001$) and difference of age with age of disease onset in proband (HR = 1.1, 95% CI(1.0 to 1.1), $p = 0.002$) were significantly associated with ulterior NCS decline. After multivariate analysis, skin amyloid deposition remained significantly and strongly associated with further worsening (HR = 10.3, 95% CI (2.4 to 45.5), $p = 0.0014$). EOVal30Met genotype, presence at baseline of cardiac denervation, skin denervation, an interventricular septum thickness superior to 12 mm, abnormal short-term heart rate variability, abnormal SUDOSCAN or neurological physical examination were not significantly associated with electric deterioration on univariate testing.

Conclusion: ATTRv carriers with intracutaneous amyloid deposition at initial evaluation were more likely to present NCS deterioration during follow-up compared to those without. Search of ICAD should be recommended during follow-up of asymptomatic carriers.

Disclosure: Nothing to disclose.

OPR-024 | Neuropathy in anti-MAG+/− IgM gammopathy: Population analysis and evaluation of old and innovative severity measures

D. Tornabene[1]; G. Cosentino[1]; M. Todisco[2]; G. Tammam[1]; E. Antoniazzi[2]; M. Gastaldi[2]; S. Scaranzin[2]; C. Morandi[2]; R. De Icco[1]; M. Corrado[1]; V. Grillo[2]; M. Varettoni[3]; E. Vegezzi[2]; E. Marchioni[2]; L. Diamanti[2]

[1]*Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy;* [2]*IRCCS C. Mondino Foundation, Pavia, Italy;* [3]*IRCCS Policlinico San Matteo Foundation, Pavia, Italy*

Background and aims: IgM Monoclonal Gammopathy (IgM-MG) often coexists with peripheral polyneuropathy. Distal demyelinating polyneuropathy (DADS) with anti-MAG antibodies is the best-known variant. Lack of appropriate endpoints poses challenges in assessing treatment efficacy. We provide a thorough clinical and paraclinical characterization of 38 anti-MAG+/– subjects with IgM-MG and evaluate various traditional and innovative measures of disease severity.

Methods: Participants underwent detailed collection of haematological, neurological, and therapeutic history, anti-MAG reactivity testing, and extensive electrodiagnostic assessment including Terminal Latency Index (TLI) determination. A broad clinical evaluation comprised multiple scales (mRS, ONLS, Berg Balance Scale, INCAT-SS, IRODS), functional tests (9-holes peg test, grip strength determination, 10-metres and 2-minutes walking test), and the EuroQoL questionnaire. A balance assessment was performed through posturography (i.e. the tracking of a standing subject's centre-of-gravity movement).

Results: 24 subjects exhibited anti-MAG reactivity, with 21 displaying electrodiagnostic signs of demyelination. Of the 14 seronegative individuals, one showed electrodiagnostic signs consistent with DADS. TLI reduction was found in at least some nerve in many demyelinating cases, but it was frequently unassessable due to nerve inexcitability or entrapment. Attached charts illustrate the performance of each assessment as a measure of disease severity.

	mRS 1 n = 20 mean age 71.6 y	mRS = 2 n = 10 mean age 76.4 y	mRS = 3 n = 7 mean age 77.7 y	p	Berg >45 n = 21 mean age 69.5 y	Berg ≤45 n = 16 mean age 79.75 y	p

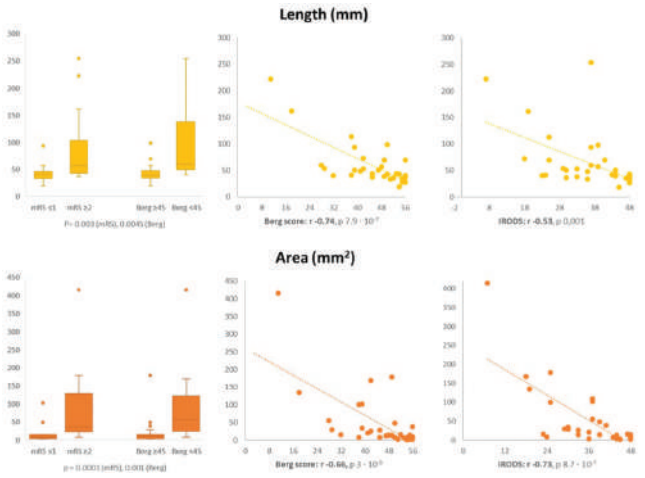
Pearson correlation coefficient for each disease measure and IRODS (left) and Berg (right) scores.



Performance of the posturography measures “length” (above) and “area” (below) as disability indexes. Data for the “open eyes” test are shown.

Conclusion: The correlation between anti-MAG antibodies and “DADS” neuropathy is robust but not universal. TLI can help the diagnosis, but not every nerve will have an index <0.25 and its utility is limited by inexcitability or false positives due to median nerve entrapment at the wrist. Posturography emerges as a potential objective, quantitative outcome for future trials.

Disclosure: Nothing to disclose.

OPR-025 | Prediction of the global functional outcome of intensive inpatient rehabilitation after stroke using machine learning

A. Sodero; S. Campagnini; M. Baccini; A. Grippo; B. Hakiki; C. Castagnoli; P. Liuzzi; C. Macchi; A. Mannini; F. Cecchi
IRCCS Fondazione Don Carlo Gnocchi onlus, Firenze, Italy

Background and aims: Prognostic data-driven solutions could support the outcome prediction and, eventually, the optimisation of the rehabilitation pathway. We aimed at the development, cross-validation, and external validation of machine learning-based prognostic models for the prediction of the global functional outcome of patients undergoing intensive inpatient rehabilitation after stroke.
Methods: Patients addressing an evidence-based intensive inpatient rehabilitation pathway within 30 days from stroke from two multicentric prospective studies were enrolled. Data related to standardized comprehensive multidimensional assessment were collected and fed within the model for feature selection (figure 1). The outcome of interest was the modified Barthel Index(mBI) at discharge. Different algorithms were optimised, nested cross-validated, externally tested, and interpretability techniques were applied for the analysis of the contributions of predictors.

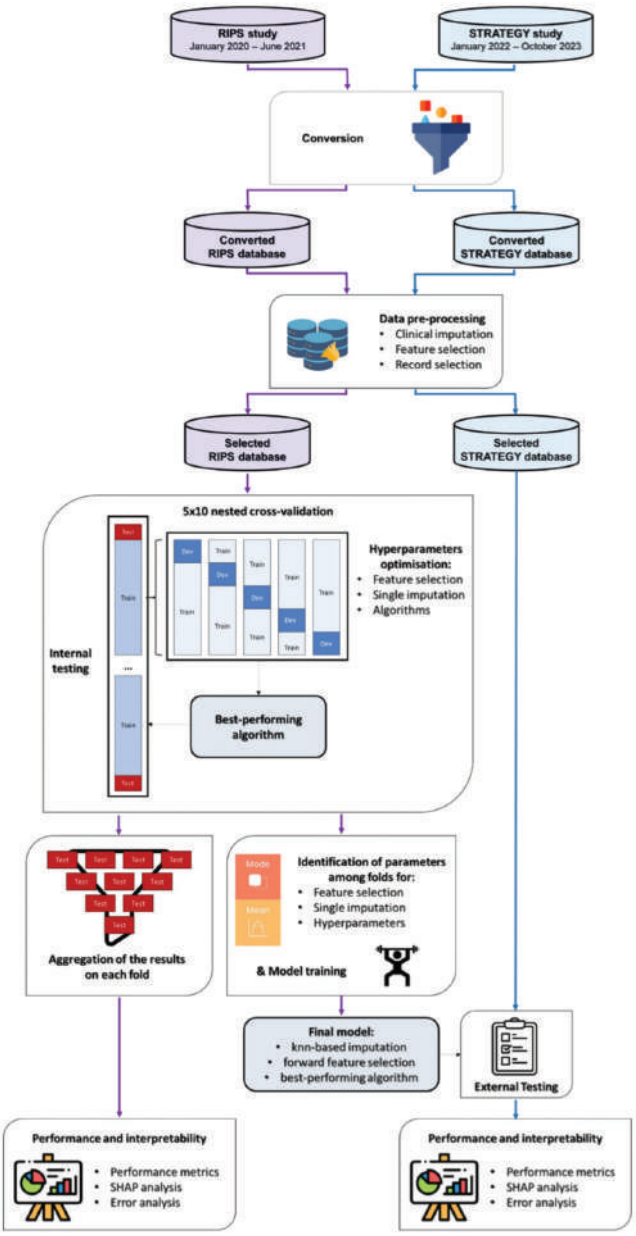

FIGURE 1 Analysis pipeline.

Results: Total numbers of 220 and 180 patients were considered for training and test sets, respectively (figure 2). Respectively a 50.9% and 56.7% of women, 79.5% and 78.9% of ischaemic, and a median [IQR] age of 80.0 [15.0] and 78.0 [17.0] were registered on the two datasets. The Support Vector Machine obtained the best validation performances and a median absolute error of 11.5 [15.0] and 9.2 [13.0] on the internal and external testing, respectively. The baseline variables providing with the main contributions to the predictions resulted in mBI, motor upper-limb score, age, and cognitive score (figure 3).

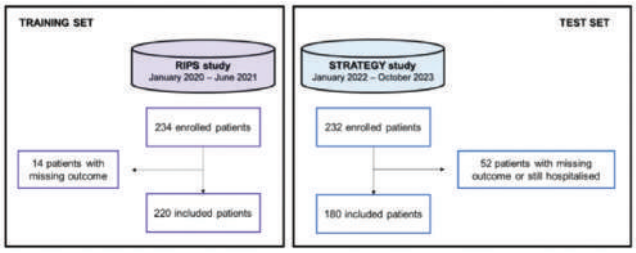

FIGURE 2 Flow chart of the study.

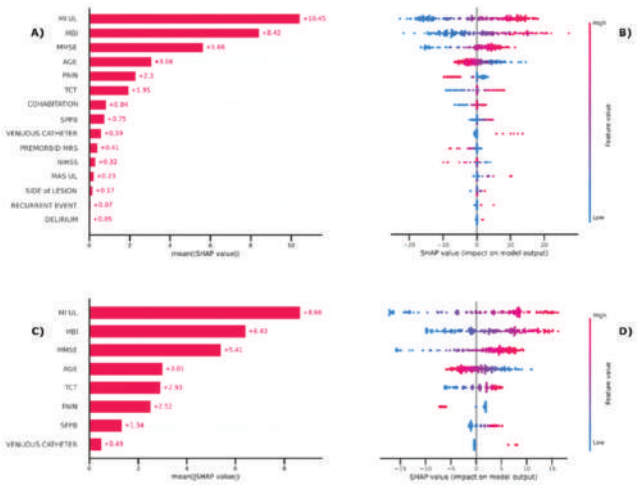

FIGURE 3 Contributions of the predictors to the outcome prediction aggregated among each fold. In panels A-C, bar plots of the global contributions are presented, whilst in panels B-D, beeswarm plots with patient-wise contributions are presented. The res.

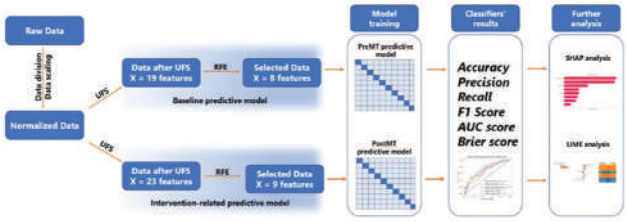
Conclusion: Our results indicate the suitability of this solution for supporting clinicians in formulating a functional prognosis at the admission to intensive inpatient post-stroke rehabilitation and in promptly identifying features potentially predicting an unfavourable outcome.
Disclosure: Nothing to disclose.

OPR-026 | **In-hospital death matters: A machine learning approach to anterior circulation mechanical thrombectomy**

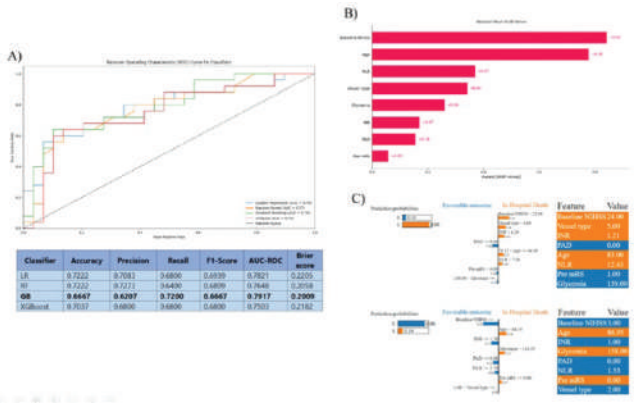
I. Petrović[1]; S. Broggi[2]; O. Tomašević[3]; A. Balenović[1]; I. Milosavljević[1]; M. Ivanišević[4]; M. Killer-Oberpfalzer[5]; J. Mutzenbach[5]; C. Hecker[5]; S. Rajić[1]; S. Pikija[5]
[1]*Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia;* [2]*ASST dei Sette Laghi, Neurology and Stroke Unit, Varese, Italy;* [3]*Faculty of Technical Sciences, Department of Systems, Signals and Control Engineering, University of Novi Sad, Novi Sad, Serbia;* [4]*Faculty of Medicine, University of Belgrade, Belgrade, Serbia;* [5]*Department of Neurology, Christian Doppler University Hospital, Paracelsus Medical University of Salzburg, Salzburg, Austria*

Background and aims: Although the popularity of mechanical thrombectomy (MT) has grown significantly in the past decade, there is still a literature gap concerning post-procedural in-hospital mortality, the main contributing factors, and the possibility of predicting it. The aim was to employ interpretable machine learning (ML), which could potentially aid in understanding existing ambiguities.
Methods: This retrospective study included 602 anterior circulation ischemic stroke patients who underwent MT. Patients were divided into two groups: (I) died ($n=133$), in which the fatal outcome occurred during the in-hospital stay, and (II) survived ($n=469$). Python 3.10.9 was used for the machine learning model build-up, and based on the input features, two models were constructed: (I) the preMT model, which consisted of baseline features, and (II) the postMT model, which included baseline and MT-related features. The ML models' training, internal evaluation, and performance testing followed feature selection. Interpretation frameworks explained the decision-making process.

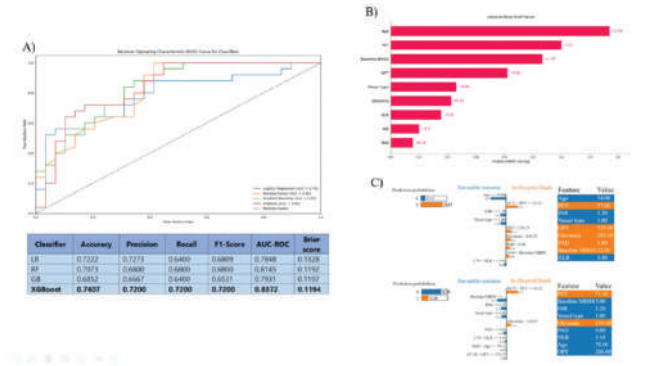


Summarized steps of the analysis. After a two-step process of feature selection, with univariate feature selection (UFS) as the first step, and Recursive Feature Elimination (RFE) as the second, models were trained, evaluated, and tested.

Results: For the preMT model (AUC = 0.792), selected features were age, baseline NIHSS value, neutrophil-to-lymphocyte ratio (NLR), INR, vessel type, peripheral arterial disease (PAD), baseline glycemia, and premorbid modified Rankin scale (pre mRS), while in the postMT model (AUC = 0.837), added features included puncture to procedure end time (PET), and onset to puncture time (OPT).



(A) Evaluation metrics of the preMT model and the receiver operating characteristic curves (ROCs) of 4 classifiers; (B) The SHAP (Shapley Additive Explanations) analysis graph; (C) Local Interpretable Model-Agnostic Explanations (LIME) plot.



(A) Evaluation metrics of the postMT model and the receiver operating characteristic curves (ROCs) of 4 classifiers; (B) The SHAP (Shapley Additive Explanations) analysis graph; C) Local Interpretable Model-Agnostic Explanations (LIME) plot.

Conclusion: To the best of our knowledge, this study represents a pioneer research that utilized interpretable models for predicting in-hospital death following anterior circulation MT. The constructed models need further extensive evaluation before they can be practically applied.

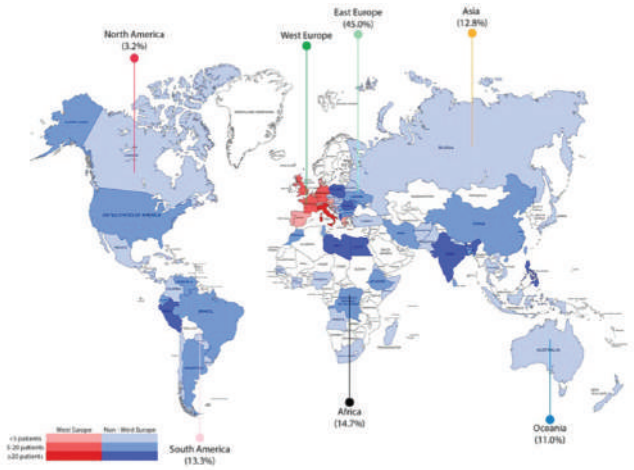
Disclosure: Nothing to disclose.

OPR-027 | Ethnic differences in access to care and treatment in patients with suspected acute stroke: A retrospective cohort study

I. Scala[1]; J. Di Giovanni[1]; P. Rizzo[1]; S. Bellavia[1]; M. Monforte[2]; A. Broccolini[2]; P. Calabresi[2]; M. Covino[3]; G. Frisullo[2]

[1]*Catholic University of Sacred Heart, Roma, Italia;* [2]*Department of Neuroscience, Sensory Organs and Chest, Fondazione Policlinico Universitario Agostino Gemelli, IRCCS, Rome, Italy;* [3]*Emergency Department, IRCCS Fondazione Policlinico Universitario Agostino Gemelli, Rome, Italy*

Background and aims: Data concerning unequal healthcare access of acute stroke patients based on ethnicity or race are inconclusive in Europeans. The primary objective was to evaluate the effect of geographic origin/race on access to acute stroke care and treatments. Secondly, we evaluated the effect of geographic origin/race on stroke risk factors, outcomes, and admission for stroke mimics.



A graphic representation of the geographical origin of the included population. The percentages refer to the number of patients from various continents compared to the total number of non-Western Europeans.

Methods: In this retrospective, cohort study, we enrolled adult patients admitted to the emergency department of a comprehensive stroke center for suspected stroke. Based on geographic origin, patients were divided into two groups: Western Europeans (WE) and non-Western Europeans (nWE). For each nWE subjects, we included four sex- and age-propensity score matched patients in the WE group. We then divided patients in three further subgroups (White/Black/Asian) based on race. Univariate comparisons were performed using Mann–Whitney, Kruskal-Wallis, and χ^2-tests, as appropriate. Logistic regression was used to perform the adjusted analyses.

Results: 618 patients were enrolled in the nWE group and 2444 in the WE group. Belonging to the nWE group is an independent predictor of lower likelihood of receiving intravenous thrombolysis ($p=0.005$). Considering Black/Asian/White subgroups, ED accesses for stroke mimics were less frequent among racial minority groups ($p=0.038$). Furthermore, Black and Asian individuals had a higher incidence of brain hemorrhages than Whites ($p=0.003$). No differences in stroke outcomes were found.

TABLE 1 Results of the multivariate logistic regression for the prediction of thrombolytic treatment.

Conclusion: Racial and ethnic disparities in healthcare are a challenging issue even in universal healthcare systems, likely due to differences in socioeconomic status, and they and should be addressed promptly through education campaigns of healthcare personnel.

Disclosure: Nothing to disclose.

OPR-028 | Polysomnographic parameters as predictors of outcome in patients with ischemic stroke: A preliminary report

M. de Scisciolo; E. Rollo; G. Della Marca; V. Brunetti
Dipartimento di Neuroscienze, Organi di Senso e Torace, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background and aims: Limited literature exists on sleep architecture in ischemic stroke (IS). This study aims to assess whether macrostructure and microstructure sleep parameters can predict outcomes in patients with IS.

Methods: Seventy-seven with IS admitted to the Stroke Unit were prospectively collected. Patients underwent 24 hour polysomnography within seven days from the stroke. Macro and micro (Cycling Alternating Pattern - CAP) sleep architecture and respiratory parameters were analyzed. Three-month modified Ranking Scale(mRS) was used as the outcome measure. Sleep parameters were analyzed between groups with excellent (mRS = 0–1) and poor outcome (mRS = 2–6) using univariate and multivariate approaches, correcting for potential confounders (sex, age, NIHSS, pre-stroke mRS).

Results: The study group showed a median age of 73 years (IQR = 20), and an admission NIHSS = 12 (IQR = 11). Forty-three patients had excellent outcome (55.8%). Median total sleep time (TST) was 374 minutes (IQR = 104). Patients with excellent outcome showed higher REM sleep [13.0% (IQR = 8.6) vs. 6.9% (IQR = 7.5); $p = 0.002$)], higher N1 stage of NREM sleep [13.3% (IQR = 10.5) vs. 8.2% (IQR = 5.7; $p = 0.001$)], higher number or sleep cycles [3 (IQR = 2) vs. 1 (IQR = 3); $p = 0.030$)], shorter daytime sleep [10 (IQR = 75) vs. 75 minutes (IQR = 126); $p = 0.005$)], and higher CAP rate [43.7% (IQR = 25.0) vs. 24.9% (IQR = 30.8); $p = 0.001$)]. None of the analyzed respiratory parameters were associated with outcome. Multivariate analysis confirmed that higher CAPrate($p = 0.030$) and less daytime sleep($p = 0.017$) were associated to excellent outcome.

Conclusion: Macro and, mostly, microstructure parameters of sleep in ischemic stroke seem to be correlated with outcome, in particular higher CAP rate is associated with better outcome. Further investigations are needed to reinforce these findings.

Disclosure: Nothing to disclose.

Neuroimaging in neuroinflammation

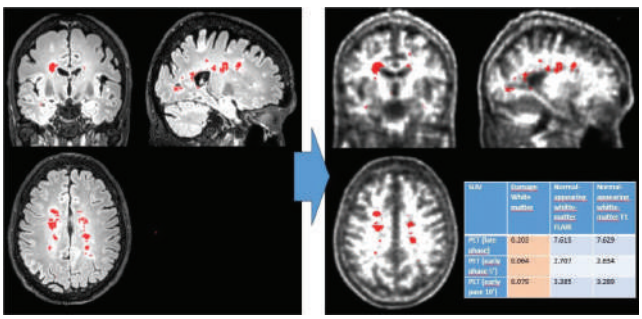
OPR-029 | Amyloid PET as biomarker of white matter damage in recently diagnosed multiple sclerosis and its clinical relationship

J. Barrios-López[1]; A. Piñeiro-Donis[2]; E. Triviño-Ibáñez[3]; P. Casa Nova-Leitao Moreira[1]; F. Segovia-Román[4]; B. Marín-Romero[5]; M. Pérez-García[6]
[1]*Neurology Department, Hospital Universitario Virgen de las Nieves, Granada, Spain;* [2]*Nuclear Medicine Department, Hospital Universitario Virgen de las Nieves, Granada, Spain;* [3]*Nuclear Medicine Department, Hospital Universitario Virgen de las Nieves, Instituto de Investigación Biosanitaria ibs.GRANADA, Granada, Spain;* [4]*Department of Signal Theory, Networking and Communications, University of Granada, Granada, Spain;* [5]*Neurology Department, Hospital Universitario Virgen de las Nieves, Granada, Spain;* [6]*Radiology Department, Hospital Universitario Virgen de las Nieves, Granada, Spain*

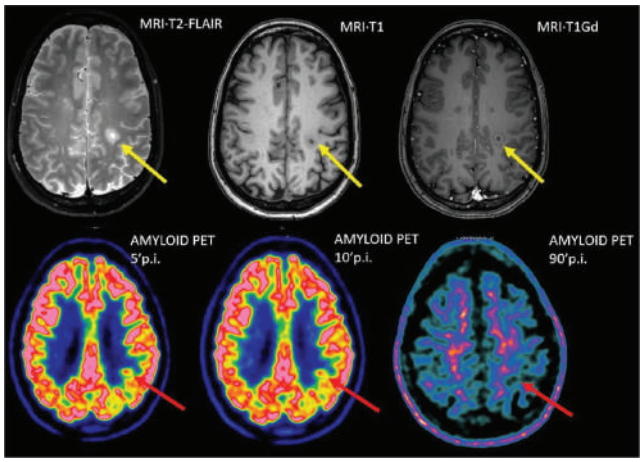
Background and aims: White matter (WM) demyelination in multiple sclerosis (MS) can be measured in vivo using amyloid positron emission tomography (PET). Our aim was to evaluate amyloid uptake in damaged (DWM) and normal-appearing WM (NAWM) of MS patients and the relation to their clinical status.

Methods: This prospective longitudinal study enrolled patients with recent MS onset between March to May 2023. Participants underwent a neurological examination, disability (EDSS), neuropsychological (SDMT) and quality of life (EQ-5D) assessment, brain MRI and 18F-florbetaben PET in early (0–10′) and late phase (90′) post-i.v., MRI and PET images were co-registered and results are presented as standardized uptake values (SUV), using cerebellum (SUVRc) and NAWM (SUVRwm) as the reference region.

Results: Ten patients were included (35.10 ± 11.32 years; 70% female). We found, both in early- and late-phase, a lower mean SUVR in DWM compared to NAWM ($p < 0.01$) in all patients. SUVRwm correlated with EQ-5D index (r:0.652, $p = 0.041$). A trend toward lower SUVRwm was observed in the highly active onset group compared to non- highly active group (0.62 ± 0.43 vs.. 3.62 ± 3.20, $p > 0.05$). Considering only highly active onset patients, SUVRwm correlated with EDSS score (rho = −0.896, $p = 0.0031$). The lesions analysis showed a correlation between SUVmean in DWM with EDSS and SDMT scores (rho: −0.534, $p = 0.004$ and rho: 0.670, $p = 0.006$, respectively); and SUVRc with SDMT (rho: 0.585, $p = 0.022$).



Standardized uptake values (SUV) analysis by co-registered MRI and amyloid PET images.



Active lesion analysis by MRI and amyloid PET images.

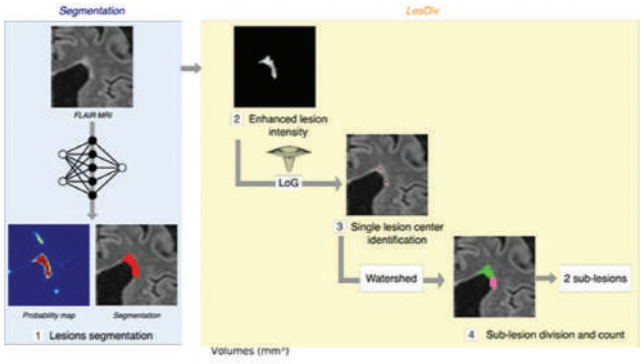
Conclusion: Preliminary results of this work in progress suggest that amyloid PET could be a promising tool to monitor myelin changes in MS and may have a predictive role in disease activity and progression.
Disclosure: This work has received funding from the call for "NEURO-RECA grants for scientific research in neurology in 2021" with file number NEURORECA-0007-2022.

OPR-030 | Validation of an automated deep learning algorithm for the identification of confluent Multiple Sclerosis lesions

M. Pasca[1]; L. Marchi[2]; A. Mariottini[2]; B. Lambert[3]; P. Rubini[3]; S. Doyle[3]; H. Dehaene[3]; A. Tucholka[3]; P. Roca[3]; S. Filippini[4]; L. Massacesi[2]

[1]Department of Neurology, "F. Ferrari" Hospital, Casarano, Lecce, Italy; [2]Department of Neurosciences, Drug and Child Health, University of Florence, Florence, Italy; [3]Pixyl, Grenoble, France; [4]Department Neurology, Florence, Italy

Background and aims: Lesion count is a crucial biomarker in Multiple Sclerosis diagnosis and follow-up. Deep Learning (DL) models are a powerful aid for this task, providing an automated segmentation of lesions. These models tend to underestimate the true number of lesions, and segment confluent lesions as a single connected component. To improve the accuracy of the lesion counting, a novel post-processing algorithm named LesDiv that can recognize individual lesions component in confluent lesions has been validated, automatically identifying single lesion center using the input FLAIR and lesion probability map produced by the DL segmentation model.
Methods: 60 MS patients with 440 clusters of lesions were included. Two neurologists, with expertise in Multiple Sclerosis MRi analysis, independently performed ground truth sub-lesion counts and delineations. To compare the algorithm with alternative methods, an alternative pipeline that uses the Hessian filter instead of the LoG (described by Dworkin et al.), named Hessian Division, was implemented.



Flowchart of our proposed LesDiv algorithm.

Results: The analysis showed excellent reliability between the two human experts in terms of sublesion counting and delineation: Mean Absolute Error (MAE) = 0.45, Pearson Coefficient (R^2) = 0.88, Dice = 0.526. LesDiv showed good reliability with the analysis performed by the two human experts: MAE = 0.75, R^2 = 0.75, Dice = 0.52, compared with Expert 1 analysis. Hessian Method showed a lower reliability with the two experts: MAE = 0.99, R^2 = 0.67, Dice = 0.48 compared with Expert 1 analysis.

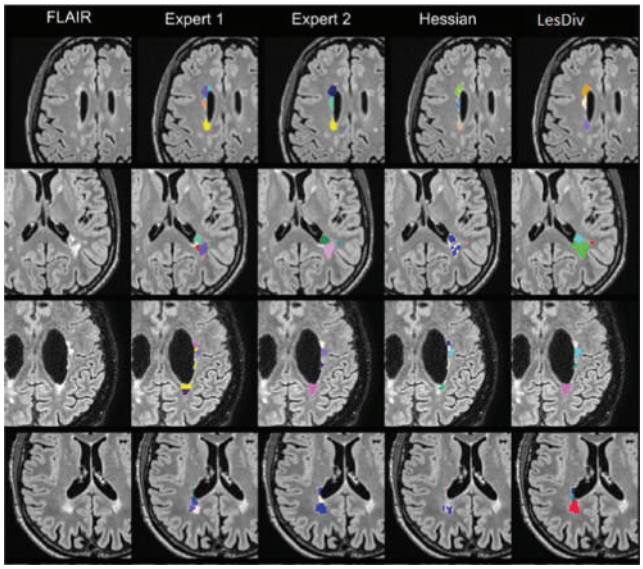


Illustration of expert counts and automated counts.

Reference count	Evaluated count	MAE (↓)	R2 (↓)	Dice (↑)
Expert 1	**Expert 2**	**0.4738**	**0.8760**	**0.5261 ± 0.3528**
LesDiv	Expert 1	0.7931	0.7515	0.5203 ± 0.4135
LesDiv	Expert 2	0.8109	0.7410	0.4827 ± 0.4000
LesDiv	Consensus	0.7134	0.7937	-
Hessian	Expert 1	0.9975	0.6763	0.4783 ± 0.3912
Hessian	Expert 2	1.0657	0.6796	0.4841 ± 0.3753
Hessian	Consensus	0.8971	0.7393	-

Comparison of experts and automated counts. MAE = Mean Average Error. R2 = Pearson correlation coefficient.

Conclusion: Lesion segmentation in MS is a complex and time-consuming analysis. LesDiv is an automated deep learning algorithm, that showed significant correlation with human analysis in the identification of single lesions from confluent MS lesions.
Disclosure: Nothing to disclose.

OPR-031 | Cellular soma and neurite density abnormalities in multiple sclerosis paramagnetic rim and core-sign lesions

P. Preziosa[1]; E. Pagani[2]; A. Meani[2]; M. Margoni[3]; M. Rubin[1]; M. Palombo[4]; M. Rocca[1]; M. Filippi[5]
[1]*Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy;* [2]*Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [3]*Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [4]*Cardiff University Brain Research Imaging Centre, School of Psychology, and School of Computer Science and Informatics, Cardiff University, Cardiff, UK;* [5]*Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy*

Background and aims: In multiple sclerosis (MS), susceptibility-weighted imaging (SWI) may reveal white matter lesions (WML) with a paramagnetic rim ("paramagnetic rim lesions" [PRLs]) or diffuse hypointensity ("core-sign lesions"), reflecting different stages of WML evolution. Using soma and neurite density imaging (SANDI) model on diffusion-weighted magnetic resonance imaging (MRI), we characterized the microstructural abnormalities of MS PRLs and core-sign lesions and their clinical relevance.
Methods: Forty MS patients and 20 healthy controls (HC) underwent a 3 T brain MRI. Using SANDI, the fractions of neurite (fneurite) and soma (fsoma) and size of soma (rsoma) were quantified in PRLs (including their core and rim separately), and core-sign lesions identified on SWI.
Results: Among 1811 WMLs, 122 (6.7%) core-sign lesions and 97 (5.4%) PRLs were identified. Compared to HC and MS normal-appearing white matter, all MS WML showed significantly lower fneurite and fsoma and higher rsoma (FDR-$p < 0.001$). Compared to isointense WML, core-sign lesions showed a significantly higher fneurite, and lower fsoma and rsoma (FDR-$p <= 0.001$). Compared to isointense WML and core-sign lesions, PRLs showed a significantly lower fneurite, higher fsoma, and higher rsoma (FDR-$p \le 0.005$). The PRL-core showed significantly lower fneurite, and higher rsoma than PRL-rim (FDR-$p < 0.001$). Lower PRL fneurite ($\beta <= -0.006$, FDR-$p \le 0.015$) and higher rsoma ($\beta >= 0.032$, FDR-$p <= 0.024$) were significantly associated with a longer disease duration and more severe disability.
Conclusion: In PRLs, the significant and clinically-relevant neurite loss and increased soma fraction and size possibly reflect increased astrogliosis and activated microglia. Core-sign lesions exhibit milder axonal loss, microglia density and astrogliosis, supporting their less destructive nature.

Background and aims: Relapsing remitting multiple sclerosis (RRMS) and myelin-oligodendrocyte antibody-associated disease (MOGAD) are distinct diseases, but their differentiation can be challenging in clinical practice due to overlapping clinical and MRI features. The application of deep learning (DL)-models to MRI is a promising approach to provide a structurally based classification of diseases, while the study of DL-derived attention maps may indicate the most relevant anatomical regions for DL-stratification. We aimed to build a MRI-based DL-model to differentiate RRMS from MOGAD and to assess group differences using probability attention maps (PAM).

Methods: In this cross-sectional study, we analysed 345 FLAIR brain MRIs from RRMS (*n*.201, 117F, mean [SD] age: 39 years [±11], median EDSS: 2 [0–8], mean [SD] disease duration: 93 months [±94]) and MOGAD (*n*.144, 81F, mean [SD] age: 41y [±13], median EDSS: 2 [0–8.5], mean [SD] disease duration: 71 months [±96]), retrospectively collected from 17 centres. Patients were divided into three independent groups (training, validation, external test sets). The study design is illustrated in Figure 1.

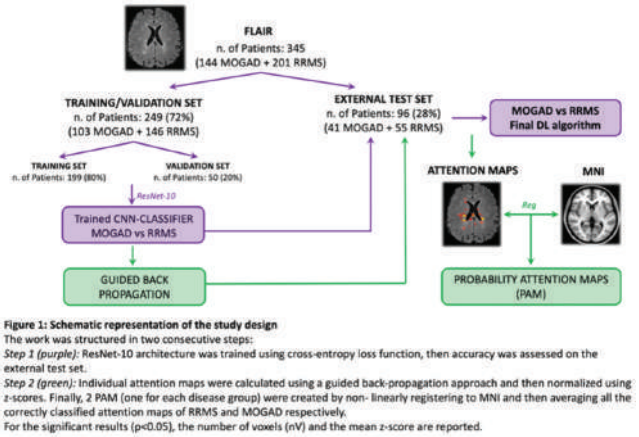

Figure 1: Schematic representation of the study design
The work was structured in two consecutive steps:
Step 1 (purple): ResNet-10 architecture was trained using cross-entropy loss function, then accuracy was assessed on the external test set.
Step 2 (green): Individual attention maps were calculated using a guided back-propagation approach and then normalized using z-scores. Finally, 2 PAM (one for each disease group) were created by non- linearly registering to MNI and then averaging all the correctly classified attention maps of RRMS and MOGAD respectively.
For the significant results ($p<0.05$), the number of voxels (nV) and the mean z-score are reported.

FIGURE 1 Schematic representation of the study design.

Results: A DL discriminatory model between the two diseases was built (accuracy/specificity/ sensitivity: 84%/85%/84%) and successfully validated in the external test set without retraining (accuracy/specificity/sensitivity: 72%/68%/76%). PAM revealed the relevant role of insula (nV: 271, *z*-score: 3.10), hippocampus (nV: 839, *z*-score: 3.44), periventricular areas (nV: 669, *z*-score: 3.47) for RRMS, while the selective role of the cingulate cortex (nV: 2360, *z*-score: 2.71) for the identification of MOGAD (Figure 2).

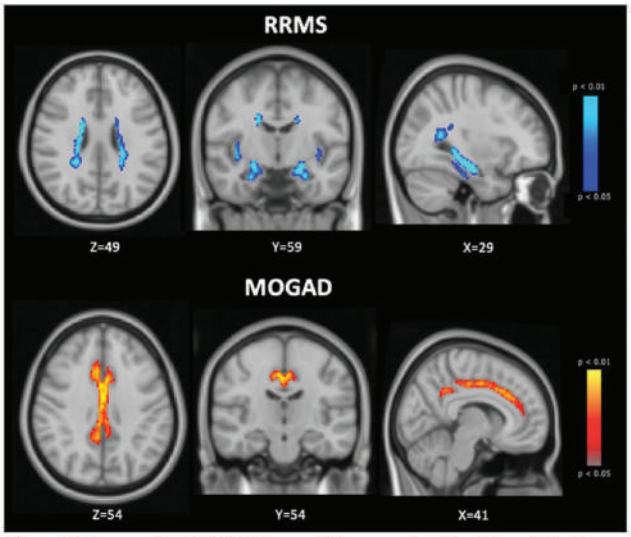

Figure 2: Topographical distributions of the areas significantly contributing to the differentiation between patients with RRMS and with MOGAD
Significant voxels are shown in a colour scale from light blue to dark blue for RRMA and from yellow to red for MOGAD, from the most to the less significant, respectively.

FIGURE 2 Topographical distributions of the areas significantly contributing to the differentiation between patients with RRMS and with MOGAD.

Conclusion: We developed a DL-model to accurately differentiate RRMS from MOGAD on FLAIR MRI. PAM provided additional clues on how damage is distributed in the two diseases.

Disclosure: The present research was conducted thanks to the 2019 ECTRIMS-MAGNIMS fellowship (awarded to R.C.). The Authors have nothing to disclose in relation to this work.

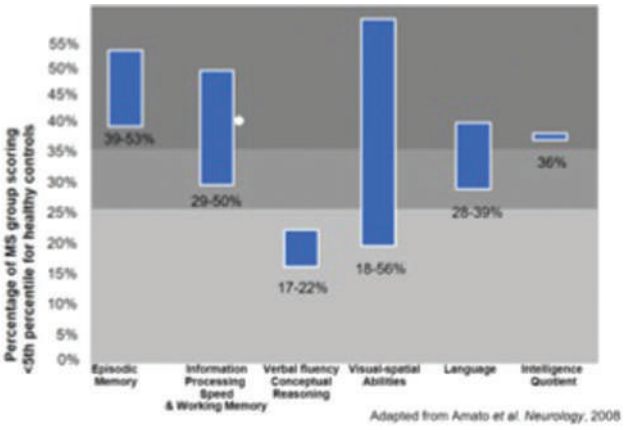
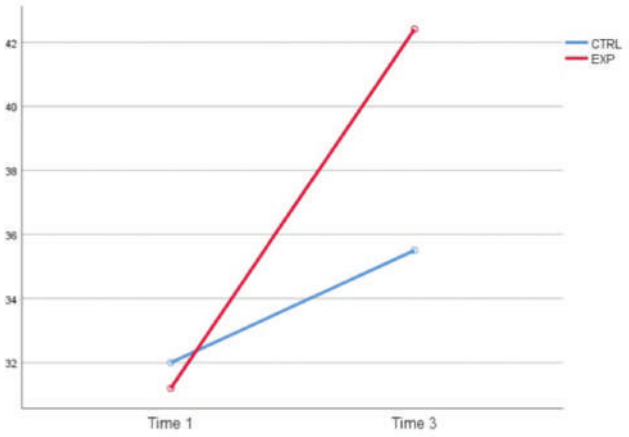
Background and aims: Cognitive impairment affects approximately 30% of pediatric onset Multiple Sclerosis (POMS) patients with a negative impact on everyday life1. The aim of this study was to evaluate the feasibility and effectiveness of a home-based, computer-assisted training of attention in patients with POMS.



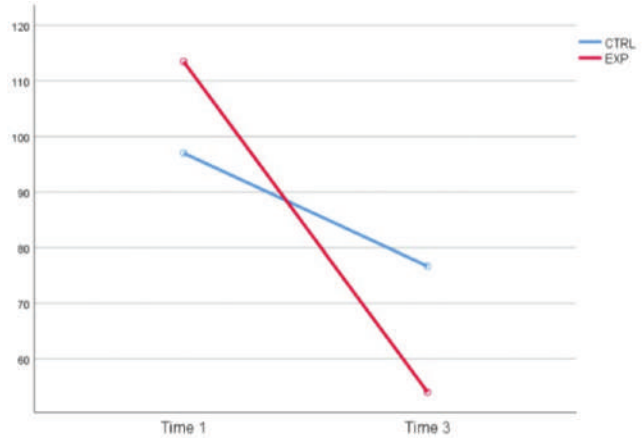
Some studies have highlighted a particular involvement of language in patients with POMS, which is commonly spared in adults. Additionally, a lower intelligence quotient (IQ) has been observed in patients with an earlier onset of the disease.

Methods: Inclusion criteria were diagnosis of MS, age 9–18 years, impairment on at least one attention test. Subjects were randomized to specific training (ST) or non-specific training (n-ST), delivered through a customized module based on attention exercises in COGNI-TRAcK2. The main feature of the ST is the implementation of working load algorithms and procedures for intensiveness regulation. The effectiveness of the ST on attention was primarily assessed on the Symbol Digit Modalities Test (SDMT)3 using an analysis of variance for repeated measures. Secondary objectives included effectiveness on other cognitive tests and everyday-life activities. The evaluations were performed at baseline, end of training, 3-month follow-up.

Results: 22 relapsing–remitting patients were included: data of 8 subjects in n-ST and 4 subjects in ST were available. As for the primary outcome, SDMT score improved in the ST group (from 31.2 at baseline to 42.4 after 3 months, $p=0.043$). This effect was evident also in Trial Making Test B ($p=0.047$). There was no benefit in other neuropsychological measures.



As for the primary outcome, mean score on the SDMT improved in the ST group (from 31.2 + 9.8 at baseline to 42.4 + 18 at the end of training, $p=0.524$) and remained stable in the n-ST group (from 32 + 7.3 at baseline to 35.5 + 9.7 at the end of training, $p=0.284$).



The positive effect of ST was also evident in Trail Making Test B, which improved in each group of patients: in ST group from 113.5 + 16.3 at baseline to 54 + 8.5 at the end of treatment ($p = 0.047$) and in n-ST group from 97 + 39 at baseline to 76.7 + 41.4 at the.

Conclusion: These preliminary findings point to a potential benefit of a home-based, computer-assisted training of attention in patients with POMS. Early rehabilitation in POMS can mitigate the negative impact of cognitive impairment in patient's lifestyle and school activities.

OPR-034 | Ambulatory 24-h continuous polysomnography as diagnostic tool for narcolepsy type 1 in adult and pediatric patients

F. Biscarini[1]; C. Zenesini[2]; L. Vignatelli[2]; F. Citeroni[2]; S. Vandi[1]; L. Barateau[3]; Y. Dauvilliers[3]; G. Plazzi[4]; F. Pizza[1]

[1]*Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio-Emilia, Italy;* [2]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Italy;* [3]*Sleep-Wake Disorders Unit, Department of Neurology, Gui-de-Chauliac Hospital, CHU Montpellier, Montpellier, France;* [4]*Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio-Emilia, Italy*

Background and aims: Narcolepsy type 1 (NT1) is diagnosed on average 10 years after the onset. We evaluated the contribution of 24-hour continuous polysomnography (PSG) as an alternative tool for the diagnosis of NT1 in adults and children.

Methods: Consecutive patients evaluated at the Bologna Narcolepsy Center from 2013 to 2022 for suspected hypersomnia were included. The 807 participants underwent 48-hour ambulatory PSG monitoring preceding the multiple sleep latency test (MSLT). The accuracy of night1 and day2 PSG was tested for the diagnosis of NT1 ($n = 322$), employing the 2023 international criteria as the standard reference for the ROC curve analysis.

Results: The detection of daytime-sleep-onset REM period (SOREMP) ≥1, with an area under the curve (AUC) of 0.84 (95% CI, 0.82–0.87), 84.4% sensitivity and 84.5% specificity, resulted superior to nighttime-PSG measures, including nighttime-SOREMP ($p < 0.001$) and comparable to 24-hour-SOREMP count. In the entire cohort, the combination of daytime-SOREMP ≥1 with cataplexy provided 78.9% sensitivity and 98.4% specificity, with AUC 0.89 (95% CI 0.86–0.91) superior to the combination of nighttime-SOREMP with cataplexy (AUC 0.78, 95% CI 0.76–0.81, $p < 0.001$) and not inferior to MSLT criteria for narcolepsy (AUC 0.90, 95% CI 0.88–0.92). These results were confirmed separately in adult and pediatric patients, except that, in pediatric patients (130/243 with NT1), nighttime-SOREMP (AUC 0.86, 95% CI 0.82–0.90) was not inferior to daytime-SOREMP ≥1.

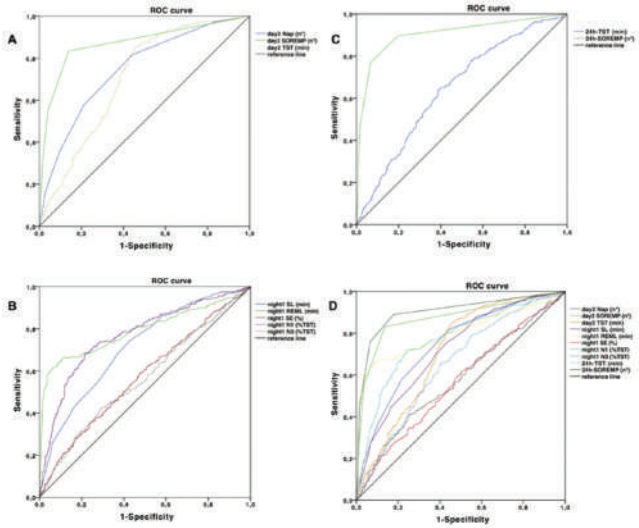

FIGURE 1 Receiver operating characteristic (ROC) curve analysis for diagnosis of narcolepsy type 1 of the polysomnographic variables from daytime (A), nighttime (B), daytime and nighttime combined (C), and all the variables together (D).

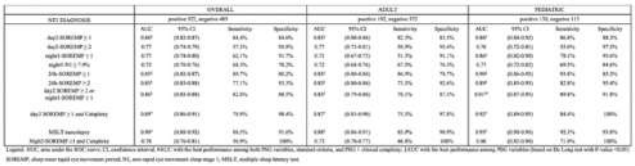

TABLE 1 Receiver operating characteristic (ROC) curve analysis for the diagnosis of narcolepsy type 1, in different age groups.

Conclusion: Continuous daytime-PSG is accurate for identifying NT1 in all age groups and appears superior to nighttime-PSG and not inferior to 24-hour monitoring. Daytime-PSG, applicable outside sleep laboratory settings, can anticipate the diagnosis of NT1 in both adults and children.

Disclosure: Nothing to disclose.

OPR-035 | Survival differences between genders in PDHA1-related pyruvate dehydrogenase deficiency

K. Merkevicius; J. Mayr; S. Wortmann

University Children's Hospital, Salzburger Landeskliniken (SALK), Paracelsus Medical University (PMU), Salzburg, Austria

Background and aims: Pyruvate dehydrogenase complex deficiency (PDHD) is the prototypic inborn error of mitochondrial metabolism, leading to neurodevelopmental disorder with lactic acidosis, CNS structural abnormalities. Disease causing variants in the X-linked PDHA1 are the most common genetic cause of PDHD, consequently, mainly males should be affected. In the literature, both genders are reported. We here assess the gender differences in survival in PDHA1- related PDHD.

Methods: Affected individuals with PDHA1- related PDHD were recruited via literature review ($n = 512$) and international collaboration ($n = 418$). All variants were (re)classified according to NM_000284.3 reference transcript, interpreted via American College of Medical Genetics (ACMG) criteria. (Likely) benign variants were excluded. Survival probability was assessed using Kaplan–Meier estimator.

Results: In total, 930 cases with known gender and genotype were included (females 51.6%, $n = 480$), harbouring a total of 324 different PDHA1 disease causing variants. The overall median survival was 12.5 years (95% Confidence interval (95% CI) 8–20 years; $n = 317$). Males had significantly ($p < 0.001$) lower survival probability than females, median survival in males and females were 3.6 years (95% CI 2.5–9.42; $n = 146$) and 22 years (95% CI 16.0–30.0; $n = 159$), respectively. Males with neonatal or infantile presentation had significantly lower survival probability than females with neonatal ($p < 0.001$; $n = 136$) or infantile ($p < 0.001$; $n = 83$) presentation.

Conclusion: Interestingly, we found equal number of cases between both genders, males had significantly lower survival probability. In females, X-inactivation could lead to milder phenotypes with better survival even with the same genotype as in males. Some males with severe phenotype could result in spontaneous pregnancy termination explaining similar frequency.

Disclosure: This abstract is part of a larger study analysing the genotypical and phenotypical landscape of PDHA1-related PDHD. This study was made possible through large collaboration with more than 150 different specialists worldwide.

OPR-036 | Abstract withdrawn

OPR-037 | Clinical and instrumental gait phenotyping in subjects with GLUT-1 deficiency syndrome

M. Corrado[1]; R. De Icco[1]; V. Grillo[1]; V. De Giorgis[1]; V. Vacchini[2]; C. Varesio[2]; M. Celario[2]; D. Trabassi[3]; S. Castiglia[3]; M. Serrao[3]; C. Tassorelli[3]

[1]*Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy;* [2]*Department of Child Neurology and Psychiatry, IRCCS Mondino Foundation, Pavia, Italy;* [3]*Department of Medical and Surgical Sciences and Biotechnologies, "Sapienza" University of Rome, Polo Pontino, Latina, Italy*

Background and aims: Gait disturbances and movement disorders are frequent in patients with GLUT-1 deficiency syndrome (GLUT1-DS), a rare disease also characterized by seizures and cognitive dysfunction. This study aimed to assess the ability of a set of instrumental gait indexes to identify gait disorders in GLUT1-DS, and to detect potential correlations with the clinical phenotype and biochemical parameters.

Methods: We recorded a 30-meter gait of 16 subjects with GLUT1-DS and of 16 matched healthy subjects (HS). We performed gait analysis with an inertial sensor. Based on trunk acceleration we calculated: spatio-temporal gait parameters, pelvic kinematics, harmonic ratios (HR), recurrence quantification analysis (RQA), stride length coefficient of variation (CV), the longest short-term Lyapunov's exponent (sLLE), and the log dimensionless jerk score (LDLJ). Along with the instrumental gait recording, we performed a comprehensive clinical and biochemical phenotyping.

Results: GLUT 1-DS (mean age 19.1 ± 13.7 years) showed lower values of HR and single support (SS) phase (Figure 1; $p < 0.05$), indicating impaired gait smoothness. Moreover, they showed higher values of CV and sLLE (Figure 2; $p < 0.01$), suggestive of higher dynamic instability and variability of gait. The CV negatively correlated with ketonemia ($r = -0.61$, $p < 0.05$). Nine subjects (52%) had clinically evident gait disorders, mainly characterized by choreo-ataxic gait.

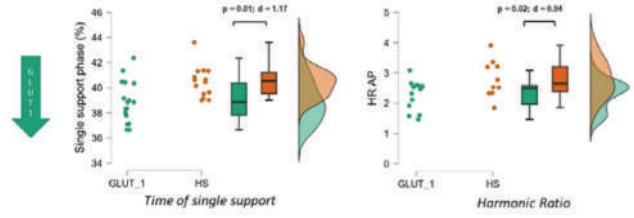

FIGURE 1 Differences in time of single support (SS) and harmonic ratio (HR) between HS (orange) and GLUT1-DS (green).

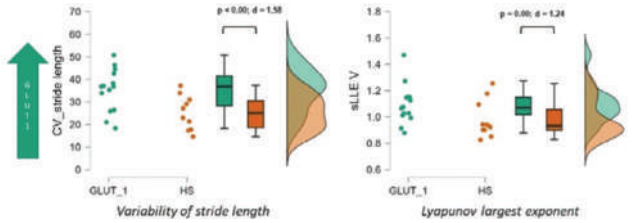

FIGURE 2 Differences in coefficient of variation (CV, i.e. variability of stride length) and the longest short-term Lyapunov's exponent (sLLE) between HS (orange) and GLUT1-DS (green).

Conclusion: GLUT1-DS exhibited multiple alterations in the trunk acceleration-derived gait indexes, which were suggestive of impaired gait stability and smoothness. Interestingly, increased gait variability correlated with low ketonemia, possibly suggesting this feature as a marker of poor therapeutic adherence.

Disclosure: Nothing to disclose.

Background and aims: Human fetal neural progenitor/stem cells (hfNPCs) transplant feasibility and safety in progressive multiple sclerosis (PMS) has been demonstrated in STEMS, a phase I clinical trial (NCT03269071). Higher dose of hfNPCs was associated with significantly lower rates of brain and gray matter (GM) atrophy after 2 years. We present long-term (LT) follow-up (FU) of STEMS trial.

Methods: Patients underwent clinical (comprehensive of Expanded Disability Status Scale [EDSS] and Symbol Digit Modalities Test [SDMT]) and brain MRI evaluation at minimum 4.5 year FU. New T2-hyperintense and Gd-enhancing lesions were counted. T2-lesion volume (T2LV), percentage brain (PBVC), GM (PGMVC) and white matter (PWMVC) volume changes were estimated.

Results: FU was available for 11/12 patients (median duration 5.6 years). At LT, EDSS and SDMT were significantly worsened compared to 2 year FU ($p <= 0.08$). Five (45%) patients showed new T2-hyperintense lesions, whereas T2LV was unchanged ($p = 0.07$); no patient showed Gd-enhancing lesions. Brain, GM and WM volumes were decreased at LT compared to 2-year FU. Interestingly, atrophy rates at LT were lower compared to the first 2-year changes (significant for PGMVC: 2-years vs. baseline = −0.76%; LT vs. 2-years = −0.47%, $p = 0.04$). No significant correlation was found between number of injected hfNPCs and variation of EDSS, SDMT or MRI measures.

Conclusion: Although no clear dose–response effect has been found in hampering disability, cognition or brain atrophy progression, lower rates of GM atrophy were found at LT FU, which could imply that hfNPCs maintain their neuroprotective effect over time.

OPR-039 | Parental smoking exposure and risk for multiple sclerosis among adults: The EnvIMS study

C. Ferri[1]; N. Merli[2]; K. Myhr[3]; T. Riise[4]; C. Wolfson[5]; M. Pugliatti[6]
[1]*Department of Neuroscience, S. Anna University Hospital, Ferrara, Italy*; [2]*Department of Neuroscience and Rehabilitation, University of Ferrara, Italy. S. Anna University Hospital, Ferrara, Italy*; [3]*Department of Clinical Medicine, University of Bergen, Norway; The Norwegian Multiple Sclerosis Registry and Biobank, Department of Neurology, Haukeland University Hospital, Bergen, Norway*; [4]*Department of Global Public Health and Primary Care, University of Bergen, Bergen, Norway/The Norwegian Multiple Sclerosis Competence Centre, Department of Neurology, Haukeland University Hospital, Bergen, Norway*; [5]*Department of Epidemiology, Biostatistics, and Occupational Health, School of Population and Global Health, McGill University, Montreal, Quebec, Canada*; [6]*Department of Neuroscience and Rehabilitation, University of Ferrara, Italy; S. Anna University Hospital, Ferrara, Italy*

Background and aims: Active smoking is a known risk factor for Multiple sclerosis (MS) development and poor prognosis. However, the impact of past exposure to parental smoking (ParS), including maternal smoking during pregnancy (MSDP) is not well defined. We aimed to investigate how these types of early age exposures affect MS risk among adults.

Methods: Using the data collected by the EnvIMS study, a large multinational case–control population-based study, we investigated the association between MS and smoking habit, MSDP and maternal/paternal smoking (MaS, PaS) in Canadian, Italian, and Norwegian populations. Data were collected with EnvIMS-Q, designed to investigate environmental exposures during early life stages. Adjusted odds ratios (aOR) for index age and participants' smoking status are presented with 95% confidence intervals (95% CI).

Results: We included 1565 Canadian, 2040 Italian, and 2674 Norwegian subjects. An association between MS and MSDP and MaS was observed among Norwegians: aOR 1.38 (1.12, 1.71) and 1.39 (1.17, 1.65), respectively. A tendency for PaS to be associated with MS was found among Canadians: aOR 1.21 (0.97, 1.51). No significant association to ParS (any) was detected in the Italian population.

Conclusion: Selective exposure to ParS at early age may differentially increase MS risk in the general population and independently from the subject's past/current smoking habit. The developmental origin of health and disease ('DOHaD') theory may help interpret these findings. The absence of an association between MS and past exposure to ParS in other populations may reflect its smaller effect on MS risk compared to other factors.

Disclosure: The authors declare no conflict of interest. The EnvIMS study was supported by Fondazione Italiana Sclerosi Multipla, FISM, grants n. 2007/R/14, and n. 2008/R/19; Financially supported by the European Union – Next Generation EU – NRRP M6C2 – Investment 2.1 Enhancement and strengthening of biomedical research in the NHS - PNRR-MAD-2022-12,376,868.

OPR-040 | Retinal layer thinning differentiates disease-modifying treatment effects in relapsing MS when using a rebaseline

G. Bsteh[1]; H. Hegen[3]; N. Krajnc[2]; P. Altmann[1]; M. Auer[3]; K. Berek[3]; B. Kornek[1]; F. Leutmezer[1]; S. Macher[1]; T. Monschein[1]; M. Ponleitner[1]; P. Rommer[1]; C. Schmied[1]; K. Zebenholzer[1]; G. Zulehner[1]; T. Zrzavy[1]; F. Deisenahmmer[3]; F. Di Pauli[3]; B. Pemp[4]; T. Berger[1]
[1]*Department of Neurology, Medical University of Vienna, Vienna, Austria*; [2]*Comprehensive Center for Clinical Neurosciences and Mental Health, Medical University of Vienna, Vienna, Austria*; [3]*Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria*; [4]*Department of Ophthalmology, Medical University of Vienna, Vienna, Austria*

Background and aims: We aimed to investigate whether retinal layer thinning measured by optical coherence tomography (OCT) can differentiate effects of disease-modifying treatment (DMT) in relapsing MS (RMS) using a rebaseling concept.

Methods: From an ongoing prospective observational study, we included RMS patients, who 1) had an OCT scan 6–12 months after DMT start (rebaseline), 2) ≥1 follow-up OCT ≥12 months after rebaseline, and 3) adhered to the DMT during follow-up. Differences between DMT substances in thinning of peripapillary retinal nerve fiber layer (pRNFL) and macular-ganglion-cell-plus-inner-plexiform layer (GCIPL) were analyzed using mixed-effects linear regression adjusting for age, sex, disease duration and relapses during follow-up.

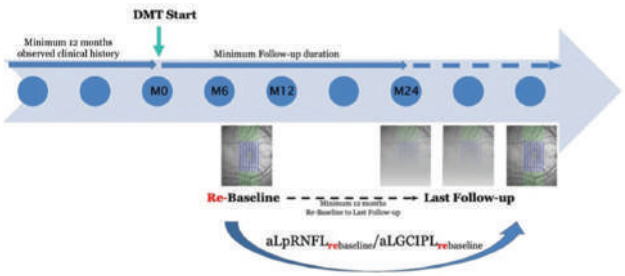

FIGURE 1 Study design.

Results: Of 291 RMS patients (mean age 30.8 years [SD 7.9], 72.9% female, median disease duration 9 months [6–94], median rebaseline-to-last-follow-up-interval 37 months [12–87]). Mean annualized percent loss rates (%/year) of retinal layer thinning in reference to dimethyl-fumarate ($n = 84$, GCIPL 0.28, pRNFL 0.53) were similar under teriflunomide ($n = 18$, GCIPL 0.34, pRNFL 0.59, not significant [ns]), glatiramer acetate ($n = 24$, GCIPL 0.32, pRNFL 0.56, ns) and interferon beta ($n = 13$, GCIPL 0.33, pRNFL 0.60, ns), appeared slightly lower under sphingosine-phosphate-1-receptor modulators ($n = 27$, GCIPL 0.19 [$p = 0.093$], pRNFL 0.42 [$p = 0.097$]) and cladribine ($n = 23$, GCIPL 0.20 [$p = 0.095$], pRNFL 0.42 [$p = 0.099$]), and were significantly lower under natalizumab ($n = 47$, GCIPL 0.09, pRNFL

0.24; $p < 0.001$ respectively) and anti-CD20 monoclonal antibodies ($n = 55$, GCIPL 0.10, pRNFL 0.23; $p < 0.001$ respectively).

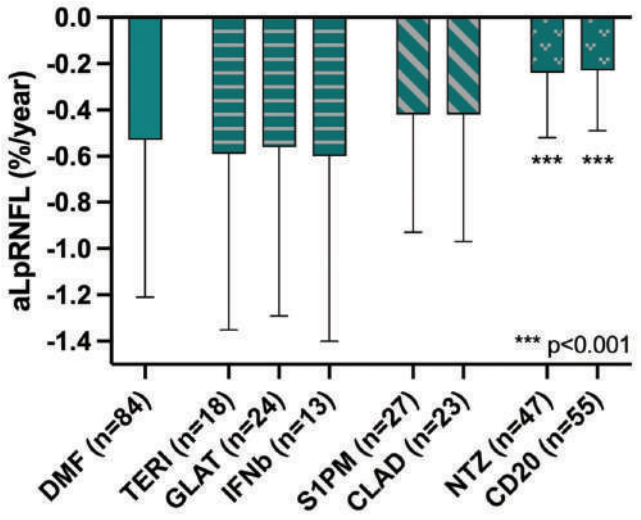

FIGURE 2 Annualized pRNFL loss differentiates disease-modifying treatment effects in RMS.

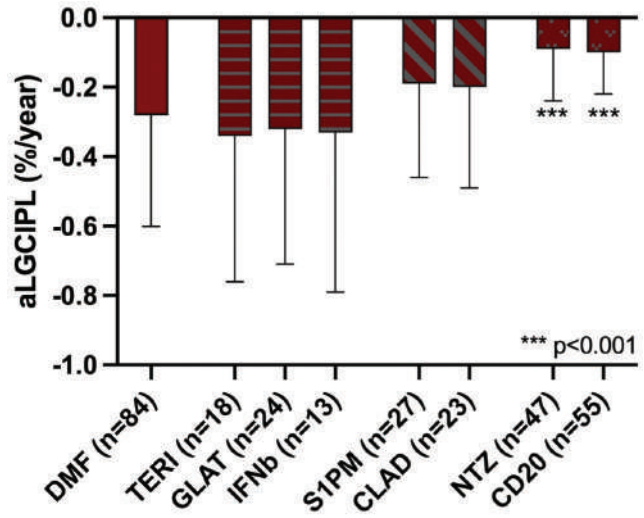

Figure 23 Annualized GCIPL loss differentiates disease-modifying treatment effects in RMS.

Conclusion: Applying a rebaseling concept, retinal layer thinning differentiates DMT effects in RMS and, thus, may be a useful biomarker to mediate DMT efficacy on neuroaxonal degeneration – at least on a group level.

Disclosure: Gabriel Bsteh: has participated in meetings sponsored by, received speaker honoraria or travel funding from Biogen, Celgene/BMS, Lilly, Merck, Novartis, Roche, Sanofi-Genzyme and Teva, and received honoraria for consulting Biogen, Celgene/BMS, Novartis, Roche, Sanofi-Genzyme and Teva. He has received unrestricted research grants from Celgene/BMS and Novartis.

OPR-041 | Longitudinal changes in the periplaque area of paramagnetic rim lesions may be associated with remyelination failure

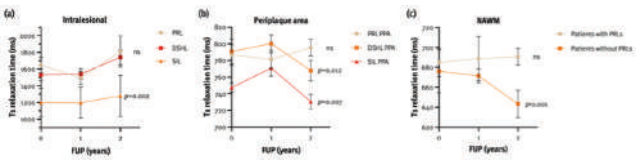
N. Krajnc[1]; V. Schmidbauer[2]; J. Leinkauf[2]; N. Gantner[2]; L. Haider[2]; G. Bsteh[1]; G. Kasprian[2]; F. Leutmezer[1]; B. Kornek[1]; P. Rommer[1]; T. Berger[1]; H. Lassmann[3]; S. Hametner[4]; A. Dal-Bianco[1]

[1]Department of Neurology, Medical University of Vienna, Vienna, Austria; [2]Medical University of Vienna, Department of Biomedical Imaging and Image-guided Therapy, Vienna, Austria; [3]Center for Brain Research, Medical University of Vienna, Vienna, Austria; [4]Division of Neuropathology and Neurochemistry, Department of Neurology, Medical University of Vienna, Vienna, Austria

Background and aims: Paramagnetic rim lesions (PRLs) are an emerging imaging biomarker in multiple sclerosis (MS) associated with a more severe disease course.

Methods: In this prospective longitudinal study, quantitative MRI metrics of PRLs, lesions with diffuse susceptibility-weighted imaging (SWI)-hypointense signal (DSHLs) and SWI-isointense lesions (SILs), their surrounding periplaque area (PPA) and normal-appearing white matter (NAWM) were measured in people with MS (pwMS) using the multi-dynamic multi-echo (MDME) sequence post-processing software "SyMRI" at baseline, after 1 and 2 years.

Results: In 15 pwMS, 18 PRLs, 31 DSHLs and 63 SILs were identified; four (26.7%) patients had no PRLs. After 2 years, intralesional T1 relaxation times increased significantly only in SILs (1200.7 (172.6) vs. 1278.6 (245.7), $p = 0.002$) but not in PRLs and DSHLs (1648.6 (402.1) vs. 1810.2 (564.6), $p = 0.154$; 1532.5 (402.1) vs. 1741.4 (328.1), $p = 0.086$, respectively). In the PPA, significantly shorter T1 relaxation times were observed for both DSHLs (790.8 (83.2) vs. 767.9 (45.9), $p = 0.012$) and SILs (747.5 (45.7) vs. 730.6 (51.2), $p = 0.007$) but not for PRLs (786.7 (52.9) vs. 795.2 (30.3), $p = 0.591$). Patients with PRLs also showed no shortened T1 relaxation times in the NAWM (685.0 (46.0) vs. 690.7 (18.5), $p = 0.830$) in contrast to patients without PRLs (676.1 (42.9) vs. 643.3 (19.4), $p < 0.001$).



Longitudinal changes in PRLs, DSHLs and SILs, their surrounding PPA and NAWM.

Conclusion: Significantly shorter T1 relaxation times in DSHL PPA and SIL PPA, but not in PRL PPA after 2 years may again point to remyelination failure in and around PRLs. T1-quantification based on MDME in and around lesions may become a useful and applicable routine marker for silent progression in pwMS.

Disclosure: The project is supported by the Multiple Sklerose Forschungsgesellschaft.

OPR-042 | CVS, CL and PRL for the diagnostic and prognostic workup of MS

S. Borrelli[1]; M. Martire[2]; A. Stölting[1]; C. Vanden Bulcke[1]; E. Pedrini[2]; F. Guisset[1]; C. Bugli[3]; H. Yildiz[4]; L. Pothen[4]; S. Elands[5]; V. Martinelli[2]; B. Smith[6]; S. Jacobson[6]; R. Du Pasquier[7]; V. van Pesch[8]; M. Filippi[2]; D. Reich[6]; M. Absinta[2]; P. Maggi[1]

Background and aims: The diagnosis of multiple sclerosis (MS) can be challenging in clinical practice. We evaluated the diagnostic performance, alone or in combination, of the central vein sign (CVS), cortical lesions (CL), and paramagnetic rim lesions (PRL), as well as their association with clinical outcomes.

Methods: This multicenter study included: (1) a cross-sectional analysis of CVS (proportion of CVS-positive lesions, or simplified determination of CVS in three/six lesions - Select3*/Select6*), CL, and PRL in 185 MS/100 non-MS cases on 3T-MRI-brain images, including 3D T2-FLAIR, T2*-EPI magnitude and phase, DIR, and MPRAGE; (2) a longitudinal analysis in 61 MS cases of progression independent of relapse and MRI activity (PIRA).

Results: The presence of ≥41% CVS-positive lesions/≥1 CL/≥1 PRL (optimal cut-offs) had 96%/94%/93% specificity, 97%/80%/60% sensitivity, and 0.99/0.88/0.77 area under the curve (AUC), respectively, to distinguish MS from non-MS cases. Select3*/Select6* showed 93%/95% specificity, 97%/89% sensitivity, and 0.95/0.92 AUC. The combination of CVS, CL, and PRL improved the diagnostic performance, especially when Select3*/Select6* were used (93%/93% specificity, 98%/97% sensitivity, 0.99/0.98 AUC; $p = 0.002/p < 0.001$). Both CL and PRL were associated with higher MS disability and severity. After 2 years follow-up, cases with >4 PRL at baseline were more likely to experience PIRA (OR 17.8, 95% CI: 2.2–144.7; $p = 0.007$), whereas no association was observed between other MRI measures and PIRA, including the number of CL.

Conclusion: The combination of CVS, CL, and PRL can improve MS differential diagnosis. CL and PRL also correlate with clinical measures of poor prognosis, with PRL being a predictor of PIRA.

Epilepsy 1

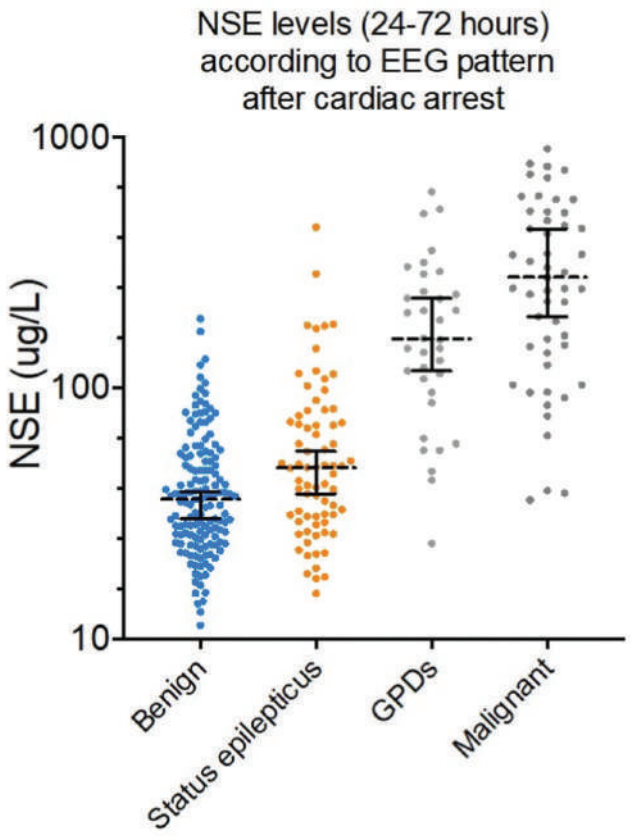
OPR-043 | Neuron-specific Enolase in Status Epilepticus versus Generalized Periodic Discharges after cardiac Arrest (NEXT-CAT)

Morotti Colleoni[1]; M. Pozzi[2]; S. Tagliabue[1]; E. Bianchi[3]; M. Normanno[1]; F. Pasini[1]; G. Cereda[1]; A. Giglio[1]; A. Stabile[1]; G. Pederzoli[1]; S. Diamanti[1]; J. Di Francesco[1]; L. Stanzani[1]; A. Coppo[2]; L. Avalli[2]; C. Ferrarese[1]; G. Foti[2]; S. Beretta[1]
[1]*Department of Neurology, Fondazione IRCCS San Gerardo dei Tintori, University of Milano-Bicocca, Monza, Italy*; [2]*Department of Intensive Care, Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy*; [3]*Mario Negri Institute for Pharmacological Research IRCCS, Milano, Italy*

Background and aims: The aim of our study was to analyse the distribution of NSE levels according to specific EEG patterns in post-cardiac arrest patients.

Methods: We conducted a prospective cohort study in patients after cardiac arrest admitted to the ICU, with at least one NSE value between 24 and 72 hours and at least one off-sedation EEG within 72 hours after cardiac arrest. Subjects were categorized in four independent EEG patterns (benign, epileptiform non-GPDs, GPDs, malignant non-epileptiform). Kruskal-Wallis test and Mann–Whitney tests were used to compare the NSE levels distribution among the four EEG patterns and in GPDs versus epileptiform non-GPDs patterns.

Results: We recruited 341 patients from 2011 to 2023. A benign EEG pattern was observed in 161 (47%), an epileptiform pattern in 84 (25%), GPDs in 43 (13%) and a malignant pattern in 53 (15%). The median NSE level were 34 ng/mL for the benign EEG pattern, 45.8 ng/mL for the epileptiform pattern, 144 ng/mL for GPDs and 320.8 ng/mL for the malignant one. The distribution of NSE levels was statistically different among the four EEG patterns ($H = 152.4$, $p < 0.0001$). NSE levels were approximately 100 ng/mL higher in patients with a GPDs pattern, compared to an epileptiform non-GPDs pattern (absolute difference 98.2 ng/mL, 95% CI 66.2–126.7; $p < 0.0001$).



The NSE levels distribution among the four EEG patterns.

Conclusion: The level of the prognostic biomarker NSE is higher in patients after cardiac arrest with GPDs compared to epileptiform activity. A more aggressive therapeutic approach could be justified for patients with epileptiform non-GPDs activity after cardiac arrest.
Disclosure: Nothing to disclose.

OPR-044 | Electroencephalographic and epileptological natural history in metachromatic leukodystrophy: A longitudinal study

G. Cutillo[1]; G. Fanelli[1]; A. Zambon[1]; M. Vabanesi[1]; G. Cecchetti[1]; A. Bellini[1]; S. Recupero[3]; M. Sarzana[3]; F. Ciotti[3]; U. Del Carro[1]; M. Natali Sora[1]; C. Baldoli[2]; A. Aiuti[3]; F. Fumagalli[3]; M. Filippi[1]
[1]*Neurology Unit and Neurophysiology Service, IRCCS Ospedale San Raffaele, Milan, Italy;* [2]*Neuroradiology Unit, IRCCS Ospedale San Raffaele, Milan, Italy;* [3]*Pediatric Immunohematology Unit and BMT Program, IRCCS San Raffaele Scientific Institute, Milan, Italy*

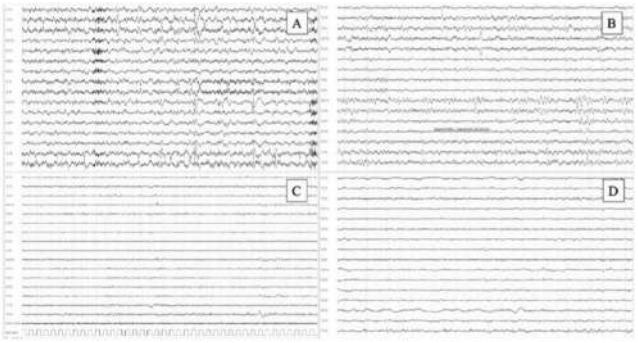
Background and aims: Metachromatic leukodystrophy (MLD) is a lysosomal storage disorder caused by mutations in the ARSA gene. Few data are available on its epileptological history.
Methods: Single-center, retrospective and prospective observational study on MLD patients enrolled in a natural history protocol (January 2000–December 2023). Data including clinical histories, EEG tracings, MRI evaluations and functional scales were collected.

Results: Fifty patients, 25 late infantile (LI), 12 early juvenile (EJ), 7 late juvenile (LJ), 6 adult-onset (AD), were included. Median follow-up was 4 years (IQR: 2–8; range: 1–20), with 360 EEG tracings. Epilepsy was documented in 76% (38/50) of patients: 80% (20/25) of LI, 100% (13/13) of EJ, 50% of AD (3/6) and 43% of LJ (3/7). Epilepsy occurred on average 30 months after disease onset in LI, 35 months in EJ, 108 months in LJ and 109 months in AD. Main seizure types reported were focal and focal-to-bilateral tonic–clonic seizures, often drug-resistant. Status epilepticus was reported in 34% (13/38) of patients, coinciding with epilepsy onset in 4/38. Disease subtypes presented distinct EEG patterns: LI presented rapid background deterioration, frequent seizures, and low-voltage rapid activity bursts. Among Juvenile-onset patients, divergent patterns were observed, with EJ having more similarities with LI group and LJ displaying a slower progression. AD presented disorganized backgrounds with sporadic focal anomalies.

MLD patients (N=50)	LI	EJ	LJ	AD
Patients N	25	12	7	6
Female (n)	14	7	4	3
Years of EEG follow-up (Median, IQR)	3 (1-4)	4 (2-6)	10 (8-14)	8 (4-12)
Age at last FU (Median, IQR)	5 (4-8)	10 (8-17)	25 (20-28)	48 (44-50)
Available tracings (N)	130	103	75	52
MLD onset, months (Median, IQR)	18 (10-25)	56 (48-67)	96 (74-170)	414 (365-487)
Epilepsy (n)	20	13	3	3
Epilepsy onset, Months from MLD onset (Average)	30	35	108	109
Status epilepticus (n)	7	3	2	1
Polytherapy, n (%)	15 (60)	12 (92)	2 (29)	2 (30)
Persistent generalized Seizures (n)	4	2	1	1

Baseline features and demographics of the patients included in the analysis, recapitulating the results section.

Conclusion: Epilepsy represent a significant comorbidity in MLD, especially LI and EJ groups, often presenting with drug-resistant seizures. MLD subtypes present different EEG evolution, hence this could represent a tool to further characterize patients, disease progression and treatment response.



Illustrative EEG epochs of four patients in advanced diseases stages. A (LI), B (EJ), C (LJ), D (AD). Different subtype shows different degrees of background disorganization and focal anomalies.

Disclosure: The study was supported by Telethon Foundation, IRCCS San Raffaele Scientific Institute, GlaxoSmithKline (GSK), and Orchard Therapeutics. The authors have no relevant disclosure related to the present work.

OPR-045 | EpilepsyPOWER a project to favor inclusion of people with epilepsy in workplaces

F. Narducci[1]; G. Baker[2]; D. Walsh[3]; N. Casalino[4]; B. Borin[4]; F. Pigni[5]; S. Louissi[5]; M. Kateva[6]; S. Duttenhöfer[7]; M. Tombini[1]; V. Di Lazzaro[1]; G. Assenza[1]

[1]Campus Bio-Medico University, Department of Medicine and Surgery, Unit of Neurology, Neurophysiology, Neurobiology and Psichiatry, Rome, Italy; [2]University of Liverpool, Department of Molecular and Clinical Pharmacology, Liverpool, UK; [3]International Bureau of Epilepsy, Dublin, Ireland; [4]Luiss Business School, Rome, Italy; [5]Grenoble Ecole de Management, Grenoble, France; [6]Chamber of Commerce and Industry Vratsa, Vratsa, Bulgaria; [7]emcra GmbH, Berlin, Germany

Background and aims: Despite good seizure control, unemployment and underemployment are more common among people with epilepsy (pwE), for several reasons. The EpilepsyPOWER is a European project, involving five Countries (Italy, Bulgaria, France, Ireland, Germany), aimed to improve PwE's workplace inclusion.

Methods: For this project, we made a systematic review on epilepsy and employment, selecting 55 articles from 1958 to 2023, analyzing employment rate and determinants of employment/unemployment. We reviewed legislation in involved countries and developed two anonymous surveys asking for PwE's employment condition, and higher education institutions (HEI) general knowledge and attitudes about epilepsy.

Results: For all considered countries, we have not found any specific job legislation. Unemployment rates ranged from similar to twice or three times the general population and above all factors, seizure control and employers' attitudes contributed mostly to unemployment. We collected 567 answers from PwE and 291 from HEI. Unemployment rates were: 7.9% in Italy, 6.7% Ireland, 8.5% France, 15% Germany, 9% Bulgaria; people fully employed: 42.9% in Italy, 53% Ireland, 31.7% France, 40% Germany, 47.9% Bulgaria. In Italy, 24.2% of pwE did not disclose their condition, whereas in Bulgaria 48.5%. HEI individuals correctly defined epilepsy as a neurological disorder, treatable in most cases. Although most respondents have seen a seizure, in some countries, they did not know how to give first aid.

Conclusion: Exploring pwE work conditions and HEI perspectives could help to spread a culture of inclusion and fight marginalization of pwE in workplaces, allowing them to attain correct employment.

Disclosure: Nothing to disclose.

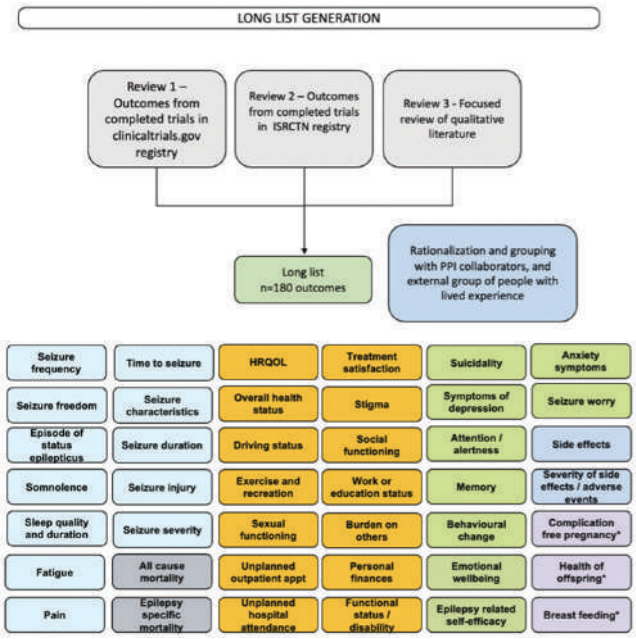
OPR-046 | An internationally derived core outcome set for adult epilepsy treatment trials: The EPSET Project

J. Mitchell[1]; A. Noble[2]; P. Williamson[2]; T. Marson[2]; EPSET Project Ineternational Working Group[3]

[1]The Walton Centre NHS FT, UK; [2]University of Liverpool, UK; [3]EPSET Project

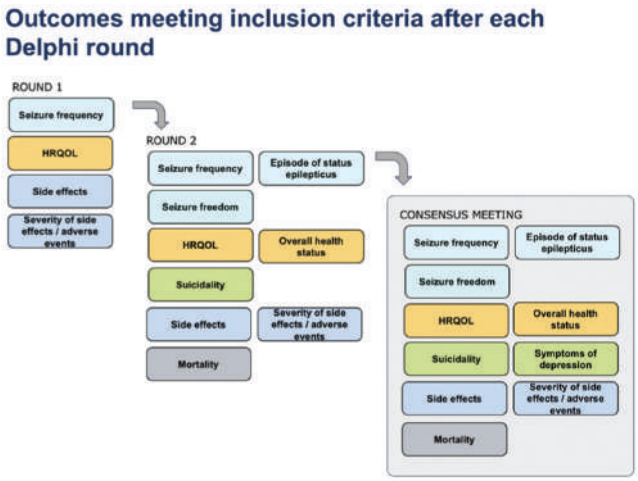
Background and aims: A Core Outcome Set (COS) is a standardised list of outcomes that should be reported as a minimum in all trials. In epilepsy, the choice of outcomes measured varies widely among existing studies, particularly in randomised controlled trials (RCTs). We have developed an internationally derived COS specific to adult epilepsy treatment trials.

Methods: We performed a rapid review of the qualitative literature exploring experiences of people with epilepsy and reviewed outcomes already measured in phase 3 and 4 epilepsy specific RCTs, to generate an outcome long-list. In collaboration with the ILAE Big Data Commission and an international group of healthcare providers, researchers, and people with epilepsy we have performed a grouping and rationalisation process and taken 42 individual outcomes to a two-stage, online Delphi survey followed by consensus meeting.



Long List of Outcomes for EPSET consensus process.

Results: 490 people with epilepsy, their representatives, healthcare professionals and researchers have completed the Delphi surveys in 7 languages, representing the global perspective. Inconclusive outcomes were discussed, and the final outcomes ratified at international online consensus meeting. The ratified COS includes a minimum set of seizure and non-seizure outcomes, that should be measured and reported as a minimum in all future clinical trials.



Outcomes achieving consensus for inclusion in the COS after each Delphi round.

Conclusion: The EPSET Project has identified a COS for adults with epilepsy and derived inter- national consensus. This will ensure that meaningful outcomes are measured in future clinical trials, that the results of trials are relevant to people with epilepsy and facilitate systematic review and meta-analysis.

Disclosure: Nothing to disclose related to the submitted work.

OPR-047 | Heart rate variability exhibits a reduced vagal output in patients with status epilepticus developing Tako-Tsubo

S. De Angelis; P. Quintieri; F. Dono; D. Liviello; S. Cipollone; G. Evangelista; S. Consoli; M. Russo; M. Dasara; F. Anzellotti; S. Sensi
Department of Neurosciences, Imaging and Clinical Sciences, "G. d'Annunzio" University of Chieti-Pescara, Chieti, Italy

Background and aims: Tako-tsubo cardiomyopathy (TTC) is an impairment of systolic function, mainly targeting the left ventricle with clinical manifestations closely resembling that of acute coronary syndrome. Although its aetiology has been related to a massive catecholamine release driven by physical and psychological stressors, certain neurologic conditions like status epilepticus (SE) also seem to increase susceptibility to TTC. However, clinical factors linking the SE to TTC are still missing. This study aims to provide reliable criteria to be employed as predictors of TTC in epileptic patients.

Methods: In this study, we examined Heart Rate Variability (HRV) changes in three patients presenting with TTC immediately after an SE. HRV analysis was performed on a 5-minute EKG recording in resting state during and after SE. HRV variability was evaluated according to time and frequency domains and non-linear analysis.

Results: During SE, a leaning towards cardiovagal output reduction was observed, as indicated by decreased RMSSD, HF, and SD1. In addition, an increased LF/HF ratio was also observed, an index that correlates with an overall increased risk of mortality. These imbalances tend to attenuate with SE resolution.

Conclusion: Data from our cohort suggest that HRV variations play a role in predicting cardiac dysfunction (and TTC) in epileptic patients. These data support the notion of a distinct undergoing interplay between sympathetic and cholinergic stimuli on myocardial motility in people with epilepsy.

Disclosure: Nothing to disclose.

OPR-048 | Status epilepticus in patients with brain tumors and metastases: A multicenter cohort study of 208 patients

A. Strzelczyk[1]; J. Rickel[1]; D. Zeeb[2]; S. Knake[2]; H. Urban[1]; J. Konczalla[1]; K. Weber[1]; P. Zeiner[1]; A. Pagenstecher[2]; E. Hattingen[1]; A. Kemmling[2]; E. Fokas[1]; S. Adeberg[2]; R. Wolff[1]; M. Sebastian[1]; T. Rusch[2]; M. Ronellenfitsch[1]; K. Menzler[2]; L. Habermehl[2]; M. Czabanka[1]; C. Nimsky[2]; L. Timmermann[2]; C. Grefkes[1]; J. Steinbach[1]; F. Rosenow[1]
[1]*Goethe-University Frankfurt;* [2]*Philipps-University Marburg*

Background and aims: Brain tumors and metastases account for approximately 10% of all status epilepticus (SE) cases. This study described the clinical characteristics, treatment, and short- and long-term outcomes of this population.

Methods: This retrospective, multi-center cohort study analyzed all brain tumor patients treated for SE at the university hospitals of Frankfurt and Marburg between 2011 and 2017.

Results: The 208 patients (mean 61.5 ± 14.7 years of age; 51% male) presented with adult-type diffuse gliomas (55.8%), metastatic entities (25.5%), intracranial extradural tumors (14.4%), or other tumors (4.3%). The radiological criteria for tumor progression were evidenced in 128 (61.5%) patients, while 57 (27.4%) were newly diagnosed with tumor at admission and 113 (54.3%) had refractory SE. The mean hospital length of stay (LOS) was 14.8 days (median 12.0, range 1–57), 171 (82.2%) patients required intensive care (mean LOS 8.9 days, median 5, range 1–46), and 44 (21.2%) were administered mechanical ventilation. All patients exhibited significant functional status decline (modified Rankin Scale) post-SE at discharge ($p < 0.001$). Mortality at discharge was 17.3% ($n = 36$), with the greatest occurring in patients with metastatic disease (26.4%, $p = 0.031$) and those that met the radiological criteria for tumor progression (25%, $p < 0.001$).

Conclusion: SE occurrence contributed to a decline in functional status in all cases, regardless of tumor type, tumor progression status, and SE refractoriness, while long-term mortality was increased in those with malignant tumor entities, tumor progressions, and refractory SE.

Disclosure: Nothing to disclose.

Ageing and dementia 2

OPR-049 | CAG repeats within non-pathological range in the HTT gene influence plasma NfL levels in prodromal Alzheimer's disease

C. Crucitti[1]; S. Mazzeo[1]; A. Ingannato[1]; G. Giacomucci[1]; J. Balestrini[1]; V. Moschini[2]; C. Morinelli[2]; G. Galdo[1]; F. Emiliani[1]; D. Frigerio[1]; D. Piazzesi[2]; S. Bagnoli[1]; S. Padiglioni[2]; V. Berti[3]; S. Sorbi[1]; V. Bessi[1]; B. Nacmias[1]

[1]Department of Neuroscience, Psychology, Drug Research and Child Health, University of Florence, Italy; [2]Research and Innovation Centre for Dementia-CRIDEM, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy; [3]Department of Biomedical, Experimental and Clinical Sciences "Mario Serio", University of Florence, Florence, Italy

Background and aims: HTT gene is involved in axon trafficking. It contains a key region of CAG repeats which is responsible, when expanded beyond 39 repeats, of Huntington's disease (HD). Expansions ranging from 27 to 35 are termed as intermediate alleles (IAs). Previous studies showed that increasing repeat length below the HD threshold in HTT confers advantageous changes, stabilizing the interaction with the brain-derived neurotrophic factor. Moreover, CAG repeats seem to affect cognitive performances of patients with Subjective Cognitive Decline (SCD) and Mild Cognitive Impairment (MCI). Here, we aimed to explore the association between CAG repeats, Alzheimer's Disease (AD) CSF biomarkers and plasma neurofilament light chain (NfL) in patients with SCD and MCI.
Methods: We included 95 patients (36 SCD and 59 MCI) who underwent neuropsychological investigation, plasma NfL analysis, CSF biomarkers analysis, Apolipoprotein E (APOE) and HTT genotype analysis. Patients were classified as prodromal AD if they had at least one positive Aβ biomarker and positive p-tau, otherwise they were defined as non-AD.
Results: We tested the association between plasma NfL and CAG repeats: in prodromal AD, this relationship was described by a quadratic model (R^2 0.243, $p=0.009$) as the NfL concentration decreases as the CAG repeat number increases up to 26 repeats (confirmed after age, diagnosis and CAG repeat number adjustment). There was no association in non-AD patients.
Conclusion: The number of CAG repeats, below the IA threshold, may play a role in SCD and MCI modulating the neurodegeneration due to AD, implying the potential of HTT 's involvement in the disease's pathophysiology.
Disclosure: Nothing to disclose.

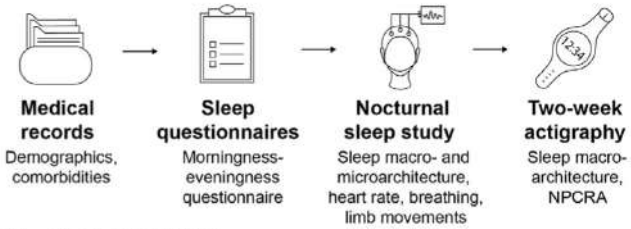
OPR-050 | Sleep and cognition: Insights from sleep microarchitecture

I. Filchenko[1]; A. Eberhard-Moscicka[2]; S. Duss[1]; M. Aktan Süzgün[1]; C. Bernasconi[1]; M. Schmidt[1]; C. Bassetti[1]

[1]Department of Neurology, University Hospital, Inselspital, Bern, Switzerland; [2]Department of Psychology, University of Bern, Bern, Switzerland

Background and aims: Sleep plays a pivotal role in cognition [Kong, 2023], however, to date little is known about the link between sleep microarchitecture and different cognitive domains [Qin, 2023]. This exploratory analysis aimed to comprehensively investigate this link.
Methods: The "Sleep and cognitive functioning" study included volunteers in good or excellent health condition (Eastern Cooperative Oncology Group grade of 0–1). Demographics, medical history, sleep architecture by polysomnography (electroencephalography [EEG] was recorded either with 6 electrodes or 256 electrodes [high-density EEG, hd-EEG]) and cognition were assessed at study inclusion (Figure 1A). Associations between cognition and sleep microarchitecture were explored using multiple linear regression with adjustment for age and arousal index.

A. Study design



B. Study population

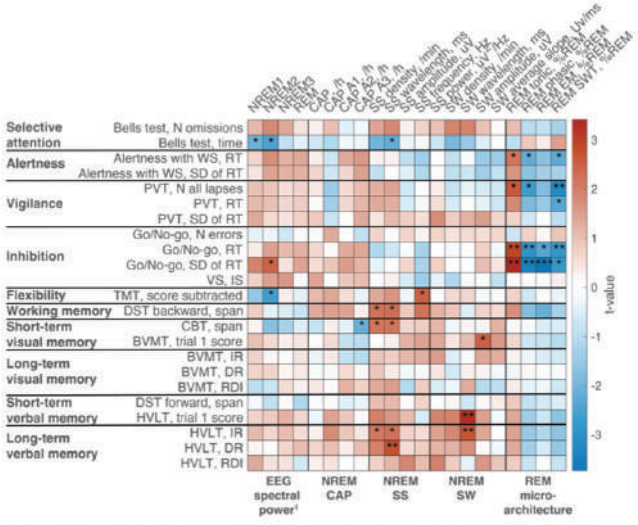
Parameter	Value
Age, years	29.00 [23.00, 35.52]
Female sex	37 (52.1)
MEQ, score	51.00 [46.00, 56.00]
Actigraphy	
Duration of actigraphy, days	14.00 [14.00, 14.00]
Time in bed, minutes	500.91 [457.80, 522.48]
SE, %	82.82 [77.11, 85.39]
Electroencephalography	
Assumed sleep, hours	7.94 [7.55, 8.33]
TRT, hour	8.43 [7.99, 8.95]
TST, hour	7.20 [5.92, 7.81]
SE, %	85.52 [76.89, 90.58]
Arousal index, /h	12.01 [4.25, 20.33]
NREM1, %TST	11.93 [7.81, 17.52]
NREM2, %TST	44.57 [37.56, 49.69]
NREM3, %TST	19.79 [15.40, 24.83]
REM, %TST	21.39 [17.65, 24.10]

Abbreviations: MEQ – Morningness-Eveningness Questionnaire, NPCRA – non-parametric circadian rhythm analysis, NREM – non-rapid eye-movement sleep, PSG –polysomnography, REM – rapid eye-movement sleep, SE – sleep efficiency, TRT – total recording time, TST – total sleep time.

Study design (A) and population (B).

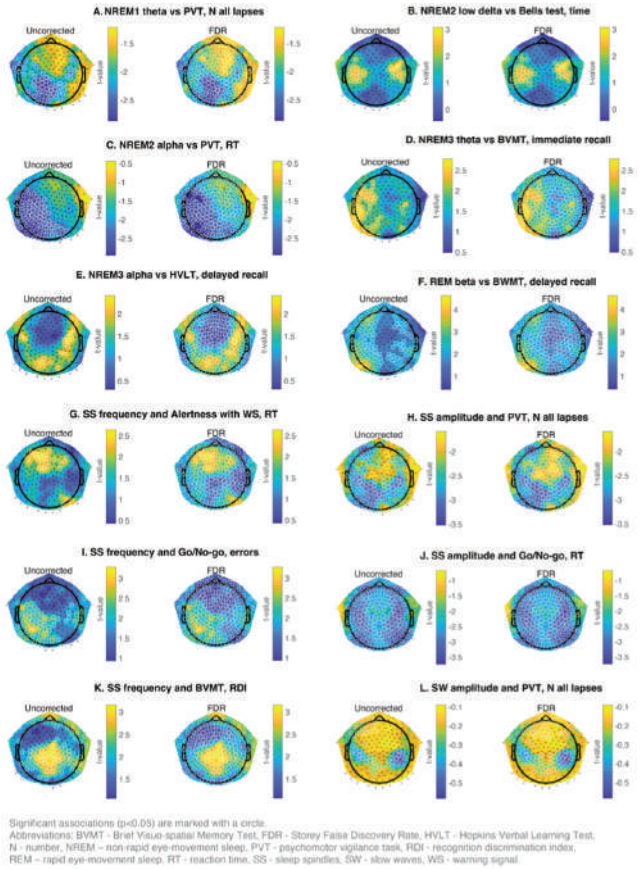
Results: 60 participants were included (median age: 52.7 years old, interquartile range (IQR) [32.9, 64.6]; 55% men; hd-EEG in 52%; Figure 1B). EEG analysis as based on 6 electrodes or their hd-EEG equivalents showed limited associations between cognition and sleep microarchitecture (e.g.,

working and visual memory with high SS density; Figure 2), whereas high-density EEG analysis identified multiple associations of interest with a distinct topography (e.g., visual memory with high EEG spectral power in beta band involving the right posterior region; Figure 3).



* p<0.05, ** p<0.01, *** p<0.001, multiple linear regression. To harmonize the directionality of the effects between different cognitive parameters, the t-values for selective attention, processing speed, attention, and executive functions, except for DST backward span, were multiplied by -1. [1]EEG spectral power is calculated for the band 0.5-40 Hz.
Abbreviations: BVMT – Brief Visuo-spatial Memory Test, CAP – cyclic alternating pattern, CBT – Corsi Block tapping test, DR – delayed recall, DST – digit span test, EM – eye movements,HVLT – Hopkins Verbal Learning Test, IR – immediate recall, IS – interference score, N – number, NREM – non-rapid eye-movement sleep, PVT – psychomotor vigilance task, REM – rapid eye-movement sleep, RDI – recognition discrimination index, RT – reaction time, SD – standard deviation, SS – sleep spindle, SW – slow wave, SWT – saw-tooth wave, TMT – Trail Making Test, VS – Victoria Stroop test.

Associations between cognition and sleep microarchitecture (basic analysis).



Significant associations (p<0.05) are marked with a circle.
Abbreviations: BVMT - Brief Visuo-spatial Memory Test, FDR - Storey False Discovery Rate, HVLT - Hopkins Verbal Learning Test, N - number, NREM – non-rapid eye-movement sleep, PVT - psychomotor vigilance task, RDI - recognition discrimination index, REM – rapid eye-movement sleep, RT - reaction time, SS - sleep spindles, SW - slow waves, WS - warning signal.

Selected associations between cognition and sleep microarchitecture (topographic analysis).

Conclusion: While these results confirm previous findings, they also expand our understanding about the link between sleep microarchitecture and cognition by providing valuable insights for the involvement of specific cortical regions. This knowledge may serve as a basis for targeted interventions to improve sleep-related cognitive function.
Disclosure: European Stroke Research foundation 2021.

OPR-051 | Neurotransmitters circuitry dysfunction in the Alzheimer's disease continuum

L. Argenti[1]; M. Losa[1]; L. Lombardo[1]; E. Peira[2]; S. Raffa[3]; G. Sambuceti[3]; F. Massa[1]; S. Garbarino[4]; D. Arnaldi[5]; S. Morbelli[6]; A. Chincarini[2]; B. Orso[1]; M. Pardini[1]
[1]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, Italy; [2]Istituto Nazionale di Fisica Nucleare (INFN), Genoa, Italy; [3]Department of Health Science (DISSAL), University of Genoa, Genoa Italy; [4]Life Science Computational Laboratory, IRCCS Ospedale Policlinico San Martino, Genova, Italy; [5]Neurophysiopatology Unit, IRCCS Ospedale Policlinico S. Martino, Genoa, Italy; [6]Nuclear Medicine Unit, AOU Città Della Salute e Della Scienza di Torino, Turin, Italy

Background and aims: The modulation of neurotransmitters circuitry in Alzheimer's disease (AD) holds promise as a potential focus for pharmacological intervention. We aimed to study the progression of neurotransmitter's networks dysfunction associated to the accumulation of misfolded proteins throughout the AD continuum.
Methods: We enrolled 90AD patients (72.8±7.02 yo) and 42 Healthy Controls (HC, 70±8.53 yo). All patients had a brain [18F] FDG-PET scan and MMSE available. As amyloidosis biomarker, 50 patients performed CSF exam and 40 an amyloid-PET. Patients were divided in two groups based on MMSE score (MMSE <24, $n=24$; MMSE ≥24, $n=66$) to study different disease stages. We performed a voxel-based analysis between AD patients and HC: in the whole group, in MMSE <24 and MMSE ≥24 groups, separately. Using JuSpace toolbox we explored the correlation between [18F]FDG-PET images and PET maps of glutamate (mGluR5), GABA (GABA-a), dopamine (D1, D2, FDOPA), serotonin (SERT, 5HT1a, 5HT1b, 5HT2a, 5HT4), noradrenaline (NAT) and choline (VAChT).
Results: In the whole AD group, the distribution of brain hypometabolism was associated with areas of 5HT2a and mGluR5 density ($p=0.029$, $p=0.034$ respectively). This remained significant in the MMSE <24 group ($p=0.006$). In the whole group, 5HT2a density correlates with a lower MMSE score and greater cerebral amyloid burden.
Conclusion: The spatial pattern of brain hypometabolism in AD is related to the distribution of specific neurotransmitters. We can speculate that areas with elevated expression of receptors involved

may be more susceptible to synaptic damage, as evidenced by brain hypometabolism.

Disclosure: Nothing to disclose.

OPR-052 | Universal prevention of dementia in Italy: A document analysis of the 21 Italian Regional Prevention Plans

S. Salemme[1]; D. Marconi[2]; S. Pani[3]; V. Casigliani[4]; A. Ancidoni[5]; G. Zamboni[6]; G. Lazzeri[2]; N. Vanacore[5]; G. Bellomo[5]

[1]School of Advanced Studies, University of Camerino, Camerino, Italy; [2]Post Graduate School of Public Health, University of Siena, Siena, Italy, Siena, Italy; [3]University of Cagliari, Cagliari, Italy; [4]University of Pisa, Pisa, Italy; [5]National Center for Disease Prevention and Health Promotion, National Institute of Health, Rome, Italy; [6]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy

Background and aims: An estimated 40% of dementia cases could be prevented through interventions targeting 12 modifiable risk factors (RFs) at different stages of life. We characterized the subnational population approaches to the prevention of dementia implemented in Italy.

Methods: We conducted a document analysis of the 21 Regional Prevention Plans (RPPs) for 2020–2025. We categorized the dementia-specific preventive interventions according to (i) type of RF targeted, (ii) target age, and (iii) target population. Indirect potential beneficial effects of interventions were defined by critically reviewing published literature on plausible relationships between RFs. Furthermore, we developed and applied to all RPPs a checklist evaluating key elements of situational analysis and prevention planning.

Results: Physical inactivity was the only RF covered by all RPPs, as a direct target of 117/248 interventions for dementia prevention. Smoking was targeted in more than 50% of RPPs, while less than 50% covered alcohol consumption and obesity. Only 25% of RPPs had dementia-specific interventions for social isolation, hypertension, and diabetes. Two RPPs targeted air pollution and only one TBI. No RPP directly covered low education, depression or hearing loss for dementia prevention. Total scores of the checklist ranged from a minimum score of 7 to a maximum of 28/63.

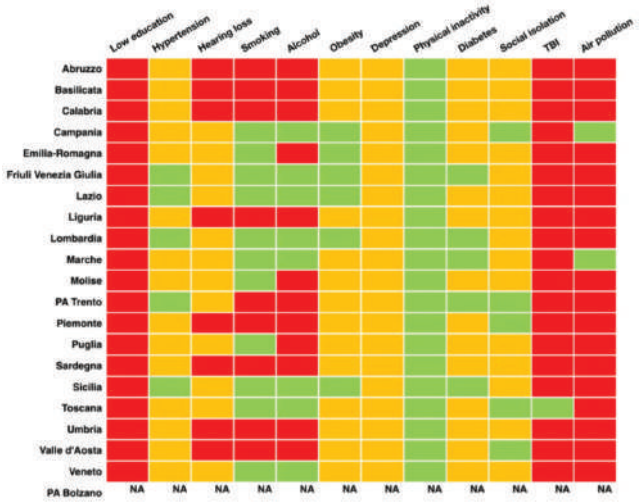


TABLE 1 Subnational coverage of potentially modifiable risk factors for cognitive decline.

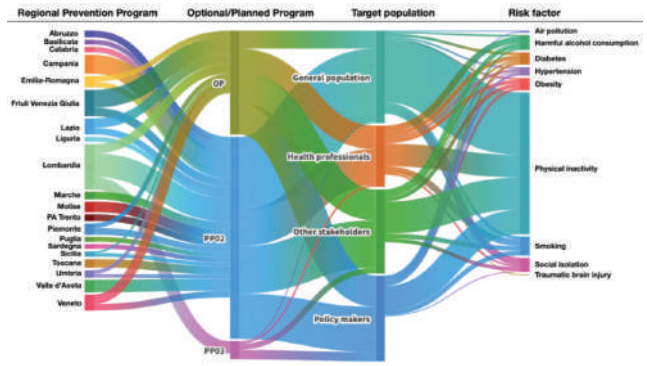
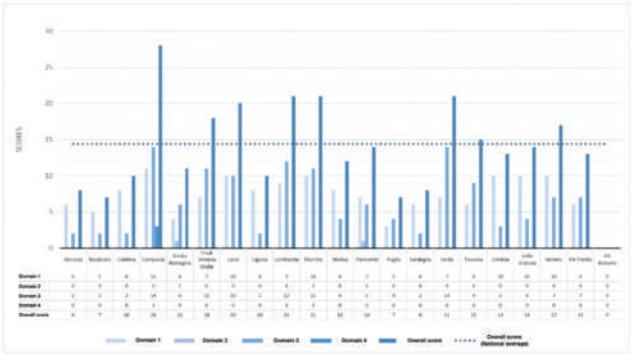


Sankey Chart of the dementia-specific preventive interventions.



Checklist scores by RPP.

Conclusion: While interventions on cardiovascular RFs can synergistically affect multiple noncommunicable diseases, their prevalence may suggest that policymakers are not fully aware of RFs more specific to dementia (e.g., social isolation and hearing loss). Therefore, policymakers, public health workers, and dementia experts should closely cooperate for the development of these policies.

OPR-053 | Neuromodulation of the mediodorsal nucleus during MRgFUS thalamotomy demonstrates a causal role in reward learning

W. Gilmour[1]; G. Mackenzie[1]; I. Barnard[1]; J. Macfarlane[2]; S. Khan[3]; A. Kanodia[4]; M. Canty[5]; T. Littlechild[5]; V. Marshall[5]; E. Newman[5]; J. Farah[6]; M. Radon[6]; A. Marcerollo[6]; D. Steele[1]; T. Gilbertson[1]

[1]Division of Imaging Science and Technology, Ninewells Hospital & Medical School, University of Dundee, Dundee, UK; [2]Medical Physics, Ninewells Hospital & Medical School, Dundee, UK; [3]Department of Neurosurgery, Edinburgh Royal Infirmary, Edinburgh, UK; [4]Department of Radiology, Ninewells Hospital & Medical School, Dundee, UK; [5]Institute of Neurological Sciences, Queen Elizabeth University Hospital, Glasgow, UK; [6]The Walton Centre NHS Foundation Trust for Neurology and Neurosurgery, Liverpool, UK

Background and aims: Evidence from basic neuroscience increasingly supports a specific role for the Medial Dorsal (MD) thalamic nucleus influencing decisions that guide reward-based learning. As common clinical syndromes of impulsivity, apathy and executive dysfunction can be explained by abnormal reward-learning across multiple clinical groups. Neuromodulation target MD nucleus may represent a potential future therapeutic intervention for disorders of cognitive control.

Methods: Thirty-five patient's undergoing MRgFUS thalamotomy for Essential Tremor targeted at ventral intermediate nucleus (Vim) performed pre-and post-operative (<24 hours) cognitive testing using the 4-armed restless bandit task. Outcome measures of task performance included probability of choosing the most rewarding bandit (Prew) and choice perseveration (Pstay). In 23 patients, post-operative masks of (< 24 hours) oedema extension into the MD nucleus were used to analyse the relationship with cortical functional connectivity and it's influence on decision making.

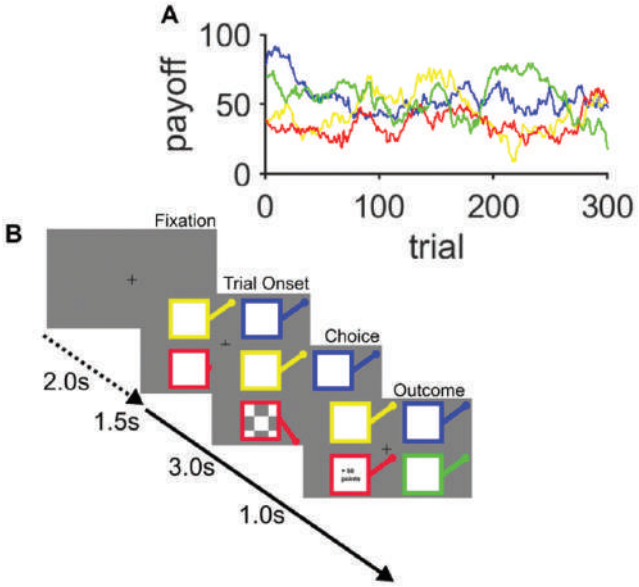

FIGURE 1 Restless bandit reinforcement learning task. (A) example of fluctuating reward payout for each of the four bandits in the task (B) example trial with screenshots of computer graphics.

Results: Post-thalamotomy, patients used a greater proportion of perseverative choices (Pstay) pre: 0.67 ± 0.07, post: 0.75 ± 0.0.05, rmANOVA, $F = 11.05$, $p < 0.001$). Task performance indexed by choices to the best bandit (Prew) was unaffected by thalamotomy (rmANOVA, $F = 3.02$, $p = 0.07$). Cortical functional connectivity with thalamotomy oedema extension into the MD nucleus predicted the extent to which the thalamotomy increased Pstay in individual patients (rho = 0.64, $p = 0.001$).

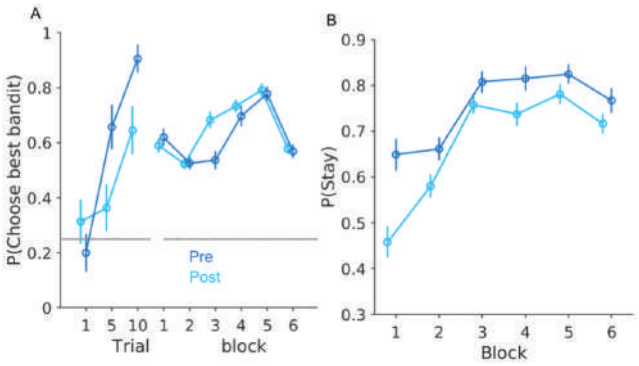

FIGURE 1 Behavioural effects of thalamotomy on task performance. Analysis binned into six- 50 trial blocks (A) probability of choosing the highest value bandit (B) Probability of choosing the same bandit on two consecutive trials (Pstay).

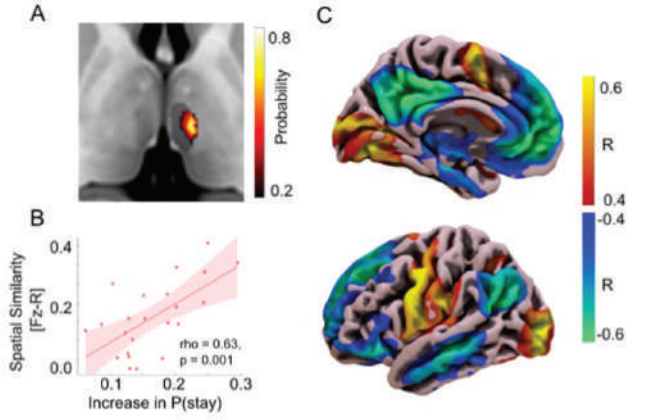

FIGURE 3 (A) Probabalistic analysis of overlap between thalamotomy ($n=23$) oedema (heatmap) with the medialdorsal thalamic nucleus (grey overlay) onto standard brain template in MNI space. (B) R map correlation and (B) cortical connectivity map.

Conclusion: MRgFUS thalamotomy can be used as an opportunity to study cognitive thalamic nuclear function. An experimental design for intra-operative thermal neuromodulation is proposed to causally map the different contributions of the thalamic nuclei to cognitive control.

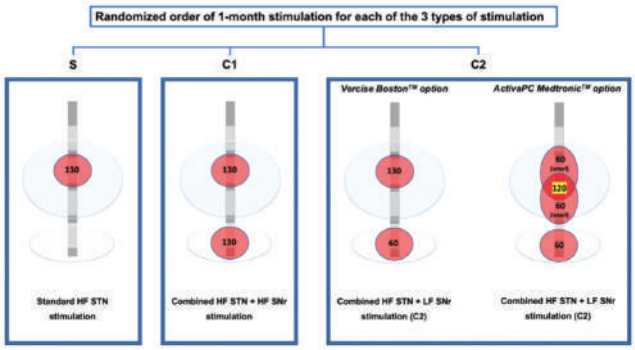
Harroch[6]; M. Zibetti[1]; M. Rizzone[1]; A. Romagnolo[1]; G. Imbalzano[1]; L. Lopiano[1]; J. Houeto[8]; M. Fabbri[6]

[1]Department of Neurosciences Rita Levi Montalcini, University of Turin, Turin, Italy; [2]Neurology Unit, Department of Translational Medicine, University of Piemonte Orientale, Novara, Italy; [3]Department of Neuroscience, Mental Health and Sense Organs (NESMOS), Sapienza University of Rome, Rome, Italy; [4]Service de Pharmacologie Médicale et Clinique, Centre Hospitalier Universitaire et Faculté de Médecine de Toulouse, Toulouse, France; [5]Service de Neurologie, Centre Hospitalier Universitaire, Toulouse, France; [6]Centre Expert Parkinson de Toulouse, CHU, Toulouse, France; [7]Department of Neurosurgery, Toulouse University Hospital, Toulouse, France; [8]Department of Neurology, NS-Park/F-CRIN network, Limoges University Hospital; Inserm, U1094, EpiMaCT - Epidemiology of chronic diseases in tropical zone, Limoges, France

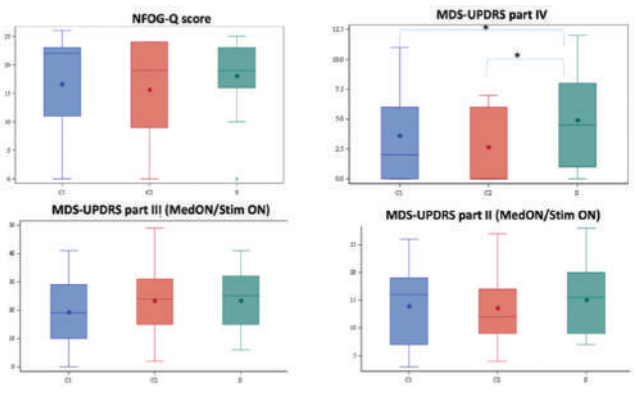
Background and aims: Freezing of gait (FoG) is a debilitating symptom of Parkinson's disease (PD) with limited response to dopaminergic medication and subthalamic deep brain stimulation (STN-DBS). Substantia nigra pars reticulata (SNr) stimulation could improve FoG.

Methods: Two double-blind, cross-over, randomized trials, following an identical protocol were conducted involving STN-DBS treated PD patients with severe FoG. Participants received: standard high frequency (HF) STN-DBS (S), combined HF-STN and SNr stimulation (C1), and combined HF-STN and low-frequency SNr stimulation (C2), for 1 month each in a randomized order. The primary endpoint was the change in the New Freezing of Gait Questionnaire (NFOG-Q) score. Secondary analyses were performed on motor complications, axial symptoms, activities of daily living, psychiatric symptoms, sleep, and patient preference.

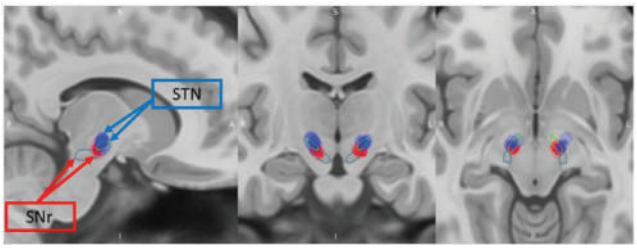


Stimulation method for S, C1, C2.

Results: Fifteen patients received at least one combined stimulation. No statistically significant difference in NFOG-Q scores was found between S, C1, and C2; one-third of patients showed a clinically significant improvement (≥8 points) with combined stimulations. Motor complications improved significantly with C1 and C2 compared to S (C1 vs. S: 3.6 ± 3.8 vs. 4.9 ± 3.8, $p=0.046$; C2 vs. S: 2.7 ± 3.1 vs. 4.9 ± 3.8, $p=0.005$). At the end of the study, 80% of patients chose combined STN-SNr stimulation. All adverse events were manageable.



Scores after one moth of the following stimulation setting: C1, C2, and S.



VTA of the STN and of the SNr for all patient included in the study in the stimulation setting C1/C2.

Conclusion: Our study did not show a statistically significant improvement in NFOG-Q, but one-third of patients experienced a clinically meaningful FoG improvement. Moreover, SNr stimulation was both safe and effective in addressing motor complications., highlighting the importance of further exploration into the effects of combined STN-SNr stimulation.

Disclosure: Nothing to disclose.

Background and aims: Levodopa-entacapone-carbidopa intestinal gel (LECIG) infusion is a recently developed device-aided therapy for advanced Parkinson's disease (PD) patients. Our aim was to present real world data (RWD) about the use of LECIG in PD patients from Spain.

Methods: A multicenter observational retrospective study of the first patients to start LECIG in Spain was performed. All neurologists with an experience of at least 2 patients treated until November 1, 2023 were invited to participate. RWD about effectiveness and safety from the medical records (V0, pre-LECIG; V1, LECIG starting; V2, post-LECIG follow-up) with a total of 246 variables was collected.

Results: Fifty-one PD patients (58.8% males; 69.7 ± 9.7 years old) from 15 Spanish centers with a mean disease duration of 13.8 ± 6.2 years were included (Table 1). Fourteen patients (27.5%) were switched directly from levodopa-carbidopa intestinal gel. The mean treatment duration was 140.7 ± 83.7 days (range, 10–302). The mean daily OFF time decreased from 5.1 ± 3 at baseline (pre-LECIG) to 1.9 ± 1.6 (post-LECIG) ($N = 45$; $p < 0.0001$). Global improvement was observed in more than 85% of the patients (Figure 1). No significant change was detected in the levodopa equivalent daily dose from V0 to V2 (Figure 2). Only 2 patients (3.9%) received 24-hour infusion and 11 (21.6%) required more than 1 cartridge per day. Eighteen patients (35.3%) had at least one adverse event related to LECIG and/or the device system. Three patients (5.9%) discontinued LECIG (Table 2).

AE, adverse event; LECIG, levodopa-entacapone-carbidopa intestinal gel.

*The patient had a severe stoma infection that required to remove the PEG and stopping LECIG. He was institutionalized and died more than 1 month later related to an acute renal failure.

TABLE 2 Adverse events collected by the neurologist in patients receiving LECIG from V1 (starting LECIG) to V2 (follow-up visit; 140.7 ± 83.7 days, range from 10 to 302).

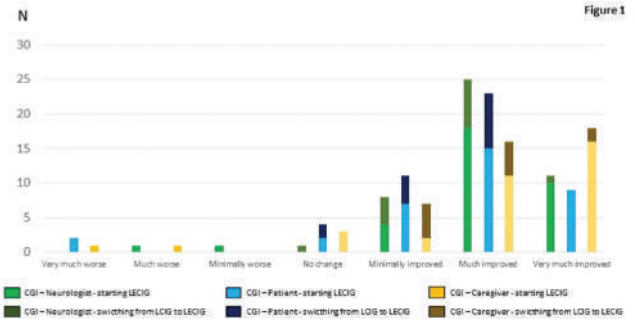

Figure 1. CGI (Clinical Global Impression of change) according to the opinion of the neurologist (N=47); patient (N=49) and caregiver (N=46) at V2 (follow-up visit). Patients who started LECIG appear in light colors and those who switched from LCIG to LECIG appear in dark colors. Improvement was observed in 59.7%, 87.7% and 89.1% of patients, respectively. LECIG, levodopa-entacapone-carbidopa intestinal gel; LCIG, levodopa-carbidopa intestinal gel.

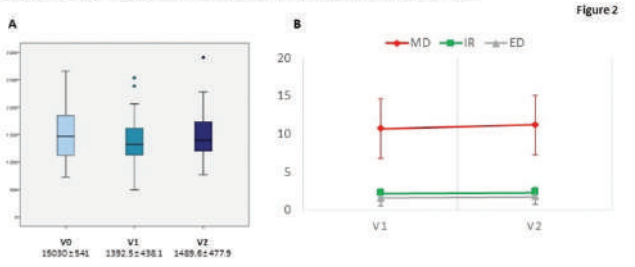

Figure 2. A. LEDD (mg) at baseline (V0; pre-LECIG), V1 (after starting LECIG) and V2 (follow-up visit; 140.9 ± 88 days, range 10 – 302). N = 34. V1 vs V0, p=0.038; V2 vs V0, p=0.489; V2 vs V1, p=0.083. Data are presented as box plots, with the box representing the median and the two middle quartiles (25–75%). B. Change from V1 to V2 in morning dose (mL; N=49; from 10.8 ± 4 to 11.8 ± 3.9; p=0.054), infusion rate (mL/h; N=46; from 2.2 ± 0.6 to 2.3 ± 0.6; p=0.112) and extra dose (mL; N=49; from 1.5 ± 0.6 to 1.7 ± 0.8; p=0.010). Data are presented as mean and standard deviation. P values were computed using the Wilcoxon signed-rank test in A and B. ED, extra dose; IR, infusion rate; LECIG, levodopa-entacapone-carbidopa intestinal gel; LEDD, levodopa equivalent daily dose; MD, morning dose.

Conclusion: LECIG was safe and effective in advanced PD patients.
Disclosure: The authors report no conflict of interest.

OPR-056 | sGFAP – A potential biomarker for disease activity in essential tremor?

L. Gattermeyer-Kell; M. Khalil; P. Opriessnig; D. Kern; S. Franthal; M. Kögl; P. Katschnig-Winter; R. Schmidt; C. Enzinger; P. Schwingenschuh

Department of Neurology, Medical University of Graz, Graz, Austria

Background and aims: Essential tremor (ET) constitutes a heterogeneous syndrome and possible neurodegeneration has been debated. We recently linked serum-NfL to cognitive decline in ET-patients with short disease duration (DD). Serum-glial fibrillary acidic protein (sGFAP) hitherto remains unstudied in ET.

Methods: Data from 36 ET-patients and 36 age, sex and body-mass-index-matched healthy controls were analyzed. sGFAP was quantified by single-molecule-array in baseline (BL) and follow-up (FU; 5 years) blood samples. ET-patients underwent clinical evaluation (Fahn-Tolosa-Marin-Tremor-Clinical-Rating-Scale-Total-Score, FTM-TS).

Results: BL and FU sGFAP did not differ between groups. In ET-patients, low BL FTM-TS was associated with higher sGFAP-increase during the observational period ($rs = -0.551$, $p = 0.002$). Shorter DD correlated with low BL FTM-TS and trended towards higher sGFAP-increase ($rs = -0.344$, $p = 0.068$). Stratification in DD below/above median (10.7 years) showed higher sGFAP-increase in short DD patients (39.6 vs. 12.6 pg/mL, $p = 0.020$). In short DD patients, high BL sGFAP correlated with high FU FTM-TS ($rs = 0.672$, $p = 0.006$) and FTM-TS-increase ($rs = 0.590$, $p = 0.021$). Stratification of ET-patients according to sGFAP-level below/above median (124.2 pg/mL) revealed that high sGFAP-patients were older at BL (70.0 vs. 60.7 years, $p < 0.001$) and disease onset (62.6 vs. 49.9 years, $p < 0.001$) than low sGFAP-patients. Annual sGFAP-increase correlated with annual FTM-TS-increase in the high ($rs = 0.587$, $p = 0.027$) but not in the low sGFAP-group. In patients with high sGFAP and short DD ($n = 8$), annual sGFAP-increase correlated with annual FTM-TS-increase ($rs = 0.738$, $p = 0.037$).

Conclusion: This study shows elevated sGFAP in elderly, late-onset ET-patients. sGFAP-increase is higher in earlier vs. later disease stages and correlates with worsening motor function, suggesting sGFAP as a possible biomarker of ET disease activity.

Disclosure: Nothing to disclose.

OPR-057 | Modelling pathology progression in Parkinson's disease phenotypes

M. Passaretti[1]; H. Zhao[2]; M. Mijalkov[1]; B. Zufiria Gerboles[1]; A. Canal Garcia[1]; J. Sun[1]; D. Vereb[1]; N. Rivera[3]; G. Volpe[2]; M. Bologna[4]; J. Pereira[1]

[1]Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, Sweden; [2]University of Gothenburg, Department of Physics, Soft Matter Lab, Gothenburg, Sweden; [3]Department of Medicine Solna, Respiratory Medicine Division, Karolinska Institutet, Stockholm, Sweden; [4]Sapienza University of Rome, Department of Human Neurosciences, Rome, Italy

Background and aims: Understanding the relationship between phenotypic heterogeneity and the spread of pathology in Parkinson's disease (PD) is challenging. The α-Synuclein Origin site and Connectome (SOC) model postulate that α-synuclein aggregation first localization and spreading determine disease evolution. Accordingly, two PD subtypes were proposed: brain-first-PD, from

central nervous system, and body-first-PD, from peripheral nervous structures. We aim to use the SOC model to differentiate PD phenotypes predicting disease progression.

Methods: 1120 de novo- PD patients, 910 prodromal-cases, and 263 healthy controls were included from the Parkinson's progression markers initiative. Patients and prodromal-cases with REM behavior disorder and/or autonomic symptoms at baseline were classified as body-first, otherwise as brain-first. All subjects underwent longitudinal (12-years) clinical protocol and magnetic resonance imaging.

Results: Body-first-PD (667) demonstrated higher motor burden and complications, worse cognitive evolution, and more severe depression compared to brain-first-PD. Body-first-PD showed bilateral medial and lateral temporal atrophy (amygdala, para-hippocampus, temporoparietal junction), cerebellum and brainstem. Brain-first-PD patients demonstrated circumscribed atrophy of the left hemisphere (angular gyrus, sensory-motor cortex, inferior frontal gyrus). Body-first-prodromal-cases (519) demonstrated similar results to body-first-PD, i.e. greater motor and cognitive impairment, involving the same domains, and grey matter atrophy in lateral temporal areas.

Conclusion: Consistent with the SOC model, the study results indicate that body-first-PD and prodromal-cases had worse disease progression and more severe brain atrophy compared to brain-first. The results underscore the importance of PD patient phenotyping since the prodromal phases. Hence, the application of the model would enable tailored therapeutic approaches and disease prevention interventions in high-risk individuals.

OPR-058 | Thoracic spinal cord stimulation may improve bradykinesia and rigidity in gait impaired Parkinson's disease

M. Højholt Terkelsen[1]; V. Hvingelby[1]; E. Johnsen[2]; M. Møller[2]; E. Hvid Danielsen[2]; T. Henriksen[3]; A. Nørgaard Glud[4]; Y. Tai[5]; A. Møller Andersen[4]; A. Knudsen[4]; K. Meier[4]; P. Borghammer[1]; E. Moro[6]; J. Hedemann Sørensen[4]; N. Pavese[1]

[1]Department of Clinical Medicine — Department of Nuclear Medicine and PET Center, Aarhus University, Aarhus, Denmark; [2]Department of Neurology, Aarhus University Hospital, Aarhus, Denmark; [3]Department of Neurology, Bispebjerg Hospital, Copenhagen, Denmark; [4]Department of Neurosurgery, Aarhus University Hospital, Aarhus, Denmark; [5]Department of Neurosciences, Imperial College Healthcare NHS Trust, London, UK; [6]Grenoble Alpes University, CHU of Grenoble, Division of Neurology, Grenoble Institute of Neuroscience, Grenoble, France

Background and aims: Gait impairment in Parkinson's disease (PD) is debilitating and often resistant to available therapies. Recently, spinal cord stimulation (SCS) has been suggested to be effective. Nevertheless, existing literature on SCS for gait problems is limited and possible mechanisms of action remain to be elucidated. This study is part of the SCS therapy for patients with PD and gait problems (STEP-PD) trial (ClinicalTrials.gov: NCT05110053), and here we aim to evaluate the effect on lower body motor symptoms and gait.

Methods: Fourteen non-demented PD patients with gait impairment were included in the trial. The Movement Disorder Society-Unified Parkinson's Disease Rating Scale (MDS-UPDRS) was assessed before surgery and at 6- and 12-month follow-ups. Total motor score, lower body and gait (LBG) subscore, and the sum of lower body bradykinesia and rigidity items (Table 1) were compared using paired t-test. Mean differences with 95% confidence intervals are presented.

Table 1

MDS-UPDRS part III: total motor score	Sum of items 3.1 – 3.18
MDS-UPDRS LBG subscore	Sum of items 3.3d, 3.3e, 3.7a, 3.7b, 3.8a, 3.8b, 3.10, 3.11, 3.12
MDS-UPDRS lower body bradykinesia and rigidity	Sum of items 3.3d, 3.3e, 3.7a, 3.7b, 3.8a, 3.8b

TABLE 1 Details of the Movement Disorder Society-Unified Parkinson Disease Rating Scale (MDS-UPDRS) scores presented. LBG, lower body gait.

Results: Thirteen patients were treated with active SCS for 6 months and eight patients were treated for 1 year. While the total motor score improved slightly after both 6 months (−2.85 points [−7.07;1.38]) and 12 months (−5.63 points [−14.03;2.78]), the LBG subscore improved by −3.38 points (−4.83;-1.93), $p = 0.0003$, after 6 months and −5.25 points (−8.93;-1.57), $p = 0.0118$, after 12 months. Furthermore, lower body bradykinesia and rigidity improved by −2.31 points (−3.75; −0.86), $p = 0.0046$, after 6 months and −3.88 points (−7.17; −0.58), $p = 0.027$, after 12 months.

Conclusion: SCS may ameliorate lower body bradykinesia and rigidity in gait-impaired PD patients. Furthermore, our results suggest that extended treatment duration could yield a greater improvement.

Disclosure: KM's institution (Aarhus University Hospital) has received travel support from Boston Scientific.

Motor neurone diseases 2

OPR-059 | Role of brain 2-[18F]FDG-PET for the differential diagnosis between ALS and ALS-mimics

Background and aims: The combination of brain and spinal cord 2-[18F]FDG-PET has shown a 81.5% accuracy in discriminating ALS and ALS-mimics in a published study. We investigated the potential role of brain 2-[18F]FDG-PET as a single marker to discriminate ALS and ALS-mimics.

Methods: Our dataset included 663 ALS cases and 40 patients referred for suspected ALS but for whom an alternative diagnosis was made (ALS-mimics) who underwent brain 2-[18F]FDG-PET at diagnosis at the ALS Centre of Turin between 2009 and 2019. We randomly collected 40 ALS cases and calculated Laplacian scores in this group. This is an algorithm for the selection of features, which correspond to the voxels. It constructs a nearest neighbour graph. Laplacian score seeks those features that respect this graph structure. We retained the top features and performed feature extraction form the two groups (ALS and mimics). Then, we randomly split the sample composed of ALS and mimics in a training set (80%) and a test set (20%). The training set was used to train the classifier (Support Vector Machine) and the test set was used to evaluate the performance of the model. The procedure was randomly repeated 10 times for internal validation.

Results: SVM showed 85% specificity and 81% sensitivity on the test set, with an error rate of 17%. The classification was based on three cerebellar clusters, situated in left anterior lobe, right uvula and right culmen.

Conclusion: Our data support the possible role of brain 2-[18F]FDG-PET as a single diagnostic marker to discriminate ALS and ALS-mimics.

Disclosure: Nothing to disclose.

OPR-060 | Morphometric analysis of spinal motor neuron degeneration in sporadic amyotrophic lateral sclerosis

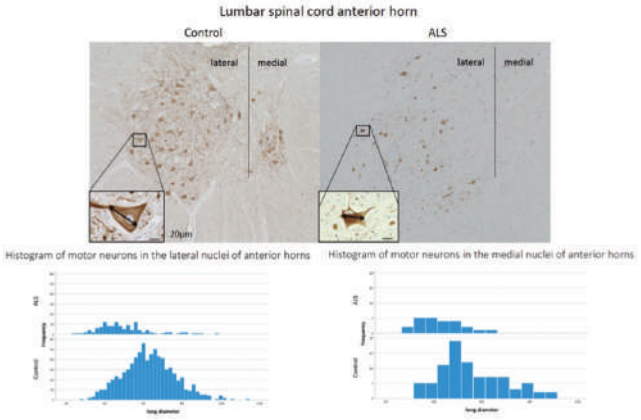
H. Aizawa[1]; S. Nagumo[2]; T. Hideyama[2]; H. Kato[2]; S. Kwak[2]; H. Terashi[2]; Y. Suzuki[3]; T. Kimura[3]

[1]*Department of Neurology, Sanno Hospital, Tokyo, Japan;* [2]*Department of Neurology, Tokyo Medical University, Tokyo, Japan;* [3]*Department of Neurology, Asahikawa Medical Center, Asahikawa, Japan*

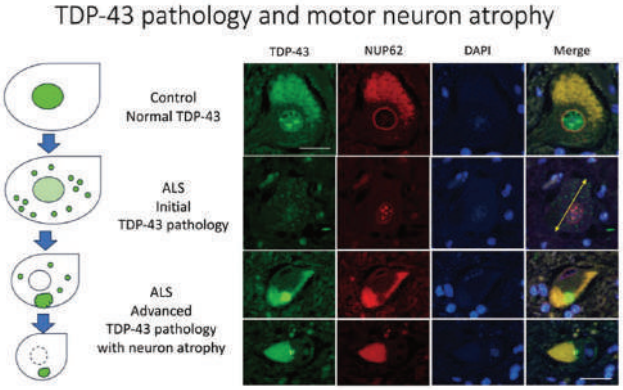
Background and aims: To clarify the relationship between TDP-43 pathology and spinal anterior horn motor neuron (AHMN) atrophy in sporadic amyotrophic lateral sclerosis (SALS).

Methods: The subjects were 8 SALS and 12 disease controls. Formalin-fixed specimens of lumbar spinal cord samples were paraffin-embedded and sectioned at the level of the fourth lumbar spinal cord with a thickness of 4 μm. Using a microscope (BZ-X800), the long diameter of neurons with nucleoli was measured in spinal AHMNs stained with anti-SMI-32 antibody. AHMNs were divided into medial and lateral nuclei for statistical processing. Among spinal AHMNs double-fluorescently stained with TDP-43 and anti-nucleoporin p62 (NUP62) antibodies against the nuclear membrane, we also measured the long diameter of AHMNs with TDP-43 in both the nucleus and cytoplasm, which are considered as initial lesions of TDP-43 pathology.

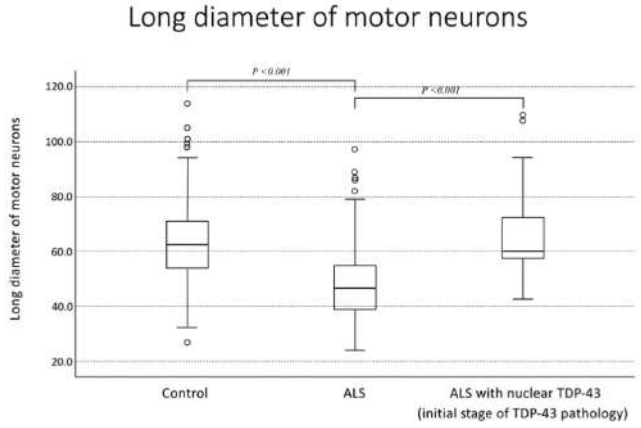
Results: The long diameter of the lumbar spinal AHMNs in SALS was smaller in the medial nucleus (42.54 ± 9.33 micrometer, $n = 24$) and the lateral nucleus (49.41 ± 13.86, $n = 129$) than in controls (medial nucleus 55.84 ± 13.49, $n = 85$, $p < 0.001$; lateral nucleus 62.39 ± 13.29, $n = 756$, $p < 0.001$, Mann–Whitney test). All 21 motor neurons with early TDP-43 pathology were in the lateral nucleus, and their long diameter (67.60 ± 18.3) was not significantly different from controls.



Histogram of spinal motor neurons.



TDP-43 pathology and motor neuron atrophy.



Long diameter of motor neurons.

Conclusion: Motor neuron atrophy in SALS does not occur at the initial stages of TDP-43 pathology, and TDP-43 pathology has already progressed in the atrophic motor neurons.

Disclosure: Nothing to disclose.

OPR-061 | Genome-wide directional effects of transcription factor binding on Amyotrophic Lateral Sclerosis

M. Torrieri[1]; M. Grassano[2]; A. Chiò[2]; M. Basso[3]; A. Calvo[2]

[1]Academic Neurology Unit, San Luigi Gonzaga University Hospital, Orbassano, Italy; [2]ALS Centre, RIta Levi Montalcini Department of Neuroscience, University of Turin, Turin, Italy; [3]Department of Cellular, Computational and Integrative Biology (CIBIO), University of Trento, Trento, Italy

Background and aims: The transcription factor (TF) c-myc has been shown to be elevated in many neurological disorders, including neurodegenerative diseases. We observed an increased activity of c-myc in astrocytes in TDP-43 mice models of Amyotrophic Lateral Sclerosis (ALS), being related to a reduction in survival, probably due to the release of an altered protein cargo by astrocytes. The aim of our study was to test the role of TFs in the pathogenesis of ALS.

Methods: We used signed LD profile (SLDP) regression to test the activity of TFs in large case–control GWAS of both ALS and frontotemporal dementia (FTD) [1,2]. SLDP regression is a validated method used to identify genome-wide directional effects of signed functional annotations on polygenic disease risk [3]. We ran SLDP regression using the 382 available TF annotations for both ALS and FTD gene data sets. Results were significant at a per-trait FDR <5%. A positive association implies a greater binding of the TFs, leading to greater expression; likewise, a negative association implies a lower binding of the TFs, leading to lower expression.

Results: We used GWAS summary statistics obtained from 12.577 ALS patients (vs. 23.475 healthy controls) and 3.526 FTD patients (vs. 9.402 healthy controls). We detected 38 and 14 significant associations respectively in ALS and FTD (Tables 1 and 2). Particularly, genetic variants determining a greater binding of c-myc were associated with an increased risk of ALS, but not FTD.

Background and aims: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disorder with a mean age of onset around 60 years. Evidence from the literature suggests the existence of a distinct clinical phenotype associated with earlier age at onset (EO-ALS). Here we aim to define the clinical phenotype of EO-ALS in comparison to late-onset ALS (LO-ALS).

Methods: We studied a cohort of 1165 ALS patients, divided in two groups: EO-ALS (onset 20–45 years), and LO-ALS (onset >45 years). Clinical phenotype, survival outcome measures and serum biomarkers were compared in the two groups Significant *p*-value was set at <0.05.

Results: We found that EO-ALS patients had significant predominance of males (72.5% vs. 60.9%, $p=0.010$), familial ALS (15.3% vs. 9.5%, $p=0.037$), spinal-onset (82.4% vs. 70.7%, $p=0.047$), progressive muscular atrophy phenotype (11.7% vs. 3.9%, $p=0.00009$). In the EO-ALS group, 1.5% had a cerebellar-ALS-plus phenotype ($p=0.00004$). Interestingly, a lower progression rate (median: 0.47 vs. 0.61, $p=0.011$) and prolonged survival (median values: 117.3 vs. 49.7 months, $p<0.001$) were observed in EO-ALS as well as a longer diagnostic delay (17.8 vs. 12.5 months, $p<0.001$). Finally, in EO-ALS serum GFAP was lower (median: 84.02 vs. 122.36 pg/mL, $p=0.011$), and CPK was higher (median: 262 vs. 160 U/L, $p<0.001$).

TABLE 1 Demographic and clinical characteristics of the study cohort, classified into the two main groups.

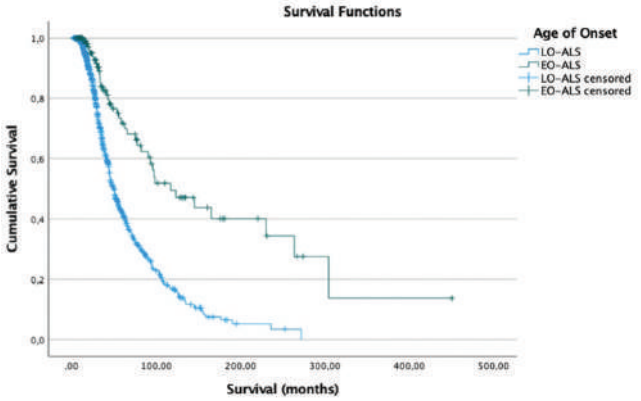

FIGURE 1 Kaplan–Meier plots of survival probabilities for EO-ALS (green line) and LO-ALS (blue line). Median values: 117.3 months for YO-ALS and 49.7 months for AO-ALS. +: censored cases.

Conclusion: Findings from our study indicate that EO-ALS is associated with prolonged survival, suggesting that different pathogenetic mechanisms or enlarged motor neurons reserve might be at play in this group of patients. Compared to previous studies, we did not confirm the previously reported higher frequency of the upper motor neuron predominant phenotype in the EO-ALS group.

Background and aims: Converging evidence suggests an early involvement of subcortical structures in the course of neuropathological progression of amyotrophic lateral sclerosis (ALS). Our aim was to explore the longitudinal evolution of structural damage to subcortical and hippocampal structures in a cohort of incident ALS patients.

Methods: Twenty-four patients with ALS and 34 healthy controls underwent at least two longitudinal clinical evaluations and brain MRI scans on a 3T scanner (median follow-up time = 0.96 years). Segmentation of subcortical and hippocampal structures was obtained. ANOVA models were performed between groups at baseline. Linear mixed effect models were used to test longitudinal trajectories of atrophy.

Results: At baseline, ALS patients showed significant bilateral reduction of hippocampal volumes compared with controls (left: $p = 0.05$; right: $p = 0.038$), and a trend toward significance for atrophy in the right thalami ($p = 0.08$). Baseline volumes of the basal ganglia were comparable between patients and controls. Longitudinally, ALS patients showed a significant reduction of grey matter volumes of the left pallidum ($p = 0.01$) and right putamen ($p = 0.02$).

Conclusion: Our results suggest a different temporal involvement of hippocampal and subcortical structures in the course of ALS, with an early involvement of hippocampi and thalami followed by a subsequent progression of damage to the basal ganglia. We highlight the importance of subcortical structural alterations for a more comprehensive understanding of ALS, supporting the use of MRI for tracking disease progression. Funding. MS and related disorders 2

OPR-064 | Relevance of paramagnetic rim and cortical lesions in MS at diagnosis: Exploring the clinical practice biomarker toolkit

A. Miscioscia; M. Puthenparampil; A. Zolin; G. Zanotelli; G. Scialpi; A. Berardi; F. Rinaldi; P. Perini; P. Gallo
Department of Neuroscience, Padova University Hospital, Padova, Italy

Background and aims: In multiple sclerosis (MS), imaging biomarkers aid the disease characterization at the time of diagnosis and support the appropriate treatment choice. The presence of paramagnetic rim lesions (PRLs) and cortical lesions (CLs) is not routinary evaluated in clinical practice. In this study, we investigated the association between a broad range of imaging biomarkers available and the clinical disability in MS patients at diagnosis.

Methods: 45 RRMS (mean disease duration: 9.6 months) underwent brain and spinal cord 3 T-MRI and OCT. Susceptibility-weighted imaging (SWI) and double inversion recovery (DIR) sequences were used to manually segment respectively PRLs and CLs. Neuroimaging metrics extracted are shown in Table 1. Regression models assessed the relationship of the lesion and atrophy metrics with physical disability (Expanded Disability Status Scale [EDSS]) and cognitive impairment (Symbol Digit Modalities Test [SDMT]).

Results: PRL and spinal cord lesion volume and count most strongly predicted EDSS. Only CL volume and count were significantly associated with SDMT score at diagnosis. In a regression model including non-rim WML and PRL volume (or count), only the latter was significantly associated with EDSS along with spinal cord volume (or count). In the same model with the two WML phenotypes grouped together, the WML volume (or count) did not reach the significance.

TABLE 2 Relationship between neuroimaging biomarkers and clinical disability. Multivariate linear regression models.

Conclusion: PRLs and spinal cord lesions describe the best association with physical disability in MS patients at diagnosis. CLs best correlate with cognitive performance. SWI and DIR sequences and the assessment of PRLs and CLs might add pivotal information at the first MS patient assessment.

Uniiversitat Autónoma de Barcelona, Barcelona, Spain;* [2]*Neurology Unit, Department of Neurosciences, Biomedicine, and Movement Sciences, University of Verona, Verona, Italy;* [3]*Neurology Service, Lausanne University Hospital (Centre Hospitalier Universitaire Vaudois), University of Lausanne, Lausanne, Switzerland;* [4]*Centre Hospitalier de Luxembourg, Luxembourg-Ville, Luxembourg, France;* [5]*Service de Neurologie, Sclérose en Plaques, Pathologies de la Myéline et Neuro-Inflammation-Hospices Civils de Lyon, Hôpital Neurologique Pierre Wertheimer, Bron Cedex, France*

Background and aims: The role of serum biomarkers to evaluate MOGAD prognosis is limited. We aim to characterize serum neuroglial biomarkers and analyze their usefulness to predict relapses and disability in MOGAD.

Methods: Retrospective longitudinal study included MOGAD and age-matched multiple sclerosis (MS) patients with serum samples obtained within 3 months from disease onset. Clinical and laboratory data were collected. Serum neurofilament light-chain (sNfL) and glial fibrillary acidic protein (sGFAP) levels were determined using Simoa. A descriptive comparison between MOGAD and MS groups was performed. Within MOGAD group, Spearman test was built to assess correlations between baseline serum biomarkers and disability at sampling, as well as Cox and linear regression analyses to predict time to second relapse and disability, respectively.

Results: Eighty-nine MOGAD and 32 MS patients were included. In MS, female were more predominant ($p=0.020$), had lower EDSS at onset ($p=0.046$), and higher presence of oligoclonal bands ($p=0.001$). Baseline sNfL levels were higher in MOGAD compared to MS ($p=0.018$). In MOGAD patients, sNfL (rho 0.289; $p=0.008$) and sGFAP (rho 0.32; $p=0.003$) correlated with EDSS at sampling. sGFAP levels were associated with EDSS at last follow-up in univariate ($p=0.017$), but lost significance in multivariate analysis. In multivariate Cox analysis, higher baseline sNfL values increased the risk of having a second relapse in MOGAD patients presenting with optic neuritis (hazard-ratio 5.88 [95% CI 1.56; 22.20]; $p=0.009$).

TABLE 2 Univariate and multivariate regression models assessing the association of baseline sGFAP and sNfL levels with EDSS at last follow-up in MOGAD patients.

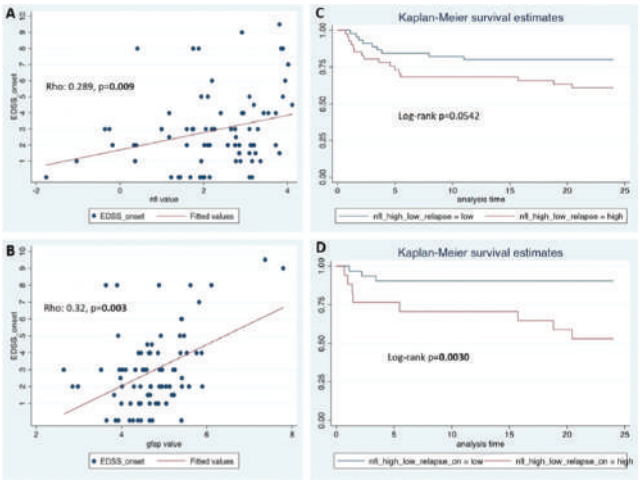

FIGURE 1 Correlation analyses between EDSS at sampling and baseline sNfL (A) and sGFAP (B). Kaplan–Meier survival curves comparing time to relapse between MOGAD patients with high or low sNfL levels in the whole cohort (C) and in the subgroup of ON (D).

Conclusion: In MOGAD patients, the neuro-axonal and astrocytic damage is related with disability at sampling. Neuro-axonal damage predicts a relapsing disease course in the subgroup of patients with optic neuritis.

OPR-066 | Profiling and modelling cellular senescence in progressive multiple sclerosis brains

M. Martire[1]; F. Fagiani[2]; E. Pedrini[2]; D. Maric[3]; D. Reich[4]; M. Filippi[5]; M. Absinta[2]

[1]*Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [2]*Translational Neuropathology Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [3]*Flow and Imaging Cytometry Core Facility, National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD, USA;* [4]*Translational Neuroradiology Section, National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD, USA;* [5]*Neurology Unit and Division of Neuroscience, IRCCS San Raffaele Scientific Institute and Vita-Salute San Raffaele University, Milan, Italy*

Background and aims: Senescent cells accumulate in age-related diseases. Whether these cells actively contribute to the tissue dysfunction leading to progressive MS is unknown. Here, we investigate the spatial distribution of senescent cells in MS brains, and we model post-inflammatory senescence using 3D hiPSC-derived organoids.

Methods: We performed single-nucleus RNA-sequencing (snRNAseq) on 31 samples of cortex and white matter (WM) from progressive MS cases ($n=10$, mean age = 49) and controls ($n=4$, mean age = 54); SenMayo gene set was applied to the snRNAseq datasets to identify senescent cells. As validation, multiplex immunofluorescence (26 primary antibodies, including the senescence marker p16INK4A+) was performed on 7 MS-tissue blocks. To model inflammation-induced senescence, we exposed 3D hiPSC-derived organoids to the CSF (10% for 24 h) from MS patients and processed by scRNAseq.

Results: In the snRNAseq datasets, endothelia were the most prominent cells featuring senescence signatures in all WM lesion stages (3-fold change [FC] increase) and MS cortex (2.3-FC). Compared to control brain, senescent microglia were twice as abundant at the chronic active lesion (CAL) edge and MS cortex; senescent astrocytes predominated in the lesion core (2-FC), CAL edge (2.6-FC), and MS cortex (2-FC). Consistently, MS brains displayed a higher number of p16INK4A+ cells compared to control, enriched within areas with chronic inflammation and at the ventricular ependyma. Using organoids, we observed that the short-term inflamed-CSF exposure promoted microglial senescence (4.2-FC relative to untreated organoids).

Conclusion: Inflammation-associated cellular senescence is pronounced in progressive MS and might potentially exacerbate tissue dysfunction, with key translational implications.

OPR-067 | Factors influencing postpartum activity in multiple sclerosis patients: A prospective study and intervention strategy

C. Oreja-Guevara; C. Martin-Romero; I. Gomez-Estevez; L. García-Vasco; E. Alba-Suarez

Neurology, Hospital Clínico San Carlos, Idissc, Madrid, Spain

Background and aims: Postpartum relapses in multiple sclerosis (MS) patients significantly impact family planning decisions, often leading to cautious reproductive choices. Neurologists frequently advise these individuals on managing their condition during and after pregnancy. Objective: to analyze the factors influencing postpartum disease activity in MS patients. Additionally, we assessed the effectiveness of a proactive strategy designed to reduce postpartum relapses.

Methods: We conducted a prospective longitudinal study involving pregnant women with MS, starting in 2015. We collected and analyzed demographic, clinical, and radiological data before pregnancy, during pregnancy, and in the postpartum period. We implemented a specific strategy to minimize postpartum relapses, including initiating treatment after delivery for active patients and conducting cranial MRI scans 2 months postpartum.

Results: The study included 128 women, with a mean age of 35 years (range 25–47). Pre-pregnancy, 28.3% had experienced relapses in the 2 years leading up to pregnancy, and similar proportions exhibited new T2 lesions (28.3%) and gadolinium-enhancing lesions (21.6%). During pregnancy, 10% experienced relapses, with 7% having clinical relapses and 22% developing new T2 lesions within 6 months postpartum. Notably, 41.4% of patients received DMT treatment within 15 days postpartum, leading to reduced postpartum relapses. Significant correlations were found between postpartum relapses and relapse history, number of relapses, and gadolinium-enhancing lesions.

Conclusion: This study highlights the importance of a targeted postpartum management strategy in reducing MS relapses. The proactive approach, involving early DMT treatment and postpartum MRI scans, effectively reduced postpartum relapses, demonstrating the potential for improved outcomes in MS patients considering pregnancy.

Disclosure: nothing to disclose related to the abstract.

OPR-068 | Disconnection of cerebellar motor areas and motor impairment in multiple sclerosis

F. Romanò[1]; B. Signoracci[1]; P. Preziosa[2]; M. Margoni[3]; E. Pagani[1]; M. Rocca[2]; M. Filippi[4]

[1]*Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [2]*Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy;* [3]*Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [4]*Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy*

Background and aims: The cerebellum is often affected in patients with multiple sclerosis (MS). It contains two motor representations: the anterior (ACMA, lobules I–V) and posterior (PCMA, lobule VIII) cerebellar motor areas. We assessed atrophy and T2-hyperintense lesion loads in these areas and their association with motor impairment.

Methods: Eighty-nine MS patients and 65 healthy controls (HC) underwent a functional assessment (gait function and hand dexterity) and structural MRI acquisition at 3.0 T. Cerebellar lobules were segmented using the SUIT atlas. Between-groups comparisons and age/sex-corrected partial correlations were assessed.

Results: Compared to HC, ACMA and PCMA were atrophic in MS ($p < 0.001$), with similar reductions between the two areas. More than 60% of MS patients had lesions in either motor lobule. ACMA volume was lower than PCMA in HC and MS ($p < 0.001$), whereas T2-hyperintense lesion load was higher in ACMA than PCMA in MS ($p = 0.040$). Patients with lesions in both areas had worse motor performance than those without lesions in either area ($p < 0.001$ for all). Patients with lesions only in the ACMA or PCMA had similar motor abilities. In patients, lower ACMA and PCMA volumes correlated with worse left-hand dexterity ($p < 0.001$), whereas higher T2-hyperintense lesion load in both ACMA and PCMA correlated with worse performance in all motor tests (r range = −0.358; −0.445, $p <= 0.001$ for all).

Conclusion: The non-homogeneous distribution of lesions suggests an increased susceptibility of the ACMA to focal demyelinating lesions. Considering correlation analyses, disconnection of cerebellar motor areas, rather than localised lobular atrophy, seems to better explain motor impairment in MS.

Disclosure: F. Romanò, B. Signoracci and E. Pagani have nothing to disclose. P. Preziosa received speaker honoraria from Roche, Biogen, Novartis, Merck, Bristol Myers Squibb, Genzyme, Horizon and Sanofi, and research support from Italian Ministry of Health and Fondazione Italiana Sclerosi Multipla (FISM). OPR-069 | Neurologic, psychiatric and sleep investigations after initial treatment of anti-LGI1 encephalitis: A prospective study

A. Muñoz-Lopeteti[1]; M. Guasp[1]; L. Prades[2]; E. Martinez-Hernandez[1]; M. Rosa-Justicia[2]; V. Patricio[2]; T. Armangué[3]; L. Rami[2]; R. Borràs[4]; J. Castro-Fornieles[5]; A. Compte[2]; C. Gaig[1]; J. Santamaria[2]; J. Dalmau[2]

[1]*Neurology Department, Institute of Neurosciences, Hospital Clínic*

de Barcelona, University of Barcelona, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [3]Pediatric Neuroimmunology Unit, Department of Neurology, Sant Joan de Déu Children Hospital, University of Barcelona, Barcelona, Spain; [4]Medical Statistics Core Facility, Hospital Clínic de Barcelona, University of Barcelona, Barcelona, Spain; [5]Department of Child and Adolescent Psychiatry and Psychology, Institute of Neurosciences, Hospital Clínic de Barcelona, University of Barcelona, Barcelona, Spain

Background and aims: Anti-LGI1 encephalitis responds well to immunotherapy, but the symptoms that remain after treatment have not been well described. We aimed to characterize the clinical features of these patients over more than 1 year after initial immunotherapy.
Methods: This prospective cohort study included individuals with anti-LGI1 encephalitis who received immunotherapy within the past year and sex and age matched healthy participants (HP). At study entry, at 6 months (not in HP), and at 12 months, participants underwent neuropsychiatric and video-polysomnography (VPSG) assessments.
Results: Between 2019 and 2022, 24 (57%) patients with anti-LGI1 encephalitis and 18 (43%) healthy participants were recruited. At study entry (median 88 days [IQR 67–155] from initial immunotherapy), all 24 patients had one or more symptoms: cognitive (83%), psychiatric (83%), insomnia (58%), REM sleep behaviour disorder (50%), faciobrachial dystonic seizures (FBDS 38%), and focal onset seizures (29%). FBDS were unnoticed in 17% and focal onset seizures in 21%. VPSG alterations included disruption of sleep structure (79% patients; 0 HP; $p=0.013$]), excessive fragmentary myoclonus (63% patients; 22% HP; $p=0.039$) and myokymic discharges (38% patients; 0 HP; $p=0.0051$). These findings led to additional immunotherapy in 63% of the patients, resulting in improvement or resolution in all cases, however at 12 months 65% remained with cognitive deficits.
Conclusion: Unsuspected but ongoing clinical and video-polysomnography alterations are common in patients with anti-LGI1 encephalitis during the year that follows initial immunotherapy. Recognition of these alterations is important because they are treatable, can be used as outcome measures in clinical trials, and may influence cognitive outcome.
Disclosure: Nothing to disclose.

OPR-070 | Clinical characterization and long-term outcome of children and adults with anti-AMPAR encephalitis

Kitasato University School of Medicine, Japan; [6]Division of Neuropathology and Neurochemistry, Department of Neurology, Medical University of Vienna, Vienna, Austria; [7]Department of Neurology, Erasmus MC, University Medical Center, Rotterdam, The Netherlands; [8]Division of Neurology, Hospital das Clinicas (HCFMUSP), Faculdade de Medicina, Universidade de Sao Paulo, São Paulo, Brazil; [9]Neuroimmunology Laboratory, IRCCS Mondino Foundation, Pavia, Italy; [10]Hospital Israelita Albert Einstein, São Paulo, Brazil; [11]Institute of Clinical Chemistry, University Hospital Schleswig-Holstein, Germany; [12]Department of Neurology, Brain Research institute, Niigata University, Japan; [13]Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain

Background and aims: Anti-α-amino-3-hydroxy-5-methyl-4-isoxazole-propionic acid (anti-AMPAR) encephalitis manifest with limbic encephalitis (LE) associated with cancer. The full clinical spectrum, prognostic factors and outcome are not well established, especially in children. We compared clinical features of children and adults and characterized the long-term outcome of anti-AMPAR encephalitis.
Methods: Clinical information of adults and children with anti-AMPAR encephalitis were reviewed from medical records.
Results: Eighty-four patients with AMPAR antibodies were included (13 children, 71 adults). Patients with other concomitant neuronal antibodies were excluded. Overall, 62% of patients presented with LE (7 children, 45 adults, $p=0.539$). Compared to adults, children experienced more frequently prodromal symptoms ($p=0.035$), movement abnormalities ($p=0.032$) and cerebellar symptoms ($p=0.025$). Brain MRI was abnormal in 68% of patients, restricted to mesio-temporal lobes (50%) or associated with extratemporal abnormalities (34%). Exclusive involvement of extratemporal areas (16%) was more frequent in children than adults (44% vs. 11%, $p=0.035$). Tumours were found only in adults (56%, mainly lung cancer and thymoma). A follow-up >24 months was available for 34 patients (4 children, 30 adults): 64% showed neurological sequelae, including cognitive (83%), psychiatric (33%), sleep (11%), and movement (6%) disorders. Twenty-two patients (65%) had a good outcome (modified Rankin scale [mRS] < 2) whereas 12 (35%) a bad outcome (mRS > 2). At multivariate analysis, failure to respond to first-line immunotherapy was the only predictor of bad outcome (OR 8.8, 95% CI 1.3–59.5, $p=0.025$).
Conclusion: Children with anti-AMPAR encephalitis present distinct clinical and radiological features compared to adults. Despite most patients respond to immunotherapy, neurological sequelae are frequent.
Disclosure: M. Spatola receives research support from La Caixa Foundation and Spanish National Research Institute (Carlos III).

OPR-071 | Brain MRI changes and their impact on cognition in the post-acute stage of anti-NMDA receptor encephalitis

M. Guasp[1]; F. Vivó[2]; E. Martinez-Heras[2]; E. Solana[2]; E. Martinez-Hernandez[1]; A. Muñoz-Lopetegi[2]; T. Armangué[2]; M. Rosa-Justicia[2]; L. Prades[2]; E. Fonseca[2]; G. Sugranyes[3]; A. Calvi[2]; E. López-Soley[2]; S. Albà-Arbalat[1]; J. Castro-Fornieles[3]; A. Compte[2]; J. Dalmau[2]; S. Llufriu[1]

Background and aims: We aimed to characterize the course of alterations in brain grey matter (GM) volumetry and diffusion-based white matter (WM) connectivity and their association with cognitive performance during the post-acute stage of anti-NMDAR encephalitis (NMDARe).

Methods: NMDARe patients were prospectively studied at 4, 8, 12 and 12–24 months from disease onset with paired cognitive and MRI assessments that quantified whole brain volume, regional GM changes, and structural integrity of WM connectivity. Differences between NMDARe patients and healthy controls (HC), similarly studied, in the longitudinal follow-up were analyzed using multilevel linear mixed-effect models.

Results: Twenty-one post-acute NMDARe patients and 19 HC were included. Compared with HC, patients showed similar global brain volume, but specific regional changes: atrophy of the middle frontal cortex, and enlargement of bilateral hippocampus and right amygdala, mainly during the first 8 months, which improved over time. NMDARe patients showed differences in 76/2020 (3.8%; $p<0.05$, family-wise error rate) WM connections, following two distinct dynamic patterns: reduced connectivity in 63/76 (83%) connections, involving bilateral cingulate, parietal cortex and deep GM, which improved rapidly (first 8 months), and increased connectivity in 13/76 (17%) connections, mainly subcortical areas, which stabilized over time. Regional atrophy and decreased WM connectivity largely explained variability in working memory (87%) and learning and memory (86%) outcomes.

Conclusion: The first 8 months of post-acute NMDARe were dominated by regional vulnerability to damage and rapid MRI improvements. In subsequent months (8–24), MRI changes slowed and mild residual volumetric and connectivity abnormalities persisted alongside protracted cognitive deficits in NMDARe patients.

OPR-072 | How to retreat patients with anti-MAG polyneuropathy after a course of rituximab? A comparison between two regimens

M. Bellucci[1]; F. Massa[1]; E. Baroncelli[1]; C. Castellano[1]; L. Marinelli[1]; C. Cabona[2]; E. Mobilia[3]; A. Lechiara[3]; F. Bozzano[3]; G. Pesce[3]; A. Schenone[1]; L. Benedetti[4]

Background and aims: Rituximab represents an effective therapy in anti-MAG polyneuropathy. However, a well-established retreatment strategy is currently lacking. We aim to compare two different retreatment protocols, upon clinical relapse vs. upon memory B cell reappearance, to evaluate whether they could be associated with an increased long-term disability.

Methods: We retrospectively evaluated 29 patients who were responsive to an initial cycle of rituximab (375/mg/m^2/week for 4 weeks), and retreated according to two different protocols: full course at the time of clinical relapse ($n=20$), or a single infusion of rituximab (375 mg/m^2) whenever the frequency of reemerging CD27+ memory B cells exceeded 0.05% in the first 2 years and 0.1% thereafter ($n=9$). The scores obtained in the validated clinical scales INCAT, MRC, ISS scales were evaluated at baseline, after 9 months and at the last follow-up visit.

Results: Comparing the scores obtained in the three clinical scales between baseline and the last follow-up, we found that patients treated upon relapse disclosed a progressively more disabling clinical course, whereas none of the patients treated upon memory B cells reappearance had a significant clinical decline compared to baseline (statistical data not presented for shortness).

Conclusion: Our findings reveal that patients treated upon clinical relapse exhibit greater levels of long-term disability than patients treated upon CD27+ lymphocyte reappearance, suggesting that the latter protocol may be an effective maintenance treatment strategy in patients with anti-MAG polyneuropathy.

Background and aims: Anti-IgLON5 disease is a newly identified rare form of autoimmune disorder characterized by anti-IgLON5 antibodies that, via an as-yet-unidentified mechanism, are associated with a brainstem-dominant tau pathology. Recent research indicates that the tau pathology may develop in a time-dependent manner, being absent or mild at early disease stages and very prominent after years of disease progression. This study aimed to precisely characterize the different tau phosphorylation steps and establish a sequence of markers at the different severity stages in an autopsy cohort.

Methods: We used immunohistochemistry to analyze the medullary region of 14 autopsy cases of anti-IgLON5 disease with different severity grades of tau pathology and varying disease durations, from 6 to 180 months. We used 13 antibodies for different tau phosphorylation sites. The presence and severity of tau pathology were assessed semi-quantitatively and compared to one PSP case and two neurologically healthy controls.

Results: We identified different tau phosphorylation sites in anti-IgLON5 disease and were able to determine a sequence of phosphorylation steps based on the disease duration. The development of cytoplasmic tau pathology seems to occur only in later disease stages, whereas alterations of the nuclear envelope were evident in the early stages.

Conclusion: Different tau phosphorylation steps occur during the progression of anti-IgLON5 disease. The establishment of a sequence of pathological disease markers adds support to the hypothesis that tauopathy might indeed be a time-dependent phenomenon. Furthermore, it may aid in the neuropathological identification of cases with mild pathology, and provides insight into the earliest stages of tauopathy.

OPR-074 | High relapse rate influences the long-term clinical outcome in anti-CASPR2 encephalitis

T. Brand[1]; S. Franken[1]; M. Vermeiren[1]; A. Van Sonderen[1]; M. de Bruijn[1]; Y. Crijnen[1]; J. Brenner[1]; R. Van Steenhoven[1]; J. Kerstens[1]; P. Sillevis Smitt[1]; S. Veenbergen[2]; M. Titulaer[1]; J. De Vries[1]

[1]Department of Neurology, Erasmus MC University Medical Centre, Rotterdam, The Netherlands; [2]Department of Immunology, Laboratory Medical Immunology, Erasmus MC University Medical Centre, Rotterdam, The Netherlands

Background and aims: Anti-contactin-associated protein-like 2 (CASPR2) encephalitis is a young disease entity, and information on long-term clinical outcome and relapse rate are limited. We aim to describe long-term clinical outcome, relapse rate and treatment efficacy to guide treatment decisions.

Methods: In this nationwide observational cohort study, patients with a confirmed diagnosis of anti-CASPR2 encephalitis were included. Clinical data were collected at diagnosis and during follow-up, both retrospectively and prospectively. In all patients, written informed consent was obtained.

Results: Forty-four patients with anti-CASPR2 encephalitis were included (42/44 [95%] male; median age at onset 65 years, range 40–86). The median follow-up time was 46.5 months, range 7–113. Relapses were present in 23/44 patients (52%). Compared to the initial disease episode, patients experienced similar but fewer symptoms during the relapse(s). However, peripheral symptoms occurred newly during a relapse in five patients. The median time to relapse was 11 months (range 3–58). At relapse, one patient was tapering prednisone, eight patients had maintenance immunotherapy, three had received Rituximab induction therapy, while 11 patients had no immunotherapy anymore. VGKC RIA titre fluctuations in serum correlated well (84%) with relapse and remission. Nine patients (24%) suffered multiple relapses. In 10 patients, a tumour was present, of which two were only discovered during a relapse.

Conclusion: The relapse rate in anti-CASPR2 encephalitis is much higher than previously anticipated, which provides a clear rationale for prolonged immunotherapy. VGKC RIA titres in serum can guide monitoring for relapses and disease course. It is recommended to repeat tumour screening when patients relapse.

Neuro-ophthalmology/Neuro-otology

OPR-075 | Idebenone treatment for Leber hereditary optic neuropathy: Time to clinically relevant recovery in the LEROS study

C. La Morgia[1]; T. Klopstock[2]; P. Yu-Wai-Man[3]; V. Carelli[1]; X. Llòria[4]
[1]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy;* [2]*Department of Neurology with Friedrich-Baur-Institute, University Hospital of Ludwig-Maximilians-Universität München, Munich, Germany;* [3]*John van Geest Centre for Brain Repair and MRC Mitochondrial Biology Unit, Department of Clinical Neurosciences, University of Cambridge, Cambridge, UK;* [4]*Chiesi Farmaceutici SpA, Parma, Italy*

Background and aims: LHON is a mitochondrial disease resulting in bilateral vision loss. In LEROS, a Phase IV, open-label interventional study (NCT02774005), visual acuity (VA) outcomes following 24 months of idebenone treatment were compared to an external matched Natural History (NH) cohort. Eyes treated with idebenone had significantly higher rates of clinically relevant recovery (CRR) from baseline at 12 and 24 months compared to the NH control group. Here, we present the cumulative percentage of eyes with a CRR from baseline (KM-estimate) by disease phase and primary mtDNA mutation as a function of treatment duration.

Methods: LEROS included patients with LHON aged ≥12 y and with a disease onset ≤5 y prior. Eyes were stratified by time since symptom onset: subacute/dynamic (≤1 y) and chronic (>1 y). CRR was defined as an improvement from "off-chart" VA to at least 1.6 logMAR, or a ≥0.2 logMAR improvement if "on-chart".

Results: The intention-to-treat (ITT) population included 196 patients. The KM-estimate of a CRR from baseline increased from 18.4% of eyes at Month 6 to 47.3% at Month 24 with idebenone treatment in the subacute/dynamic phase, and from 18.2% to 29.1% in the chronic phase. Improvement of visual acuity was also observed in sub-analyses by mtDNA mutation in both subacute/dynamic and chronic eyes (Table 1).

	Month 6	Month 12	Month 18	Month 24
Subacute/dynamic eyes (≤1 year after onset of symptoms)				
Overall	18.4% [13.3, 25.1]	34.9% [28.0, 43.1]	38.8% [31.5, 47.2]	47.3% [38.4, 57.1]
m.11778G>A	13.0% [7.4, 22.3]	25.5% [17.2, 36.9]	28.6% [19.8, 40.4]	37.7% [26.7, 51.4]
m.3460G>A	14.4% [6.3, 31.2]	33.4% [20.0, 52.3]	33.4% [20.0, 52.3]	33.4% [20.0, 52.3]
m.14484T>C	30.7% [19.1, 46.9]	53.9% [39.4, 69.8]	60.0% [45.0, 75.5]	80.0% [56.6, 95.5]
Chronic eyes (>1 year after onset of symptoms)				
Overall	18.2% [13.2, 24.7]	26.7% [20.6, 34.1]	28.2% [21.9, 35.7]	29.1% [22.7, 36.9]
m.11778G>A	17.5% [11.8, 25.6]	22.2% [15.6, 30.9]	23.2% [16.5, 32.1]	24.6% [17.6, 33.8]
m.3460G>A	13.2% [5.1, 31.4]	26.0% [13.2, 47.4]	26.0% [13.2, 47.4]	26.0% [13.2, 47.4]
m.14484T>C	31.2% [15.4, 56.8]	61.2% [39.5, 83.2]	70.9% [46.9, 91.0]	70.9% [46.9, 91.0]

TABLE 1 Kaplan–Meier estimates of cumulative CRR [95% CI] from baseline.

Conclusion: Longer duration of idebenone treatment (beyond 1 y) further improved visual outcomes regardless of LHON disease phase. This improvement was most pronounced for eyes with the m.14484T>C mutation.

OPR-076 | Abstract withdrawn

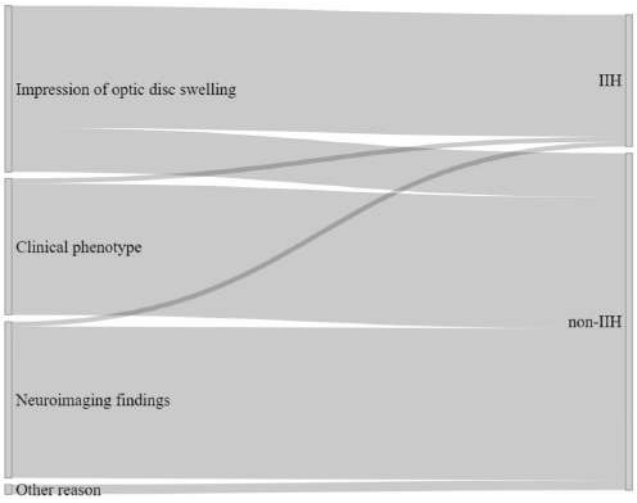
OPR-077 | Zebra or Horse: Diagnostic process, misdiagnosis, and bias in suspected idiopathic intracranial hypertension

N. Skadkær Hansen[1]; J. Juhl Korsbæk[1]; S. Hamann[2]; R. Jensen[1]
[1]*Danish Headache Center, Department of Neurology, Rigshospitalet-Glostrup, University of Copenhagen, Copenhagen, Denmark;*
[2]*Department of Ophthalmology, Rigshospitalet-Glostrup, Copenhagen, Denmark*

Background and aims: Misdiagnosis of Idiopathic Intracranial Hypertension (IIH) is prevalent and potentially harmful. We evaluate the diagnostic process in IIH and the impact of National Guideline (NG) on IIH management.

Methods: Retrospective observational study of patients referred to the Danish Headache Center bysuspected IIH,Jan 2020 to Sep 2022. We retrieved data on diagnostic work-up (DW) and duration, causes for suspecting IIH, and mismanagement, and compared outcomes by final diagnosis (confirmed versus disproven IIH (non-IIH)) and by period before and after the NG. Level of significance was Bonferroni-corrected to $p < 0.002$.

Results: 124 patients were referred. We excluded IIH relapse ($n = 22$) and secondary intracranial hypertension($n = 6$) leaving 96 patients with suspected new-onset IIH. We confirmed IIH in 28% and disproved IIH in 72% Confirmed IIH was discovered by optic disc swelling in 93%. Neuroimaging indicating intracranial hypertension ($n = 1$) and clinical phenotype ($n = 1$) aided little in finding true cases, but often elicited IIH suspicion suggesting anchoring bias with premature closure. False-positive misdiagnosis affected 9%, false-negative misdiagnosis affected 2%. DWU was significantly more comprehensive and faster in confirmed IIH compared to non-IIH. Mismanagement dropped by implementation of the NG (from 44% to 20%, $p = 0.022$), whereas diagnostic accuracy remained low (38% before vs. 21% after, $p = 0.11$).



Causes for initial IIH suspicion and final diagnosis.

Conclusion: Optic disc swelling is the main determinant leading to correct IIH diagnostics. Ophthalmic evaluation is urgent and decisive in suspected IIH and should guide DWU to mitigate unnecessary investigations. Neuroimaging and clinical phenotype have little diagnostic value and introduce bias. A national guideline optimizes the diagnostic process.

Disclosure: N. S. Hansen received funding from the Novo Nordic Foundation during the conduction of the work. J. J. Korsbæk received funding from the Lundbeck Foundation, Rigshospitalet-Glostrup and Odense University Hospital. S. Hamann received funding from the VELUX Foundation. R. OPR-078 | OCT in multiple sclerosis: beyond the optic neuritis versus non-optic neuritis universe

S. Matos; A. Jorge; I. Pais; A. Martins; I. Correia; C. Nunes; M. Macário; S. Batista; J. Lemos

Neurology Department, Coimbra University Hospital Centre, Coimbra, Portugal

Background and aims: When using optical tomography studies(OCT) in multiple sclerosis(MS) eyes are usually classified as having had clinical optic neuritis(ON), subclinical ON, or as otherwise normal. We believe such approach undermines the importance of further including and classifying eyes with signs indicative of retrochiasmal/chiasmal disease(RCD/CD).

Methods: Objectives. To analyze eyes with OCT, evidence of RCD/CD in a large database of MS patients. Methods. Eyes of MS patients examined with OCT were classified as normal, with clinical ON(diagnosed >6 months prior), subclinical ON(>7 micra inter-eye retinal nerve fiber layer[RNFL] thickness difference and/or > 4 micra inter-eye ganglion cell layer[GCL] thickness difference), subclinical or clinical CD(bilateral and congruent nasal GCL loss), subclinical or clinical RCD(bilateral and congruent homonymous GCL loss) and subclinical (non-localizing) involvement (color and/or statistical RNFL/GCL map abnormalities not fulfilling criteria above).

Results: We included 273 eyes. 177(64.8%) of our MS patients had OCT abnormalities, 32.9% of which were subclinical. Eyes had evidence of ON only ($n = 86$, 31.5%), RCD/CD ($n = 36$, 13.1%), and non-localizing findings ($n = 55$, 20.1%). When comparing between normal, ON, and RCD/CD eyes, disease duration in the right eye was different between groups ($p = 0.020$), being greater in RCD/CD ($p = 0.019$) and ON ($p = 0.029$), than in normal eyes. Disease duration in the left eye was near-significantly different between groups ($p = 0.076$), being greater in RCD/CD ($p = 0.037$) than in normal eyes. Relapse rate in the 2 years prior in the right eye, was near-significantly different between groups ($p = 0.086$), being greater in RCD/CD ($p = 0.036$) than in ON eyes.

Conclusion: Our work supports the use of OCT for identifying MS-related damage of chiasmal and retrochiasmal pathways.

Disclosure: Nothing to disclose.

OPR-079 | Clinical features, video-oculographic profile, and treatment in spinocerebellar ataxia type 27B (SCA27B)

S. Fenu[1]; D. Di Bella[2]; E. Sarto[2]; D. Pareyson[1]; C. Pisciotta[1]; S. Magri[2]; E. Salsano[1]; F. Taroni[2]

[1]Unit of Rare Neurological Diseases, Department of Clinical Neurosciences, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milano, Italy; [2]Unit of Medical Genetics and Neurogenetics, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milano, Italy

Background and aims: Spinocerebellar ataxia type 27B (SCA27B) is a late-onset, autosomal-dominant disorder caused by a GAA-repeat

expansion in the FGF14 gene and characterized by oculomotor abnormalities. This study aims to detail the oculomotor profiles of SCA27B patients and assess the efficacy of 4-aminopyridine.

Methods: Eight genetically confirmed SCA27B patients underwent clinical and video-oculographic examinations using EyeSeeCam. Six received 4-aminopyridine to evaluate its effect on nystagmus.

Results: The cohort consisted of six males and two females, mean age 69 ± 10.3 years, with disease duration of 6.6 ± 3 years. All displayed oculomotor abnormalities at both clinical and instrumental examination; half reported diplopia. Video-oculography showed reduced smooth pursuit gain in all tested patients (6/6), but normal saccade metrics (8/8). Nystagmus was present in all, predominantly downbeat (7/8) and gaze-evoked (3/8), with normal vestibulo-ocular reflex gains (8/8). Treatment with 4-aminopyridine led to both subjective and objective improvement in 5/6 cases, which was significant in three patients (see Figure) and mild in two. Only one patient had no benefit.

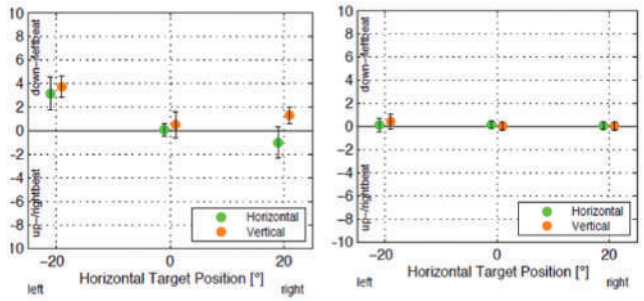

FIGURE 1 Gaze Holding assessment before and after treatment with 4-aminopyridyne shows complete disappearance of nystagmus.

Conclusion: SCA27B patients exhibit primarily vestibulocerebellar impairments, with significant smooth pursuit and nystagmus abnormalities but no saccadic or vestibulo-ocular reflex alterations. 4-aminopyridine was effective in treating nystagmus in most patients, highlighting the potential of targeted therapy in SCA27B management. Further research is needed to optimize treatment strategies.

Disclosure: Nothing to disclose.

Muscle and neuromuscular junction disorder

OPR-080 | Efgartigimod in non-AChR myasthenia gravis: a 24 months experience

C. Antozzi[1]; R. Frangiamore[1]; E. Rinaldi[1]; F. Vanoli[1]; F. Andreetta[1]; S. Bonanno[1]; L. Maggi[1]; R. Arnaboldi[2]; A. Pinna[2]; R. Mantegazza[1]
[1]Neuroimmulogy and Muscle Pathology Unit Fondazione IRCCS Istituto Neurlogico C. Besta, Milan Italy; [2]argenx Italy, Milan, Italy

Background and aims: The neonatal Fc receptor (FcRn) inhibitor Efgartigimod (EFG) has been approved for treatment of generalized Myasthenia Gravis (gMG) with anti-AChR antibodies. We investigated the efficacy of EFG in non-AChR gMG along a clinical follow-up of 2 years.

Methods: We treated 13 patients with gMG without anti-AChR antibodies: 5 MuSK+, 2 LRP4+ and 6 triple-negative (confirmed by live CBA). EFG was administered according to the GENERATIVE protocol (consisting of a Fixed period of 2 treatment cycles of 4 infusions at weekly intervals, followed by a Flexible period during which EFG was given in case of clinical worsening) starting from November 2021. Outcomes were evaluated by means of the MG-ADL, QMG, and MGC scores.

Results: The mean follow-up was 14.5 ± 6.7 months. Meaningful improvement was observed with the clinical scores adopted (MG-ADL: −5.5 ± 3.64; MGC: −8.5 ± 6.54; QMG: −4.84 ± 4.92). The number of cycles/year was 3.9 ± 0.99. The interval between cycles was 8.9 ± 3.8 weeks. MG-ADL improvement greater than 5 points was recorded in 49% of patients. 46% of patients required hospitalization during the 2 years before treatment with EFG; during EFG none of the patients was hospitalized or required immunomodulation. No major side effects or infusion related reactions occurred.

Conclusion: EFG was effective in non-AChR gMG and modified significantly the course of the disease. Our experience strengthens the role of FcRn inhibition as a new effective tool in the management of MG without anti-AChR antibodies, as demonstrated by RCT in AChR-associated gMG. A longer follow-up will be available at the time of the meeting.

OPR-081 | A real-life comparison of eculizumab and efgartigimod in generalized myasthenia gravis patients

C. Pane[1]; V. Di Stefano[2]; N. Cuomo[1]; A. Sarnataro[1]; C. Vinciguerra[5]; L. Bevilacqua[5]; M. Camapnile[1]; F. Brighina[2]; N. Rini[2]; G. Puorro[1]; A. Marsili[1]; M. Garibaldi[3]; L. Fionda[4]; F. Saccà[6]
[1]NSRO Department, Federico II University, Naples, Italy; [2]Department of Biomedicine, Neuroscience and Advanced Diagnostic (BIND), University of Palermo, Palermo, Italy; [3]Neuromuscular and Rare Disease Centre, Sant'Andrea Hospital, Rome, Italy.; [4]Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Faculty of Medicine and Psychology, SAPIENZA University of Rome, Rome,

Italy; [5]*Neurology Unit, Department of Medicine, Surgery and Dentistry, University of Salerno, Salerno, Italy*; [6]*GENESIS Department, Federico II University, Naples, Italy*

Background and aims: Eculizumab (ECU) and Efgartigimod (EFGA) are approved for the treatment of generalized Myasthenia Gravis (gMG). Objective of our study is to describe their clinical response in a real-life setting.

Methods: We included patients receiving either ECU or EFGA as part of our clinic practice and retrospectively collected data on the MG activities of daily living (MG-ADL), quantitative MG scale (QMG), MG deterioration/crises, adverse events, and prednisone use.

Results: We enrolled 63 patients, 32 treated with ECU and 31 with EFGA (Table 1). Median follow-up was 234 days. Both treatments were well tolerated. Patients treated with EFGA were more likely to suspend treatment (HR 3.732; CI 1.041, 13.385; $p=0.043$; Figure 1A). Main reason was MG deterioration, patient choice, adverse event. ECU decreased the MG deterioration/crises rate more than EFGA (OR 0.545, CI 0.363, 0.818; $P=0.003$; Figure 1B). By week 24, MG-ADL decreased by −6.5 points for ECU and −5.0 for EFGA ($p=0.188$; Figure 2A); the QMG decreased by −8.0 for ECU and −2.9 for EFGA ($p=0.003$; Figure 2B). Mean prednisone reduction at follow-up was −21.3 mg for ECU and −8.1 mg for EFGA ($p=0.026$). Speed of CS reduction was −13.1 mg/month for ECU and −3.2 mg/month for EFGA ($p=0.001$).

Table 1. Baseline Demographics

Variable	Eculizumab (n=32)	Efgartigimod (n=31)	Total (n=63)

MG-ADL	11.0±3.4	9.9±4.2	10.5±3.8
QMG	17.8±6.1	15.3±5.2	16.5±5.8

AChR-Ab+ = anti-acetylcholine receptor antibody positive; PY = Pyridostigmine; CS = Corticosteroids; NSIST = Non-steroidal Immunosuppressants; MG-ADL = Myasthenia Gravis Activities of Daily Living scale; qMG = Myasthenia Gravis quantitative scale. * 6 patients treated with Efgartigimod were seronegative, and 3 were Ab-MuSK+.

TABLE 1 Patient demographics.

Conclusion: Eculizumab and Efgartigimod proved to be both effective treatments in a real world setting as they reduced MG-ADL and QMG in difficult to treat gMG patients. Patients treated with ECU were less likely to suspend treatment or show a deterioration/crisis. Prednisone sparing effect and reduction speed was higher with Eculizumab.

Disclosure: F.S. received public speaking honoraria from Alexion, argenx, Biogen, Genpharm, Madison Pharma, Mylan, Novartis, Roche, Sanofi, Teva, Viatris, Zai Lab; he also received compensation for Advisory boards or consultation fees from Alexion, Almirall, argenx, AstraZeneca, Avexis, Biogen, Dianthus, Forward Pharma, Lexeo Therapeutics, Novartis, Reata, Sandoz, Takeda; he is PI in clinical trials for Alexion, argenx, Immunovant, Novartis, Prilenia, Sanofi.

OPR-082 | Childbirth and neonatal outcomes in a nationwide myasthenia gravis cohort

J. Lindroos[1]; M. Bjørk[1]; J. Cohen[2]; K. Danielsson[3]; O. Hikmat[4]; J. Hoff[5]; N. Gilhus[1]

[1]*Department of Clinical Medicine, University of Bergen, Bergen, Norway/ Department of Neurology, Haukeland University Hospital, Bergen, Norway*; [2]*Centre for Fertility and Health, Norwegian Institute of Public Health, Oslo, Norway*; [3]*Department of Obstetrics and Gynaecology, Haukeland University Hospital, Bergen, Norway*; [4]*Department of Paediatrics and Adolescent Medicine, Haukeland University Hospital, Bergen, Norway/ Department of Clinical Medicine, University of Bergen, Bergen, Norway*; [5]*Faculty of Health Studies at VID Specialized University, Bergen, Norway*

Background and aims: Myasthenia Gravis (MG) muscle weakness can complicate childbirth. Transient neonatal myasthenia gravis (TNMG) can result from maternofetally transferred autoantibodies. Our aim was to estimate the risks at childbirth in a maternal MG-cohort.

Methods: A cohort study using nationwide data from the Medical Birth Registry of Norway. Maternal MG was identified by MG-diagnosis or pyridostigmine-use, in current or prior pregnancy. All MG-exposed and unexposed singleton live births in Norway 1999–2022 were compared. Main outcomes were mode of delivery (caesarean section (CS) vs. vaginal, emergency CS vs. vaginal, elective

CS, and operative vaginal vs. non-operative vaginal), induction of labour, TNMG-rate and neonatal ward admission. Odds ratios (OR) with robust standard errors adjusted for year of birth, maternal age, parity and co-habitation were calculated.

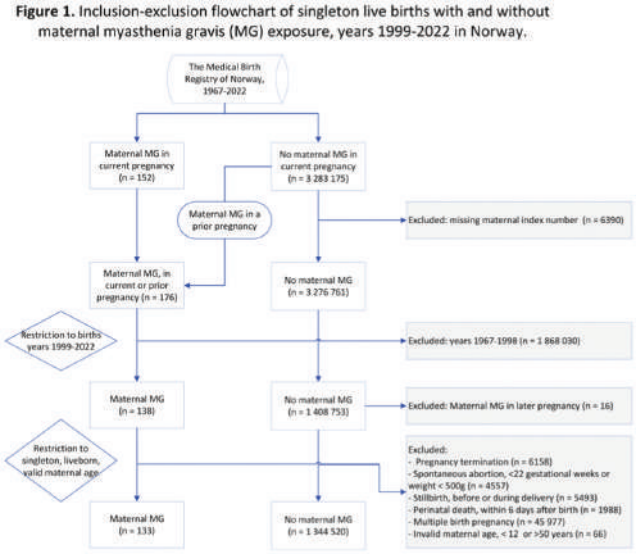

FIGURE 1 Inclusion–exclusion flowchart of singleton live births with and without maternal myasthenia gravis (MG) exposure, years 1999–2022 in Norway.

Results: 133 MG-births and 1,344,520 unexposed births were included. Maternal MG did not significantly increase the risk for CS (aOR 1.32, 95% CI: 0.87–1.99). Elective CS (1.90, 1.10–3.30) and induced labour (1.56, 1.05–2.33) were more common with MG. The emergency CS rate was 10% for both groups (0.97, 0.54–1.76). Among MG-exposed children, five (4%) had TNMG and 38% were admitted to neonatal ward, compared to 10% of unexposed (5.47, 3.85–7.77).

Table 1. Obstetrical and neonatal outcomes among all singleton live births with and without maternal MG exposure in Norway 1999-2022.

	Maternal MG	No maternal MG		
Outcome	N (%)	N (%)	OR (95% CI)	aOR[1] (95% CI)
CS total[2]	27/ 133 (20.3)	204 862/ 1 344 520 (15.2)	1.42 (0.93 - 2.16)	1.32 (0.87 - 1.99)
Elective CS	15/ 133 (11.3)	75 510/ 1 344 520 (5.6)	2.14 (1.25 - 3.65)	**1.90 (1.10 - 3.28)**
Emergency CS	12/ 118 (10.2)	128 768/ 1 268 426 (10.1)	1.00 (0.55 - 1.82)	0.97 (0.54 - 1.76)
Operative vaginal delivery[3]	14/ 106 (13.2)	124 896/ 1 139 658 (11.0)	1.24 (0.70 - 2.17)	1.31 (0.73 - 2.34)
Induction of labour	34/ 133 (25.6)	240 766/1 344 518 (17.9)	1.57 (1.07 - 2.32)	**1.56 (1.05 - 2.33)**
Admission to neonatal ward	49/ 129 (38.0)	131 750/ 1 298 806 (10.1)	5.43 (3.80 - 7.74)	**5.47 (3.85 - 7.77)**
TNMG	5/133 (3.8)	0	NA	NA

Abbreviations: MG; myasthenia gravis; N, number; aOR, adjusted odds ratio; CI, confideoce interval; CS, Caesarean section; TNMG, transient neonatal myasthenia gravis; NA, not applicable

[1] Adjusted for maternal age, year of birth, parity, mother's co-habitation status
[2] Elective, emergency or unspecified C-section
[3] Use of vacuum or forceps

TABLE 1 Obstetrical and neonatal outcomes with and without maternal MG exposure among all singleton live births in Norway 1999–2022.

Conclusion: The risks for elective CS and induced labour were increased, but not for emergency CS, suggesting that pregnancy planning helps avoid complications in MG-women. Few MG-exposed children had TNMG, but 38% were admitted to a neonatal ward. All children of mothers with MG should be observed in-hospital for minimum 2–3 days as TNMG symptoms often develop with delay.

Disclosure: N.E. Gilhus has received financial support from UCB, Argenx, Janssen, Merck, Roche, Alexion, Immunovant, Huma, Denka, Grifols, and Dianthus. Bjørk, M H. has received speaker honoraria and/or served on scientific advisory boards for Teva, Eisai, AbbVie, Pfizer, Novartis, Lundbeck, Angelini Pharma, Jazz pharmaceuticals, and Lilly during the last 5 years. None of the assignments concerned treatment of Myasthenia Gravis. Lindroos, JLV; Cohen, JM; Danielsson, KC; Hikmat, O; Hoff, JM: Nothing to disclose.

OPR-083 | Automatic method for jitter estimation in electromyographic signals

A. Malanda[1]; C. Valle[1]; D. Stashuk[2]; O. Garnés[3]; J. Rodríguez[1]; J. Navallas[1]

[1]*Electrical, Electronics and Communication Engineering, Public University of Navarra, Pamplona. Spain;* [2]*System Design Engineering Department, University of Waterloo, Waterloo, Canada;* [3]*Neurophysiology Service, Jiménez Díaz Foundation University Hospital*

Background and aims: Neurophysiological jitter measurement using concentric needle electrodes is a laborious and difficult task, because potentials from several fibers may appear in the recordings due to the large recording areas of these electrodes. This work presents an automatic method that estimates jitter from motor unit potential (MUP) trains recorded using single-fiber or concentric needle electrodes.

Methods: MUP intervals likely being formed by only one muscle fiber potential are detected. Then jitter measurement is performed between pairs of these intervals. 132 electromyographic signals were recorded from 8 patients with disorders of the neuromuscular junction or different neuropathies, using a Keypoint system and facial-concentric electrodes. These signals were decomposed into several MUP trains using DQEMG software. Jitter was then estimated manually, using a home-made graphical interface (Figure 1A,B) and using the automatic method (Figure 1C,D).

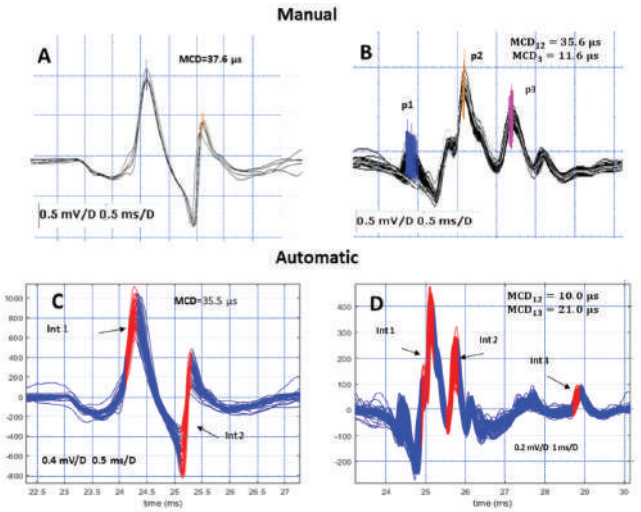

FIGURE 1 Examples of MUP trains analyzed by the manual method, with marked negative peaks and the obtained MCD values (A, B). The same MUP trains analyzed with the automatic method, with highlighted valid intervals and MCD values (C, D).

Results: From 96 MUP trains valid for the analysis, 102 automatic and 84 manual jitter measurements were obtained. Comparative analysis (Figure 2) yielded a mean of jitter differences of 1.74 µs, a mean of absolute differences of 2.73 µs and values of −2.62, −0.35, 2.53 and 7.56 µs for the 5th, 25th, 75th and 95th percentiles of the jitter differences distribution, respectively.

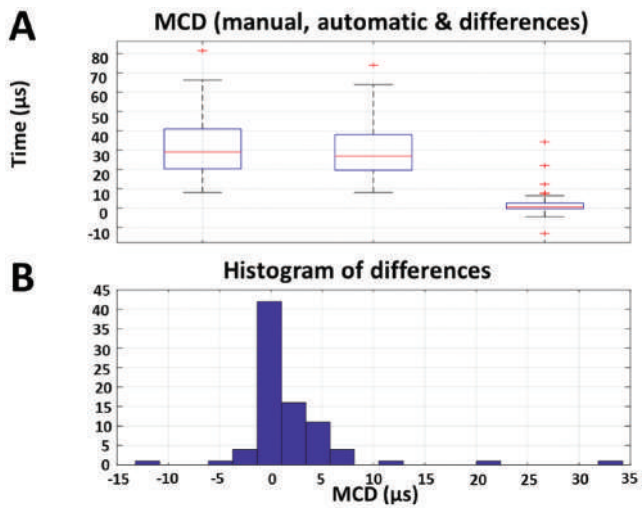

FIGURE 2 Boxplots of MCD values obtained by manual and automatic methods and of the difference in MCD values (A). Histogram of the difference in MCD values (B).

Conclusion: Although more extensive tests are still required, these results suggest that the proposed automatic jitter estimation method may be a valuable technique for clinical practice.

Disclosure: This work has been funded by the Department of Health of the Government of Navarra (project GN2022/29) and by the Spanish Ministry of Science and Innovation (project PID2022-136620OB-I00).

Epilepsy 2

OPR-084 | The lifetime outcomes of antiseizure medication in patients with mesial temporal lobe epilepsy and hippocampal sclerosis

A. Dias; P. Henning; W. Ferreira; M. Alvim; C. Yasuda; F. Cendes
Laboratory of Neuroimaging, Department of Neurology, UNICAMP, Campinas, Brazil

Background and aims: To evaluate the lifetime seizure frequency in patients with mesial temporal lobe epilepsy and hippocampal sclerosis (mTLE-HS).

Methods: We studied 118 patients with mTLE-HS followed at UNICAMP. We reviewed the seizure frequency, age, duration of epilepsy, dosages and type of antiseizure medications (ASM) used. Patients were split into 3 groups: seizure-free (no seizures in the last 2 years or more of follow-up), fluctuating (seizure-freedom periods of 1 year or longer) or pharmacoresistant (never had a seizure-free period of more than 1 year). Pharmacoresistant patients did not undergo surgery either because they refused it or had contraindications. Patients who underwent surgery were not included in this study.

Results: The mean age was 56.13 years and mean follow-up was 20.25 years (range 3–47, SD 9.83). 35.6% ($n=42$) had right-TLE, 50% ($n=59$) left-TLE and 14.4% ($n=17$) bilateral-TLE. Thirty-six (30.5%) were seizure-free, 39 (33.05%) had a fluctuating course and 43 (36.45%) were pharmacoresistant. There were no differences among groups in relation to the age they became seizure-free, age of epilepsy onset, epilepsy duration, epilepsy family history, number of ASM used over the years or number and type of ASM in use at the last follow-up ($p>0.074$). The most common ASM was carbamazepine.

Conclusion: Three clinical evolution patterns were observed among patients with mTLE-HS who did not underwent surgery: pharmacoresistant, fluctuating seizure control/pharmacoresistant, and seizure-free. We found no significant differences in the main clinical features among groups. Further studies are necessary to define the factors that could predict these three outcome profiles.

OPR-085 | Exploring the long-term effects of COVID-19 in patients with epilepsy: A multicenter Italian observational study

C. Corniello[1]; F. Dono[1]; M. Russo[1]; F. Lombardo[1]; G. Evangelista[1]; S. Consoli[1]; F. Narducci[2]; G. Assenza[2]; C. Liguori[3]; C. Calvello[3]; S. Sensi[1]

[1]*Department of Neuroscience, Imaging and Clinical Science, "G. d'Annunzio" University of Chieti-Pescara, Chieti, Italy*; [2]*Unit of Neurology, Neurophysiology, Neurobiology, Department of Medicine, University Campus Bio-Medico of Rome, Rome, Italy*; [3]*Neurology Unit, University Hospital of Rome Tor Vergata, Viale Oxford, 81, 00133, Rome, Italy*

Background and aims: A growing evidence in the literature support that patients recovered from COVID-19 may develop novel neurological and psychiatric symptoms lasting from weeks to months. This condition, labeled as "long COVID", can be observed more frequently in patients with chronic diseases. The aim of this study is to identify the long-term effects of COVID-19 in people with epilepsy (PwE).

Methods: PwE aged >18 who accessed to three epilepsy centers in the center of Italy during the first pandemic wave between March 2020 and December 2021 were enrolled. According to a documented clinical and laboratory SARS-CoV-2 infection, patients were divided into two groups: COVID+ and COVID-. Epilepsy features (i.e., seizure frequency, treatment), and neurological and psychiatric symptoms were collected at baseline and at 6- and 12-month follow-up visits in both groups.

Results: 39 patients in COVID+ group (17/22 M/F, age: 40.6 ± 18.6 years, 33 focal epilepsy, 6 generalized epilepsy) and 91 patients in COVID- (42/49 M/F, age: 42.9 ± 19.7 years, 69 focal epilepsy, 22 generalized epilepsy) met the inclusion criteria. At 6-month, COVID+ group showed a need for antiseizure medication dose adjustment compared to COVID- group ($p < 0.0001$). An increased diagnosis of psychiatric (i.e., anxiety and depression) and neurological (i.e., cognitive) symptoms was observed in the COVID+ group at both 6- and 12-month ($p < 0.0001$). At 12-month, up to 40% of patients in the COVID+ group revealed an increased seizure frequency ($p = 0.002$).

Conclusion: These findings suggest that PwE with previous SARS-CoV-2 infection may develop psychiatric and neurological long-lasting effects.

Disclosure: Nothing to disclose.

OPR-086 | Evolution into electrical status epilepticus during sleep in patients with self-limited focal epilepsies

M. İriş[1]; M. Atacan Yaşgüçlükal[2]; C. Yalçınkaya[1]; V. Demirbilek[1]

[1]*Department of Neurology, Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Istanbul, Turkey*; [2]*Department of Neurology, Haseki Research and Training Hospital, Health Sciences University, Istanbul, Turkey*

Background and aims: Self-limited focal epilepsies of childhood (SeLFE), while predominantly considered benign, are known to potentially manifest with electrical status epilepticus during sleep (ESES) in a minority of patients.

Methods: The medical records of individuals diagnosed with one of the SeLFE syndromes according to the ILAE 2022 diagnostic criteria, who have been followed in our center between 1989–2023, were retrospectively analyzed. At least two awake and sleep EEGs were performed during a minimum 2-year follow-up. ESES is considered as spike and wave discharges occupying ≥50% of NREM sleep with symmetrical or mildly asymmetrical bilateral or unilateral hemispheric distribution.

Results: Among 144 patients with SeLFE, 57(39.6%) were diagnosed with self-limited epilepsy with centrotemporal spikes (SeLECTS); 65(45.1%) with self-limited epilepsy with autonomic seizures (SeLEAS); and 22 (15.3%) with childhood occipital visual epilepsy (COVE). The mean age of seizure onset was 7.6 years, 5.6 years, 8.5 years, respectively. Twelve (8.3%) evolved into ESES (5 from SeLECTS, 6 from SeLEAS, 1 from COVE). Time elapsed between onset of first seizure and evolution into ESES ranged from 5.2 to 75 months (mean: 26.8±19.8), 6.2–42.8 months (mean: 20.1±14.7 for patients with SeLECTS; 5.2–75.0 months (mean: 32.7±24.5) with SeLEAS, and 25.0 months with COVE). All except one patient had also cognitive or behavioral regression and one patient was diagnosed with Landau–Kleffner syndrome.

Conclusion: The most recent definition of ILAE highlights that SeLFEs are no longer recognized as "benign" epilepsies. Even with a low incidence rate, clinicians should always be cautious about the risk of ESES development in these syndromes.

Disclosure: Nothing to disclose.

OPR-087 | Thalamic atrophy and parahippocampal cortical surface area may distinguish clinical response in temporal lobe epilepsy

P. Henning; A. Dias; W. Ferreira; B. Campos; M. Alvim; C. Yasuda; F. Cendes

Laboratory of Neuroimaging, Department of Neurology, UNICAMP - Campinas, Brazil

Background and aims: To correlate response to antiseizure medication (ASM) with cortical surface area (CSA) and subcortical volumes (SV) in patients with mesial temporal lobe epilepsy with hippocampal sclerosis (mTLE-HS).

Methods: 111 patients with mTLE-HS who did not undergo surgery because they refused it, had contraindications, or had good seizure control with ASM (mean follow-up of 21.8 years) were categorized in three groups: pharmacoresponsive (seizure-free in the last 2 years or more), fluctuating-response (seizure-freedom periods of 1 year or longer) and pharmacoresistant (never had a seizure-free period of more than 1 year). T1-weighted MRIs (1 × 1 × 1 mm) were processed with Freesurfer-6.0. We analyzed the following regions of interest for CSA: inferior, middle and superior temporal gyrus, parahippocampal gyrus and insula. Volumes of thalamus, hippocampus and

amygdala, along with the CSA from each ASM response-groups were compared with 112 controls.

Results: Groups were balanced for age, sex, and side of HS. Each ASM response-group had 37 patients. Compared with controls, ipsilateral hippocampal volumes were reduced in all groups ($p < 0.0001$) without difference among groups. There was no difference in the contralateral hippocampal volumes among groups. Volumes of ipsilateral and contralateral thalami were reduced in the pharmacoresistant group ($p < 0.003$), and the contralateral thalamus was reduced in pharmacoresponsive and fluctuating-response groups ($p < 0.006$). Amygdala was reduced in the pharmacoresponsive group ($p = 0.03$). Ipsilateral parahippocampal CSA was reduced in the pharmacoresistant group ($p = 0.013$). Other CSA did not differ among groups.

Conclusion: Bilateral thalamic atrophy and reduced ipsilateral parahippocampal CSA appears to distinguish pharmacoresistant mTLE-HS from those with better response to ASM.

Disclosure: CEPID - FAPESP: "The Brazilian Institute of Neuroscience and Neurotechnology (BRAINN)", grant 2013/07559–3; CNPQ 315953/2021–7.

OPR-088 | Real-world data on continuous deep brain stimulation of the anterior nucleus of the thalamus for drug-resistant epilepsy

R. Morcos[1]; J. Sarto[2]; M. Carreño[2]; M. Centeno[2]
[1]*Neurology Department, Hospital Universitario Vithas Madrid, Spain;*
[2]*Neurology Department, Hospital Clinic Barcelona, Barcelona, Spain*

Background and aims: This study aimed to evaluate the efficacy and safety of bilateral deep brain stimulation (DBS) of the anterior nucleus of the thalamus (ANT) in patients with drug-resistant epilepsy (DRE), focusing on continuous stimulation settings.

Methods: A retrospective review was conducted on eight patients with focal DRE who underwent bilateral ANT-DBS. Clinical and seizure data were collected, and stimulation parameters were adjusted to maximize clinical benefit. Patients were followed for a mean of 51 months, and changes in seizure frequency were assessed.

Results: Continuous ANT-DBS demonstrated a significant (>50%) reduction in seizure frequency for all patients, with a mean reduction of 68%. The most severe seizure type showed the greatest response to stimulation. None of the patients achieved seizure freedom, but all experienced a transient post-implantation seizure-free period. Psychiatric adverse events were reported in 50% of patients, primarily depression, but they were manageable.

Case	Age, sex	Etiology	Seizure types	Localization	Seizure reduction	Adverse events	Follow-up
1	43, male	Unknown	FAS, FIAS	NOT LOCALIZED	99%	No	11.5 y
2	33, female	Anti-GAD encephalitis	FAS, FIAS	TEMPORAL (BILATERAL)	90%	Depression	8 y
3	22, male	HSV 1 encephalitis	FAS, FIAS, FBTCS	TEMPORAL (BILATERAL)	79%	Depression (worsened)	3.5 y
4	40, male	Unknown	FIAS, FBTCS	MULTIFOCAL	99%	No	3.5 y
5	57, female	Unknown	FIAS	MULTIFOCAL	67%	No	2.5 y
6	24, male	Unknown	FIAS	FRONTAL, INSULA	71%	Apathy	2 y
7	46, male	Immune	FAS, FBTCS	MULTIFOCAL	14%	No	1,75 y
8	52, female	Type I FCD	FAS, FIAS	FRONTAL	22%	No	1 y

TABLE 1 Summary of results. FAS, focal aware seizure; FIAS, focal impaired awareness seizure, FBTCS, focal to bilateral tonic–clonic seizure.

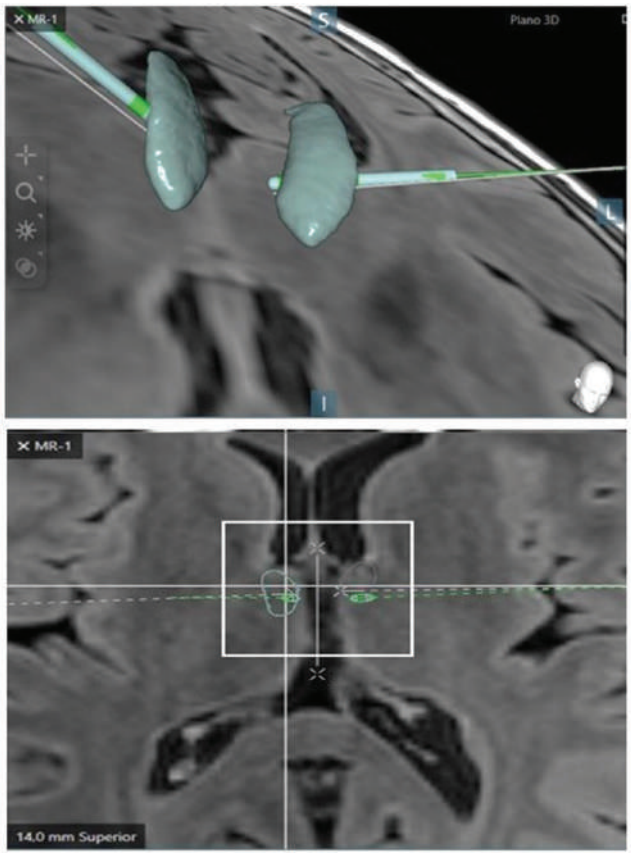

Image 1 and 2. MRI reconstruction of DBS implantation: 3D (top) and axial planes (bottom).

Conclusion: This study highlights the effectiveness of continuous ANT-DBS in reducing seizures for patients with DRE who are not candidates for resective surgery. The findings suggest that continuous stimulation may offer a valuable alternative to intermittent settings. The study underscores the importance of precise electrode placement and a network-focused approach in selecting DBS targets. Overall, ANT-DBS presents a safe and promising option for improving the quality of life in patients with drug-resistant epilepsy.

Disclosure: Nothing to disclose.

Autonomic nervous system diseases

OPR-089 | Abnormal dopamine transporter imaging in pure autonomic failure – A follow-up study

G. Chiaro[1]; R. Alnasser Alsukhni[1]; G. Ingle[1]; K. Bhatia[2]; C. Mathias[3]; J. Bomanji[4]; V. Iodice[1]
[1]*Autonomic Unit, National Hospital for Neurology and Neurosurgery, London, UK;* [2]*Department of Clinical and Movement Neurosciences, UCL Queen Square Institute of Neurology, University College London, London, UK;* [3]*UCL Queen Square Institute of Neurology, Faculty of Brain Sciences, University College London, London, UK;* [4]*Institute of Nuclear Medicine, UCLH NHS Foundation Trust, London, UK*

Background and aims: Abnormal dopaminergic transporter imaging in pure autonomic failure (PAF) is a potential biomarker of central nervous system involvement as described in our pilot study of 10 PAF patients. In this follow-up study, we evaluated the prevalence of abnormal 123I-Ioflupane dopamine transporter SPECT (DaTSCAN) in a larger, prospective cohort of patients with PAF and assessed the rate of phenoconversion to more widespread alpha synucleinopathies.
Methods: Consecutive PAF patients underwent a multimodal assessment including cardiovascular autonomic function testing performed with the Finapres NOVA and DaTSCAN, as part of the Queen Square Autonomic Prodromal Project (QSA-PRODROMAL).
Results: 70 patients with PAF with a median disease duration of 6 (IQR 3–10) years were identified. 22 developed a more widespread synucleinopathy (7 Parkinson's disease, 4 dementia with Lewy bodies, 2 multiple system atrophy-cerebellar [MSA-C], 9 multiple system atrophy-parkinsonian). All phenoconverters had an abnormal DaTSCAN, apart from 2 patients who converted to MSA-C. In patients who underwent DaTSCAN while still retaining a PAF phenotype, the median lag between imaging and phenoconversion was 8 IQR (4–16) months. 48 patients retained a PAF phenotype at last follow-up and 4 of them had an abnormal DaTSCAN. These had a clinical REM sleep behaviour disorder. There were no differences in demographics, autonomic function, or plasma catecholamine spillover between PAF patients with normal or an abnormal DaTSCAN.
Conclusion: DaTSCAN is a biomarker of subclinical central nervous system involvement in PAF and can predict phenoconversion to more widespread alpha-synucleinopathies in patients with a prodromal phase of up to 9 years.
Disclosure: The authors have nothing to disclose.

OPR-090 | The role of plasma norepinephrine level in differential diagnosis of alpha-synucleinopathies

G. Carrozzo[1]; P. Guaraldi[2]; I. Cani[1]; L. Baldelli[1]; G. Giannini[1]; L. Sambati[2]; G. Barletta[1]; P. Cortelli[1]; G. Calandra-Buonaura[1]
[1]*Department of Biomedical and NeuroMotor Sciences (DIBINEM), Alma Mater Studiorum, University of Bologna, Bologna, Italy and IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy;* [2]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy*

Background and aims: The alpha-synucleinopathies, including Parkinson's Disease (PD), Dementia with Lewy Body (DLB), Multiple System Atrophy (MSA) and Pure Autonomic Failure (PAF), differ for specific configurations of abnormal alpha-synuclein aggregation across the nervous system. The variation in autonomic dysfunction observed in these conditions is attributed to the differing degrees of involvement of Autonomic Nervous System at central or peripheral level or both. This results in different patterns of plasma level of the neurotransmitter norepinephrine (NE), that could help to differentiate alpha-synucleinopathies.
Methods: We collected blood samples for NE measurement during supine rest (at 20th and 25th min) and at 10th min of the orthostatic phase or at the occurrence of orthostatic intolerance during Head-Up Tilt Test (HUTT), from 331 subjects (61 controls, 72 PD/DLB; 147 MSA, 51 PAF).
Results: Preliminary results showed a significant higher increment of plasma NE during HUTT in PD/DLB (mean ± SD; 155.9 ± 130.2 pg/mL) compared to MSA (82.9 ± 101.4 pg/mL) in absence of a significant difference in supine NE levels (PD/DLB, 250.3 ± 137.7 pg/mL; MSA, 259.5 ± 160.5 pg/mL). Comparisons with the other groups and cut-off values evaluation are ongoing.
Conclusion: Our findings suggest that plasma NE patterns could potentially differentiate alpha-synucleinopathies in the early stages of the diseases, representing a biomarker for differential diagnosis.
Disclosure: Nothing to disclose.

OPR-091 | Cardiovascular autonomic signature of hereditary transthyretin amyloidosis

I. Cani[1]; M. Gianoli[1]; G. Barletta[2]; R. Rinaldi[2]; S. Longhi[3]; C. Gagliardi[3]; N. Galiè[3]; P. Cortelli[1]; P. Guaraldi[2]
[1]*Department of Biomedical and NeuroMotor Sciences (DIBINEM), Alma Mater Studiorum - University of Bologna, Italy;* [2]*UOC Clinica Neurologica Rete Metropolitana NEUROMET, IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy;* [3]*UO Cardiologia, IRCCS Policlinico Sant'Orsola-Malpighi, Bologna, Italy*

Background and aims: Autonomic dysfunction is a fundamental hallmark in the neurological presentation of hereditary transthyretin amyloidosis (ATTRv). Despite its diagnostic significance, there is a notable lack of instrumental studies examining the cardiovascular autonomic involvement in ATTRv individuals.
Methods: To characterized cardiovascular autonomic functions in a single-center cohort of subject with ATTRv through standardized cardiovascular reflex tests (CRTs) including head-up tilt test (HUTT), Valsalva maneuver (VM), deep breathing, cold face test and handgrip test (Finapres Medical System). For comparative analysis, an equivalent number of healthy controls (HC) with similar age and sex distributions were recruited.

Results: The cohort included 65 ATTRv subjects (age 59.77 (14.56), 42% female). During HUTT, ATTRv subjects displayed decreased BP and HR responses compared to HC; with four patients experiencing orthostatic hypotension. All indexes of VM were reduced in ATTRv compared to HC (overshoot: 20 vs. 41 mmHg; phase IIb-IIa: 6 vs. 15 mmHg; Valsalva ratio: 1.33 vs. 1.75). BP responses to cold face and hand grip tests were also attenuated in ATTRv compared to HC. Additionally, the inspiration/expiration ratio during deep breathing was reduced in ATTRv subjects. Among ATTRv cohort, 23 subjects were asymptomatic with no neurological or cardiological involvement. ATTRv carriers differed from HC, exhibiting significantly lower BP responses during HUTT and reduced overshoot at VM, indicating early autonomic involvement in ATTRv.

Conclusion: This study represents the largest investigation into autonomic cardiovascular regulation in ATTRv. CRT documented cardiovascular autonomic impairment in ATTRv subjects. Additionally, ATTRv carriers displayed early autonomic dysfunction, preceding the onset of neurological and cardiological manifestation. These findings provide crucial insights for earlier diagnosis and timely intervention.

Disclosure: Nothing to disclose.

OPR-092 | The catastrophic nature of vasovagal syncope in cardiovascular self-organized criticality

N. Navasiolava[1]; A. Robin[1]; M. Custaud[1]; J. Fortrat[2]
[1]*Univ Angers, Inserm, CNRS, Équipe CARME, SFR ICAT, Angers, France; Centre de Recherches Cliniques, CHU Angers, France;* [2]*Univ Angers, Inserm, CNRS, Équipe CARME, SFR ICAT, Angers, France; Service de Médecine Vasculaire, CHU Angers, France*

Background and aims: The recent elucidation of self-organized criticality dynamics within the cardiovascular system (CV-SOC) presents a potential explanatory framework for the occurrence of vasovagal syncope. Self-organized criticality, a universal theory governing natural systems, posits the spontaneous emergence of unexpected large events, termed catastrophes. This study investigates the hypothesis that vasovagal syncope represents a catastrophic manifestation within the CV-SOC. To test this hypothesis, we conducted assessments of CV-SOC preceding an orthostatic challenge.

Methods: Thirty-five healthy volunteers underwent an orthostatic test involving lower body negative pressure (LBNP, −50 mmHg) in the supine position to simulate orthostatic fluid shifts. Tolerance to the test was defined as completion without symptoms or no blood pressure dropping below 80 mmHg. Beat-by-beat heart rate was recorded in the supine position for 20 min 2 days before LBNP to determine the slope of the distribution of long bradycardia (aL), a descriptive CV-SOC index. We compared subjects classified as orthostatic intolerant and tolerant.

Results: Nineteen subjects were intolerant, and 16 were tolerant (10 and 6 female, respectively). Despite similar heart rates between groups (67 ± 2 and 65 ± 2 bpm for intolerant and tolerant, respectively), the aL index significantly differed (0.14 ± 0.01 and 0.18 ± 0.01, T test, $p < 0.01$) between tolerant and intolerant subjects.

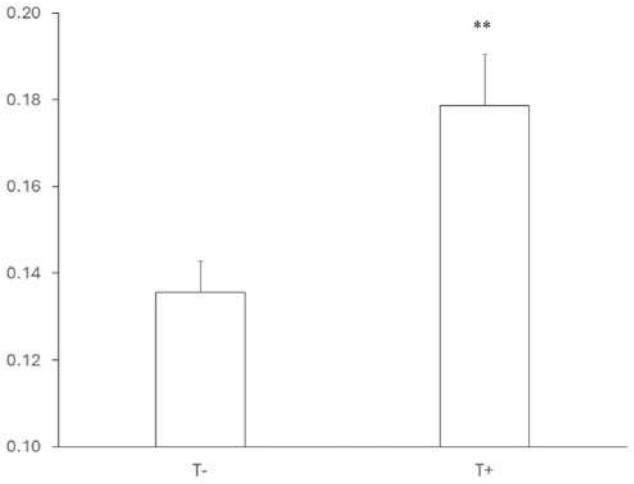

Fig. Slope of the statistical distribution of bradycardia occurrence (no unit) as index of self-organized criticality dynamics in healthy subjects non-tolerant and tolerant to an orthostatic test (T− and T+, respectively). **: $p < 0.01$, unpaired *T* test.

Conclusion: This study not only affirms the self-organized criticality nature of cardiovascular dynamics but also provides compelling evidence linking vasovagal syncope to this inherent nature. Vasovagal syncope, within this framework, emerges as a catastrophic event within the self-organized criticality dynamics of the cardiovascular system.

Disclosure: The VIVALDI study was funded by the European Space Agency (ESA), and the French National Center of Space Studies (Centre National d'Études Spatiales, CNES, funding n° 4800001118.

OPR-093 | Intracranial baroreflex: A review

E. Schmidt[1]; N. Nasr[2]; M. Kermorgan[3]; A. Pavy Le Traon[3]
[1]*Neurosurgery, Toulouse, France;* [2]*Neurology, Poitiers, France;* [3]*Neurology, Toulouse, France*

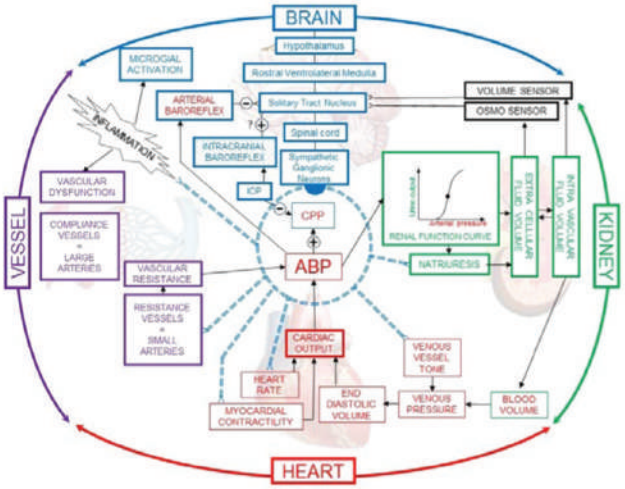
Background and aims: In 2018, two independent teams demonstrated that intracranial pressure (ICP) influences the level of sympathetic activity. A modest physiological increase in ICP leads to an increase in directly recorded sympathetic nerve activity in mice, sheep and humans. This novel regulatory mechanism represents an intracranial baroreflex, bridging ICP and the autonomic nervous system (ANS). Over the last 6 years, data have been published to investigate the role of intracranial baroreflex in physiology and pathology.

Methods: We analysed the literature published on the intracranial baroreflex in the last 6 years to provide an up-to-date review and highlight the most important facts.

Results: 1. Astrocytes seem appear to function as intracranial baroreceptors and may play a role in ANS control. 2. Modest ICP

increase induced by head-down tilt increases sympathetic activity. 3. Intracranial baroreflex is attenuated in an ovine model of renovascular hypertension. 4 Acute ICP rise was associated with a significant increase in heart rate variability and baroreflex sensitivity.

Conclusion: The effect of ICP on the ANS and the concept of a physiological intracranial baroreflex are now supported by convergent and independent data. Intracranial and extracranial (i.e. arterial) baroreflexes behave in opposition, with excitatory and inhibitory effects on the sympathetic activity, respectively. We propose an integrated physiological scheme of ABP regulation, including intracranial and extracranial baroreflexes, which may be involved in the fine-tuning of ABP. However, the exact role of the intracranial baroreflex in the pathophysiology of sympathetic overactivity and hypertension requires further investigation.



Intracranial baroreflex in ABP regulation.

Disclosure: no.

OPR-094 | Cutaneous phosphorylated-synuclein: An early diagnostic biomarker for pure autonomic failure

S. Koay[1]; V. Provitera[2]; G. Caporaso[2]; E. Vichayanrat[1]; F. Valerio[1]; S. Johnstone[1]; M. Lunn[3]; M. Nolano[4]; V. Iodice[1]

[1]*Autonomic Unit, The National Hospital for Neurology and Neurosurgery, Queen Square, London, UK;* [2]*Neurology Department, Skin Biopsy Laboratory, Istituti Clinici Scientifici Maugeri IRCCS, Telese Terme, Italy;* [3]*Queen Square Centre of Neuromuscular Diseases, UCL Queen Square Institute of Neurology, London, UK;* [4]*Department of Neurosciences, Reproductive Sciences and Odontostomatology, University Federico II of Naples, Naples, Italy*

Background and aims: Pure autonomic failure (PAF) is a predominantly peripheral alpha-synucleinopathy, presenting with progressive autonomic failure in the absence of other neurological features. Atypical presentations may lead to diagnostic uncertainty. We studied whether cutaneous phosphorylated-synuclein (p-syn) could distinguish between PAF, multiple system atrophy (MSA), and non-synucleinopathy related autonomic failure, and its correlation with quantitative markers of autonomic failure.

Methods: Patients underwent autonomic questionnaires, cardiovascular autonomic testing (Finapres) and bilateral distal leg skin biopsies. We noted whether p-syn was present in nerves supplying autonomic adnexa, including sweat glands, blood vessels, arrector pili muscles, and subepidermal fibres, dermal fibres and nerve fascicles (maximum autonomic subscore 3 and total p-syn score 6 for each sample, average calculated for both sides).

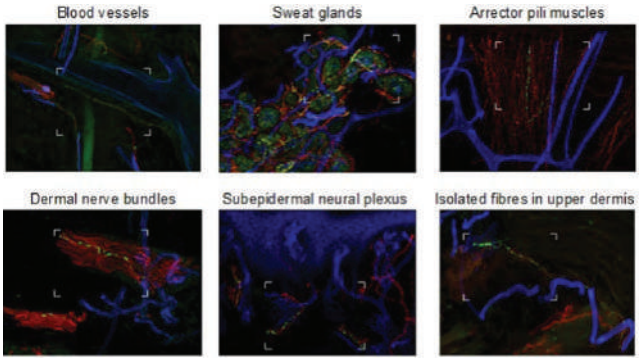


FIGURE 1 Summary of structures used for calculating autonomic p-syn subscore (3 structures in top panel) and total p-syn score (all 6 structures). Figure adapted from Nolano 2022, with permission from IOS Press.

Results: Thirty-six individuals were studied (11 PAF, 13 MSA, 12 non-synucleinopathy related autonomic failure). P-syn was present in 22/22 (100%) PAF biopsies, 19/26 (73%) MSA biopsies, and 0/22 (0%) non-synucleinopathy biopsies. Total p-syn score was significantly higher in PAF (median 4.5) compared to MSA (median 1, $p < 0.001$). Autonomic p-syn subscore correlated with quantitative markers of autonomic failure related to impaired control of total peripheral resistance, including orthostatic intolerance ratio on tilt (rho = 0.63; $p = 0.0004$) and blood pressure recovery time following Valsalva manoeuvre (rho = 0.44; $p = 0.03$), as well as patient-reported orthostatic intolerance (rho = 0.57; $p = 0.006$).

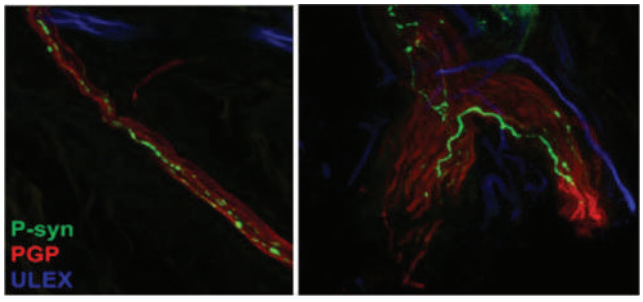

FIGURE 2 Confocal images of cutaneous p-syn deposits from a patient with PAF. P-syn is seen to co-localise along nerve fibres, marked with PGP (protein G peptide), running within dermal nerve bundles.

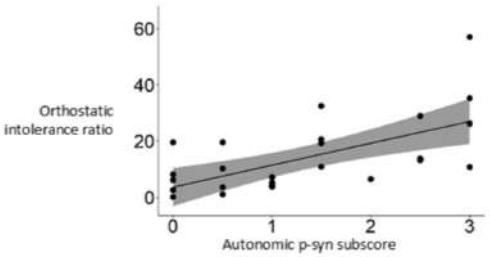

FIGURE 3 Cutaneous autonomic p-syn score correlated with orthostatic intolerance ratio on tilt (change in systolic blood pressure in mmHg divided by time tolerated on tilt in minutes, to a maximum of 10 min).

Conclusion: Cutaneous p-syn was abundant in PAF and represents a promising early diagnostic biomarker to help distinguish between predominantly peripheral and central alpha-synucleinopathies, and non-synucleinopathy related autonomic failure. P-syn deposition on autonomic nerves may impair control of total peripheral resistance giving rise to symptomatic orthostatic hypotension.

Maillet[6]; A. Pegat[7]; D. Psimaraas[5]; M. Rafiq[8]; G. Picard[1]; V. Desestret[1]; I. Quadrio[2]; J. Honnorat[1]; B. Joubert[1]

[1]French Reference Center on Paraneoplastic Neurological Syndromes and Autoimmune Encephalitis, Hospices Civils de Lyon, Hôpital Neurologique, Bron; UMR MELIS team SynatAc, INSERM1314/CNRS5284, Lyon, France; [2]Lyon Neuroscience Research Center, HCL, Lyon, France; [3]Centre Hospitalier de Lille, Lille, France; [4]Centre Hospitalier de Bordeaux, Bordeaux, France; [5]Hospital Group Pitié-Salpêtrière, Paris, France; [6]Immucare, Lyon, France; [7]Service ENMG et Pathologies Neuromusculaires, HCL, Lyon, France; [8]Centre Hospitalier de Toulouse

Background and aims: Diagnostic and prognostic biomarkers are lacking in immune checkpoint inhibitors (ICI)-related encephalitis. We aimed to characterize the clinical features of ICI encephalitis patients, and identify diagnostic biomarkers and outcome predictors.

Methods: This retrospective study included all patients with possible or definite ICI-encephalitis whose samples and clinical data were studied in the Lyon Neurological Hospital (2015–2023). Response to treatment was defined as CTCAE (v5.0) grade <3. S-100 calcium-binding protein, neurofilament light chain (NfL) and glial fibrillary acidic protein levels were measured in 27 definite ICI-encephalitis patients and 16 controls.

Results: Seventy-six patients were identified, including 67 (88%) with definite ICI-encephalitis (median age, 67 years, 66% male). A focal syndrome was observed in 43/67 patients (64%; limbic encephalitis, rapidly-progressive cerebellar ataxia, and/or brainstem encephalitis), while 24 (36%) had meningoencephalitis, a non-focal syndrome with frequent altered mental status (92%) and pleocytosis (100%). Meningoencephalitis patients had less frequent abnormal brain MRI findings (33% vs. 62%, $p=0.025$), PNS-related antibodies (4% versus 84%, $p<0.001$), and neuroendocrine cancers (4% versus 49%; $p<0.001$) than focal encephalitis patients. Serum NfL > 273.5 pg/mL discriminated definite ICI-encephalitis patients from controls with sensitivity of 88% and specificity of 81%. Focal ICI-encephalitis patients responded less to treatment (15%) than ICI-meningoencephalitis patients (72%, $p<0.001$), and PNS-related antibodies were negatively associated with treatment response (adjusted OR 0.05; 95% CI [0.01; 0.21]). Thirty-two patients (48%) died during the study period (median 7 months of follow-up).

Conclusion: Analysis of serum NfL facilitates the diagnosis of ICI-encephalitis, and focal encephalitis and PNS-related antibodies are associated with worse treatment response.

Disclosure: Nothing to disclose.

OPR-096 | Outcome and risk of relapse in GABAAR encephalitis

C. Papi[1]; C. Milano[2]; T. Iizuka[3]; M. Simabukuro[4]; L. Marmolejo[5]; E. Aguilar[5]; R. Iorio[6]; T. Armangué[7]; F. Graus[5]; J. Dalmau[5]; M. Spatola[5]

Background and aims: Autoimmune encephalitis with antibodies against γ-aminobutyric acid type A receptor (GABAAR) is characterized by prominent seizures and multifocal brain lesions. Limited data are available on relapse risk and long-term outcome. The study aim was to report clinical course and outcome of patients with GABAAR encephalitis.

Methods: Clinical information was obtained retrospectively from medical records. Patients were included if GABAAR antibodies were

identified by 2 techniques (rat brain tissue and live cell-based assays) in serum or cerebrospinal fluid.

Results: Nineteen patients with GABAAR encephalitis were included, 3 (16%) children and 16 (84%) adults. At onset, 17 (89%) patients developed seizures, evolving to status epilepticus in 12 (63%), alone or accompanied by other neurological symptoms, most commonly cognitive disturbances (74%). Tumor (mainly thymoma) was found in 11 (58%) patients. Brain MRI showed cortico-subcortical T2/FLAIR abnormalities in 15 (79%) patients and isolated cerebellar lesions in 2 (11%). Immunotherapy resulted in clinical improvement in 14/16 (88%) patients. Nine (47%) patients had clinical relapses (median 1, range 1–3 relapses), manifesting with seizures in 7 (78%). Older age was associated with clinical relapses ($p = 0.0206$). After a median follow-up of 19 months (range 1–59), 4 (21%) patients were dead, 6 (32%) completely recovered, and 9 (47%) partially recovered. Cognitive disturbances were the most frequent neurological sequelae (5/9, 56%). Overall, 10/11 (91%) patients were seizure-free at last follow-up, 9/10 (90%) on antiseizure medications.

Conclusion: In GABAAR encephalitis, relapses are not rare, often manifesting with seizure recurrence. Half of the patients are left with residual neurological deficits, mainly cognitive disturbances.

OPR-097 | Ataxia and movement disorders in autoimmune encephalitis and paraneoplastic neurological syndromes

J. Kerstens[1]; Y. Crijnen[1]; J. Brenner[1]; R. van Steenhoven[1]; M. de Bruijn[1]; A. van Sonderen[1]; M. van Coevorden-Hameete[1]; D. Bastiaansen[1]; M. Vermeiren[1]; J. de Vries[1]; S. Veenbergen[2]; P. Sillevis Smitt[1]; M. Titulaer[1]

[1]*Department of Neurology, Erasmus MC University Medical Centre, Rotterdam, The Netherlands;* [2]*Department of Immunology, Erasmus MC, University Medical Centre Rotterdam, Rotterdam, The Netherlands*

Background and aims: Movement disorders (MD) are well-recognized symptoms of autoimmune encephalitis (AIE) and paraneoplastic neurological syndromes (PNS). Although a large variety of MD has been described in different antibody-associated syndromes, the frequency of MD remains unknown for most antibodies. This knowledge is important to aid in early diagnosis and develop rational antibody testing strategies.

Methods: We reviewed a large cohort of all known Dutch patients with antibody-associated AIE/PNS ($n = 927$) to describe associated movement disorders (MD) and (cerebellar) ataxia. The most common antibodies were LGI1 ($n = 182$, 19.6%), NMDAR ($n = 166$, 17.9%), high-titer GAD65 ($n = 122$, 13.2%) and Hu ($n = 114$, 12.3%). Sensory ataxia and faciobrachiodystonic seizures were not considered MD.

Results: MD were present in 337/901 (37.4%) and were the first and/or predominant symptom in 193/297 (65.0%) and 214/297 (72.1%), respectively. Ataxia was by far the most common ($n = 159$, mainly Yo and GAD65), followed by stiff-person syndrome ($n = 50$, mainly GAD65 and GlyR) and chorea ($n = 35$, mainly NMDAR, IgLON5 and CV2). AIE/PNS associated with antibodies against Yo and Tr presented (almost) exclusively with MD (more specifically ataxia, in 29/30 and 4/4, respectively), while the lowest MD frequency was observed with GABAbR (7/59, 11.9%) and LGI1 (5/182, 2.7%).

Conclusion: MD are common in AIE and PNS, occurring in over a third of the patients. Their frequency varies greatly between subtypes. MD can be the first, predominant and even the only manifestation of these disorders. AIE and PNS should be in the differential diagnosis of new-onset MD, especially in the case of cerebellar ataxia and chorea.

OPR-098 | Demographic and HLA-related specificities in LGI1-antibody encephalitis

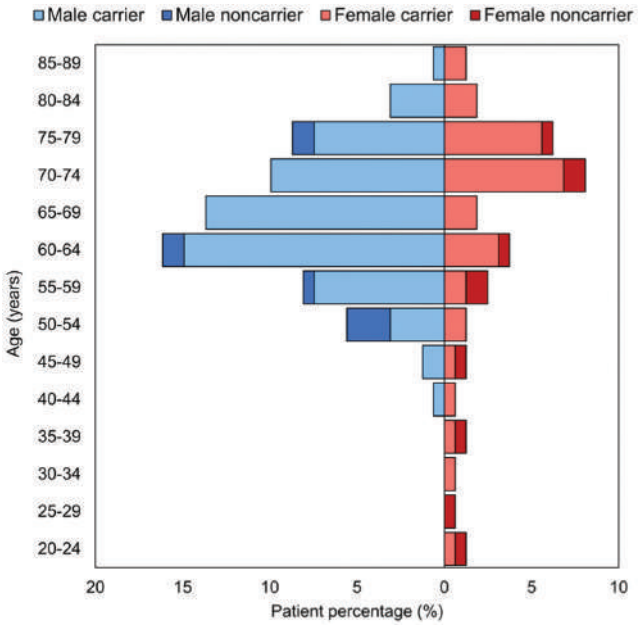
L. Campetella[1]; M. Villagrán-García[1]; A. Farina[1]; M. Villard[1]; M. Benaiteau[1]; N. Timestit[2]; G. Picard[1]; V. Rogemond[1]; B. Joubert[1]; J. Honnorat[1]; S. Muñiz-Castrillo[3]

[1]*French Reference Center for Paraneoplastic Neurological Syndromes and Autoimmune Encephalitis, Hospices Civils de Lyon, Lyon, France and MeLiS – UCBL-CNRS UMR 5284 – INSERM U1314, Université Claude Bernard Lyon 1, Lyon, France;* [2]*Department of Biostatistics, Hospices Civils de Lyon, Lyon, France;* [3]*Stanford Center for Sleep Sciences and Medicine, Stanford University, Palo Alto, CA, USA*

Background and aims: Patients with autoimmune encephalitis with leucine-rich glioma-inactivated 1 (LGI1) antibodies typically are older men and very often carry HLA-DRB1*07:01. Herein, we aimed to investigate clinical and prognostic features according to patients age, sex, and HLA carrier status.

Methods: Retrospective chart review of 224 patients with isolated LGI1-antibody positivity in serum and/or cerebrospinal fluid registered at the French Reference Center database. After computing percentiles of age distribution, patients were divided into three age subgroups: old, ≥79 years; typical, 52–78 years; young, ≤51 years. Poor outcome was defined as modified Rankin scale (mRS) >2.

Results: Among 224 patients, 148 (66%) were male, and 179 (80%) belonged to the typical age subgroup. In three-way comparisons, female sex ($p=0.003$) and temporal lobe seizures ($p<0.001$) were more common in the younger subgroup ($n=20$, 9%), while older patients ($n=25$, 11%) presented more frequently facio-brachial dystonic seizures ($p=0.034$) and had higher mRS both at nadir ($p<0.001$) and last follow-up ($p=0.001$). Non-DRB1*07:01 carriers ($n=19/161$, 12%) were more frequently female ($p=0.044$, Figure 1) and had poorer outcome ($p=0.021$). In a multivariate analysis, older age (odds ratio [OR]:1.12, 95% confidence interval [CI]: [1.05; 1.19]; $p=0.001$), female sex (OR: 3.4, 95% CI [1.07; 10.87]; $p=0.039$), and higher mRS at nadir (OR: 5.43, 95% CI [2.86; 10.3]; $p<0.001$) were independently associated with poor outcome, while carrying DRB1*07:01 was protective (OR: 0.04, 95% CI [0.007; 0.22]; $p<0.001$).



Population pyramid of the 161 patients with available HLA-DRB1*07:01 carrier status.

Conclusion: Clinical manifestations differ among age subgroups, whereas poor outcome is associated with certain demographic (older age and female sex) and genetic (non-DRB1*07:01 carrier status) features.

Disclosure: Macarena Villagrán-Garcia is supported by a research grant from Fundación Alfonso Martín Escudero (Spain).

OPR-099 | Predictors of annualized attack rates in AQP4-IgG+ NMOSD patients treated with rituximab or classical immunosuppression

Background and aims: Aquaporin-4-IgG-positive neuromyelitis optica spectrum disorder (AQP4-IgG+ NMOSD) primarily manifests with attacks of optic neuritis or myelitis. Immunosuppression can prevent attacks but may be associated with risks, e.g. infections. We compared the efficacy and risk of rituximab and classical immunosuppressive agents in AQP4-IgG+ NMOSD patients.

Methods: We compared annualized attack rates (AAR), infection rates (IR, infections per time) and laboratory parameters during rituximab (RIX), azathioprine (AZA), mycophenolate mofetil (MMF) and methotrexate (MTX) treatment cycles in a multicentric, retrospective cohort from the German Neuromyelitis Optica Study Group (NEMOS) registry.

Results: We analyzed 570 treatment episodes in 251 patients. Mean AAR during RIX treatment episodes was significantly lower than with AZA (0.24 vs. 0.61, $p<0.001$, Mann–Whitney U). The IR did not differ between RIX ($N=238$) and all other treatment episodes ($N=332$, 0.38 versus 0.44, $p=0.81$, Mann–Whitney U). We identified the IR, leukocyte count and IgM serum concentration as predictors for (higher) AAR. Time from diagnosis to treatment and sex showed no effect. During rituximab treatment episodes, higher neutrophil and B cell counts, and higher IgM serum concentration were associated with higher AAR.

Conclusion: Rituximab is associated with lower AAR, but not with higher infection rates than classical immunosuppressives. Whether the IR constitutes a risk factor for attacks needs to be evaluated prospectively.

OPR-100 | Topography of NREM oscillations is associated with circadian preference and rhythmicity

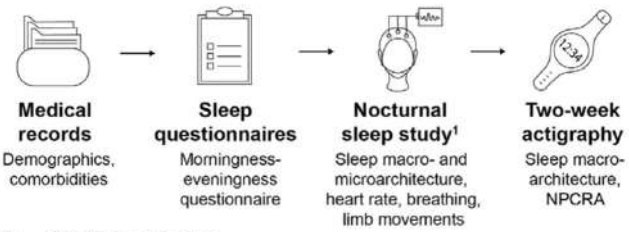
I. Filchenko[1]; A. Eberhard-Moscicka[2]; C. Gutierrez Herrera[3]; S. Bauer-Gambelli[1]; S. Duss[1]; C. Cajochen[4]; C. Bernasconi[1]; M. Schmidt[1]; C. Bassetti[1]

[1]*Department of Neurology, University Hospital, Inselspital, Bern, Switzerland;* [2]*Department of Psychology, University of Bern, Bern, Switzerland;* [3]*Department of Biomedical Research (DBMR), Inselspital University Hospital Bern, University of Bern, Bern, Switzerland;* [4]*Centre for Chronobiology, University Psychiatric Clinic Basel, Basel, Switzerland*

Background and aims: Homeostatic and circadian processes play a pivotal role in sleep regulation. However, little is known about the association of NREM oscillations with circadian rhythm characteristics accessed within clinical routine. This exploratory analysis aimed to comprehensively address this link.

Methods: This analysis is based on the pooled data from two observational studies and includes volunteers in good or excellent health condition (Eastern Cooperative Oncology Group grade of 0–1). Clinical history, circadian parameters (i.e., Morningness-Eveningness Questionnaire and actigraphy) and NREM sleep architecture (i.e., sleep spindle [SS] and slow wave [SW] density and morphology according to 256-electride electroencephalography) were assessed at study inclusion (Figure 1A). Association between NREM architecture as dependent variables and circadian parameters as independent variables were explored using multiple linear regression with adjustments for age and arousal index.

A. Study design



B. Study population

Parameter	Value
Age, years	29.00 [23.00, 35.52]
Female sex	37 (52.1)
MEQ, score	51.00 [46.00, 56.00]
Actigraphy	
Duration of actigraphy, days	14.00 [14.00, 14.00]
Time in bed, minutes	500.91 [457.80, 522.48]
SE, %	82.82 [77.11, 85.39]
Electroencephalography	
Assumed sleep, hours	7.94 [7.55, 8.33]
TRT, hour	8.43 [7.99, 8.95]
TST, hour	7.20 [5.92, 7.81]
SE, %	85.52 [76.89, 90.58]
Arousal index, /h	12.01 [4.25, 20.33]

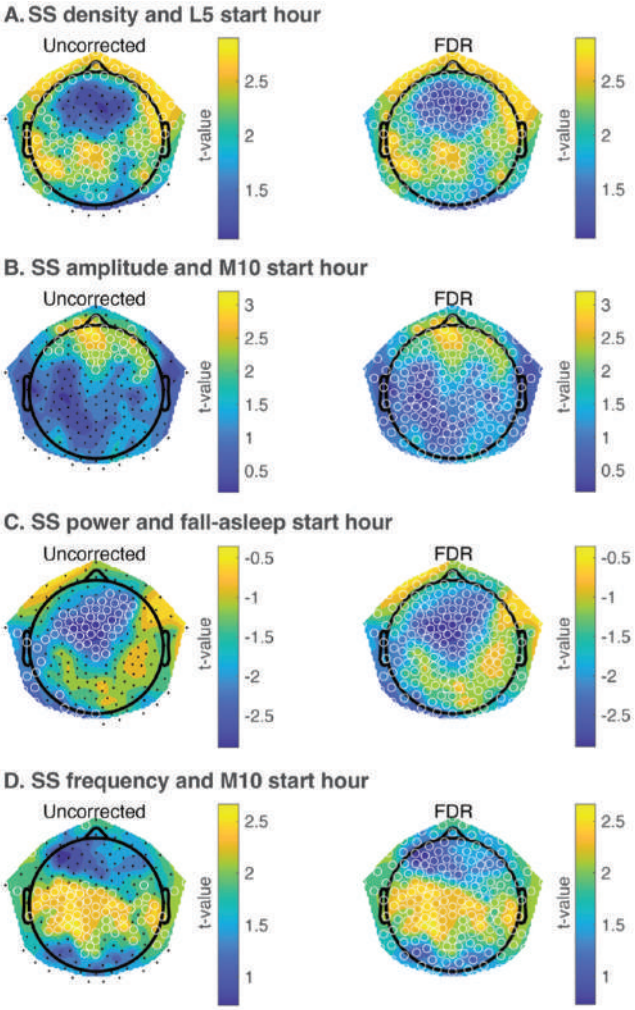
NREM2, %TST	44.57 [37.56, 49.69]
NREM3, %TST	19.79 [15.40, 24.83]
REM, %TST	21.39 [17.65, 24.10]

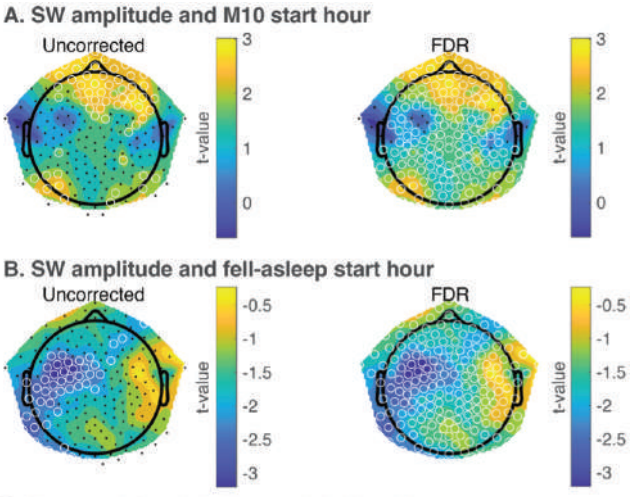
Abbreviations: MEQ – Morningness-Eveningness Questionnaire, NPCRA – non-parametric circadian rhythm analysis, NREM – non-rapid eye-movement sleep, PSG –polysomnography, REM – rapid eye-movement sleep, SE – sleep efficiency, TRT – total recording time, TST – total sleep time.

Results: Data of 71 participants was analyzed (age: median 29.0 interquartile range (IRQ) [23.0, 35.5] years old; 52% women; Figure 1B). SS were prevalently associated with circadian parameters (Figure 2; e.g., high SS density in posterior and pre-frontal regions vs. late L5 hour), whereas only limited associations between SW and circadian parameters were identified (Figure 3; e.g., high frontal SW amplitude vs. late M10 hours).



Significant associations (p<0.05) are marked with a circle.
Abbreviations: FDR - Storey False Discovery Rate, L5 - least five active hours, M10 - maximal ten active hours, SS - sleep spindles.

Selected associations between circadian parameters and sleep spindles.



Significant associations (p<0.05) are marked with a circle.
Abbreviations: FDR - Storey False Discovery Rate, M10 - maximal ten active hours, SW - slow waves.

Selected associations between circadian parameters and slow waves.

Conclusion: Circadian rhythm is associated with NREM oscillations in a domain- and topography-specific manner, with evening preference being linked to favourable electroencephalographic markers. This knowledge may serve as a basis for targeted interventions for sleep–wake disorders.

Disclosure: European Stroke Research foundation 2021 and Interfaculty Research Cooperation grant of the University of Bern "Decoding sleep".

OPR-101 | The impact of physical exercise and ketogenic diet on narcolepsy: A randomized, controlled trial

F. Tepel[1]; H. Cintosun[1]; D. Borth[1]; G. Lammers[2]; U. Kallweit[3]
[1]Centre for Narcolepsy and Hypersomnia, Clinical Sleep and Neuroimmunology, Institute of Immunology, University Witten/Herdecke, Germany; [2]Leiden University Medical Centre, Department of Neurology, Leiden, The Netherlands, and Sleep Wake Centre SEIN, Heemstede, The Netherlands; [3]Center for Narcolepsy and Hypersomnias, Clinical Sleep and Neuroimmunology, Institute of Immunology, University Witten/Herdecke, Germany and ORFEA Sleep Clinic, Witten, Germany

Background and aims: Narcolepsy treatment involves pharmacological and non-pharmacological therapies. This trial aimed to evaluate the efficacy of two specific non-pharmacological treatments for narcoleptics: regular physical activity and ketogenic diet, respectively.
Methods: In a 10-week trial on adults with type 1 narcolepsy (NT1), three groups were studied: regular physical activity, ketogenic diet, and control. Assessment included clinical data, treatments, Power Walking Test, and pre/post questionnaires. The sport group adhered to a training plan, keto group followed a high-fat, low-carb diet, and controls maintained routine. Questionnaires covered sleep, life quality, well-being, fatigue, recovery, and stress.
Results: In total, 60 patients (41 female, mean age: 34 years) with NT1 were randomized; 44 completed the study. ESS improved from 13.9 to 11 points ($p < 0.009$) in the sports group, and 16.3 to 13.2 points ($p < 0.005$) in the keto group. For controls, no significant change was found. PSQI improved from 9.3 to 6.6 points ($p < 0.005$) in the sports group only. Quality of life measures (WHO-5) improved from 12.3 to 15.8 points ($p < 0.027$) in the sports groups, and from 9.3 to 13.4 points ($p < 0.013$) in the keto group. Stress levels were reduced from 13.6 to 10.3 ($p < 0.007$) in the sports group.
Conclusion: Regular physical training or a ketogenic diet effectively reduce daytime sleepiness in narcolepsy. Quality of quality, well-being, and physical aspects of life quality are also improved by regular physical training in particular. These treatments offer a convenient, cost-effective, and efficient therapeutic option alongside pharmacological measures.

Disclosure: No disclosures.

OPR-102 | Widespread white matter axonal loss in narcolepsy type 1

J. Gool[1]; A. de Brouwer[1]; L. Shan[2]; J. Bol[3]; A. Hoogendoorn[4]; Y. van der Werf[3]; G. Lammers[1]; L. Jonkman[3]; R. Fronczek[5]; G. Schenk[3]
[1]*Stichting Epilepsie Instellingen Nederland (SEIN), Sleep–Wake Centre, Heemstede, the Netherlands;* [2]*Department Neuropsychiatric Disorders, Netherlands Institute for Neuroscience, an Institute of the Royal Netherlands Academy of Arts and Sciences, Amsterdam, The Netherlands;* [3]*Anatomy&Neurosciences, Amsterdam UMC location Vrije Universiteit Amsterdam, Amsterdam, The Netherlands;* [4]*Department of Psychiatry, Amsterdam UMC location Vrije Universiteit Amsterdam, Amsterdam, The Netherlands;* [5]*Department of Neurology, Leiden University Medical Centre, Leiden, The Netherlands*

Background and aims: Narcolepsy type 1 (NT1) is a debilitating neurological disorder marked by hypocretin deficiency (or orexin), causing excessive daytime sleepiness and cataplexy. Brain imaging studies have suggested global white matter irregularities in NT1, with unknown underlying histopathological correlates. Consistent with expected hypocretin projection patterns, the cerebellum was least affected. In a globally unique sample of human NT1 postmortem brain tissue, we assessed axonal and myelin integrity through immunohistochemical microscopy.

Methods: Postmortem brain sections from four NT1 donors and 10 controls were assessed for axonal density, axonal injury and myelin integrity. Regions of interest included subregions of the midbrain, corpus callosum, cortical regions (anterior cingulate and occipital cortex), and the cerebellum as a control region (Figure 1). Manual axon count and staining intensity assessed axonal density. Area percentage immunoreactivity of phosphorylated neurofilament chains evaluated axonal injury. Myelin integrity was assessed using staining intensity analyses.

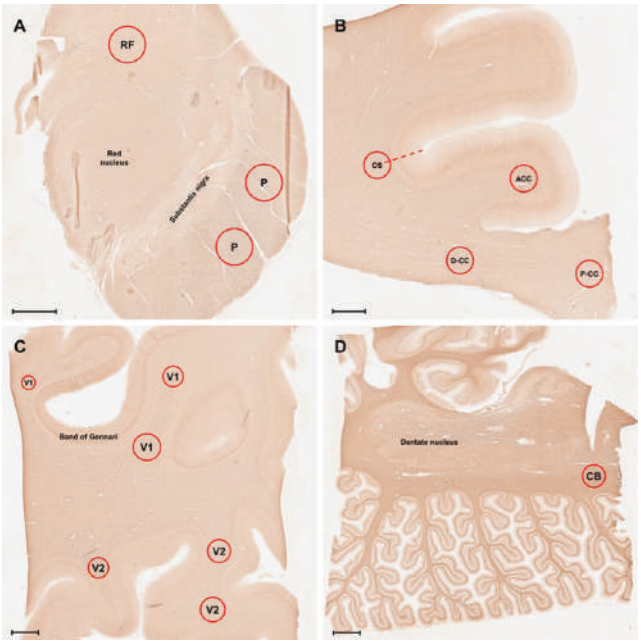


FIGURE 1 The regions of interest: (A) reticular formation and pyramidal tract, (B) proximal and distal corpus callosum, anterior cingulate gyrus and cingulate sulcus, (C) primary and secondary visual cortices, (D) cerebellum. Scale bar is 2 mm.

Results: Significantly reduced axonal density was observed in NT1 compared to controls in the reticular formation, pyramidal tract, corpus callosum and anterior cingulate gyrus (Figure 2). No significantly different axonal density was seen in the cerebellum nor in the axonal staining colour intensity, axonal injury and myelin integrity measures, except for lower secondary visual cortex myelin density in NT1.

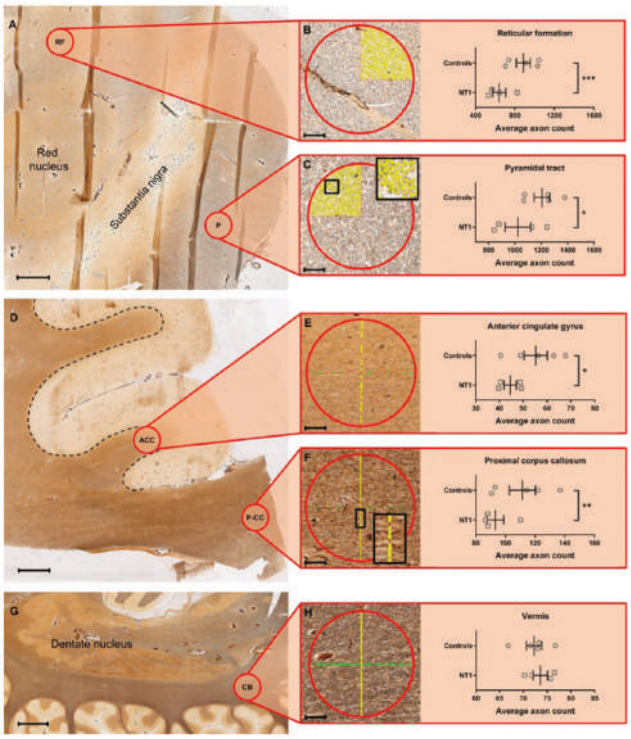

FIGURE 2 Axon counting results: (A–C) reticular formation (RF) and pyramidal tract (P), (D–F) proximal corpus callosum (P-CC), anterior cingulate gyrus (ACC), (G, H) cerebellum (CB). Scale bar is 2 mm for A, D, G and 100 μm for B, C, E, F, H.

Conclusion: In NT1, there is widespread lower axonal density within and outside the ascending reticular activating system. These results align with prior in-vivo brain imaging reports and typical hypocretin projection patterns, and may contribute to the pathophysiology of NT1, possibly stemming from hypocretin deficiency and/or chronic sleep–wake alterations.

Disclosure: Nothing to disclose.

OPR-103 | Sleep-related hypermotor epilepsy vs. disorders of arousal: Diagnostic interobserver reliability of homemade videos

L. Vignatelli[1]; L. Licchetta[1]; G. Maineri[1]; G. Loddo[1]; F. Baccari[1]; G. Bruschi[2]; L. Taruffi[2]; L. Nobili[3]; P. Tinuper[2]; F. Provini[1]; F. Bisulli[1]; on behalf of SHE-DOA Study Group[1]

[1]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy;* [2]*Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy;* [3]*Child Neuropsychiatry, IRCCS, G. Gaslini Institute, Department of Neuroscience (DINOGMI), University of Genoa, Genoa, Italy*

Background and aims: Video-polysomnography is the reference standard for diagnosing Sleep-related Hypermotor Epilepsy (SHE)1. However, it entails high hospitalization costs and it is not exempt from the possibility of failing to capture rare events. Homevideo recording (HVR) can help the diagnosis of SHE2 but its diagnostic value remains uncertain. This study aims to assess the reliability of HVR in distinguishing between SHE and NREM Disorders of arousal (DOA) among neurologists with different clinical expertise.

Methods: We selected HVRs (performed by caregivers in real-world setting) capturing 20 typical sleep-related events from 10 patients with SHE and 10 with DOA. Thirteen experts and 20 general neurologists were invited to classified each HVR as "SHE", "DOA" or "unknown", based on seizure semiology. The experts was then asked to discuss each case, providing agreed key semeiological features for diagnosis. Baseline interobserver reliability (IR) among raters, and among general neurologists before and after experts' discussion, was calculated using Kappa statistics.

Results: The global raw agreement was 74.9% ("moderate" IR, Kappa 0.54). Agreement among experts was 75.3% ("moderate" IR, Kappa 0.55). Among general neurologists agreement improved from 74.5% at baseline to 83.8% after training, corresponding to IR "moderate" (Kappa 0.54) and "substantial" (Kappa 0.69), respectively.

Conclusion: Baseline reliability of HVR for diagnosing SHE versus DOA was found globally moderate. Educational training, focused on behavior patterns, enhanced agreement among non-expert neurologists. These data highlight HVR as a reliable diagnostic tool in most cases for differentiating SHE from other paroxysmal non-epileptic manifestations, thereby reducing health care costs and disparities.

Background and aims: Orexin system mainly regulates sleep–wake cycle, but there is also growing evidence of its impairment in neurodegenerative diseases(NDs). In this study, we investigated cerebrospinal-fluid(CSF) orexin levels in patients with different NDs compared to non-demented controls. We included patients

with mild or moderate–severe Alzheimer's disease(mAD, msAD), behavioral variant of Frontotemporal Dementia(bv-FTLD), non-fluent primary aphasia(NFPA) and idiopathic normal pressure hydrocephalus(iNPH).

Methods: Patients and controls underwent between 2012 and 2015 a neurological assessment and a lumbar puncture for CSF biomarker analysis. We evaluated 76 AD(mAD = 45, msAD = 31), 34 FTLD(bv-FTLD = 12, NFPA = 22), 13 iNPH patients and 91 controls. CSF orexin levels were also correlated with β-amyloid42(Aβ42), total-tau(t-tau), phosphorylated-tau(p-tau) and clinical data.

Results: CSF concentrations of Aβ42, t-tau, p-tau and orexin were significantly different comparing all groups ($p < 0.001$). The highest CSF orexin levels were found in the iNPH (263.31 ± 56.89). NFPA (210.86 ± 61.99) and msAD (173.04 ± 19.76) showed higher CSF orexin concentrations compared to controls (145.18 ± 27.01) ($p < 0.001$). CSF orexin levels were similar between Bv-FTLD (190.12 ± 100.84), mAD (130.76 ± 21.70) patients and controls. Considering the correlation analysis, only in the controls the CSF levels of Aβ42 and t-tau correlated with orexin ($p = 0.014$; $p < 0.001$). Only in the mAD and msAD groups, Mini Mental State Examination scores correlated with CSF orexin levels ($r = -0.54$; $p < 0.001$; $r = -0.92$; $p < 0.001$; respectively).

Conclusion: This study documented significant differences in CSF orexin levels in NDs patients, with the highest levels in iNPH. Our findings highlight the possibility to add orexin to the CSF biomarker panel for the early identification of NDs causing cognitive impairment and dementia.

Disclosure: Nothing to disclose.

OPR-105 | Burden of illness study among patients with central disorders of hypersomnolence in France, Germany and Italy

Y. Dauvilliers[1]; G. Plazzi[2]; U. Kallweit[3]; S. Crawford[4]; L. Jönsson[5]; G. Kobelt[6]

[1]*Sleep-Wake Disorders Center, Department of Neurology, Gui-de-Chauliac Hospital, University of Montpelier, Montpellier, France;* [2]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy; Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy;* [3]*Center for Narcolepsy and Hypersomnias, Professorship for Narcolepsy and Hypersomnolence Research, Department of Medicine, Witten/Herdecke University, Witten, Germany;* [4]*Takeda Development Center Americas, Inc., Cambridge, MA, USA;* [5]*Karolinska Institutet, Solna, Sweden;* [6]*EHE International GmBH, St Moritz, Switzerland*

Background and aims: Narcolepsy type 1 (NT1) and 2 (NT2) and idiopathic hypersomnia (IH), are rare, chronic neurological disorders with a high disease burden; however, no studies have attempted to establish the relationship between patient burden and disease severity.

Methods: This cross-sectional, observational, anonymous online/email survey assessed patient burden for participants with NT1, NT2, and IH. Questions included demographics, work-force participation, disease symptoms, daily activities, coping strategies, resource consumption, and quality of life (QoL: EQ-5D-5L). Disease severity was assessed with a visual analog scale (VAS; range 0–10) and three validated instruments (Epworth Sleepiness Scale [ESS], Narcolepsy Severity Scale [NSS-CT], and Idiopathic Hypersomnia Severity Scale [IHSS]). Participants were recruited via clinical sites, patient associations, and registries across Europe.

Results: This interim analysis included 487 participants with complete disease severity data from the first three countries reaching enrolment targets. Mean (range) age was 37 (18–89) years. Mean (range) ESS scores were above normal for NT1/NT2 (15.0 [0–24]) and IH (13.2 [0–22]); self-reported disease severity ranged from 6.2 to 6.9 (VAS). Mean (range) NSS-CT scores were higher (greater severity) for NT1 (20.1 [0–47]) and NT2 (15.2 [1–34]) vs. IH (13.1 [0–40]); IHSS scores were higher (greater severity) for IH (32.4 [5–48]) vs. NT1 (27.0 [4–49]) or NT2 (28.7 [8–44]). Excessive sleepiness and daily naps were reported by 71% and 73%. 82% of participants were treated. Among 66% working participants, 70% reported disease affecting their work negatively. QoL was inversely related to disease severity.

Conclusion: These results illustrate the effect of narcolepsy/IH disease severity on patient-reported quality of life.

Disclosure: YD: Received funds for seminars, board engagements and travel to congresses from Avadel, Bioprojet, Idorsia, Jazz, Orexia, and Takeda GP: Received honoraria for board engagements from Bioprojet, Idorsia, Jazz, Orexia, and Takeda. Neuroimaging in neurodegeneration

OPR-106 | Motor reserve impact on nigrostriatal vulnerability and motor severity in Parkinson's disease

A. Galli[1]; A. Pilotto[1]; A. Rizzardi[1]; C. Zatti[1]; M. Ogliani[1]; A. Lupini[1]; C. Hansen[2]; R. Romijnders[2]; S. Caminiti[3]; E. Premi[4]; S. Lucchini[5]; F. Bertagna[5]; B. Paghera[5]; W. Maetzler[2]; M. Nucci[6]; S. Mondini[6]; A. Padovani[1]

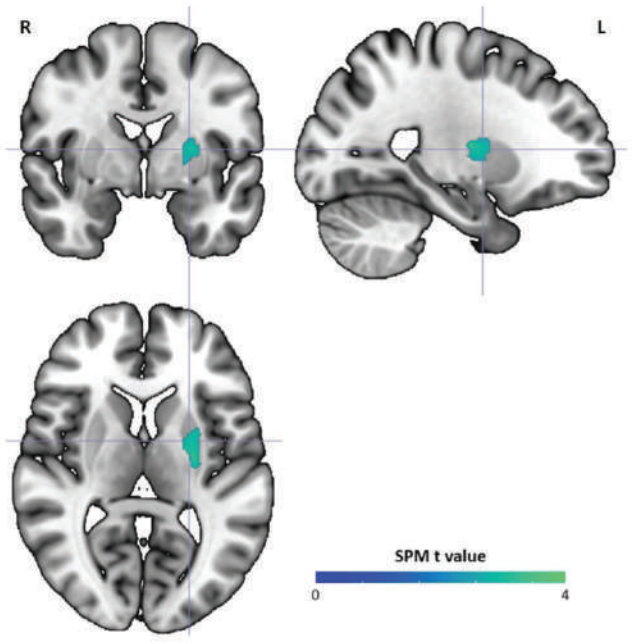
[1]*Department of Clinical and Experimental Sciences, University of Brescia, Italy;* [2]*Department of Neurology, University Hospital Schleswig-Holstein and Kiel University, Kiel, Germany;* [3]*Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy;* [4]*Stroke Unit, ASST Spedali Civili of Brescia, Italy;* [5]*Nuclear Medicine Unit, University of Brescia, Italy;* [6]*Department of General Psychology, University of Padua, Padua, Italy*

Background and aims: Increasing evidence supports beneficial effects of lifelong physical activities on cognition or mobility. Recently, motor reserve (MR) has been associated with a greater ability to cope with

normal or pathological motor-skill decline. This study investigated the possible impact of MR on dopamine binding and motor severity in early-diagnosed patients with Parkinson's Disease (PD).

Methods: Drug-naïve PD patients underwent cognitive and motor assessment- and 123I-FP-CIT-SPECT imaging. Gait parameters were evaluated in normal, fast and dual-task conditions using Mobile Health Technologies (MHT) in supervised setting. Motor Reserve Index questionnaire (MRIq) was administered and individuals were categorized into high-MR or low-MR. The relationship between MR and dopamine binding was assessed using a voxel-wise regression model. Clinical differences between high and low-MR patients were assessed using two-sample t-test, whereas differences in gait parameters were explored using a MDS-UPDRS-III, sex and height-adjusted ANCOVA model.

Results: Forty drug-naïve PD patients entered the study (age 68.35 ± 7.5). MR was negatively correlated with dopamine binding in left putamen and pallidum in the voxel-wise model. High vs.. low-MR PD had similar demographics, motor, and cognitive severity. Only in motor dual-task conditions, high-MR vs. low-MR PD showed lower step-time ($p = 0.002$), motor cost ($p < 0.001$), step-time variability ($p = 0.045$), and higher step-length ($p = 0.045$).



Voxel-wise regression showing negative correlation between MRIq and dopamine binding.

Conclusion: MR emerged as important modulator of dopamine nigrostriatal circuitries at onset of PD, with an impact on motor impairment and performances assessed by MHT. These mechanisms might explain the heterogeneity of progression and response to treatments in early disease phases and need to be verified in ongoing longitudinal studies.

Disclosure: Nothing to disclose.

OPR-107 | Nerve ultrasound in Friedreich's Ataxia

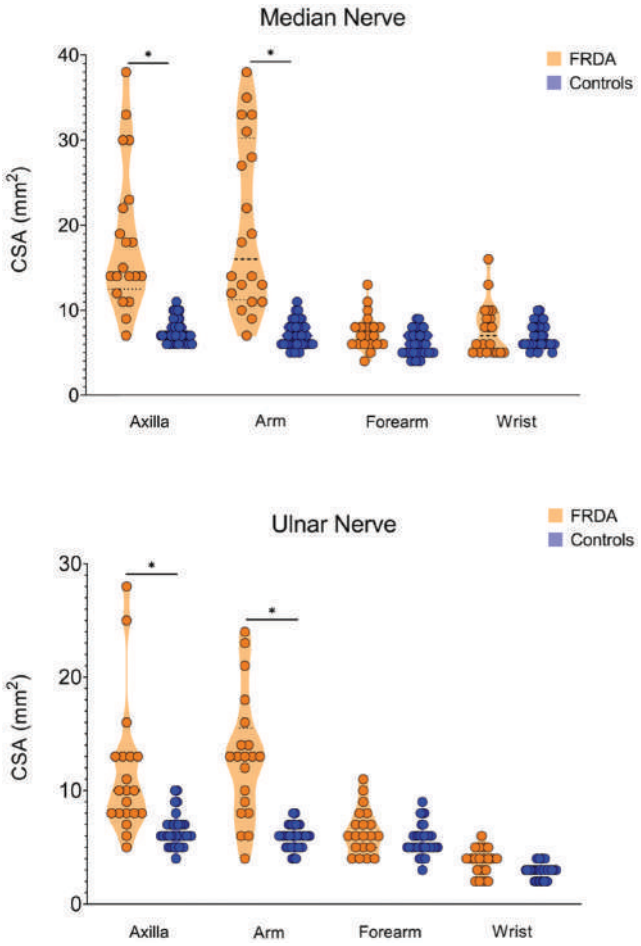
G. Di Pietro[1]; P. Falco[1]; E. Ciofffi[2]; E. Galosi[1]; G. De Stefano[1]; G. Di Stefano[1]; C. Leone[1]; V. Martines[3]; S. Perotti[4]; C. Casali[2]; A. Truini[1]

[1]Department of Human Neuroscience, Sapienza University, Rome, Italy; [2]Department of Medico-Surgical Sciences and Biotechnologies, University of Rome Sapienza, Latina, Italy; [3]Neuroradiology Department, Policlinico Umberto I, Rome, Italy; [4]Department of Radiological, Oncological and Anatomo-Pathological Sciences, Sapienza University of Rome, Italy

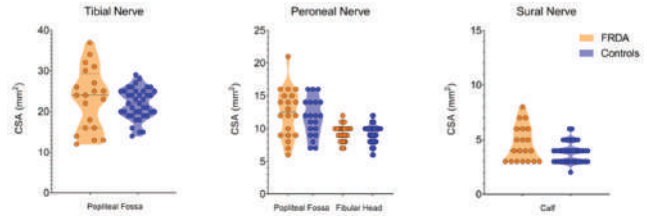
Background and aims: Friedreich's Ataxia (FRDA) is the most common hereditary ataxia, it is caused by GAA expansion of the FXN gene. Frataxin mutations lead to a damage of the Peripheral Nervous System producing a sensory neuropathy. The mechanism underling this manifestation is still a matter of debate. It is thought to be a ganglionopathy but alterations along the nerve have also been observed. In this study, we tested the usefulness of nerve ultrasound in the assessment of peripheral neuropathy in FRDA.

Methods: We prospectively enrolled 9 consecutive FRDA patients (39.3 ± 8.3 years, 2 Males). Anamnestic data, neurological examination (Scale for the Assessment and Rating of Ataxia (SARA), Activities of Daily Living (ADL 0–36) and Instrumental Activities of Daily Living (IADL)), Nerve Conduction Study (NCS) and peripheral nerves high-resolution ultrasound (HRUS) were collected. For each patient, 26 nerve sites were evaluated both quantitatively (Cross Sectional Area (CSA) assessment) and qualitatively. CSA values were compared with 20 healthy volunteers.

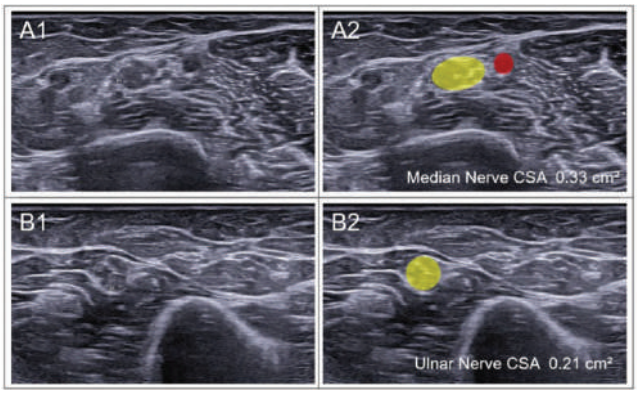
Results: In FRDA, HRUS showed a significant nerve enlargement of the Median and Ulnar nerves at the axilla and at the arm ($p < 0.001$). The cumulative count of affected nerve sites was directly associated with clinical disability, as assessed by SARA, ADL 0–36, and INCAT score, while displaying an inverse correlation with IADL.



Cross Sectional Area of Median and Ulnar nerves as assessed with high resolution nerve ultrasound examination in patients with Friedreich's ataxia (orange) and control participants (blue).



Cross Sectional Area of Tibial, Peroneal and Sural nerves as assessed with high resolution nerve ultrasound examination in patients with Friedreich's ataxia (orange) and control participants (blue).



High resolution nerve ultrasound examination showing an enlarged Median (A) and Ulnar (B) nerves at the arm in Friedreich's ataxia. Yellow circles indicate the nerves and red circles indicate the arteries.

Conclusion: Nerve ultrasound can detect alterations along the nerves in Friedreich's Ataxia. While NCS do not correlate with disease severity, HRUS shows a strong correlation with disease severity scores. Nerve ultrasound is a valuable tool in the assessment of Friedreich's Ataxia.

Disclosure: Nothing to disclose.

OPR-108 | Choroid plexus volume as a novel candidate neuroimaging marker of the Alzheimer's continuum: A prospective cohort study

J. Jiang; W. Li; S. Jiang; J. Xu
Beijing Tiantan Hospital, Capital Medical University, China

Background and aims: The clinical role and potential mechanisms of the choroid plexus (ChP) in Alzheimer's disease (AD) remains unclear.

Methods: This prospective cohort study enrolled 607 participants (110 HCs, 269 MCI, and 228 AD dementia). Relationship between ChP volume and CSF hallmarks (Aβ42, Aβ40, Aβ42/40, tTau, and pTau), neuropsychological tests (MMSE, MoCA, NPI, and ADL scores), and multimodal neuroimaging measures were analyzed. The mediating effects of ChP volume were examined on the relationship between CSF hallmarks and neuropsychological tests. The ChP volume performance to differentiate the presence/absence of cerebral Aβ42 deposition was determined using ROC analysis.

Results: The participants' mean age was 65.99 ± 8.79 years. Patients with AD dementia exhibited a larger baseline ChP volume than the other participants. ChP volume enlargement correlated with decreased Aβ42 and Aβ40 levels; lower MMSE and MoCA and higher NPI and ADL scores; lower volume, cortical thickness, and corrected cerebral blood flow in other cognition-related regions. ChP volume alone mediated and ChP–hippocampal volume combined chain mediated the association of CSF Aβ42 and Aβ40 levels with the MMSE scores (16.91%, 37.15%, 14.25%, and 27.82%, respectively). ChP volume better identified the presence/absence of cerebral Aβ42 deposition than hippocampal volume (AUC: 0.762 vs. 0.724). Generalized linear mixed-effects models discerned that baseline ChP volume was associated with subsequent decline and faster worsening in the MMSE, MoCA, and ADL scores with 10.03 ± 4.45 months' follow-up.

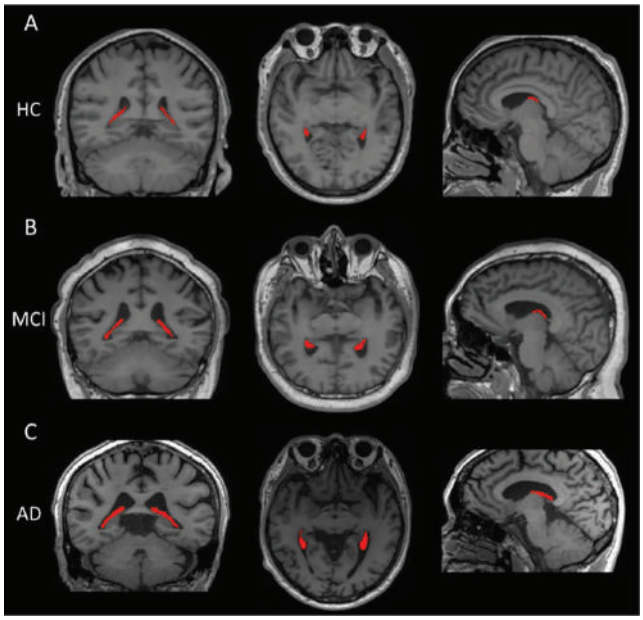


FIGURE 1 Comparisons among three representative 3D-T1 weighted images of the ChP volume in the three groups.

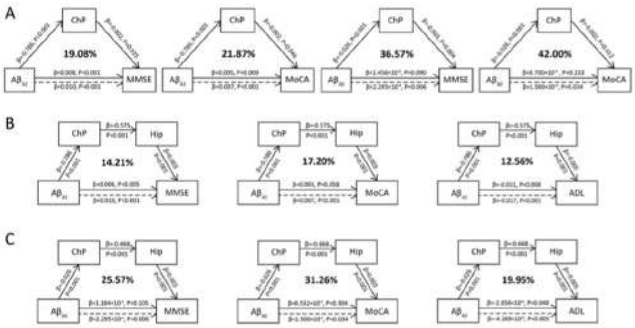

FIGURE 2 Simple and chain-mediating effects of ChP volume on the association of CSF hallmarks and neuropsychological tests.

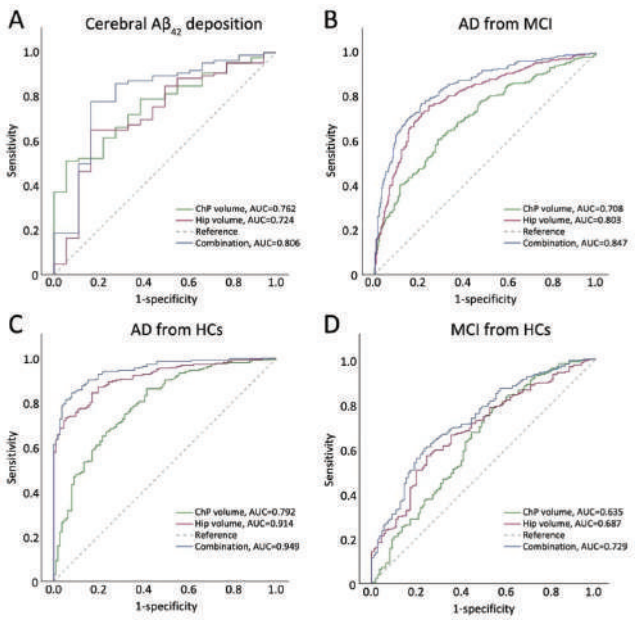

FIGURE 3 Receiver operating characteristic curves for choroid plexus and hippocampal volume for discriminating the absence/presence of cerebral pathological deposition, and distinguishing different disease stages.

Conclusion: ChP volume is a novel, candidate, non-invasive neuroimaging marker associated with neurodegenerative changes in Alzheimer's continuum. It can detect early cerebral Aβ42 deposition and predict prognosis in clinical practice.

Disclosure: Nothing to disclose.

OPR-109 | A data-driven and dynamic network connectivity approach differentiates atypical patterns in Alzheimer's disease

L. Pini[1]; L. Brusini[2]; A. Griffa[3]; F. Cruciani[2]; G. Allali[3]; G. Frisoni[4]; M. Corbetta[1]; G. Menegaz[2]; I. Boscolo Galazzo[2]

[1]Department of Neuroscience, University of Padova, Italy; [2]Department of Engineering for Innovation Medicine, University of Verona, Italy; [3]Leenaards Memory Center, Department of Clinical Neurosciences, Lausanne University Hospital, Lausanne, Switzerland; [4]Memory Clinic and LANVIE - Laboratory of Neuroimaging of Aging, University Hospitals and University of Geneva, Switzerland

Background and aims: From a macro-scale perspective, Alzheimer's disease (AD) can be conceptualized as a network-based syndrome, characterized by polysynaptic communication abnormalities assessed through functional magnetic resonance imaging (fMRI). The molecular hallmark of AD encompasses abnormalities involving amyloid-beta (A), tau (T) protein accumulation, and medial temporal lobe neurodegeneration (N).

Methods: In this study, we hypothesized that distinct ATN patterns would demonstrate specific spatiotemporal synchronization patterns measured using resting-state fMRI (rs-fMRI). We included individuals from the ADNI project. Dynamic functional connectivity (dFC) outcomes were measured using co-activation

patterns derived from the posterior cingulate cortex in 152 controls (74 ± 9 yrs) and projected to 334 patients (74 ± 10 yrs). ATN patterns were identified through a low-dimensional approach in conjunction with a K-means algorithm. Univariate, and multivariate approaches were applied to assess biological, behavioral, and dFC differences. Finally, we applied linear and non-linear classifiers to investigate whether dFC could predict ATN classifications.

Results: We identified three main ATN clusters. The first group displayed mild pathological alterations. The second cluster exhibited typical behavioral impairment alongside AD pathology. The third cluster demonstrated similar behavioral impairment but a divergent T (low) and N (high) pattern, suggestive of non-AD pathology. Univariate and multivariate analyses revealed two dFC patterns encompassing the default mode network and the occipito-temporal cortex linked, respectively, with typical and atypical ATN patterns. DFC exhibited an accuracy of approximately 90% in predicting ATN groups.

Conclusion: These results support the key association between macro-scale and molecular AD alterations. Notably, dFC markers can assist in identifying patients with AD-like clinical profiles but with different underlying pathologies.

Disclosure: Nothing to disclose.

OPR-110 | Is it time to utilise nerve ultrasonography in the journey of amyotrophic lateral sclerosis (ALS) diagnosis?

R. Abdelnaby[1]; A. Samy Shabib[2]; M. Hossam El Din Moawad[3]; T. Salem[4]; M. Wagih Youssef Awad[5]; P. Dawoud Awad[6]; I. Maallem[7]; H. Atwan[8]; S. Adel Rabie[9]; K. Ashraf Mohamed[10]; H. Abdelmageed[11]; M. Karkour[12]; M. Elsayed[13]; M. S. Cartwright[14]

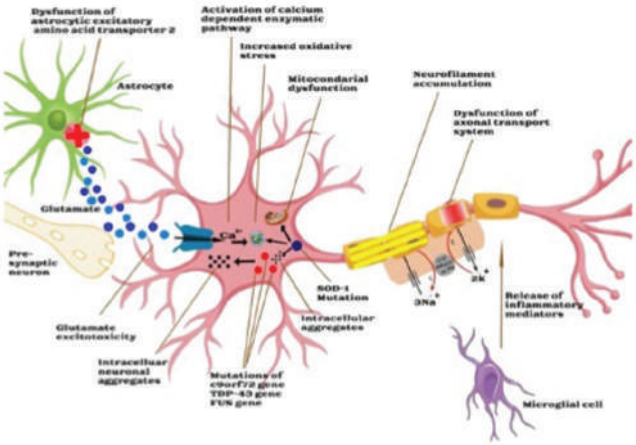
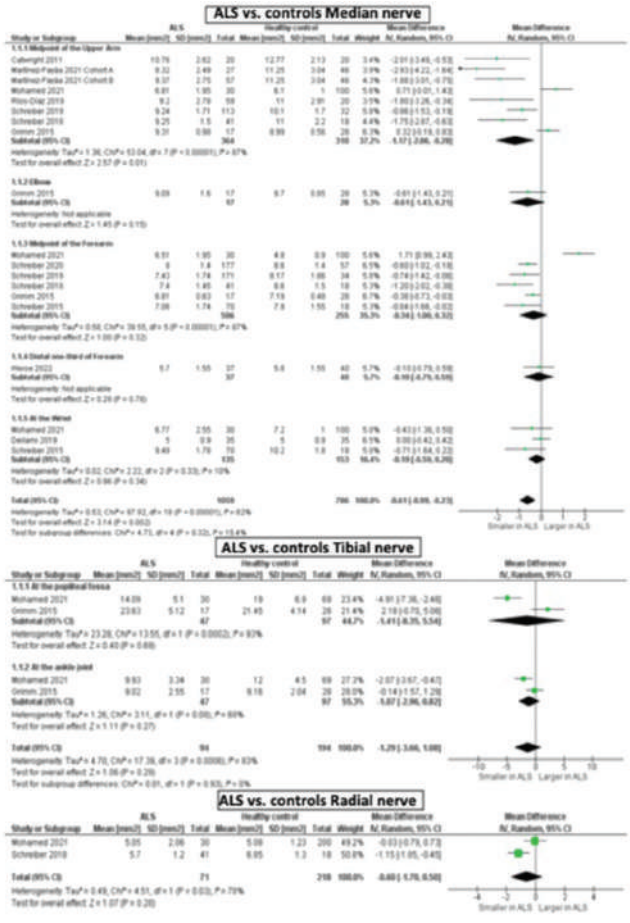
Background and aims: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease affecting upper and lower motor neurons, causing progressive atrophy of muscles, hypertonia, and paralysis. This study aimed to assess the difference in CSA of several peripheral nerves, vagus and cervical roots measured via US between ALS patients and healthy controls to identify the main nerves that have atrophy during ALS.



Dysfunction of the molecular pathway in ALS. (Figure created by BioRender).

Methods: A systematic search was conducted on Cochrane, Clarivate Web of Science, PubMed, Scopus, and Embase for the mesh terms nerve, ultrasonography, and amyotrophic lateral sclerosis. A quality assessment and a double-arm meta-analysis were performed.

Results: 17 studies with a total of 935 ALS patients and 604 controls were included in this review. The overall mean difference showed that individuals with ALS had a significantly smaller CSA in comparison to healthy controls for median, ulnar, C6 root, and phrenic nerves. However, no significant difference in the CSA was found in radial, vagal, sural and tibial nerves.



Mean difference of bilateral median, tibial and radial nerves CSAs between ALS patients and healthy controls.

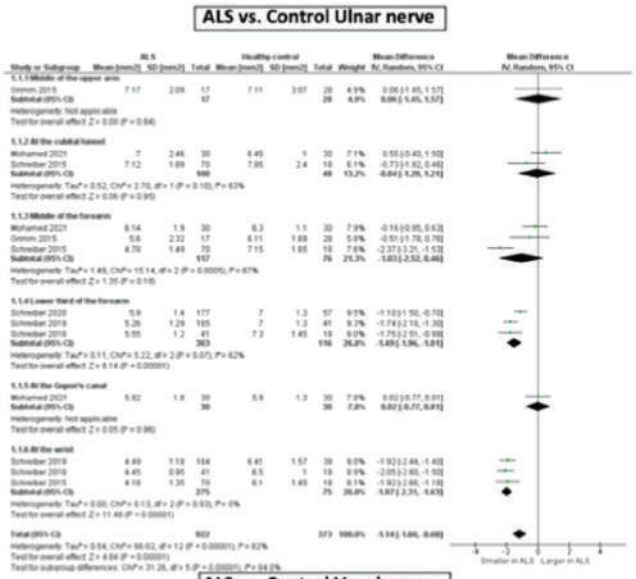


Table 3. Mean difference of CSA values for nerves reported by single studies.

Study	Nerve measured	Controls Mean (mm^2)	Controls SD	Controls Number	ALS Mean (mm^2)	ALS SD	ALS Number	MD (mm^2)	P
Noderu2014	C6 root	7.6	1.6	37	5.34	1.6	35	2.26	<0.001
Suratov2021	Phrenic (Rt)	1.62	0.45	28	1.08	0.39	38	0.54	<0.00001
	Phrenic (Lt)	1.39	0.31	28	1.02	0.34	38	0.37	<0.00001

Mean difference of bilateral ulnar, vagal, C6 root and phrenic nerves CSAs between ALS patients and healthy controls.

Conclusion: Our results confirmed anatomic sites to potentially differentiate individuals with ALS from healthy controls such as the median nerve at the mid-arm and the ulnar nerve at the wrist and the lower third of the forearm.

Disclosure: Nothing to disclose.

Headache & pain 2

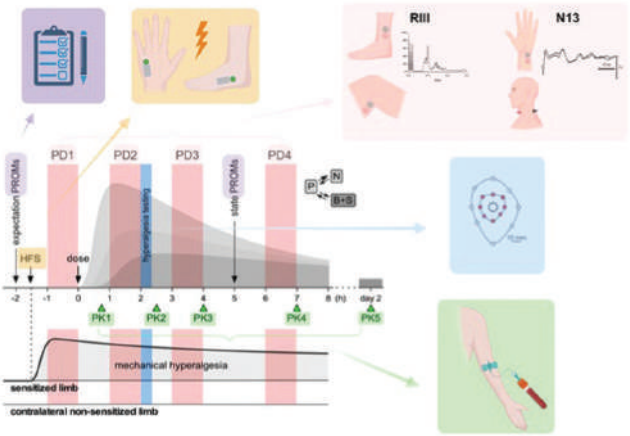
OPR-111 | **Evaluating the impact of lacosamide, pregabalin, and tapentadol on spinal biomarkers in human subjects**

C. Leone[1]; G. Di Pietro[1]; O. Caspani[2]; A. Mouraux[4]; L. Garcia Larrea[3]; R. Treede[2]; A. Truini[1]

[1]*Department of Human Neuroscience, Sapienza University of Rome;* [2]*Mannheim Faculty of Medicine, Heidelberg Univerrsity;* [3]*NeuroPain Lab, Lyon Centre for Neuroscience, INSERM U1028, Neurological Hospital of Lyon & University Claude Bernard, Lyon, France;* [4]*Institute Of NeuroScience (IONS), UC Louvain*

Background and aims: The BioPain subtopic of IMI-PainCare project aimed to test the effectiveness of selected biomarkers for evaluating drug effects and target interactions in new analgesic development. Within this framework, the BioPain-RCT2 assessed the efficacy of lacosamide, pregabalin, and tapentadol against placebo on neurophysiological spinal biomarkers, specifically the RIII flexion reflex and the cervical N13 component of somatosensory evoked potentials, under normal and hyperalgesic conditions induced by high-frequency electrical skin stimulation (HFS).

Methods: A multi-center, double-blind, placebo-controlled 4-period, 4-way crossover pharmacodynamic and pharmacokinetic study in healthy subjects. Spinal biomarkers were measured before and at three time points after administering the three medications and placebo. The study evaluated drug effects on neurophysiological responses in induced hyperalgesia and normal states. It included blood samples for PK analysis. The primary statistical analysis focused on changes in RIII area and N13 amplitudes under tapentadol, with secondary analyses on other treatments' impacts.



Experimental design.

Results: Three different centres enrolled 24 subjects. The blinded analysis showed an effect of tapentadol on the R3 area and a trend towards the significance of pregabalin at the sensitized side, not reaching the set significance level (0.025). No significant effect of drugs on the N13 was observed. Exploratory analysis showed drug effects on the RIII threshold compared to placebo, with tapentadol and PGB also affecting pain ratings.

Conclusion: Tapentadol, and to a lesser extent Pregabalin, prevent the spinal excitability changes induced by secondary hyperalgesia models as assessed with the RIII reflex. This experimental design failed to identify a significant effect of tapentadol on the sensitized N13.

OPR-112 | Brain connectivity changes induced by monoclonal antibodies targeting the CGRP pathway in migraine patients

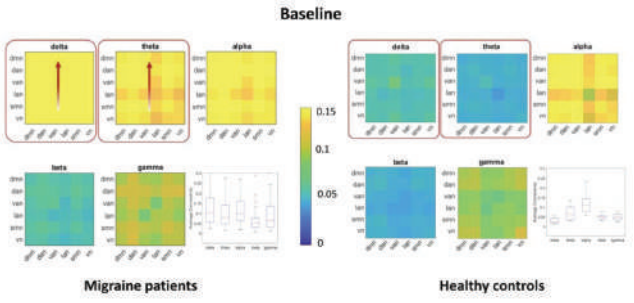
E. Mazzotta[1]; R. De Icco[1]; M. Corrado[1]; V. Grillo[1]; G. Vaghi[1]; F. Cammarota[1]; F. Bighiani[1]; M. Semprini[3]; A. Putorti[1]; D. Martinelli[1]; M. Allena[2]; G. Sances[2]; C. Tassorelli[1]

[1]Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; [2]Headache Science & Neurorehabilitation Unit, IRCCS Mondino Foundation, Pavia, Italy; [3]Italian Institute of Technology, Genova, Italy

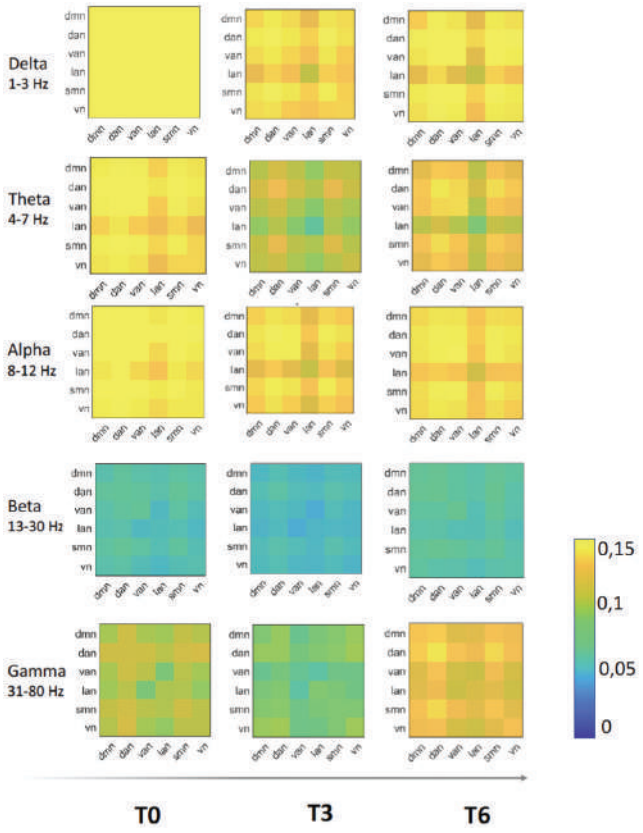
Background and aims: Previous studies demonstrated central and peripheral changes related to monoclonal antibodies directed against the CGRP pathway (mAbs) administration, without reaching a consensus on their mechanism of action. Our study aims to evaluate differences in resting state networks (RSNs) connectivity in migraine patients (MiG) undergoing mAbs treatment.

Methods: This is a prospective, real-life, open label study based on three HD-EEG recordings, namely T0 at baseline, T3 and T6 after 3 and 6 months of mAbs treatment. We assessed connectivity for separate frequency bands (alpha, beta, gamma, theta and delta) for six RSNs: default mode network (DMN), dorsal and ventral attention networks (DAN-VAN), language network (LAN), somatomotor network (SMN) and visual network (VN). We also performed a single HD-EEG assessment in healthy controls (HCs).

Results: We evaluated 62 migraine patients (age 45.4 ± 12.0 years, 54 females, 56.4% with chronic migraine) and 32 HCs (age 38.0 ± 14.0, 16 females). At T6, 62.9% of patients qualified as Responders (reduction in MMDs ≥50% when compared to baseline). At baseline, migraine patients presented an enhanced connectivity in delta and theta frequency bands compared to HCs for all analysed RSNs. At T6, connectivity in the delta and theta bands became comparable between Responders and HCs, while Non-responders maintained higher connectivity in the delta and theta bands compared to both HCs and Responders.

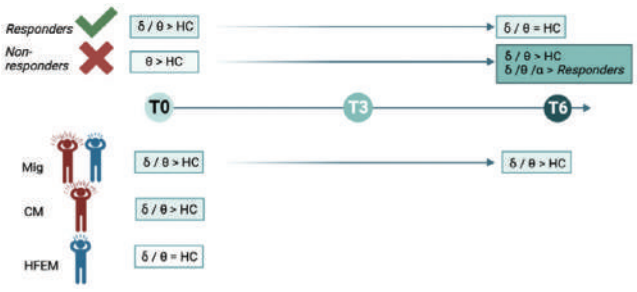


Comparison of inter-network connectivity between migraine patients and healthy controls at baseline. Average RSN connectivity is reported in the box and whiskers plot with median connectivity values for each band and related interquartile ranges.



Longitudinal inter-network seed-based connectivity analysis. Comparison between migraine patients in different treatment timepoints (T0: baseline, T3: 3 months of mAbs treatment, T6: 6 months of mAbs treatment). Coding is color-based ranging from blue, re.

Conclusion: Our study demonstrated an enhanced slow frequencies whole-brain connectivity in migraine patients. Treatment with anti-CGRP monoclonal antibodies induced a positive modulation of functional connectivity in the delta and theta bands in Responder patients.



Summary of study findings. Mig: migraine patients, CM: chronic migraine, HFEM: high frequency episodic migraine patients.

Disclosure: Nothing to disclose.

OPR-113 | Role of specific microRNAs in cluster headache: correlation with disease phenotype and neuropeptide levels

F. Cammarota[1,2]; R. De Icco[1,2]; F. Bighiani[1,2]; M. Corrado[1,2]; G. Vaghi[1,2]; A. Antoniazzi[1,2]; E. Mazzotta[1,2]; V. Grillo[1,2]; R. Greco[1,2]; C. Demartini[1,2]; A. Zanaboni[1,2]; M. Francavilla[1,2]; S. Franchini[1,2]; M. Allena[1,2]; G. Sances[1,2]; C. Tassorelli[1,2]

[1]*Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy;* [2]*Headache Science and Neurorehabilitation Unit, IRCCS Mondino Foundation, Pavia, Italy*

Background and aims: The role of specific microRNAs was studied in episodic and chronic migraine, but their possible involvement in cluster headache is yet to be elucidated. Our objective is to evaluate the role of specific microRNAs in episodic cluster headache in active phase (AeCH), remission phase (ReCH), chronic cluster headache (cCH), and healthy controls (HCs).

Methods: In this cross-sectional study, we assessed gene expression of miR-382-5p, miR-34a-5p, and miR-155 in peripheral blood mononuclear cells (Relative Quantification). AeCH and cCH patients were assessed outside of an acute cluster headache attack.

Results: We enrolled 18 AeCH (45.7 ± 12.8 years, 14 males, 16.3 ± 9.6 attacks/week), 7 ReCH (48.6 ± 19.8 years, 5 males), 10 cCH (50.1 ± 16.2 years, 9 males, 21.4 ± 18.8 attacks/week), and 14 HCs (45.4 ± 15.2 years, 2 males). miR-382-5p expression was higher in AeCH (1.7 ± 0.8) when compared to ReCH (0.8 ± 0.2) and HCs (0.3 ± 0.1) ($p < 0.005$ for all comparisons). miR-34a expression was higher in AeCH (1.7 ± 0.4) when compared with ReCH (1.0 ± 0.3), cCH (1.2 ± 0.3) and HCs (0.5 ± 0.2) ($p < 0.001$ for all comparisons). miR-155 expression was lower in HCs (0.4 ± 0.1) compared to all CH subgroups ($p = 0.001$ for all comparisons), with no difference among AeCH (1.7 ± 0.5), ReCH (1.3 ± 0.3) and cCH (1.3 ± 0.5).

Conclusion: miR-382-5p, miR-34a-5p and miR-155 expression is increased in cluster headache when compared to HCs. MiR-382-5p and miR-34a-5p were associated with disease activity, being higher in AeCH patients when compared to ReCH. MicroRNAs expression of cCH was in-between active and remission phases of episodic cluster headache patients. Our data supports the role of specific microRNAs in the pathophysiology of different primary headaches.

OPR-114 | Evaluation of perivascular and extracellular space properties in migraine: A potential index for glymphatic clearance

R. Messina[1]; F. Genovese[1]; E. Pagani[2]; I. Cetta[1]; L. Zanandrea[1]; B. Colombo[3]; M. Rocca[1]; M. Filippi[1]

[1]*Neurology Unit and Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy;* [2]*Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [3]*Neurology Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy*

Background and aims: The glymphatic system is a network of perivascular spaces (PVS) that facilitates fluid exchange and peptide clearance in the brain. We aim to investigate if glymphatic dysfunction contributes to migraine pathophysiology, and examine its variations between patients studied during the interictal phase and those studied while experiencing headache.

Methods: One hundred twenty migraine patients (95 interictal, 25 with headache) and 53 controls underwent diffusion tensor (DTI) and susceptibility weighted (SWI) magnetic resonance imaging. Using DTI and SWI, we computed the Diffusion Along Perivascular Space (DTI-ALPS) index, reflecting diffusivity in the PVS near the left lateral ventricle. This index serves as a proxy for regional glymphatic function. Based on previous evidence showing an association between glymphatic function and changes within intra/extracellular compartments, we employed neurite orientation dispersion and density imaging to evaluate voxel-wise maps of white matter extracellular (EVF) and intracellular (IVF) volume fraction. Thus, providing a comprehensive insights into the glymphatic system functioning. Age- and sex-adjusted between-group comparisons were run using R and FSL software.

Results: Compared to controls, migraine patients were older (mean age: patients 39 (12), controls 41 (14), $p = 0.02$) and had a higher proportion of female subjects (female: patients 82, controls 24, $p = 0.006$). We found no significant differences between patients and controls, neither concerning the DTI-ALPS index nor regarding EVF and IVF. No differences were even observed between subgroups of patients.

Conclusion: These results suggest the absence of abnormalities in the PVS and white matter extracellular compartment, indicating normal functioning of the glymphatic system in migraine.

Disclosure: Nothing to disclose in relation to this work.

OPR-115 | Defining mechanisms and new treatments for headache in raised intracranial pressure

O. Grech[1]; E. Rubio-Beltran[2]; E. Stanyer[3]; A. Labastida-Ramirez[2]; G. Lavery[4]; L. Hill[5]; P. Holland[2]; A. Sinclair[1]

[1]*Institute of Metabolism and Systems Research, College of Medical and Dental Sciences, University of Birmingham, Birmingham, UK;* [2]*Headache Group, Wolfson Sensory, Pain and Regeneration Centre,*

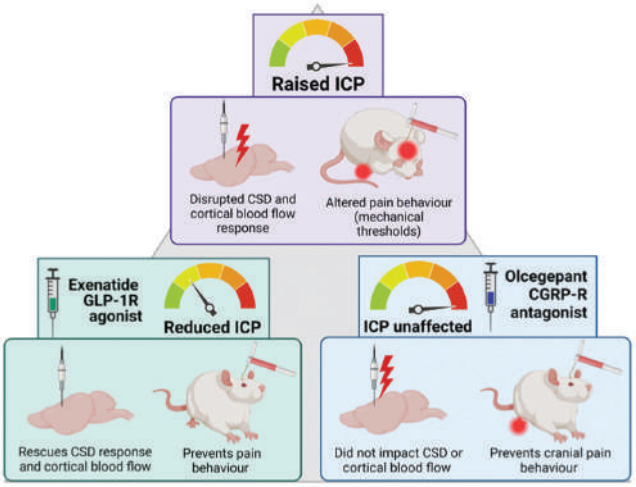
Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UK; [3]Sleep and Circadian Neuroscience Institute, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, UK; [4]Centre for Systems Health and Integrated Metabolic Research, Department of Biosciences, School of Science and Technology, Nottingham Trent University, Clifton Campus, Nottingham, UK; [5]School of Biomedical Sciences, Institute of Clinical Sciences, University of Birmingham, Birmingham, UK

Background and aims: Elevated intracranial pressure (ICP) is associated with migraine-like headaches, but the mechanisms are unclear. Glucagon-like peptide-1 (GLP-1) receptor agonism can reduce ICP, while migraines are associated with increased calcitonin gene-related peptide (CGRP), and therapeutic benefits are observed with CGRP blockade. We investigated migraine mechanisms in a raised ICP rat model, investigating the effects of GLP-1 receptor agonism and CGRP inhibition on ICP and nociception.

Methods: A validated rat model with intracisternal kaolin injection hindering CSF drainage was used. Mechanical hyperalgesia via von Frey filament testing, steady-state potential and cortical blood flow responses to cortical spreading depression (CSD) were assessed. Responses were investigated following treatment with GLP-1 receptor agonist exenatide or CGRP receptor antagonist olcegepant.

Results: Kaolin increased ICP [median(range) 15.96 mmHg (8.97) $n=8$] controls [6.02 mmHg (1.79) $n=6$ $p=0.0007$]. Mechanical thresholds were reduced in raised ICP (mean(SD) hind paw baseline: 5.78 g (2.81), day 7 3.34 g (2.22) $p<0.001$, periorbital baseline: 6.13 g (2.07), day 7 2.35 g (1.91) $n=12$ $p<0.001$). Raised ICP drastically altered CSD responses [depolarisation duration raised ICP: 108.81 s (222.12) $n=11$, controls 37.54 s (108.38) $n=9$ $p=0.038$, repolarisation duration raised ICP: 1824.26 s (3499.54) $n=12$, controls 86.96 s (140.05) $n=9$ $p<0.0001$]. CBF change was also reduced (85.55% (30.84) $n=9$) versus controls (217.64% (37.70) $n=8$ $p<0.0001$).

Conclusion: These data suggest that elevated ICP results in mechanical hyperalgesia, a sign of cutaneous allodynia. GLP-1 receptor agonism reduced ICP, prevented changes in mechanical thresholds and restored responses to CSD. CGRP receptor antagonism prevented periorbital pain behaviour, indicating a potential role for CGRP in driving pain responses associated with elevated ICP.



Increased ICP resulted in mechanical hyperalgesia and altered CSD responses. Reducing ICP via GLP-1 receptor agonism restored mechanical thresholds and CSD responses, while CGRP receptor antagonism prevented periorbital pain behaviour.

Ageing and dementia 1

EPR-001 | Five-year hospital readmission rates of older patients with or without use of central nervous system depressant medications

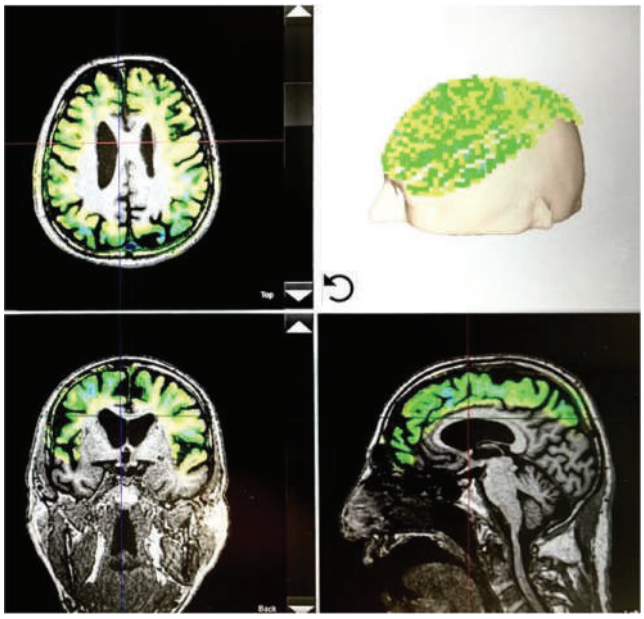
T. Breines Simonsen[1]; M. Torheim Bjelkarøy[1]; T. Ghazal Siddiqui[1]; S. Cheng[1]; C. Lundqvist[2]
[1]*Health Services Research Unit, Akershus University Hospital;* [2]*Health Services Research, Akershus University Hospital and Inst. Clin. Med, University of Oslo, Norway*

Background and Aims: Older patients are particularly sensitive to inhibitory CNS effects of prescription drugs, and are more often afflicted by multimorbidity and polypharmacy, which may augment these issues. We have shown associations between use of CNS depressant drugs (CNSDs) and cognitive function, quality of life, multimorbidity and mortality. In this prospective longitudinal follow-up study, we examined hospital readmissions among older patients in relation to their use of CNSDs (opioids, sedatives and hypnotics).
Methods: Consecutively recruited patients aged 65–90 among inpatient admissions to medical departments of a large university hospital. Written informed consent was a pre-requisite. Medication information and sociodemographics were collected and patients were tested using validated cognitive instruments, quality of life scales and pain assessments. Follow-up was over 5 years from index admission, surviving patients were reassessed in person, mortality data and readmissions data were accessed through electronic patient records.
Results: 246 patients were included (56% females). 100 were CNSD users, 146 non-users. Age at inclusion was 75 (95% CI 74–76) for non-users and 79 (CI 77–80) for users ($p < 0.001$). At 5-year follow-up, 52% had died with significantly higher mortality among CNSD users. Females were more commonly CNSD users ($p < 0.001$). There was no difference in readmissions (number of readmissions or total number of readmission days) between users and non-users whether or not analysis was performed on all included patients or only on those that were alive after 5 years.
Conclusion: CNSDs use was associated with mortality but not readmissions.
Disclosure: Research funding by Lundbeck Pharma and various lecture honoraria are acknowledged.

EPR-002 | Safety and efficacy of transcranial pulse stimulation in Alzheimer's disease

A. Günes; M. Beglau; M. Köhne; U. Sprick
Department of Brain Stimulation, Alexius/Josef Hospital, Neuss, Germany

Background and Aims: Alzheimer's disease (AD) is the most common form of dementia worldwide. Recently, transcranial pulse stimulation (TPS) has opened up the possibility of non-invasive brain stimulation using focussed ultrasound pulses. Since 2022, we have been one of the first centers worldwide using TPS and present the data collected so far.
Methods: Dementia screening was carried out on the basis of the currently valid German guideline. Each of our patients received six therapy sessions within two weeks with an energy amount of 0.2 mJ/mm^2 per individual pulse and a total number of 6000 pulses/session. Thanks to 3D navigation based on MRI images, pulses were applied individually bilaterally to the frontal, parietal and temporal cortex. We have treated a total of 86 patients with AD to date. The Color–Word Interference Test (Stroop Test) with the following pre/post design was used in 52 patients for close monitoring of executive function and working memory: t0 pre-stimulation, t1 after 6 treatments.
Results: The mean age was 75.8 years (54% female) with an average Mini Mental State Examination score of 21.8 points. 82% patients were able to maintain or improve their speed in the Stroop Test. No long-term side effects were observed in any patient.
Conclusion: We conclude that with the help of TPS, an improvement in cognitive deficits in patients with AD is possible. The present study is the largest data collection on this topic to date. Sham-controlled trials with larger samples are needed to prove the effectiveness of the treatment in patients with AD.



3D neuronavigation of TPS.

EPR-003 | Plasma p-tau217 as a useful biomarker to track AD progression in non-demented persons

A. Mendes[1]; F. Ribaldi[1]; A. Lathuiliere[1]; N. Ashton[2]; S. Janelidze[3]; H. Zetterberg[2]; M. Scheffler[4]; F. Assal[5]; V. Garibotto[6]; K. Blennow[2]; O. Hansson[3]; G. Frisoni[1]

[1]Laboratory of Neuroimaging of Aging (LANVIE), University of Geneva, Geneva, Switzerland; [2]Department of Psychiatry and Neurochemistry, Institute of Neuroscience & Physiology, the Sahlgrenska Academy at the University of Gothenburg, Mölndal, Sweden; [3]Clinical Memory Research Unit, Lund University, Sweden; [4]Division of Radiology, Geneva University Hospitals, Geneva, Switzerland; [5]Division of Neurology, Department of Clinical Neurosciences, Geneva University Hospitals and Faculty of Medicine, University of Geneva, Geneva, Switzerland; [6]Laboratory of Neuroimaging and Innovative Molecular Tracers (NIMTlab), Geneva University Neurocenter and Faculty of Medicine, University of Geneva, Geneva, Switzerland

Background and Aims: Plasma biomarkers have been investigated to assess their efficacy in the early identification of Alzheimer's disease (AD). This is especially significant during the pre-dementia stages to enable a prompt intervention. Thus, the goal of this study was to test differences in plasma biomarkers between the cognitively unimpaired (CU) and mild cognitive impairment (MCI) groups and evaluate how they correlated with the traditional biomarkers in a Geneva Memory Center non-demented cohort.

Methods: The sample consisted of 100 subjects (CU = 33; MCI = 67). Plasma (p-tau217, p-tau231, p-tau181, GFAP, and NfL), amyloid-PET centiloid, tau-PET SUVr, and MRI (hippocampal volume) from these people were used in the study. The differences between CU and MCI in plasma biomarkers were addressed using Mann–Whitney tests. Additionally, we calculated the association between plasma and traditional biomarkers using Pearson correlation.

Results: All plasma biomarkers, except p-tau231, demonstrated statistically significant differences between CU and MCI ($p < 0.05$). However, p-tau217 revealed a higher effect size ($\delta = 0.95$) between clinical stages in comparison with other biomarkers (δrange = 0.25–0.41). Likewise, p-tau217 showed the highest correlation coefficient with centiloid ($r = 0.63$) and tau-SUVr ($r = 0.79$). For the hippocampal volume, p-tau181 revealed the highest correlation ($r = -0.42$).

Conclusion: Plasma p-tau217 showed higher disparities between CU and MCI individuals, as well as higher correlations with centiloid and tau-SUVr. This implies that p-tau217 could serve as a valuable indicator for monitoring the AD progression, as it exhibits a stronger association with conventional measures.

Disclosure: Nothing to disclose.

EPR-004 | Cognitive decline associated to baseline plasma NfL, p-tau217 and tau-PET SUVr in mild cognitive impairment subjects

A. Mendes[1]; F. Ribaldi[1]; A. Lathuiliere[1]; N. Ashton[2]; S. Janelidze[3]; H. Zetterberg[2]; M. Scheffler[4]; F. Assal[5]; V. Garibotto[6]; K. Blennow[2]; O. Hansson[3]; G. Frisoni[1]

[1]Laboratory of Neuroimaging of Aging (LANVIE), University of Geneva, Geneva, Switzerland; [2]Department of Psychiatry and Neurochemistry, Institute of Neuroscience & Physiology, the Sahlgrenska Academy at the University of Gothenburg, Mölndal, Sweden; [3]Clinical Memory Research Unit, Lund University, Sweden; [4]Division of Radiology, Geneva University Hospitals, Geneva, Switzerland; [5]Division of Neurology, Department of Clinical Neurosciences, Geneva University Hospitals and Faculty of Medicine, University of Geneva, Geneva, Switzerland; [6]Laboratory of Neuroimaging and Innovative Molecular Tracers (NIMTlab), Geneva University Neurocenter and Faculty of Medicine, University of Geneva, Geneva, Switzerland

Background and Aims: Plasma biomarkers are being extensively researched in relation to Alzheimer's disease (AD) due to their potential to facilitate widespread screening. One possible application of the plasma biomarkers is the prediction of cognitive decline in non-demented individuals, such as the mild cognitive impairment (MCI) population. However, the comparison of the predictive levels of cognitive deterioration between plasma and traditional biomarkers is still not clear. Therefore, we compared how plasma (i.e., p-tau181, p-tau231, p-tau217, GFAP, NfL, and Aβ42/40) and neuroimaging biomarkers (i.e., amyloid-PET centiloid, tau-PET global-suvr, and hippocampal volume) predict cognitive decline in the Geneva Memory Center cohort.

Methods: A total of 67 MCI subjects were included in this study. Linear mixed-effect regression models were performed to assess the association between baseline levels of each biomarker and cognitive decline. Lastly, we calculated sample sizes for future AD preventive clinical trials, considering the inclusion of plasma biomarker positivity.

Results: Cognitive decline was significantly predicted by baseline plasma NfL ($\beta = -0.53$) and p-tau217 ($\beta = -0.59$), and tau-SUVR ($\beta = -0.91$) ($p < 0.05$). Finally, we showed that if NfL is added to the criteria for future AD clinical trials, the number of people in the samples could drop by as much as two-thirds if they have positive amyloid-PET and tau-PET scans.

Conclusion: Plasma biomarkers NfL and p-tau217 significantly predict cognitive decline as tau-SUVR during MCI. Moreover, identifying at-risk amyloid-positive subjects using plasma NfL can reduce sample sizes for future clinical trials.

Disclosure: Nothing to disclose.

EPR-005 | ATN system and disease-modifying treatment eligibility in a hospital-based cohort

E. Canu[1]; G. Rugarli[2]; F. Coraglia[3]; S. Basaia[1]; G. Cecchetti[4]; S. Calloni[5]; P. Vezzulli[5]; E. Spinelli[2]; R. Santangelo[6]; F. Caso[7]; A. Falini[8]; G. Magnani[7]; M. Filippi[9]; F. Agosta[2]

Background and Aims: To apply the AT(N) classification to a cohort of patients with Alzheimer's disease (AD) and related disorders, and to investigate how many cases would be eligible for the disease-modifying treatments.

Methods: We conducted a retrospective evaluation of 429 patients referred to the Memory Center of IRCCS San Raffaele Hospital in Milan. Patients underwent clinical/neuropsychological assessments, lumbar puncture, structural brain imaging, and positron emission tomography (FDG-PET). Patients were stratified according to AT(N) classification, group comparisons were performed and the number of eligible cases for anti-β amyloid monoclonal antibodies was calculated.

Results: Sociodemographic and clinical features were similar across groups. Although the clinical presentation was similar, the A+T+N+ group showed more severe cognitive impairment in memory, language, attention, executive, and visuospatial functions compared to other AT(N) groups. Notably, T+ patients demonstrated greater memory complaints compared to T- cases. FDG-PET outperformed MRI and CT in distinguishing A+ from A- patients. Although the 60.8% of the observed cases were A+, only the 17.2% were eligible for amyloid-targeting treatments.

Conclusion: The AT(N) classification is applicable in a real-world clinical setting. The classification system provided insights into clinical management and treatment strategies. Low cognitive performance and specific regional FDG-PET hypometabolism at diagnosis are highly suggestive for A+T+ or A-T+ profiles. This work provides also a realistic picture of the proportion of AD patients eligible for disease-modifying treatments emphasizing the need for early detection. Funding. Foundation Research on Alzheimer Disease. Cofunding from Next Generation EU/National Recovery and Resilience Plan, Investment PE8-Project Age-It.

EPR-006 | Association between genetic and fluid biomarkers of glymphatic pathology and clinical phenotypes in Parkinson's disease

E. de Natale[1]; A. Terry[1]; H. Wilson[1]; H. Wright[1]; J. Wollaston Moss[2]; L. Knowles[2]; F. Niccolini[3]; S. Albayati[4]; M. Politis[1]
[1]*Neurodegeneration Imaging Group, University of Exeter Medical School, London, UK;* [2]*Royal Devon University Healthcare NHS Foundation Trust, Exeter, UK;* [3]*Frimley Health NHS Foundation Trust & St George's University Hospitals, UK;* [4]*East Kent Hospitals University NHS Foundation Trust, Ashford, UK*

Background and Aims: Dysfunction of the glymphatic system is implicated in Parkinson's disease (PD) pathophysiology, but the precise mechanisms remain elusive. We present preliminary findings from an ongoing cross-sectional cohort study examining the role of single nucleotide polymorphisms (SNPs) in the Aquaporin-4 (AQP4) gene, as well as blood levels of AQP4 and S100β, as markers of glymphatic and astrocytic pathology, in relation to disease grading, staging, and sleep outcomes in PD.
Methods: A total of 176 PD patients underwent assessments of motor and non-motor symptoms, with particular emphasis on sleep parameters using the Parkinson's disease Sleep Scale (PDSS), Epworth Sleepiness Scale (ESS), Insomnia Severity Index (ISI), and cognitive performance through the Montreal Cognitive Assessment (MoCA) and Cambridge Neuropsychological Test Automated Battery (CANTAB). Venous blood samples were analysed for variants in SNPs of the AQP4 gene, as well as plasma levels of AQP4, S100β and total α-synuclein.
Results: In the entire cohort, lower plasma S100β levels correlated with higher MDS-UPDRS part 3 (rho = -0.245, $p=0.001$), higher total MDS-UPDRS (rho = -0.276, $p<0.001$), higher Hoehn & Yahr (rho = -0.196, $p=0.012$) scores, and lower PDSS scores (rho=0.237, $p=0.007$). Higher total plasma α-synuclein levels correlated with lower AQP4 levels (rho = -0.194, $p=0.011$). Carriers of the AQP4 rs162007 SNP demonstrated higher ESS scores ($p=0.01$) and lower blood α-syunclein ($p=0.045$). Carriers of the rs162009 SNP exhibited elevated ESS scores ($p=0.02$) and a trend towards higher AQP4 plasma levels ($p=0.06$).
Conclusion: These findings suggest a role of genetic and peripheral markers of glymphatic pathology in determining PD phenotypes associated with altered sleep and cognition.
Disclosure: Nothing to disclose.

EPR-007 | Copper and ceruloplasmin: Relationship with CSF biomarkers in Alzheimer's disease

M. Coelho[1]; C. Bernardes[1]; P. Faustino[1]; J. Durães[1]; M. Lima[1]; D. Duro[1]; I. Baldeiras[2]; M. Leitão[2]; I. Santana[1]; M. Tábuas-Pereira[1]
[1]*Neurology Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal;* [2]*Neurochemistry laboratory, Center for Neuroscience and Cell Biology, Coimbra, Portugal*

Background and Aims: Despite the prevailing amyloid cascade hypothesis in Alzheimer's disease (AD) pathophysiology, numerous alternative pathways, including neuroinflammation, oxidative stress and lysosomal dysfunction, have been implicated in the disease. Emerging studies propose a potential involvement of copper and ceruloplasmin in AD pathophysiology, given the binding sites for copper on both amyloid precursor protein and beta-amyloid (Aβ), along with the observed association between cerebrospinal fluid ceruloplasmin and disease progression. This study aimed to determine the relationship between copper and ceruloplasmin levels and the cerebrospinal fluid biomarker profile in AD.
Methods: Serum copper and ceruloplasmin levels were assessed in AD-diagnosed patients supported by biomarkers. Univariate analyses, including Spearman correlations and t-student tests, were conducted. Linear regressions, adjusting for relevant variables, were performed to investigate the association between copper, ceruloplasmin and cerebrospinal fluid biomarkers.
Results: A total of 132 patients were included (60.6% female). The mean age was 68.8 ±7.7, with a mean onset age of 65.4 ±7.7. In linear regression, Aβ42 was associated with Aβ40 ($\beta=0.040$, 95 % CI = [0.033, 0.047], $p<0.001$) and copper ($\beta=175.11$, 95 % CI = [18.39, 331.82], $p=0.029$). Tau was associated with ceruloplasmin ($\beta=3184.50$, 95 % CI = [246.33, 6122.68], $p=0.034$) and ptau ($\beta=6.61$, 95 % CI = [5.38, 7.83], $p<0.001$). Ptau was associated with tau ($\beta=0.091$, 95%CI = [0.074, 0.108], $p<0.001$), and Aβ40 ($\beta=0.008$, 95 % CI = [0.005, 0.012], $p<0.001$).
Conclusion: These findings contribute valuable in vivo evidence, emphasizing the association of serum copper and ceruloplasmin with AD biomarkers, underscoring the potential significance of copper and ceruloplasmin in metal metabolism regulation and modulation of oxidative stress and inflammation in AD.
Disclosure: Nothing to disclose.

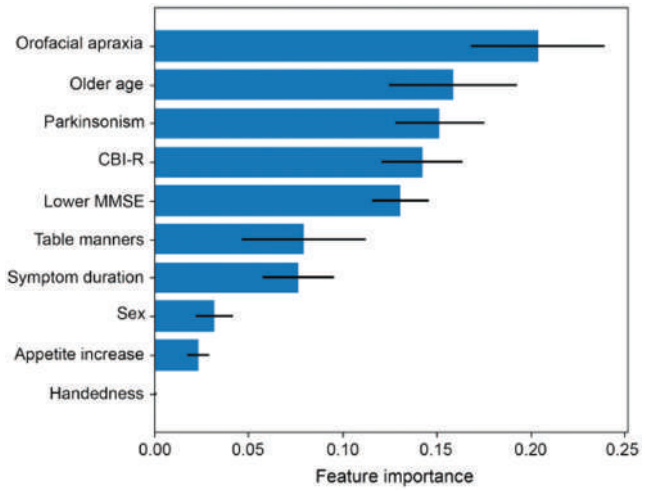
EPR-008 | Risk of dysphagia in primary progressive aphasia: demographic, clinical, behavioural and neuroanatomical features

S. Mazzeo[1]; E. Mulroy[2]; J. Jiang[2]; M. Lassi[2]; J. Johnson[2]; C. Hardy[2]; J. Rohrer[2]; J. Warren[2]; A. Volkmer[3]
[1]*Vita-Salute San Raffaele University, Milan, Italy; Research and Innovation Centre for Dementia-CRIDEM, University of Florence, Azienda Ospedaliera-Universitaria Careggi, Florence, Italy;* [2]*Research and Innovation Centre for Dementia-CRIDEM, University of Florence, Azienda Ospedaliera-Universitaria Careggi, Florence, Italy;* [3]*Department of Psychology & Language Sciences, University College London, London, UK*

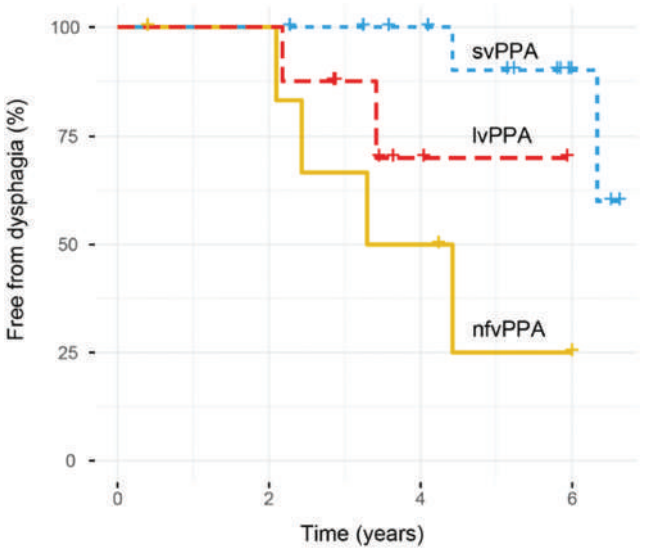
Background and Aims: We aim to investigate clinical, neuropsychological, and neuroanatomical features associated with dysphagia in patients with primary progressive aphasia (PPA).
Methods: 56 PPA patients were enrolled in this study (21 nonfluent/agrammatic variant PPA (nfvPPA), 22 semantic variant PPA (svPPA), 13 logopenic variant PPA (lvPPA)). The presence of dysphagia at baseline or development of dysphagia during follow-up was recorded. Demographic, clinical, and behavioural data were used as candidate input features to train a random forest machine learning

model. Brain MRI scans were processed using voxel-based morphometry (VBM) to assess neuroanatomical associations.

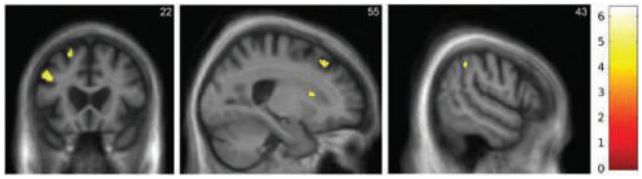
Results: Dysphagia at baseline was more prevalent in nfvPPA (43%) compared to svPPA (5%) and lvPPA (0%). The machine learning model revealed a hierarchy of features that accurately predicted dysphagia in the nfvPPA group, with the most important being orofacial apraxia, followed by age, presence of parkinsonism, Cambridge Behavioural Inventory Revised (CBI-R), Mini Mental State Examination (MMSE) score, decline in table manners, and symptom duration (Figure 1). During follow-up, dysphagia developed in eight (17%) of initially non-dysphagic PPA patients, with nfvPPA showing a significantly higher proportion. Cox's regression analysis revealed lower MMSE, presence of orofacial apraxia, and higher CBI-R scores as predictors of dysphagia (Figure 2). Neuroanatomically, dysphagia in nfvPPA was associated with regional grey matter atrophy in the left middle frontal gyrus, right superior frontal gyrus, right supramarginal gyrus, and right caudate (Figure 3).



Bar chart showing the relative importance (with 95% confidence intervals) of clinical features associated with dysphagia (at baseline) in patients with nonfluent/agrammatic variant primary progressive aphasia.



Kaplan-Meier survival analysis for proportions of patients developing dysphagia during follow-up in each primary progressive aphasia syndromic group. nfvPPA ($n=12$), svPPA ($n=21$) and lvPPA ($n=13$).



Statistical parametric maps showing regional grey matter differences between subgroups of patients with nfvPPA who did and did not report dysphagia, based on a voxel-based morphometric analysis of their brain MR images

Conclusion: This is the first study that identified demographic, clinical, behavioural, and neuroanatomical features associated with dysphagia in nfvPPA, providing valuable insights into identifying PPA patients at risk of dysphagia.

Disclosure: Nothing to disclose.

EPR-009 | Diagnostic Reliability of PET and CSF Biomarkers in Diagnosis of Alzheimer's Disease in a Real-World Setting

S. Goeschl[1]; S. Klotz[2]; S. Silvaieh[1]; T. Parvizi[1]; R. Wurm[1]; E. Berger-Sieczkowski[1]; T. König[1]; H. Untersteiner[1]; G. Regelsberger[2]; E. Gelpi[2]; E. Stögmann[1]

[1]*Department of Neurology, Medical University of Vienna, Vienna, Austria;* [2]*Institute of Neurology, Medical University of Vienna, Vienna, Austria*

Background and Aims: Amyloid-PET and cerebrospinal fluid (CSF) biomarker analysis are the gold standard diagnostic tools for Alzheimer's disease (AD). High concordance rates are described for diagnostic sensitivity and specificity between PET and CSF, however, in the individual patient setting, proof of amyloid positivity can be ambiguous. We aim here to study patients with AD in comparing the sensitivity of Amyloid-PET and CSF analysis for diagnostic accuracy.

Methods: Patient data from 2017 to 2022 was retrieved and statistically analyzed. Patients with a diagnosis of AD or MCI due to AD (per NIA-AA definition) with amyloid-PET and CSF analysis were included. Amyloid-PET results were visually assessed for cerebral amyloidopathy. Analysis of CSF biomarkers amyloid-beta-42 and Innotest Amyloid Tau Index (IATI; calculated amyloid-beta-42/240+[1.18xt-Tau]) were conducted via INNOTEST, and we define CSF biomarker positivity as amyloid-beta-42 <500 pg/mL and/or IATI <1.

Results: We included 63 patients. Median age of onset was 60.5 (SD10.9). Median duration to amyloid-PET was 3.1 years (SD2.5) and to CSF analysis 2.6 years (SD2.5). 71% of patients had positive amyloid-PET and CSF biomarkers. In patients with positive amyloid-PET (84%), 0% were CSF biomarker negative. In patients with

negative amyloid-PET (16%), 100% were CSF biomarker-positive. In patients with positive CSF biomarkers (100%; 87% amyloid-beta-42; 97% IATI), 16% were amyloid–PET-negative.

Conclusion: We find no complete concordance between PET and CSF analysis. CSF biomarkers show high positivity rates when considering both amyloid-beta-42 and IATI. In cases of strong suspicion of AD pathology, both PET and CSF analysis should be performed to avoid false-negative results.

Disclosure: Nothing to disclose.

Autonomic nervous system diseases

EPR-010 | Autonomic dysfunction in minimal change multiple system atrophy

W. Cheshire[1]; H. Sekiya[2]; P. Tipton[1]; O. Ross[2]; R. Uitti[1]; D. Dickson[2]
[1]*Department of Neurology, Mayo Clinic, Jacksonville, Florida, USA;*
[2]*Department of Neuroscience, Mayo Clinic, Jacksonville, Florida, USA*

Background and Aims: Minimal change multiple system atrophy (MSA) has been reported as an early pathologic form in which glial cytoplasmic inclusions are found in the striatonigral or olivopontocerebellar systems but without neuronal loss. Autonomic nervous system involvement, a defining feature of MSA, has not been specifically investigated in minimal change MSA, which is presumed to be preclinical. We sought to characterize autonomic dysfunction in minimal change MSA.

Methods: Clinical histories, neurologic examinations, and autonomic test results were reviewed in 6 cases of pathologically confirmed minimal change MSA.

Results: All 6 cases were men, their average age 61. All had signs of parkinsonism, and 5 had a history of dream-enactment behavior. Symptoms of autonomic dysfunction included lightheadedness in 5, constipation in 6, urinary dysfunction in 6, urinary overflow incontinence in 5, erectile failure in 3, exercise intolerance in 1, anhidrosis in 1, and orthostatic syncope in 1. Orthostatic hypotension was present in 5, 4 of whom required pharmacologic treatment. Three were dependent on catheterization to empty their bladders. Three had undergone autonomic testing, which showed normal postganglionic sudomotor function and mildly reduced cardiovagal function. Cardiovascular adrenergic function was moderately impaired in one and normal in another. Average composite autonomic severity score was 3.5.

Conclusion: We found evidence of clinical autonomic dysfunction in all cases of minimal change MSA. Our findings support the conclusion that autonomic involvement is an early feature of MSA and that impaired central nervous system autonomic function precedes neuronal loss.

Disclosure: Nothing to disclose.

EPR-011 | Autonomic functions and dopaminergic correlates in Dementia with Lewy Body: A preliminary study

C. Bonomi[1]; A. Martorana[1]; C. Serafini[1]; C. Motta[1]; N. Mercuri[2]; C. Rocchi[2]
[1]*UOSD Memory Clinic, University of Rome "Tor Vergata", Rome, Italy;*
[2]*Neurology Unit, University of Rome "Tor Vergata", Rome, Italy*

Background and Aims: Both autonomic failure and nigrostriatal denervation are well-known features of dementia with Lewy body (DLB). However, the relationship between the two has been poorly investigated. We aimed to assess cardiovascular and sudomotor autonomic function tests (AFTs) in DLB and to evaluate the relationship between AFTs and 123I-ioflupane dopamine transporter uptake at single photo-emission computed tomography (DAT-SPECT).

Methods: 15 DLB patients and 20 healthy controls (HC) underwent head-up tilt-test (HUTT), Valsalva Maneuver, deep-breathing, cold-face, hand-grip test (HG), electrochemical skin conductance (ESC). DLB patients also underwent DAT-SPECT, we used the DaTQUANT software for semi-quantitative analysis.

Results: DLB patients showed lower delta heart rate at third minute of HUTT ($p=0.016$), Valsalva Ratio ($p<0.001$) and Overshoot ($p=0.004$), lower delta systolic (ΔSBP, $p=0.002$) and diastolic blood pressure (ΔDBP, $p<0.001$) at HG, lower inspiration-espiration difference at deep-breathing ($p=0.004$), and lower hands-feet ESC than HC (both $p=0.003$). Of all the AFTs, only HG responses correlated with striatal DaTQUANT measures: HG ΔDBP strongly inversely correlated with bilateral uptake of 123I-FP in the anterior (Right: rho -0.691, p 0.004; Left: rho -0.676, p 0.006) and posterior putamen (Right: rho -0.769, $p<0.001$; Left: rho -0.663, p 0.007).

Conclusion: Despite the absence of overt orthostatic hypotension, DLB patients showed covert dysautonomia encompassing adrenergic and parasympathetic dysfunction. Moreover, the functioning of sympathetic peripheral efferent pathways to vessels, reflected by HG ΔDBP, was inversely associated with nigrostriatal denervation. This could suggest the presence of different profiles of peripheral-predominant versus central-predominant impairment in DLB patients.

Disclosure: Nothing to disclose.

Background and Aims: Autonomic Nervous System (ANS) disorders have a high prevalence both in the general population and in several neurological conditions, but information on clinical autonomic training opportunities across Europe is currently limited. Here we evaluated the current state of autonomic education, clinical skills and post-graduate educational preferences among European neurology residents and neurologists.

Methods: A 23-item questionnaire was distributed online among European neurologists and neurology residents. The questions covered demographic characteristics, clinical autonomic training received and preferred post-graduate educational format. Clinical autonomic knowledge was self-assessed with five basic multiple-choice questions.

Results: Two-hundred eighty-five individuals answered the survey (60% female, mostly 25–34 years-old). Most respondents trained in East/South/Greater Europe (75%), were practicing neurology for

Table 1 – Survey demographics, training and learning preferences in ANS disorders and response to multiple-choice questions.

Total number of responders	285
Gender	Female – 170 (60%)
Age	
- 18 - 24	2 (1%)
- 25 - 34	131 (46%)
- 35 - 44	68 (24%)
- 45 - 54	33 (12%)
- 55 - 64	34 (12%)
- 65+	17 (6%)
Training country region	
- East/South/Greater Europe	215 (75%)
- West/North Europe	70 (25%)
Working country region	
- East/South/Greater Europe	210 (74%)
- West/North Europe	75 (26%)
For how many years have you been practicing in Neurology?	
- Resident	77 (27%)
- Less than 5 years	53 (19%)
- 5 – 10 years	35 (12%)
- More than 10 years	104 (36%)
- Past practice	16 (6%)
Setting of current practice	
- Public hospital	99 (35%)
- University hospital	192 (67%)
- Private practice	30 (11%)
- Private clinic	31 (11%)
- Other	4 (1%)
- Not applicable	5 (2%)
Formal training received in ANS	
- Compulsory rotation during the residency	13 (5%)
- Compulsory educational course during the residency	21 (7%)
- Facultative rotation during the residency	17 (6%)
- Facultative educational course in the residency context	26 (9%)
- Part of another educational course (e.g., post-graduate courses, congresses)	75 (26%)
- Autonomic topics were discussed within other rotations (i.e. movement disorders, clinical neurophysiology, etc)	134 (47%)
- No training at all	91 (32%)
Autonomic field of training during residency	
- Syncope and other cardiovascular disorders	180 (63%)
- Bladder dysfunction	96 (34%)
- Bowel dysfunction	51 (18%)
- Sexual dysfunction	35 (12%)
- Thermoregulatory disorders	47 (17%)
- Ophthalmological disorders	36 (13%)

EAN/EFAS survey on autonomic training and clinical autonomic skills of European residents and neurologists.

>10 years (42%) and worked in university hospitals (67%). Eighty percent of respondents reported that ANS disorders were covered in the neurology curriculum during their medical studies. During their neurology residency, people mostly received ANS training within rotations in other neurological sub-specialities (47%). The most frequently trained ANS complaint was syncope (63%), followed by bladder, bowel, thermoregulatory, ophthalmological, or sexual disorders. Self-confidence in assessing and managing autonomic domains followed the same order. All responders stated that clinical autonomic skills are important for a good clinical neurological practice, 92% would like to increase their ANS knowledge. The self-assessment questions highlighted knowledge gaps in the management of neurogenic bladder disturbances.

Conclusion: To date, clinical autonomic training has mostly focused on the cardiovascular autonomic domain and European neurologists and residents feel the need to increase their clinical autonomic knowledge.

Disclosure: Nothing to disclose.

EPR-013 | A predominant sympathetic drive may underlie sleep, thermoregulatory and cardiovascular abnormalities in PSP

F. Baschieri[1]; L. Sambati[2]; P. Antenucci[3]; I. Cani[4]; A. Cecere[2]; P. Guaraldi[2]; P. Cortelli[5]; F. Provini[5]; G. Calandra-Buonaura[5]

Background and Aims: Sleep-wake cycle and the autonomic nervous system (ANS) can be impaired in neurodegenerative diseases. We aimed to explore the possible interaction between ANS and sleep-wake cycle abnormalities in Progressive Supranuclear Palsy (PSP).

Methods: We prospectively recorded 48-h video-polysomnography, body core temperature (BcT) and blood pressure (BP) (Portapres® Model-2, Finapres Medical Systems, The Netherlands) in 15 PSP patients (disease duration 5.7 ±2.6 years) under controlled environmental conditions. We analysed sleep parameters (Table 1) and state-dependent modulation for BcT, BP and heart rate (HR) from the last 24 hours of recording.

Sleep-wake cycle parameters of PSP patients

Dark period	
TST (min)	286.8 ± 118.3§
Sleep efficiency (%)	52.9 ± 20.1§
WASO (min)	231.9 ± 137.2*
Awakenings (n)	37.7 ± 15.5
N1 (%)	24.2 ± 13.7*
N2 (%)	45.1 ± 9.1§
N3 (%)	24.2 ± 14.7*
REM (%)	9.9 ± 8.7§
PLMI	56.0 ± 44.2
AHI	8.1 ± 5.3
Light period	
TST (min)	51 ± 46.9
N1 (%)	54.2 ± 25.3
N2 (%)	33.6 ± 20.9
N3 (%)	11.9 ± 16.2
REM (%)	0.3 ± 1.1
Dark + Light (24 h)	
TST (min)	337.8 ± 131.9
N1 (%)	26.3 ± 12.0
N2 (%)	41.6 ± 14.9
N3 (%)	23.6 ± 13.6
REM (%)	8.5 ± 7.2

TST = total sleep time; WASO = wake after sleep onset; PLMI = periodic limb movement index; AHI = apnoea hypopnea index; * increased compared to normative values for this age group; § decreased compared to normative values for this age group.

Results: Patients slept less than 5 h/night with frequent awakenings, however daytime naps were shorter than 60 min and mainly represented by light sleep resulting in a 24-h total sleep time lower than the recommended 7 hours of sleep. Compared to younger controls, PSP slept less during both day and night but only 2 patients reported excessive daytime sleepiness. There were no significant differences in sleep parameters in patients according to the presence of sleep disorders. Compared to controls patients showed significantly higher BcT values and a higher MESOR. Twelve patients presented a reduced/non/reverse-dipping BP pattern.

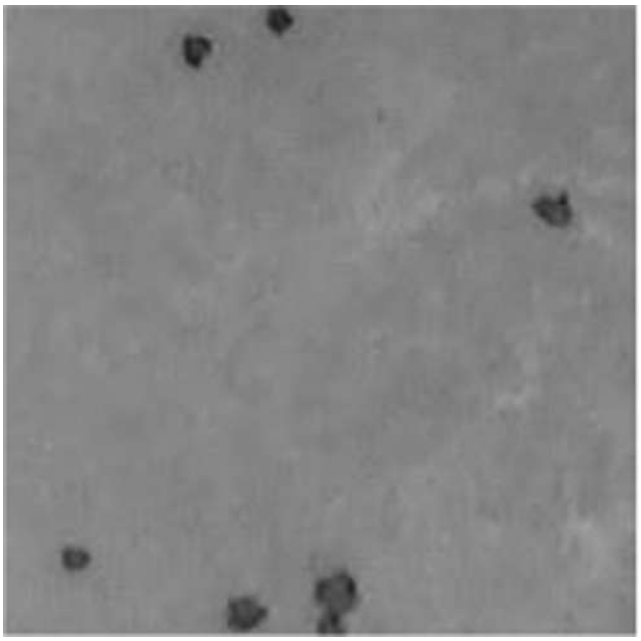
Conclusion: PSP patients showed a significant reduction of sleep during night-time not associated with a compensatory increase of sleep during daytime leading to a profound sleep deprivation. This hyperarousal state may be related to reduced homeostatic sleep drive. Increased BcT values and abnormal BP profile may also reflect a primary ANS involvement.

Disclosure: Nothing to disclose.

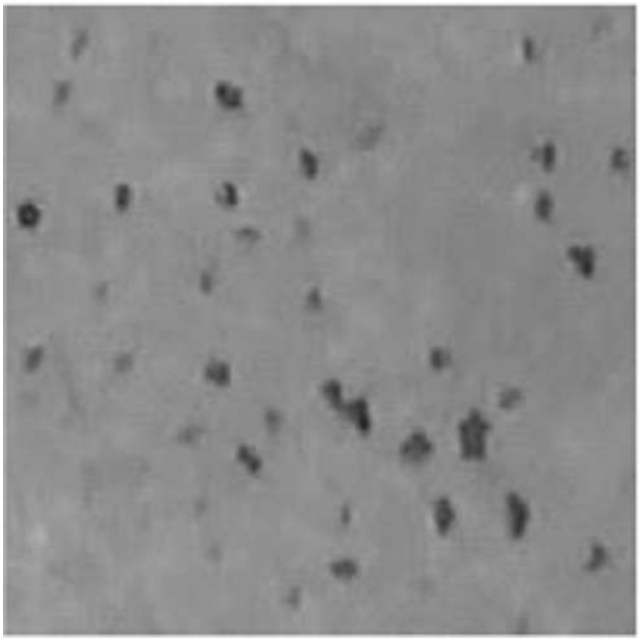
EPR-014 | The dynamic sweat test in patients with pure autonomic failure: A pilot study

A. Torrente[1]; S. Koay[2]; S. Johnstone[3]; L. Sander[2]; G. Chiaro[3]; G. Ingle[3]; G. Caporaso[4]; V. Provitera[4]; M. Nolano[5]; V. Iodice[2]
[1]*Autonomic Unit, National Hospital for Neurology and Neurosurgery, Queen Square, London, UK; Department of Biomedicine, Neuroscience and Advanced Diagnostics, University of Palermo, Palermo, Italy;* [2]*Autonomic Unit, National Hospital for Neurology and Neurosurgery, Queen Square, London, UK; Department of Brain, Repair and Rehabilitation, University College London Queen Square Institute of Neurology, London, UK;* [3]*Autonomic Unit, National Hospital for Neurology and Neurosurgery, Queen Square, London, UK;* [4]*Neurology Department, Skin Biopsy Laboratory, Istituti Clinici Scientifici Maugeri IRCCS, Telese Terme, Italy;* [5]*Neurology Department, Skin Biopsy Laboratory, Istituti Clinici Scientifici Maugeri IRCCS, Telese Terme, Italy; Department of Neurosciences, Reproductive Sciences and Odontostomatology, University Federico II of Naples, Naples, Italy*

Background and Aims: The dynamic sweat test (DST) is an established tool for the evaluation of sudomotor function. We aimed to characterize the sudomotor pattern of patients affected by pure autonomic failure (PAF) with the DST, and to evaluate its usefulness in distinguishing patients with phenoconversion to overt parkinsonism.
Methods: As part of an ongoing longitudinal study on alpha-synucleinopathies (QSA-PRODROMAL), consecutive patients with an initial diagnosis of PAF and available DST data were included. Patients were followed up in clinic and diagnoses were revised at follow-up. Number of activated sweat glands, mean gland sweat production, and total sweat of a 1 cm^2 area of upper and lower limbs were investigated (Figures 1 and 2). Data were analysed using non-parametric tests, presented as median and interquartile ranges.



Left leg DST results at the time of sweat glands confluence in a PAF patient, area 1 cm2, drops count 7, sweat output per gland 2.24 nL/min, total area sweat output 15.70 nL/cm^2/min.



Right leg DST results at the time of sweat glands confluence in an MSA-P patient, area 1 cm^2, drops count 35, sweat output per gland 1.96 nL/min, total area sweat output 68.63 nL/cm^2/min.

Results: 34 patients (11F, age 62 [57–71] years) with an initial diagnosis of PAF were included. 7 patients phenoconverted (4MSA-P, 2DLB, and 1PD), while 27 retained a PAF phenotype. There was a trend, although not statistically significant, in reduction of total sweat production, both for upper (PAF 213.99 [99.07–406.57], non-PAF 415.92 [120.72–552.53] nL/cm^2/min, $p = 0.641$) and lower (PAF 47.63 [23.39–140.43], non-PAF 116.16 [60.35–181.58] nL/cm^2/min, $p = 0.066$) limbs.
Conclusion: Total sweat production measured with a quantitative postganglionic sudomotor test might be lower in patients with predominantly peripheral autonomic involvement (PAF phenotype) compared to the ones with widespread alpha-synucleinopathies. DST may possibly aid in distinguishing different phenotypes, but future studies and wider samples are needed to confirm the role of such technique.

EPR-015 | Autonomic assessment in patients with hereditary transthyretin amyloidosis and asymptomatic carriers – A follow-up study

L. Sander[1]; G. Chiaro[2]; A. Torrente[3]; G. Ingle[2]; A. Carr[4]; C. Whelan[5]; J. Gillmore[5]; M. Reilly[4]; C. Mathias[6]; V. Iodice[1]
[1]*Autonomic Unit, The National Hospital for Neurology and Neurosurgery, London, UK; Department of Brain, Repair and Rehabilitation, University College London Queen Square Institute of Neurology, London, UK;* [2]*Autonomic Unit, The National Hospital for Neurology and Neurosurgery, London, UK;* [3]*Autonomic Unit, The National Hospital for Neurology and Neurosurgery, London, UK; Department of Biomedicine, Neuroscience and Advanced Diagnostics (Bi.N.D.), University of Palermo, Palermo, Italy;* [4]*Centre for Neuromuscular Diseases, Department of Neuromuscular Diseases, UCL Queen Square Institute of Neurology and the National Hospital of Neurology and Neurosurgery, London, UK;* [5]*National Amyloidosis Centre, Division of Medicine, University College London, London, UK;* [6]*Department of Brain, Repair and Rehabilitation, University College London Queen Square Institute of Neurology, London, UK*

Background and Aims: Hereditary transthyretin amyloidosis (ATTRv) is a progressive disease with early, disabling autonomic manifestations in 40%–80% of patients. With effective targeted disease-modifying treatments (DMT) markers of disease progression are needed. This study describes progression of autonomic failure (AuF) in ATTRv patients and asymptomatic carriers using autonomic function testing (AFT) and ambulatory blood pressure (BP) monitoring (ABPM).

Methods: 53 patients and 6 TTR mutation carriers (31%F, mean age 54 [range 28–78]y; one individual became symptomatic during follow-up [FU]) had AFT at baseline (BL) and at FU (median interval 23 [range 7–133] months) using Finapres NOVA. 45 subjects (6 carriers) had ABPM with FU. Three AuF stages were defined: normal AFT (0), mild parasympathetic and/or sympathetic impairment (I), severe AuF with neurogenic orthostatic hypotension (II). BP dipping profile was defined according to the consensus criteria.

Results: All six subjects (2 carriers) with initial stage 0 developed stage I within 4 years. Progression from stage I to II was detected in 4/27 patients within 2 years, one patient on DMT improved to stage 0. Eight out of 24 patients improved from stage II to stage I within 2 years (one started DMT). No carrier had stage II AuF. ABPM showed normal dipping profile in 15 subjects (one carrier) at BL, 7/15 developed pathologic dipping profile at FU.

Conclusion: Cardiovascular autonomic failure and impaired circadian BP profile are frequent, early features in ATTRv, with progression over time. Carriers showed subclinical, mainly parasympathetic dysfunction. Improvement in AuF can occur with DMT but further studies are warranted to assess treatment effects in detail.

Disclosure: LS holds a grant from the University of Basel, Switzerland. GC, SJ, AT, GTI, CA, CJW, MMR, CJM: nothing to disclose. JDG provides consultancy for Alnylam, AstraZeneca, Bridgebio, Ionis, Intellia and ATTRalus. EPR-016 | Octreotide improves PPH and orthostatic tolerance in patients in patients with alpha-synucleinopathies

R. Alnasser Alsukhni[1]; E. Vichayanrat[1]; G. T Ingle[1]; C. J Mathia[2]; V. Iodice[1]
[1]*Autonomic Unit, National Hospital for Neurology and Neurosurgery, London, UK;* [2]*UCL Queen Square Institute of Neurology, Faculty of Brain Sciences, University College London, London, UK*

Background and Aims: Postprandial hypotension (PPH) is common in patients with autonomic failure although the pathophysiology remains unclear. The effect of octreotide on PPH and orthostatic hypotension (OH) has not been fully evaluated in patients with alpha synucleinopathies, particularly with improving orthostatic tolerance levels.

Methods: We retrospectively evaluated patients with established diagnoses of cardiovascular autonomic failure due to alpha-synucleinopathy with postprandial hypotension who were assessed at our autonomic centre between 2013 and 2021 and underwent cardiovascular autonomic assessment, liquid meal challenge test pre and post-octreotide. Autonomic function testing included tilt table, standing, pressor tests, heart rate responses to Valsalva manoeuvre and deep breathing using Finapres NOVA.

Results: Sixty-seven patients were included (8 patients with Parkinson's disease, 19 with Multiple System Atrophy, and 40 with Pure autonomic failure) with a mean age of 64.4 years and a median disease duration of 6 years. Octreotide improved both OH and PPH. It delayed the onset of orthostatic hypotension ($p = 0.006$), time to maximal BP drop ($p < 0.001$), decreased the magnitude of BP drop in pre-meal tilt by 22.9 mmHg systolic and 12.8 mmHg diastolic ($p < 0.001$), delayed the onset of PPH ($p = 0.006$), decreased the magnitude of maximal PPH (20 mmHg systolic and 12mmHg diastolic) and resolved PPH in 28 patients (42% of the patients) ($p < 0.001$).

Conclusion: Octreotide significantly improved both OH and PPH and the associated orthostatic tolerance in individuals with alpha-synucleinopathy.

Disclosure: The authors have no information to disclose.

EPR-017 | Nocturnal supine blood pressure during head-up tilt sleeping in Parkinson's disease and parkinsonism

S. Shmuely[1]; A. van der Stam[1]; N. de Vries[1]; D. Smeenk[1]; Y. Wang[2]; A. Fanciulli[3]; G. Wenning[3]; B. Bloem[1]; R. Thijs[2]
[1]*Radboud University Medical Center; Donders Institute for Brain, Cognition and Behavior; Department of Neurology; Center of Expertise for Parkinson & Movement Disorders; Nijmegen, The Netherlands;* [2]*Department of Neurology, Leiden University Medical Centre, Leiden, The Netherlands;* [3]*Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria*

Background and Aims: The co-occurrence of supine hypertension and orthostatic hypotension due to autonomic failure is common in

people with Parkinson's disease (PD) or parkinsonism such as multiple system atrophy (MSA). Head-up tilt sleeping is an intervention that potentially tackles both. So far, the effect of tilted sleeping on the supine blood pressure (BP) has not been investigated.

Methods: This is an interim analysis of the Heads-Up trial (NCT05551377), on the first 12 participants (PD: 10, MSA: 2). Participants slept horizontal for one baseline week, and then gradually increased the sleeping angle to either 1°, 6° and 12° or to 6°, 12° and 18°, for two weeks each. In this interim analysis, the baseline and the 12° angle were used according to the intention-to-treat principle, irrespective of adherence. Data from the night-time ambulatory BP measurement were extracted. Nocturnal BP was recorded twice per hour, and the change score was calculated to examine the mean and 95% confidence interval (CI) of the difference in nocturnal supine BP.

Results: A reduction in the nocturnal systolic BP (mean = -5 mmHg; CI [-14, 5]) and diastolic BP (mean = -9 mmHg; CI [-20, 3]) was found, showing a tendency towards a lower nocturnal BP while sleeping in a 12° full body tilt compared to horizontal sleeping. We noted substantial interindividual differences in effect size.

Conclusion: We found a trend towards a positive effect of head-up tilt sleeping on nocturnal supine BP. Further analysis of the complete Heads-Up cohort allows us to examine the reasons behind substantial interindividual differences.

Disclosure: This project was supported by MJFF grant MJFF-020200.

EPR-018 | Multimodal autonomic biomarkers differentiate pure autonomic failure from other alpha-synucleinopathies

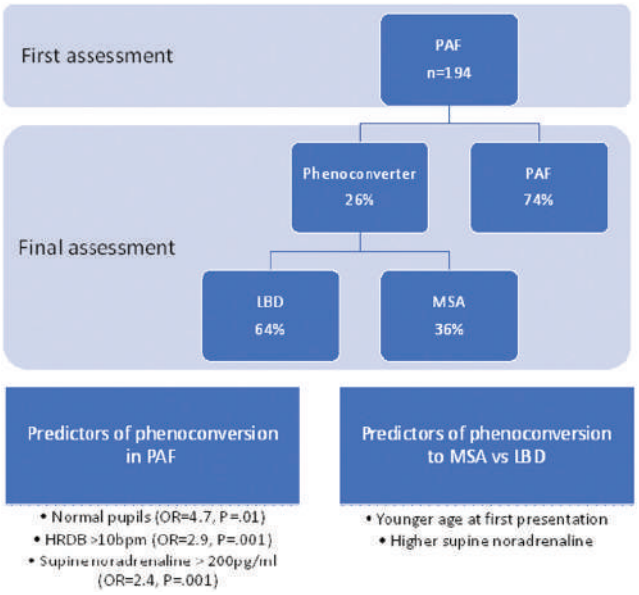
S. Koay[1]; E. Vichayanrat[1]; F. Bremner[2]; F. Valerio[1]; R. Mackenzie[1]; G. Ingle[1]; P. McNamara[1]; G. Chiaro[1]; L. Watson[1]; M. Lunn[3]; C. Mathias[1]; V. Iodice[1]

[1]*Autonomic Unit, National Hospital for Neurology and Neurosurgery, Queen Square, London, UK;* [2]*Neuro-ophthalmology Dept, National Hospital for Neurology and Neurosurgery, Queen Square, London, UK;* [3]*Queen Square Centre for Neuromuscular Diseases, National Hospital for Neurology and Neurosurgery, Queen Square, London, UK*

Background and Aims: Pure autonomic failure (PAF) presents with progressive autonomic failure without other neurological features. A third later develop central neurological features, fulfilling criteria for multiple system atrophy (MSA) and Lewy body diseases (LBD), including Parkinson's disease and Dementia with Lewy bodies. We hypothesized that multimodal autonomic biomarkers could distinguish between PAF, MSA and LBD, and predict phenoconversion in patients presenting with PAF.

Methods: 391 patients were studied with cardiovascular autonomic testing (Finapres systems), plasma catecholamines, pupillometry, and COMPASS-31 autonomic symptom and SF-36 quality of life questionnaires. Patients presenting with PAF were followed up to monitor for the emergence of central neurological features. Autonomic biomarkers at initial assessment were used in a logistic regression model to identify predictors for final diagnosis.

Results: Patients with a final diagnosis of PAF ($n = 146$) had significantly greater orthostatic hypotension on tilt, lower supine noradrenaline, and sympathetic pupillary deficits at initial assessment compared to both MSA ($n = 157$) and LBD ($n = 88$). 26% presenting with PAF phenoconverted to MSA/LBD after median follow-up of 13 years (IQR 7–18 years), with normal pupils (OR 4.7; $p = .01$) and supine noradrenaline >200 pg/mL (OR 2.4; $p < .001$) at first assessment predicting future phenoconversion. Patients with PAF reported more severe orthostatic intolerance with similarly diminished quality of life compared to MSA.



Multimodal biomarkers at initial assessment predicting phenoconversion from PAF to MSA or LBD by final assessment HRDB: heart rate variability with deep breathing.

Conclusion: We found greater orthostatic hypotension, lower supine noradrenaline and more frequent sympathetic pupillary deficits in PAF compared to other alpha-synucleinopathies, suggestive of greater post-ganglionic adrenergic denervation. Severe symptomatic orthostatic hypotension is associated with marked physical disability in PAF, even in the absence of other neurological features.

Cerebrovascular diseases

EPR-019 | Cerebral amyloid angiopathy in Alzheimer's disease: A comparison between different versions of the Boston criteria

A. Morotti[1]; A. Pilotto[1]; A. Galli[1]; D. Zanola[1]; S. Caratozzolo[1]; R. Gasparotti[2]; A. Padovani[1]

[1]*Neurology Unit, Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy;* [2]*Neuroradiology, Department of Surgical Specialties, Radiological Sciences and Public Health, University of Brescia, Brescia, Italy*

Background and Aims: Cerebral amyloid angiopathy (CAA) is a common small vessel disease and the main driver of iatrogenic amyloid-related imaging abnormalities in Alzheimer's disease (AD). We investigated the prevalence of CAA imaging features, and compared different versions of the Boston Criteria for CAA diagnosis in AD subjects.

Methods: Single center retrospective analysis of patients with mild cognitive impairment (MCI) or early stage dementia due to AD. Hemorrhagic (cerebral microbleeds, CMB; cortical superficial siderosis, cSS) and non-hemorrhagic (severe enlarged perivascular spaces in the centrum semiovale, EPVS; subcortical multispot white matter changes) were evaluated on magnetic resonance images. CAA was rated as absent, possible or probable based on the original (V1.0), modified (V1.5), and last updated (V2.0) Boston Criteria.

Results: A total of 75 subjects were included (mean age 71.6+8.1 years, 46.7% males, mean disease duration 2.6+2.0 years) of whom 68 (90.7%) had MCI-AD. EPVS and subcortical multispot white matter changes were highly prevalent (54.7% and 36.0% respectively) whereas lobar CMB and cSS had a lower frequency (1 lobar CMB 16.0%, > 2 lobar CMB 12.0%; focal cSS 1.3%, disseminated cSS 6.7%). EPVS presence was associated with a higher lobar CMB burden. CAA frequency increased from V1 (14.7% possible and 9.3% probable) to V1.5 (13.3% possible and 13.3% probable) and V2.0 (42.7% possible and 26.7% probable).

Conclusion: Non-hemorrhagic CAA features are more common than hemorrhagic markers in AD and more than one in four patients has probable CAA according to the V 2.0 Boston criteria. These findings might inform future trials.

Disclosure: Dr. Morotti declares consulting and advisory board activity for EMC-REG International and AstraZeneca.

EPR-020 | Investigating the impact of anemia on survival after acute ischemic stroke: A nationwide registry-based cohort study

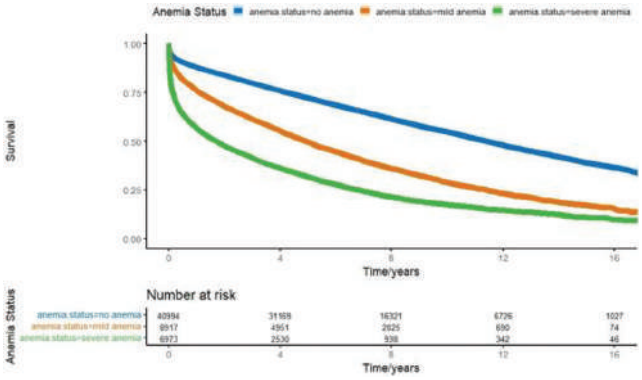
H. Wong[1]; C. Low[1]; C. Yau[1]; Y. Teo[1]; Y. Teo[2]; L. Yeo[3]; C. Sia[2]; B. Tan[3]

[1]*Yong Loo Lin School of Medicine, National University of Singapore, Singapore;* [2]*Department of Cardiology, National University Heart Centre, Singapore;* [3]*Division of Neurology, Department of Medicine, National University Health System, Singapore*

Background and Aims: Anemia at presentation of acute ischemic stroke (AIS) is associated with significant morbidity and mortality. The comparative impact of anemia severity on long-term survival after AIS has not been well studied.

Methods: All patients with first onset AIS from 2005 to 2019 in the Singapore Stroke Registry were included. They were stratified according to anemia status, as no anemia, mild anemia (Hb 11 to <13g/dL) and severe anemia (Hb <11g/dL). The primary outcome was longitudinal mortality. Patients without an event were censored at the end of the registry period (2019). The Cox proportional hazards regression was used to assess the association between post-AIS mortality and anemia. The Kaplan-Meier method was used to compare survival probabilities between groups.

Results: A total of 56,884 patients were analyzed, of which 40,994 (72.1%) had no anemia, 8917 (15.7%) had mild anemia, and 6973 (12.2%) had severe anemia. Patients with mild/severe anemia were older than patients without anemia ($p < 0.001$). Patients with mild anemia (HR 1.35, 95% CI 1.31 to 1.39, $p < 0.001$) and severe anemia (HR 1.90, 95% CI 1.84 to 1.96, $p < 0.001$) were at significant greater risk for mortality than patients without anemia, after adjustment for gender, ethnicity, age, history of transient ischemic attack, ischemic heart disease, smoking, diabetes, hyperlipidemia, hypertension, atrial fibrillation, and treatment with thrombolytics and antiplatelets. The long-term survival of patients with anemia is markedly worse than those without anemia ($p < 0.001$).



Kaplan Meier Curve.

	Unadjusted model		Multivariable-adjusted model^	
Anemia Status	HR (95% CI)	P	HR (95% CI)	P
Overall (30,079 events out of 56,884)				
No anemia	-		-	
Mild anemia	2.03 (95% CI 1.98 to 2.09)	<0.001	1.35 (95% CI 1.31 to 1.39)	<0.001
Severe anemia	3.26 (95% CI 3.16 to 3.36)	<0.001	1.90 (95% CI 1.84 to 1.96)	<0.001

^ Adjusted for age, gender, ethnicity, age, history of transient ischemic attack, history of ischemic heart disease, history of atrial fibrillation, smoking, diabetes, hypertension, treatment with thrombolytics and antiplatelets

Cox regression analyses for longitudinal mortality by anemia groups.

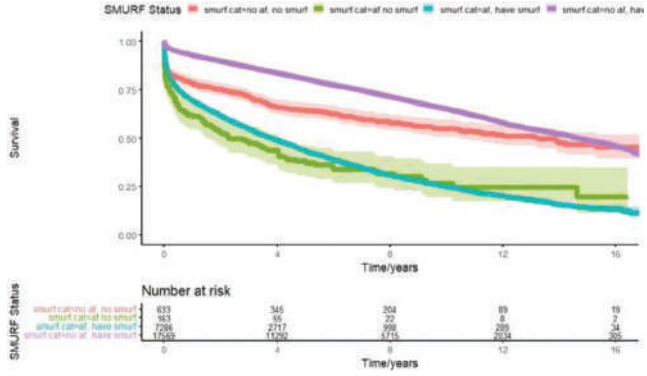
Conclusion: An increasing severity of anemia is associated with poorer survival outcomes in AIS patients.

Disclosure: Nothing to disclose.

EPR-021 | Impact of SMuRF and atrial fibrillation on mortality after Ischemic Stroke: A Nationwide Registry-based cohort study

H. Wong[1]; C. Yau[1]; C. Low[1]; Y. Teo[1]; Y. Teo[2]; L. Yeo[3]; C. Sia[2]; B. Tan[3]
[1]*Yong Loo Lin School of Medicine, National University of Singapore, Singapore;* [2]*Department of Cardiology, National University Heart Centre, Singapore;* [3]*Division of Neurology, National University Heart Centre, Singapore*

Background and Aims: Existing literature suggests an inverse relationship between standard modifiable risk factors (SMuRF) – comprising smoking, hypertension, diabetes, hyperlipidemia, and mortality in patients with myocardial infarction. The occurrence of this paradox in patients with acute ischemic stroke (AIS) has not been investigated.
Methods: Patients with first onset AIS between 2005 and 2019 and with complete information regarding SMuRF components and history of atrial fibrillation (AF) in the Singapore Stroke Registry were included. They were classified as (i) no AF and no SMuRF (633, 2.5%); (ii) history of AF but no SMuRF (163, 0.6%); (iii) history of AF with SMuRF (7286, 28.4%); (iv) no AF with SMuRF (17569, 68.5%). The primary endpoint was longitudinal mortality. Patients without the event were censored at the end of the registry period (2019). The Cox proportional hazards regression was used to assess the association between mortality, SMuRF and AF. The Kaplan-Meier method was used to evaluate survival between groups.
Results: AF+ and SMuRF- patients with first onset AIS had significantly higher incidence of mortality (HR 1.32, 95% CI 1.05 to 1.65, $p=0.017$) than AF- and SMuRF- patients, after adjustment for age, gender, ethnicity, anemia, history of transient ischemic attack, ischemic heart disease, and treatment with thrombolytics and antiplatelets. AF- and SMuRF+ patients were associated with the lowest mortality rate (HR 0.62, 95% CI 0.55 to 0.71, $p<0.001$) in the multivariate model.



Kaplan-Meier Survival Curves.

	Unadjusted model		Multivariable-adjusted model^	
Anemia Status	HR (95% CI)	P	HR (95% CI)	P
Overall (9979 events out of 25,651)				
AF- and SMuRF-	-		-	
AF- and SMuRF+	0.62 (95% CI 0.55 to 0.71)	<0.001	0.62 (95% CI 0.55 to 0.71)	<0.001
AF+ and SMuRF-	2.44 (95% CI 1.95 to 3.06)	<0.001	1.32 (95% CI 1.05 to 1.65)	0.017
AF+ and SMuRF+	2.22 (95% CI 1.96 to 2.51)	<0.001	0.96 (95% CI 0.84 to 1.09)	0.5

^ Adjusted for age, gender, ethnicity, age, anemia, history of transient ischemic attack, history of ischemic heart disease, treatment with thrombolytics and antiplatelets

Cox regression analyses of mortality by SMuRF and AF groups.

Conclusion: Patients with AF have an increased risk of mortality after AIS. The impact of SMuRF on mortality is paradoxical in stroke patients without AF.
Disclosure: Nothing to disclose.

EPR-022 | Predictors of stroke mimics in emergency department: An easy-to-use mimics prediction score

I. Scala[1]; M. Monforte[2]; J. Di Giovanni[1]; P. Rizzo[1]; S. Bellavia[1]; A. Broccolini[2]; P. Calabresi[2]; M. Covino[3]; G. Frisullo[2]
[1]*Catholic University of Sacred Heart, Largo Francesco Vito 1, 00168, Roma, Italy;* [2]*Department of Neuroscience, Sensory Organs and Chest, Fondazione Policlinico Universitario Agostino Gemelli, IRCCS, 00168 Rome, Italy;* [3]*Emergency Department, IRCCS Fondazione Policlinico Universitario Agostino Gemelli, 00168 Rome, Italy*

Background and Aims: Early differential diagnosis between stroke and stroke mimics is a challenge in the management of acute patients in the Emergency Department (ED). The primary aim of this study is to identify diagnostic predictors of stroke mimics based on demographic, clinical parameters and vital signs acquired in the ED during the triage phase of patients with suspected stroke. Secondly, we aimed to develop a diagnostic score predictive of stroke mimics.
Methods: In this retrospective, observational study, we enrolled patients admitted to the ED of a comprehensive stroke center for suspected stroke. Univariate comparisons were performed using Mann–Whitney U-test, Kruskal–Wallis and chi-squared test, as appropriate. Logistic regression was used to perform the adjusted analyses. We then computed a predictive score based on each variable's β coefficient.
Results: 2768 patients with a suspected diagnosis of stroke were included in the study of whom 1189 (43%) with stroke mimics. After multivariate logistic regression we observed that age, systolic blood pressure, speech and motor disorders, previous stroke, hemiplegia and congestive heart failure were independent predictors of stroke, while sensory disorders, headache, seizure, disorientation, syncope, dementia and renal disease were predictors of stroke mimics. Based on machine learning prediction model, we developed an easy-to-use score based exclusively on triage data that can accurately discriminate strokes from stroke mimics.

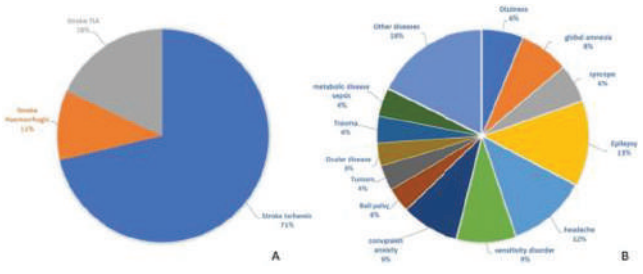


FIGURE 1. Graphics illustrating the prevalence of each stroke subtype (panel A) and of different types of stroke mimics diagnosis (panel B) in our patient population.

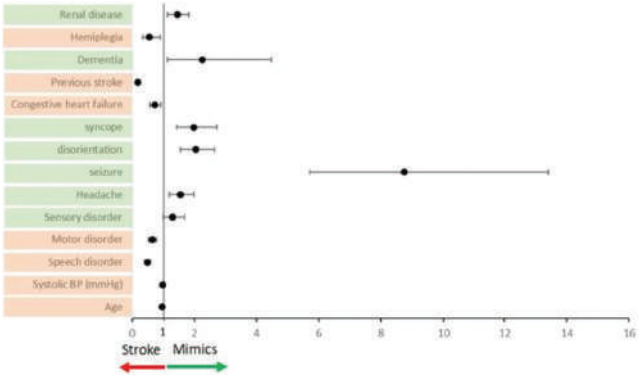

FIGURE 2. The forest plot of the multivariate logistic regression analysis for the discrimination between stroke and stroke mimics.

TABLE 1. The predictive score for the discrimination between stroke and stroke mimics. Negative values are suggestive for stroke mimics, while positive values for stroke. An overall score ≥4 is associated with a 87.8% probability of stroke diagnosis.

RISK FACTOR	CATEGORIES	REFERENCE VALUE (Wa)	βi (Wa − Wxxx)	Points

Renal disease	No	**0**	0	0
βi = 0.3706	Yes	1	0.3706	1

Conclusion: The identification of independent predictors of stroke mimics and the new mimics score could be useful tools for emergency physicians to stratify patients with suspected stroke and direct them towards a more appropriate diagnostic and therapeutic pathway.

Disclosure: Nothing to disclose.

EPR-023 | Acute imbalance syndrome (AIS) versus acute vestibular syndrome (AVS): differentiation matters

K. Möhwald[1]; H. Hadzhikolev[1]; L. Eberle[1]; P. Jaufenthaler[1]; M. Strupp[1]; K. Jahn[2]; J. Conrad[3]; A. Zwergal[1]

[1]*Department of Neurology & German Center for Vertigo and Balance Disorders, DSGZ, LMU University Hospital, LMU Munich, Germany;* [2]*Schön Klinik Bad Aibling, Department of Neurology, Bad Aibling, Germany;* [3]*Division for neurodegenerative Diseases, Department of Neurology, University Medicine Mannheim, Germany*

Background and Aims: Stroke is a major differential diagnosis in patients with acute vertigo/dizziness/imbalance. Diagnostic tests like HINTS are optimized for presentations with spontaneous nystagmus (SPN), called acute vestibular syndrome (AVS). However, in recent studies a relevant proportion of patients with stroke-related vertigo/dizziness had no SPN, but postural imbalance. For this phenotype, the term acute imbalance syndrome (AIS) was coined. We outlined the pathoanatomical differences of AIS/AVS and its clinical implications.

Methods: Seventy-five patients (66.7 ±12.6 y) with acute vertigo/dizziness/imbalance due to MRI-proven stroke were included and classified as AIS/AVS documenting vestibular/ocular motor/postural signs. Stroke lesion distribution was depicted in MNI space and supplemented by structural disconnectome mapping. Multivariate lesion symptom mapping based on support-vector regression and disconnectome mapping were applied.

Results: AIS was diagnosed in 58%, AVS in 39%, central positional vertigo in 3% of patients. In AIS, lesions were located in the anterior cerebellar lobe/deep cerebellar nuclei (SCA/PICA territory) connecting to the bilateral pontomesencephalic tegmentum. AVS stroke lesions were mostly located in the posterior cerebellar/

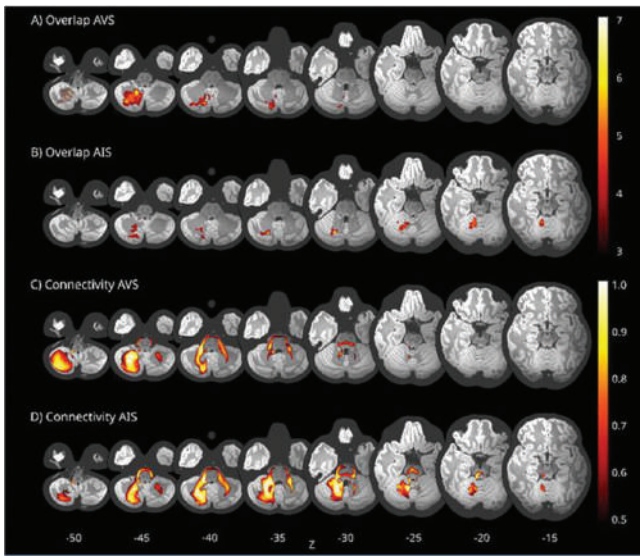

FIGURE 1. Lesion distribution and structural connectivity in the AVS and AIS subgroups. Warmer colors represent more lesion overlap or a higher degree of probability of connections.

flocculonodular lobe (PICA/AICA territory) and connected to the ipsilesional vestibular nucleus (VN)/bilateral medial longitudinal fascicle (MLF). SPN intensity correlated with voxels in the cerebellar lobules VI-IX connecting to VN/MLF.

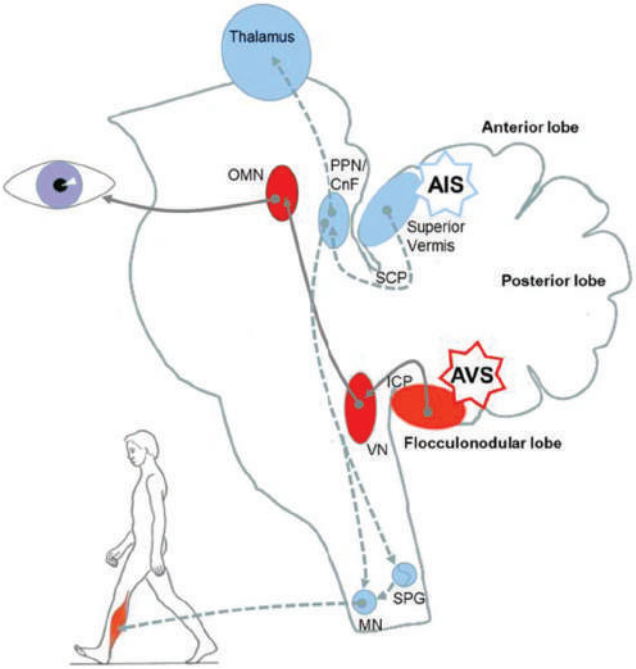

FIGURE 2. Pathophysiology of AIS and AVS.

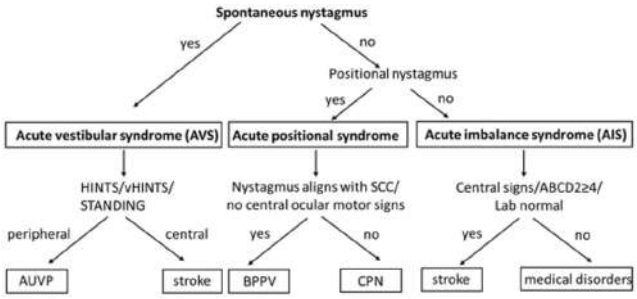

FIGURE 3. Clinical pathways for differentiation of AVS, AIS and acute positional syndrome.

Conclusion: AIS accounts for more than half of patients with stroke-related vertigo/dizziness/imbalance. AIS lesions were located in the anterior cerebellar lobe disturbing cerebellar-pontomesencephalic networks for posture/gait control. AVS lesions affected the posterior cerebellar/flocculonodular lobe and associated vestibulo-ocular reflex networks. Recognition of both clinical phenotypes is essential to identify all strokes among patients with vertigo/dizziness in the ER.

Disclosure: Nothing to disclose.

EPR-024 | Abstract withdrawn

EPR-025 | Cerebral atrophy patterns identify patients at risk of delirium following thrombectomy of large vessel occlusion stroke

M. Hahn[1]; L. Brockstedt[2]; S. Gröschel[1]; A. Othman[2]; K. Gröschel[1]; T. Uphaus[1]

[1]Department of Neurology, University Medical Center of the Johannes Gutenberg University Mainz, Germany; [2]Department of Neuroradiology, University Medical Center of the Johannes Gutenberg University Mainz, Germany

Background and Aims: Post-stroke-delirium has been linked to worse outcome in patients with acute cerebrovascular disease; identification of individuals at risk may prevent delirium and thereby improve outcome. We investigate the role of cerebral atrophy and white matter lesions (WML) as predictive factors for the development of post-stroke-delirium in patients with large vessel occlusion (LVO) ischemic stroke treated by mechanical thrombectomy (MT).

Methods: 747 patients (53.4% female) prospectively enrolled in the Gutenberg-Stroke-Study (May 2018–November 2022) were analyzed with regard to diagnosis of delirium during hospital stay. Native computed tomography (CT)-imaging based parameters of cerebral atrophy (global cortical atrophy [GCA] score, posterior atrophy score [Koedam], medial temporal lobe atrophy [MTA] score) and WML (Fazekas score) were compared on univariate level. Multiple logistic regression analysis (adjusted for age, sex and variables with differences on univariate level) was conducted to identify an independent predictive value of cerebral atrophy and WML for development of delirium.

Results: We report 8.2% of patients (61/747) developing delirium following MT of LVO. Pathological age-adjusted cerebral atrophy scores were more frequent in patients with delirium (GCA: 54.1% versus 38.5%, $p=0.015$; Koedam:31.1% versus 16.1%, $p=0.004$; MTA:24.6% versus 11.7%, $p=0.004$), whereas premorbid clinical diagnosis of dementia (6.6% versus 4.1%, $p=0.360$) and burden of WML were similar. In multiple logistic regression analysis, pathological MTA score resulted as an independent predictor of delirium (aOR [95%CI]: 2.126 [1.065–4.244], $p=0.033$).

Conclusion: Besides conventional risk factors, pathological MTA scores may be an easy-to-apply criterium to identify individuals at risk of developing delirium following MT of LVO, allowing for targeted preventive measures.

EPR-026 | Non-contrast CT markers as a predictor for underlying cerebral amyloid angiopathy

S. Schriemer[1]; O. de Bruin[1]; M. Wermer[2]; E. van Etten[1]
[1]*Department of Neurology, Leiden University Medical Centre, Leiden, The Netherlands;* [2]*Department of Neurology, University Medical Centre Groningen, Groningen, The Netherlands*

Background and Aims: Non-contrast CT (NCCT) markers of intracerebral haemorrhage (ICH) are associated with haematoma expansion and poor clinical outcome. However, their prevalence in different ICH aetiologies, such as sporadic cerebral amyloid angiopathy (sCAA), Dutch-type hereditary CAA (D-CAA), and deep perforator arteriopathy (DPA), remains unclear. We assessed the prevalence of NCCT markers in ICH-patients and established if they can predict CAA as underlying aetiology.
Methods: We assessed CT scans of initial and recurrent ICHs of consecutive patients with sCAA, D-CAA, and DPA, for the presence of 9 NCCT markers: black hole sign, blend sign, island sign, satellite sign, swirl sign, irregular shape, fluid level, hypodensity, and heterogeneous density. We compared their prevalence between the three aetiologies and used binomial regression models to identify NCCT markers predictive for underlying CAA (sCAA and D-CAA) compared to DPA.
Results: We assessed 316 NCCT scans from 231 ICH-patients (mean age 69, 52% female): 64 with sCAA, 67 with D-CAA, and 100 with DPA. In 40% of NCCTs no markers were present. The blend, island, and satellite sign were seen more often in both sCAA and D-CAA patients, while hypodensity was found more often in patients with DPA (all $p < 0.01$). In regression analyses, the island (OR = 7.0, 95%CI:1.4–34.4), blend (OR = 4.8, 95%CI:1.4–16.7), and satellite signs (OR = 4.0, 95%CI:1.8–8.9) were associated with underlying CAA, while CAA was less often present in case of hypodensity (OR = 0.4, 95%CI:0.2–0.7).
Conclusion: The blend, island, and satellite sign are associated with underlying CAA, while hypodensity is associated with DPA. These markers may help identify the underlying cause of ICH.
Disclosure: Nothing to disclose.

Spinal cord and root disorders

EPR-027 | Longitudinally extensive myelopathy: When do you biopsy the spinal cord?

A. Chaudhuri[1]; K. Farrell[2]
[1]*Department of Neurology, Queen's Hospital, Romford, UK;*
[2]*Department of Neurology, West Hertfordshire Hospitals NHS Trust*

Background and Aims: A neuroinflammatory demyelinating disorder is the likely diagnosis in adolescents and young adults presenting with a subacutely progressive paraplegia with longitudinally extensive intrinsic signal change within the spinal cord. However, failure to respond to immunotherapy should alert the clinician to consider alternative diagnosis.
Methods: Two young Asian patients (F = 17 y; M = 21 y) were diagnosed with treatment-refractory double seronegative NMOSD based on their clinical evaluation and MRI changes. Symptom onset in the female patient followed COVID-19 vaccination; the male patient had a preceding febrile illness. P100 latencies in VEP were prolonged in the female patient. MRI signal abnormalities and lesion enhancement were in keeping with the changes reported in longitudinally extensive transverse myelitis.
Results: There was minimal response to high dose corticosteroids, anti-CD20 monoclonal antibody (rituximab) and human IVIg in the female patient. No treatment response was seen after high dose steroids and antiviral (aciclovir) in the male patient. Due to the relentless progression of myelopathy, biopsy of enhancing spinal cord lesion was undertaken in both patients that confirmed the diagnosis of high-grade spinal cord astrocytoma. Despite radiotherapy, both patients succumbed to death within 6 months of the confirmed tissue diagnosis.
Conclusion: Failure of clinical response to steroids, rituximab, IVig and/or plasma exchange should alert clinicians to seek a tissue diagnosis of seronegative patients with longitudinally extensive signal abnormalities within spinal cord. The possibility of high-grade astrocytoma must be considered in treatment-refractory monophasic double-seronegative NMOSD presenting with a progressive myelopathy.
Disclosure: There is no competing interest.

EPR-028 | Autonomic dysreflexia and dysfunction—A case series and literature review

V. Hvingelby[1]; T. Bech[2]; M. Andersen[2]; E. Hagen[2]
[1]*Aarhus University Hospital, Department of Nuclear Medicine and PET;* [2]*Westdanish Center for Spinal Cord Injury, Hospital Unit Central Region, Denmark*

Background and Aims: One potential complication to spinal cord injury (SCI), autonomic dysfunction can be triggered by a multitude of stimuli. In cases where the injury is sustained above Th6, potentially life-threatening attacks of spiking blood pressure may occur termed autonomic dysreflexia (AD). Here, we present a series of four individuals experiencing AD from our specialized rehabilitation center and expand upon this through a systematic review of the literature on autonomic dysfunction
Methods: A prospective enrollment of four persons with SCI and concomitant AD was performed. Case histories and charts are reported. A review according to PRISMA guidelines was performed. Keywords were autonomic dysfunction or dysautonomia and SCI across PubMed, EMBASE and Cochrane Library of Clinical Trials (CENTRAL).
Results: The case series presented here displays the large degree of heterogeneity in the incipient stimuli and the time to development

of AD. A particularly important point, AD adversely affected rehabilitation and quality of life of all four patients. Literature search returned 247 studies on different aspects of autonomic dysfunction secondary to SCI. Autonomic dysfunction occurs at very high frequency and may in some cases life-threatening complications. This is especially prevalent in cases cardiovascular dysregulation. Gastrointestinal and urological complications were also prevalent with a clinically significant impact on quality of life.

Conclusion: Autonomic dysreflexia and dysfunction present a complex aspect of SCI whose impact and treatment is incompletely understood. Restorative treatments are in general not available. Causes, natural history and progression remain issues in need of clarification in order to improve potential restorative therapies.

Disclosure: The authors declare there is nothing to disclose.

EPR-029 | Serum Glial fibrillary acidic protein is associated with motor function in adult Spinal muscular atrophy

E. Kesenheimer[1]; M. Wendebourg[1]; L. Sander[1]; C. Neuwirth[2]; N. Braun[2]; M. Weber[2]; A. Orleth[3]; A. Maleska Macesci[3]; M. Sinnreich[4]; J. Kuhle[3]; R. Schläger[1]

[1]Department of Neurology and Department of Clinical Research, University Hospital Basel, University of Basel, Basel, Switzerland; [2]Neuromuscular Diseases Unit/ALS Clinic, Kantonsspital St. Gallen, St. Gallen, Switzerland; [3]Department of Neurology and Department of Clinical Research, University Hospital Basel, and Research Center for Clinical Neuroimmunology and Neuroscience Basel (RC2NB), University of Basel, Basel, Switzerland; [4]Deparment of Neurology and Department of Biomedicine, University of Basel, Basel, Switzerland

Background and Aims: In adult spinal muscular atrophy (SMA), there is an unmet need for biomarkers to monitor the disease progression and treatment response. 5q-SMA mouse models have provided evidence of astrocyte activation and increased levels of Glial fibrillary acidic protein (GFAP). Aims of this study were to assess serum GFAP (sGFAP) levels in patients with 5q-SMA and age- and sex matched healthy controls (HCs), as well as associations with clinical disability in SMA, namely Motor Function Measure (MFM) and 6-Minute-walk-test (6-MWT).

Methods: We prospectively examined twenty patients with 5q-SMA, types 2 and 3 (mean age/SD 41.3/11.6y, 9 women) and twenty age- and sex-matched HCs (mean age/SD 41.7/11.4y, 9 women). sGFAP concentrations were measured using the ultrasensitive single molecule array (Simoa) technology. Associations between sGFAP concentrations and MFM and 6-MWT were analyzed using Spearman Rank correlations and linear regression analyses.

Results: In patients with SMA, sGFAP concentrations were significantly elevated by 52% ($p=0.021$) compared to age- and sex-matched HCs. Significant associations were found between sGFAP concentrations and MFM (rho: −0.61, $p=0.006$) and 6-MWT (rho: −0.69, $p=0.019$). In linear regression analyses, sGFAP concentrations accounted for 43% of MFM variance and 35% of 6-MWT variance, respectively.

Conclusion: sGFAP concentration, a marker of astrocyte dysfunction, is elevated in adult patients with SMA and inversely correlates with metrics of motor function and endurance in ambulatory patients. Further longitudinal studies are necessary to evaluate the potential of this novel biomarker as a marker for disease progression and therapeutic response in SMA.

Disclosure: The study was funded by Biogen. The funder did not play any role in the concept and design of the study and acquisition, analysis, and interpretation of the data.

EPR-030 | A spatiotemporal atlas of acute spinal cord injury

Y. Fang

Interdisciplinary Research Center on Biology and Chemistry, Shanghai Institute of Organic Chemistry, Chinese Academy of Sciences, Shanghai, China

Background and Aims: Spinal cord injury (SCI) triggers a cascade of intricate molecular and cellular changes that determine its outcome.

Methods: Spatial transcriptomics (ST) is a recent emerging technology that enables high-throughput measurement of gene expression while retaining the anatomic information. In this study, we have developed a bioinformatic toolset to resolve the spatiotemporal organization of the injured spinal cord and quantitatively assess in situ cell-cell communication following SCI.

Results: By analyzing existing single-cell RNA-sequencing datasets alongside our spatial data, we delineate a unique subpopulation of astrocytes, termed Astro-GMii, that migrate from white matter to grey matter and become reactive and neuro-supportive during the acute phase of SCI. Further, we identify Igfbp2 as a molecular marker and driver of Astro-GMii, as its overexpression promotes astrocyte migration, proliferation and reactivity. Moreover, we demonstrate that the conditioned medium derived from Igfbp2-overexpressing astrocytes, as well as the secreted IGFBP2 protein alone, foster neurite outgrowth. Finally, by administering IGFBP2 in vivo, we observe a significant reduction in neuronal loss and remarkable improvements in functional recovery in mice with SCI.

Conclusion: Together, this study not only provides a comprehensive molecular atlas of SCI but also exemplifies how the rich resource can be applied to endow cells and genes, such as Astro-GMii and Igfbp2, with new functional insight and therapeutic potential.

Disclosure: Nothing to disclose.

EPR-031 | Spinal dural arteriovenous fistulas – A single center experience

F. Ferreira[1]; T. Pedro[2]; L. Albuquerque[2]; P. Pereira[3]; R. Soares-dos-Reis[1]

[1]Department of Neurology, Centro Hospitalar Universitário de São João, Porto; [2]Department of Neuroradiology, Centro Hospitalar Universitário de São João, Porto; [3]Department of Neurosurgery, Centro Hospitalar Universitário de São João, Porto

Background and Aims: Spinal dural arteriovenous fistulas (SDAVF) are a rare subtype of vascular malformation, which leads to venous congestion and subsequent progressive myelopathy, leading to considerable morbidity in affected patients. We aim to describe clinical and imaging features of patients with SDAVF.

Methods: We conducted an observational retrospective study including all patients diagnosed with SDAVF at our hospital over the last 15 years, confirmed by digital subtraction angiography (DSA), using keyword search through spinal cord DSA reports.

Results: We included 13 patients in our study, whose detailed characteristics are presented in Table 1. The median age at diagnosis was 59 years and 7 patients were female. The median time from symptom onset to SDAVF diagnosis was 9 months, and most patients presented with more than one symptom at the time of diagnosis. Five patients had a misdiagnosis before confirmation of SDAVF, and 4 underwent targeted treatment for those suspected conditions. Most patients underwent surgical treatment (62%) and one patient was treated with a combined endovascular and surgical approach. There was no statistically significant difference between modified Aminoff and Logue's Scale (mALS) scores assessed before treatment and at 24-months follow-up after treatment (Table 2).

TABLE 1. Characteristics of patients with SDAVFs.

Characteristic	
Age (years)	55 (36-74)
Men, n (%)	6 (46)
Symptom onset, n (%)	
Progressive	12 (92)
Abrupt	1 (8)
Primary symptom, n (%)	
Lower extremity weakness	3 (23)
Sensory abnormality	3 (23)
Complex symptoms	7 (54)
Misdiagnosis, n (%)	5 (38)
Inflammatory	3 (23)
Neoplastic	1 (8)
Infectious	1 (8)
Time from symptom onset to SDAVF diagnosis (months), median (Q25%-Q75%)	9 (1-17)
Imaging findings on spinal cord MRI	
SDAVF location, n (%)	
Above T7	2 (15)
T7-T12	6 (46)
Below T12	5 (39)
Presence of flow-voids, n(%)	12 (92)
Length of spinal cord edema, median (Q25%-Q75%)	6 (0-12)
Time from symptom onset to SDAVF treatment (months), median (Q25%-Q75%)	10 (2-18)
Treatment modality, n (%)	
Endovascular embolism	1 (8)
Neurosurgery	8 (62)
Combined treatment	1 (8)
None	3 (23)
Recurrence, n (%)	2 (15)
Reintervention, n(%)	2 (15)

TABLE 2. Comparison between modified Aminoff and Logue's Scale (mALS) before and after treatment

mALS, median (Q25%-Q75%)	Before treatment	24-months follow-up after treatment	Delta-mALS, median (Q25%-Q75%)
Gait	3 (2-4)	4 (2-4)	0 (-0,5 – 1,5)
Urination	1 (0-2)	2 (0-2)	0 (-0,5 – 2)
Defecation	0 (0-1)	0 (0-2)	0 (-0,5 – 2)

Conclusion: Despite adequate treatment, our patients did not exhibit substantial improvement, which could possibly be related to delayed diagnosis and intervention. SDAVF remains a source of considerable morbidity in affected individuals, exerting a significant impact on their quality of life even following proper diagnosis and treatment.

Disclosure: Nothing to disclose.

EPR-032 | Gender-based analysis of perioperative and early postoperative complications in tubular microdiscectomy

H. Hashim[1]; G. Hasan[2]; A. Al-Obaidi[3]

[1]University of Warith Al-Anbiyaa, College of Medicine; [2]Royal Private Hospital; [3]University of Baghdad, College of Medicine

Background and Aims: After spine surgery, many factors, including variations in anthropomorphic parameters and co-morbidities, may contribute to the difference in complication rates between both genders. Previous literature suggests that gender may affect the incidence of specific spinal disorders, such as lumbar degenerative disc disease, lumbar disc radiculopathy, and cauda equina syndrome.

Methods: This retrospective multicenter study, conducted in two specialized spine centers in Baghdad, Iraq, involved 302 patients with lumbar disc herniation (174 males and 128 females) from January 2016 to January 2022. Data collection included comprehensive assessments of clinical and surgical outcomes, utilizing the Core Outcome Measures Index (COMI) score at two, six, and twelve weeks.

Results: 134 males (77%) and 104 females (81%) were below 40 years old, while 40 males (23% of males) and 24 females (18.8% of females) were 40 or older. There was a significant difference in mean operative times ($p < 0.001$). The most common specific complication was spondylodiscitis with 6 males (3.4% of males) and 3 females (2.3% of females), while the most common general complication was post-op back spasm with 6 males (3.4% of males) and 4 females (3.1% of females).

Conclusion: Gender has a minimal impact on most perioperative and early postoperative complications. Longer operative times in females raise questions about gender-specific differences across spine surgeries and specialties, necessitating further research.

Disclosure: Nothing to disclose.

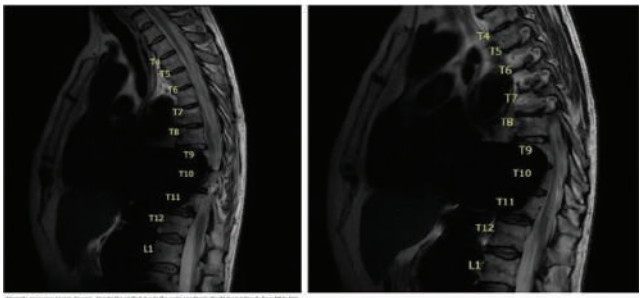
EPR-033 | Local fibrinolysis in a patient with spinal cord ischaemia secondary to abdominal aortic surgery

J. Ortega-Macho[1]; L. Franco-Rubio[2]; M. Moreu-Gamazo[3]; P. Gutiérrez-Bedia[1]; A. Marcos-Dolado[4]; R. Ginestal-López[4]; C. Gómez-Escalonilla[4]; M. Malaret-Segurado[1]; A. Maruri- Pérez[1]; J. Obregón-Galán[1]; E. López-Valdés[4]

[1]2nd year Neurology Resident. Hospital Universitario Clínico San Carlos, Neurology Department, Madrid, Spain, [2]3rd year Neurology Resident. Hospital Universitario Clínico San Carlos, Neurology Department, Madrid, Spain; [3]Interventional Neuroradiodiagnostic Specialist. Hospital Universitario Clínico San Carlos, Neurology Department, Madrid, Spain; [4]Specialist Neurology Area Practitioner. Hospital Universitario Clínico San Carlos, Neurology Department, Madrid, Spain

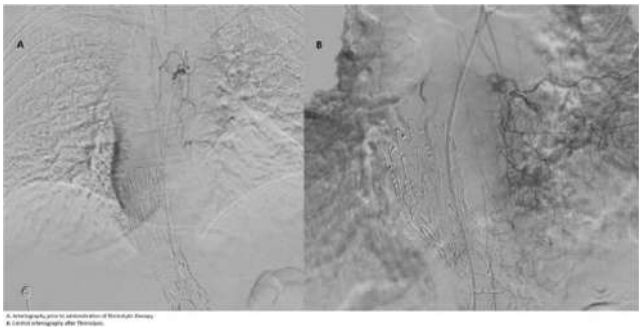
Background and Aims: Acute spinal cord ischemia (AMI) is an uncommon yet severe condition that results in substantial functional impairment for the patients. Diagnosis can be challenging at times, and there is a lack of robust evidence supporting the local fibrinolytic therapy.

Methods: We present the clinical case of a 63-year-old female patient with a history of smoking, hypertension, hypercholesterolemia and recent surgery to exclude abdominal aortic aneurysm by endoprosthesis, who presented with a progressive episode of less than 1 week duration of disabling low back pain and lower limb allodynia with sudden worsening in the Emergency Department. Examination revealed an almost complete spinal cord syndrome with moderate-severe paraparesis, hyperreflexia, inexhaustible clonus, tactoalgesic hypoesthesia at D8-D10 and urinary retention. Magnetic resonance imaging showed a signal abnormality in the posterior half of the spinal cord of recent onset extending from D8 to D11, consistent with spinal cord ischaemia (Image 1). Angiography showed an anterior spinal artery occlusion at the level of D6 (Image 2A).



Magnetic resonance images showing, despite the artefact due to aortic prosthesis, the T2 hyperintensity from D8 to D11.

Results: 7 mg of intra-arterial tissue plasminogen activator were administered into the left D6 radicular branch of the anterior spinal artery. Angiographic control was performed 10 minutes later and showed increased flow in the vessel (Image 2B). The patient experienced significant neurological improvement, which was observed immediately and maintained during 6 months of clinical follow-up at a regional rehabilitation hospital and neurology outpatient clinics (Table 1).



A. Arteriography prior to administration of fibrinolytic therapy. B. Control arteriography after fibrinolysis.

	AT THE BEGGINING OF HOSPITALISATION		AT THE END OF HOSPITALISATION	
	RIGHT LEG	LEFT LEG	RIGHT LEG	LEFT LEG

** Muscle balance based on MRC strenath scale*

Clinical examination before and after the fibrinolytic therapy.

Conclusion: Local fibrinolytic therapy may emerge as a potentially useful intervention, with standardized use offering benefits for a subset of patients.

Disclosure: Nothing to disclose.

EPR-034 | Clinico-radiologic characteristics of spontaneous spinal cord infarction in Korean patients: A single-center study

H. Seok[1]; M. Eun[2]

[1]Department of Neurology, Dongsan Hospital, Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Department of Neurology, School of Medicine, Kyungpook National University, Kyungpook National University Chilgok Hospital, Daegu, Republic of Korea

Background and Aims: Spinal cord infarction (SCI) is a rare condition, accounting for less than 1% of all strokes, which has resulted in limited research on the subject. Therefore, our aim was to determine the clinical features associated with spontaneous SCI in Korean patients.

Methods: In this retrospective analysis, we reviewed the medical records of individuals diagnosed with spontaneous SCI at Keimyung University Dongsan Hospital between 2017 and 2023.

Results: We identified 23 patients (13 male, 10 female) with a mean age of 65.6±11.0 years. The median time from onset to hospital arrival was 20.4 (6.4–60.7) hours. Notable presentations included complete cord syndrome (34.8%) and hemicord syndrome (30.4%). The etiology of SCI remained undetermined in a significant proportion of patients (60.9%), although laboratory test results suggested a high risk of atherosclerosis, hypercoagulability, or inflammation. The initial MRI was negative in 52.2% of cases, but subsequent scans revealed lesions in two-thirds of patients, predominantly in the cervical cord (20.0%), thoracic cord (45.0%), and conus (20.0%). On admission, the mean modified Rankin Scale (mRS) was 3.9 ±1.4, and 52.2% of patients were confined to a wheelchair. Common symptoms included dysuria (69.6%) and adjacent pain (47.8%). Treatment included antiplatelet agents and statins. At discharge, the mean mRS was 3.6 ±1.6 and 47.8% of patients remained wheelchair bound. At a mean of 5 (2.0–12.0) months after discharge, the mRS improved to 2.6 ±1.4, with only 13.6% requiring a wheelchair.

Conclusion: This study provides insight into the clinical and radiological characteristics of spontaneous SCI in the Korean population.

Disclosure: Nothing to disclose.

EPR-035 | Long-term potentiation plasticity is impaired in AQP4-NMOSD patients

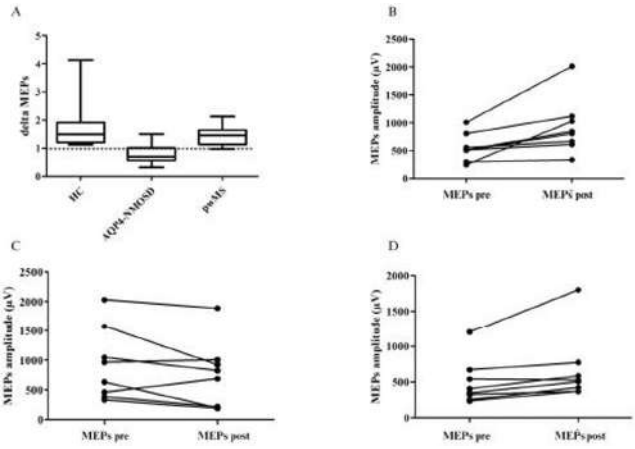
A. Cruciani[1]; F. Capone[1]; S. Haggiag[2]; L. Prosperini[2]; F. Santoro[1]; S. Ruggieri[2]; F. Motolese[1]; F. Pilato[1]; V. Pozzilli[1]; G. Musumeci[1]; V. Di Lazzaro[1]; C. Gasperini[2]; C. Tortorella[2]

[1]*Department of Medicine and Surgery, Unit of Neurology, Neurophysiology, Neurobiology, and Psychiatry, Università Campus Bio-Medico di Roma, Via Alvaro del Portillo, 21 – 00128 Roma, Italy*; [2]*Department of Neurosciences, S. Camillo-Forlanini Hospital, C.ne Gianicolense 87, 00152, Rome, Italy*

Background and Aims: Aquaporin-4-positive neuromyelitis optica spectrum disorder (AQP4-NMOSD) is usually characterized by a poor recovery from the attacks and the appearance of few asymptomatic interictal MRI lesions. The impairment of cortical plasticity might be the mechanism underlying these observations. This study aimed to explore neuroplasticity in AQP4-NMOSD patients by examining intermittent theta burst stimulation (iTBS) long-term potentiation (LTP), in AQP4-NMOSD and multiple sclerosis (MS) patients.

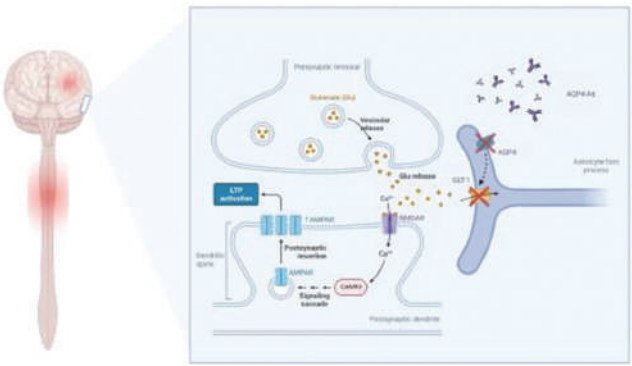
Methods: We enrolled 8 right-handed AQP4-NMOSD, 8 relapsing-remitting MS (RRMS) and 8 healthy control (HC). For each group we evaluated motor evoked potentials (MEPs) before an intermittent theta-burst (iTBS) stimulation. Five minutes after iTBS we reassess MEPs.

Results: A significant difference in post iTBS MEPs modification (delta MEPs) was observed among the three groups (*p*: 0.006). Post-hoc comparison revealed that patients with AQP4-NMOSD significantly differed from both HC and patients with MS (*p*: 0.012 and 0.022 respectively). No baseline differences in MEPs amplitude were identified.



Panel A: Distribution of delta MEPs values of the three populations. There is statistically significance differences between AQP4-NMOSD patients and HC and between AQP4-NMOSD patients ad pwMS. Changes in MEPSs amplitude after iTBS in HC (Panel B), AQP4-NM.

Conclusion: Our pilot study demonstrates for the first time in vivo, a LTP impairment in patients with AQP4-NMOSD. This deficit in plasticity mechanisms could elucidate crucial clinical features of AQP4-NMOSD and aligns with animal model studies proposing AQP4 as a pivotal channel in glutamatergic transmission Furthermore, the concept of an impaired LTP in AQP4-NMOSD patients could pave the way to future rehabilitation approaches.



Schematic representation of glutamatergic excitotoxicity induced by AQP4 antibodies. The AQP4 trafficking dysregulation caused by the AQP4-Ab presents in NMOSD patients caused an impaired function in the GLT-1 leading to an accumulation of glutamate in th.

Disclosure: Nothing to disclose.

EPR-036 | Clinical presentation and disease course in a series of eight patients with neurosarcoidosis

A. Liampas[1]; C. Taliadoros[2]; E. Papagianni[3]; M. Pantzaris[1]; A. Koupparis[3]; E. Zamba[2]; K. Kleopa[2]
[1]*Center for Multiple Sclerosis and Related Disorders, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus;* [2]*Center for Neuromuscular Disorders, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus;* [3]*Epilepsy Center, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus*

Background and aims: Sarcoidosis is an immune-mediated multisystem disorder characterized by granulomatous inflammation of affected organs. Neurosarcoidosis is a form of sarcoidosis affecting the central or the peripheral nervous system and is usually associated with other peripheral organ involvement, but it may occur in isolation.
Methods: Retrospective analysis of patients who were diagnosed with neurosarcoidosis with or without other organ involvement at the Cyprus Institute of Neurology and Genetics.
Results: Eight patients were included, of which 3 were female. The mean age at onset disease was 56.5 ± 14.0 (range: 30–73) years old. The mean duration of follow-up was 3 + 1.9 years. Two out of 8 cases presented with isolated neurosarcoidosis. Cranial nerve involvement was present in 5 out of 8 cases, of which the facial nerve was the most commonly affected; 4 patients presented Bell's palsy. One patient presented with normal pressure hydrocephalus, a rare presentation of neurosarcoidosis. Five out of six patients had increased cerebrospinal fluid (CSF) angiotensin converting enzyme (ACE) level with a mean value of 2.31 + 0.9 umol/min/L (normal range: <1.2 umol/min/L). Two of five patients presented elevated CD4+/CD8+ levels, while oligoclonal band pattern showed a great variability. In regards to treatment, all patients received oral corticosteroids and 4 patients also received azathioprine, with good overall response.
Conclusion: Neurosarcoidosis is a relatively uncommon and challenging diagnosis, especially in the absence of systemic manifestations. This case series highlights both common and rare complications of neurosarcoidosis with the goal to facilitate better recognition and timely management of the disease.
Disclosure: Nothing to disclose.

EPR-037 | Role of pregnancy in MOG antibody-associated disease activity and pregnancy outcomes

P. Faustino[2]; A. Francis[1]; F. Chan[1]; B. Chen[1]; S. Delgado[3]; G. Greco[4]; J. Palace[1]; M. Leite[1]
[1]*Department of Clinical Neurosciences, Oxford University Hospitals NHS Foundation Trust;* [2]*Neurology Department, Centro Hospitalar Universitário de Lisboa Central, EPE;* [3]*Neurology Department, Hospital Fernando da Fonseca;* [4]*Department of Brain and Behavioral Sciences, Università degli Studi di Pavia, Pavia, Italy*

Background and Aims: The relation between MOGAD and pregnancy is not fully understood, despite recent studies showing a higher attack rate in the puerperium. We aim to determine the pregnancy role in MOGAD disease activity, and characterize MOGAD effect on pregnancy outcomes.
Methods: This observational retrospective study included all women with any pregnancy and MOGAD diagnosis registered at NMO highly specialized service, Oxford, until December 2023. Baseline variables and pregnancy details were collected. Pregnancy outcomes and pregnancy-related disease attacks were analysed. We defined as pregnancy-related attacks those that occurred in the year previous to estimated date of conception, during pregnancy and in the first year postpartum. A sub analysis assessed if disease activity was influenced by pregnancy through logistic binary regression. The annualized relapse rate (ARR) and its association with pregnancy was also calculated.
Results: We identified ninety-one women with a total of 205 pregnancies. Preeclampsia (2.2%) and miscarriage (11.2%) rate were within expected range. There was an increase in ARR in the nine months postpartum, higher in the first three months, reaching 2.125 in patients with pregnancy-related presenting attack, and 0.973 in those with NMOSD previously diagnosed. We analysed other factors related to a higher relapse risk and did not find any significant association.
Conclusion: Our results showed clear high MOGAD activity in the postpartum period, particularly at the disease presentation, suggesting that pregnancy & puerperium may be a "disease trigger". There was no clear association between MOGAD and pregnancy outcomes.
Disclosure: Nothing to disclose.

EPR-038 | Development Of Multiplexed Electroanalytical Biosensing Platforms For The Clinical Diagnosis Of Alzheimer's Disease

A. Montero-Calle[1]; M. Garranzo-Asensio[1]; A. Valverde[2]; P. San Segundo-Acosta[1]; E. Povedano[2]; R. Rodriguez-Torrente[2]; J. Pingarron[2]; S. Campuzano[2]; R. Barderas[1]
[1]*Chronic Disease Programme (UFIEC), Instituto de Salud Carlos III, Majadahonda, Madrid, Spain;* [2]*Analytical Chemistry Department, Complutense University of Madrid, Madrid, Spain*

Background and Aims: Novel biomarkers for the early diagnosis of Alzheimer's disease (AD) are needed. Among the new approaches

developed in the last years, circulating autoantibodies (AAbs) and their target proteins (autoantigens) are promising candidate biomarkers to aid in AD early diagnosis. We aimed here to validate the potential of electrochemical biosensors for AD-diagnosis based on the amperometric measurement of AD-specific plasma autoantibodies.

Methods: An immunoplatform based on the use of Halo-MBs (magnetic beads) modified with previously validated AD autoantigens was developed. Autoantigens were cloned and expressed as HaloTag fusion peptides/proteins in mammalian cells. Their oriented covalent immobilization to MBs allowed for the efficient and selective capture of AAbs from plasma. Finally, signal was developed by amperometric transduction on disposable electrodes using the H_2O_2/HQ (hydroquinone) system.

Results: AAbs against two aberrant AD-associated peptides, four peptide autoantigens identified by Phage Microarrays, and three full-length AD autoantigens identified by multiomics analyses were differentially detected in AD patients from controls. Thus, we described here the first multiplexed bioplatform for AD diagnosis by targeting AD-specific plasma AAbs. The analytical operational characteristics of this biosensor demonstrated its significant clinical diagnostic potential in a single test and in less than 90 minutes.

Conclusion: These results acknowledge a reliably and minimally invasive method for AD diagnosis based on amperometric biosensing platforms detecting plasma autoantibodies against AD-specific autoantigens with a high sensitivity and specificity, and a high potential as point-of-care (POC) devices for the clinical diagnosis of AD by liquid biopsy and in less than 90 minutes.

Disclosure: Nothing to disclosure.

EPR-039 | Brain biopsies in unexplained neurological disorder have a high diagnostic and therapeutic yield, while being safe

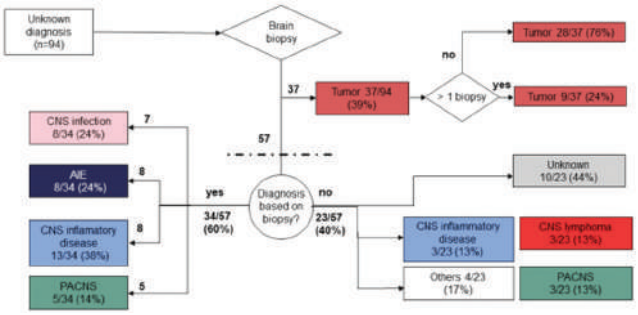
R. van Steenhoven[1]; S. Salih[2]; J. de Vries[1]; R. Verdijk[3]; M. Gardeniers[4]; M. Geurts[1]; J. Bromberg[1]; I. Smets[1]; C. Geurts van Kessel[5]; P. Sillevis Smitt[1]; R. Balvers[2]; M. Titulaer[1]

[1]Department of Neurology, Erasmus MC University Medical Center, Rotterdam, The Netherlands; [2]Department of Neurosurgery, Erasmus MC University Medical Center, Rotterdam, The Netherlands; [3]Department of Pathology, Erasmus MC University Medical Center, Rotterdam, The Netherlands; [4]Department of Radiology, Erasmus MC University Medical Center, Rotterdam, The Netherlands; [5]Department of Virology, Erasmus MC University Medical Center, Rotterdam, The Netherlands

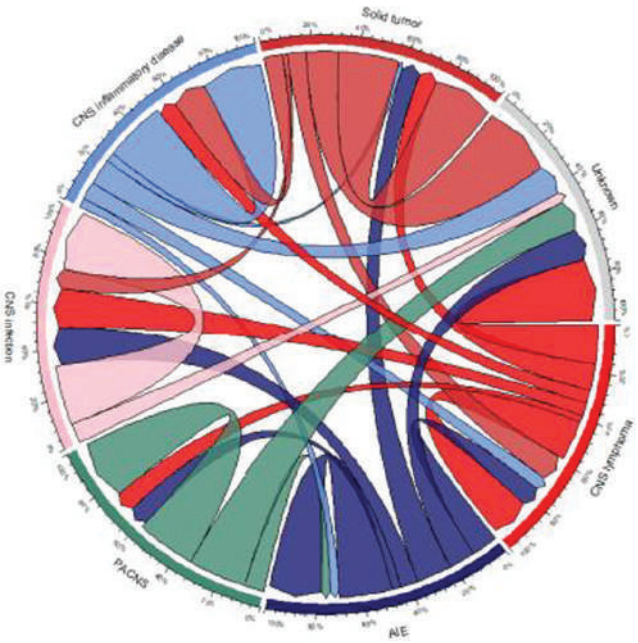
Background and Aims: Major progress has been made in the diagnosis of central nervous system (CNS) disorders, as various minimally invasive diagnostic techniques were introduced. Consequently, the role of brain biopsies in CNS disorders is unknown. We aimed to study the diagnostic yield, therapeutic implications and safety of brain biopsies in CNS disorders with unknown etiology.

Methods: In this retrospective cohort study, all adult patients who were referred for a diagnostic work-up to our academic center with neuroinflammatory, neuro-oncological and virological expertise and underwent brain biopsy between January 2010 and December 2023 were included. Typical cases of CNS neoplasms and infections were not analyzed. Brain biopsies were evaluated with respect to diagnostic and therapeutic impact and complication rate.

Results: A biopsy was performed in 636 patients, of whom 542 had a typical phenotype with matching pathological diagnosis. Ninety-four patients with CNS disorder of unknown cause, with 105 biopsies, were analyzed (44% female, median age 58 years, range 19-79). Final diagnoses included CNS neoplasms (37/94, 39%), CNS inflammatory disorders (13/94, 14%), CNS infections (8/94, 9%), autoimmune encephalitis (8/94, 9%), and primary angiitis of the CNS (5/94, 5%). The first biopsy had a diagnostic impact in 65%, increasing up to 75% after repeated biopsies. In 75% of the cases, brain biopsy changed the treatment strategy. Biopsy was complicated by symptomatic intracranial haemorrhage in 4/105 biopsies (4%).



Flowchart showing diagnostic categories based on brain biopsy.



Chord diagram showing shift of diagnoses: before versus after brain biopsy.

Conclusion: In a selected population of patients with unexplained CNS disorders, the diagnostic yield and therapeutic impact of brain biopsies are high, while being relatively safe.

Disclosure: P.A. Sillevis Smitt holds a patent for the detection of anti-DNER, he received research support from Euroimmun. M.J. Titulaer has filed a patent, on behalf of the Erasmus MC, for methods for typing neurologic disorders and cancer, and devices for use therein; has received research funds for serving on a scientific advisory board of Horizon Therapeutics, for consultation at Guidepoint Global LLC, for consultation at UCB, for teaching colleagues at Novartis; and has received an unrestricted research grant from Euroimmun AG and from CSL Behring.

EPR-040 | Optic neuropathies related to immune checkpoint inhibitors: a case series and systematic review of the literature

S. Cuzzubbo[1]; E. Louis[2]; E. Philippakis[3]; B. Baroudjian[4]; C. Lebbé[4]; A. Couturier[3]; A. Carpentier[1]

[1]Service de Neurologie, AP-HP, Hôpital Saint Louis, Université Paris Cité, Paris, France; [2]Service de Neurologie, AP-HP, Hôpital Saint Louis, Paris, France; [3]Service de Ophtalmologie, AP-HP, Hôpital Lariboisière, Paris; [4]Service de Dermato-oncologie, AP-HP, Hôpital Saint-Louis, Paris

Background and Aims: Optic neuritis related to immune checkpoint inhibitors (ICIs) have been rarely reported and poorly described. However, their knowledge is essential to promptly manage them since a persistent visual decline is reported in approximately half of the patients.

Methods: We report a retrospective series of patients with an ICI-related optic neuropathy referred to our departments between 2018 and 2022, and a systematic search of the literature with the aim to describe their features, outcome and tolerance of ICI reintroduction. Based on the evidence or not of optic nerve impairment at the MRI or visual evoked potentials, we distinguished cases of papillitis or optic neuritis.

Results: We identified three patients in our institution and 35 cases from the literature. The symptoms occurred after a median time of 10 weeks and three doses of ICIs. The most common pattern consisted of painless reduction of visual acuity and bilateral papilledema. Papillitis were commonly associated with uveitis (71%) whereas optic neuritis with other neurotoxicities (29%). In 66% of published cases, a visual deficit persisted despite the use of corticosteroids. Unlike other reports, all patients of our series experienced a complete recovery. Given such a quick improvement, we continued the ICIs in two patients, with good tolerance.

Conclusion: We found two main clinical patterns: (i) papillitis, usually associated with other intraocular inflammation, and (ii) optic neuritis, more often associated with other neurological toxicities and which lead to a worse outcome. Based on our experience, ICI treatment discontinuation is not mandatory in case of non-severe optical neuropathies.

Disclosure: No disclosure of interests to declare.

EPR-041 | MOG antibody titres in relapsing disease: Implications to clinical practice

T. Gakharia[1]; V. Lee[2]; M. Lim[3]; A. Siddiqui[2]; T. Rossor[2]; P. Waters[5]; Y. Hacohen[2]; D. Champsas[4]

[1]Tbilisi State Medical University; [2]Evelina London Children Hospital, Children's neurosciences, London; [3]Evelina London Children Hospital, Faculty Life Sciences & Medicine, Kings College Hospital, London; [4]Evelina London Children Hospital, Neuroradiology,King's College Hospital, London; [5]Great Ormond Street Hospital for Children, University College London Institute of Neurology, London

Background and Aims: Myelin oligodendrocyte glycoprotein IgG (MOG-IgG) of titres 200 or more are considered positive/diagnostic for MOG associated disease (MOGAD). Early reports suggest patients who become seronegative are less likely to relapse but some patients showed otherwise. To compare relapsing paediatric MOGAD patients who remain persistently seropositive versus those who are reported as seronegative on follow-up.

Methods: retrospective review of clinical and paraclinical data of patients with relapsing MOGAD who had ongoing long term follow-up, and at least two serum samples tested for MOG-IgG by live cell-based assay

Results: Among 41 patients with MOGAD, 15 (36.5%) had a relapsing course. Mean follow-up duration 78.5months with 11 being persistently seropositive over mean of 5.6 (range 0.92–14) years 7 females; mean 8.3 (range 4–11) years; Both seropersistent and seroconverting groups did not differ on presentation and subsequent demyelinating phenotypes, both clinically and radiologically. Seroconverting group had mean 5.7 $\pm$2.25 relapses with annualized relapse rate (ARR) of 0.63 $\pm$0.382. Seropersistent group had a mean of 2.9 $\pm$0.59 relapses with ARR of 0.85 $\pm$0.484. Mean time to seropersistent relapse was 43.6 months ($N=25$, range 2–120) versus seroconverting relapses 85.7 months ($N=7$; range 60–121). 57% of seronegative relapses had titres of 1:100. Disease-modifying therapies were commenced in 11/15 patients after the second clinical event. Overall, despite the seronegative status, follow-up extended disability status scale was worse.

Conclusion: Paediatric MOGAD patients can relapse after a seronegative test result, most of whom still have detectable serum MOG-IgG but below the diagnostic cut-off. It may be useful for titres to be included in MOG-Ab results to support clinical interpretation, particularly in relapsing disease.

Disclosure: Nothing to disclose.

EPR-042 | Activity and Manufacturing of KYV-101 Anti-CD19 CAR T Cells Derived from Patients With Neurological Autoimmune Diseases

S. Park[1]; S. Sandoval[1]; J. Bravo[1]; H. Kim[1]; J. Cheng[1]; R. Sengupta[1]; K. Walker[1]; T. Van Blarcom[1]
[1]*Kyverna Therapeutics, Inc., Emeryville CA*

Background and Aims: B-cell targeting therapies demonstrate potential in neurological autoimmune diseases, but unmet needs remain, including treatment-free remission. KYV-101, a first-in-class, fully human autologous anti-CD19 chimeric antigen receptor (CAR) T-cell therapy, demonstrated promising clinical results in a myasthenia gravis (MG) patient (Haghikia et al. Lancet Neurology. 2023). KYV-101 holds promise to elicit deep, broad B-cell depletion and immune reset with a single infusion.

Methods: Autologous T cells were collected and enriched from patients with multiple sclerosis (MS) or MG. KYV-101 was generated by transducing T cells with a lentiviral vector encoding a fully human anti-CD19 CAR. Preclinical KYV-101 functional potency was assayed (cytokine release; cytotoxicity) in co-cultures with patient-derived CD19+ B cells, and CD19+ or CD19− control cells. Manufacturing expansion and functional potency from a clinical cohort of KYV-101 treated patients were also assessed.

Results: In preclinical assays, KYV-101 from MS patients induced greater dose-dependent cytotoxicity and IFN-gamma increases against CD19+ cells versus untransduced T cells and negligible responses following co-culture with CD19− cells. In the clinical cohort, KYV-101 manufactured from MS ($n=2$) and MG ($n=6$) patients displayed CD19-specific functional activity. Fold expansion ranges for KYV-101 from patients with MS ($n=2$) and MG ($n=6$) were 32.5–61x and 15.5–50x (Day 8; pre-harvest), respectively, which were similar to previously observed expansion from non-neurological autoimmune diseases.

Conclusion: KYV-101 from neurological autoimmune diseases shows activity specific for CD19+ cells. Manufacturing showed successful and consistent expansion across diseases. These data support further clinical investigation of KYV-101 as a novel therapy for neurological autoimmune diseases.

EPR-043 | Serological markers of clinical improvement in musk myasthenia gravis

V. Damato[1]; G. Spagni[2]; S. Falso[2]; B. Sun[3]; A. Vincent[3]; A. Evoli[2]
[1]*Department of Neurosciences Drugs and Child Health, University of Florence, Italy;* [2]*Department of Neuroscience, Università Cattolica del Sacro Cuore, Rome, Italy;* [3]*Nuffield Department of Clinical Neuroscience, University of Oxford, UK*

Background and Aims: In the last decade there has been a significant improvement in the clinical outcome of myasthenia gravis with antibodies against the muscle-specific tyrosine kinase (MuSK-MG), due to earlier recognition and effective treatments. However, biomarkers of disease severity and outcome are still lacking. In this study, we explored the role of (a) total MuSK-IgG levels; (b) MuSK-IgG subclasses; and (c) MuSK-IgG affinity as possible biomarkers of outcome in MuSK-MG patients.

Methods: Total MuSK-IgGs were quantified by flow cytometry and cell-based assay (CBA) serial dilutions. MuSK-IgG subclasses were analysed by flow cytometry. SAffCon assay was used for determining MuSK-IgG affinity.

Results: Forty-three sera were obtained at different time-points from 20 MuSK-MG patients, of whom 9/20 were treated with rituximab. In individual patients, MuSK-IgG levels decreased paralleling clinical improvement, either as measured by flow cytometry or by CBA end-point titration. In all samples, MuSK-IgG4 was the most frequent isotype, irrespective of disease outcome. We observed a significant reduction of MuSK-IgG4 and, to a lesser extent, of -IgG2 in patients with favourable clinical outcomes. Similar findings were confirmed in the subgroup of patients treated with rituximab. In a single patient, MuSK-IgG affinity increased after symptom exacerbation, while total MuSK-IgG and IgG4 levels remained stable, suggesting that affinity maturation can be a driver of clinical worsening.

Conclusion: Through a multimodal investigational approach, we showed that total MuSK-IgG levels, MuSK-IgG4 and -IgG2 levels and MuSK-IgG affinity can represent promising biomarkers of disease outcome in MuSK-MG and may be useful in guiding treatment choices.

Disclosure: Nothing to disclose.

Cognitive neurology/neuropsychology

EPR-044 | Cognitive intra-individual variability as a modifier or outcome in speed of processing training in adults with HIV

D. Vance[1]; A. Azuero[1]; M. Vinikoor[2]; J. Schexnayder[1]; F. Puga[1]; B. Galatzan[1]; J. Byun[1]; C. Xiao[1]; H. Phaowiriya[1]; D. James[3]; E. Kay[1]; P. Fazeli[1]
[1]*School of Nursing, University of Alabama at Birmingham;* [2]*Heersink School of Medicine, University of Alabama at Birmingham;* [3]*Edson College of Nursing and Health Innovation, Arizona State University*

Background and Aims: Variability in cognitive performance within an individual, known as Cognitive Intra-Individual Variability (IIV), can arise from compromised cognitive control due to brain pathology. Individuals with HIV-Associated Neurocognitive Disorder (HAND) may experience increased cognitive IIV. We examined whether: 1) Speed of Processing (SOP) decreases cognitive IIV, and 2) cognitive IIV modifies the effects of SOP training in individuals with HAND or borderline HAND.

Methods: In this 3-group experimental design, 216 people living with HIV (PLWH) with HAND were randomized to either: 1) 10 hours

of SOP training ($n = 70$); 2) 20 hours of SOP training ($n = 73$), or 3) 10 hours of Internet Navigation Control Training ($n = 73$). Participants completed a seven-domain cognitive battery at baseline, posttest after training, and years 1 and 2 follow-up; from this, the coefficient of variation (CoV) served as the cognitive IIV dispersion score for each of the assessment points. Participants also completed a gold-standard measure of SOP (i.e., the Useful Field of View Test) at baseline, at posttest immediately after training, and at year 1 and year 2 follow-up assessments.

Results: Linear mixed-effect models did not reveal a clear pattern of SOP training effects on cognitive IIV. Yet, a three-way interaction tests between time, group, and baseline IIV CoV [$F(6, 453.96) = 1.74$, $p = 0.11$], and time, group, and baseline IIV CoV median split indicator [$F(6, 467.84) = 2.024$, $p = 0.061$] suggested potential moderation effects.

Conclusion: This study confirms that SOP training does not improve cognitive IIV; however, cognitive IIV may modify the effects of SOP training.

EPR-045 | Interoception, emotion, and social cognition in neurodegenerative diseases: a meta-analysis

J. Hazelton[1]; F. Carneiro[2]; M. Maito[3]; A. Legaz[3]; Y. Chen[4]; F. Richter[5]; S. Baez[6]; A. Ibáñez[7]

[1]Latin American Brain Health Institute, Universidad Adolfo Ibáñez, Santiago, Chile; Cognitive Neuroscience Center, Universidad de San Andres, Buenos Aires, Argentina; The University of Sydney, Brain and Mind Centre, School of Psychology, Sydney, Australia; [2]Laboratory of Neuropsychophysiology, Faculty of Psychology and Education Sciences, University of Porto, Porto, Portugal; Faculty of Medicine, University of Porto, Porto, Portugal; Department of Neurology, ULS do Alto Ave, Guimarães, Portugal; [3]Latin American Brain Health Institute, Universidad Adolfo Ibáñez, Santiago, Chile; Cognitive Neuroscience Center, Universidad de San Andres, Buenos Aires, Argentina; [4]Department of Neurology, Memory and Aging Center, Weill Institute for Neurosciences, University of California San Francisco, San Francisco, California, USA; [5]Deutsches Herzzentrum der Charité, Department of Cardiothoracic and Vascular Surgery, Berlin, Germany; Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany; [6]Universidad de los Andes, Bogota, Colombia; Global Brain Health Institute (GBHI), University of California San Francisco (UCSF), CA, USA; Trinity College Dublin, Dublin, Ireland; [7]Latin American Brain Health Institute, Universidad Adolfo Ibáñez, Santiago, Chile; Cognitive Neuroscience Center, Universidad de San Andres, Buenos Aires, Argentina; GBHI, UCSF, CA, USA; Trinity College Dublin, Dublin, Ireland

Background and Aims: Deficits in interoception, emotion, and social cognition are observed in various neurodegenerative diseases, and are likely due to degeneration within the allostatic-interoceptive network. Indeed, indirect evidence from individual imaging modality studies suggests a shared neurobiological basis underlying these impairments. Here, we employed a multimodal imaging meta-analytical approach to identify shared and disease-specific neural substrates in neurodegeneration for interoception, emotion, and social cognition deficits.

Methods: Using the Activated Likelihood Estimate (ALE) method, we conducted several meta-analyses, encompassing studies meeting inclusion criteria: metrics for interoception, emotion, or social cognition; neurodegenerative diseases (including dementias, parkinsonian and motor neuron disorders and multiple sclerosis); and neuroimaging (structural: MRI voxel-based morphometry; functional: fMRI and FDG-PET).

Results: From 20,593 studies, 149 met inclusion criteria (47 interoception, 58 emotion, 44 social cognition). Dysfunctions in interoception, emotion, and social cognition implicated a shared network involving the anterior cingulate cortex, insula, orbitofrontal cortex, amygdala, and thalamus across neurodegenerative diseases in both single and conjunction meta-analyses. Further, we replicated these results in behavioural-variant frontotemporal dementia (bvFTD) in subgroup analyses.

Conclusion: Our findings provide the meta-analytic evidence of common network dysfunction within the allostatic-interoceptive brain network, contributing to shared deficits in interoception, emotion, and social cognition across diverse neurodegenerative diseases and imaging modalities, as well as evidence supporting the unique role of this network in bvFTD. Future longitudinal research is needed to identify when deficits in interoception, emotion, and social cognition arise in neurodegenerative diseases. This will inform potential biomarkers of disease progression and will help to further refine our understanding of neurodegenerative processes.

Disclosure: The authors have received institutional and/or commercial support, unrelated to the present work. No conflicts of interest exist.

EPR-046 | Salience and executive control networks dynamism and cognition in neuromyelitis optica spectrum disorder

M. Gueye[1]; N. Tedone[2]; P. Valsasina[3]; M. Filippi[4]; M. Rocca[1]
[1]*Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy;* [2]*Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy;* [3]*Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [4]*Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy*

Background and Aims: Salience (SN) and executive control networks (ECN) play a relevant role in cognitive functions. In neuromyelitis optica spectrum disorder (NMOSD), dynamic variations of brain connectivity within these networks have never been explored. We investigated static (S) and time-varying (TV) functional connectivity (FC) abnormalities of SN and ECN and their cognitive correlates in NMOSD patients.

Methods: Cognitive evaluation (Rao Battery) and 3.0T resting-state functional MRI were obtained from 34 right-handed anti-aquaporin-4 antibody-positive NMOSD patients and 39 sex- and age-matched healthy controls (HC). TVFC was estimated through sliding-window correlation analysis using the left and right dorsolateral prefrontal cortex (BA9) and the left insula as seeds. Mean connectivity indicated SFC.

Results: In NMOSD patients, the most frequently impaired domains were complex attention (44.8%), verbal memory (23.3%), fluency (12.9%) and visual memory (9.7%). Compared to HC, NMOSD patients showed significantly reduced SFC and TVFC of SN, mainly located in the bilateral temporal lobe ($p < 0.05$, corrected). NMOSD patients also exhibited reduced SFC in several regions of ECN ($p < 0.05$, corrected), including bilateral frontal and parietal lobes, right temporal lobe, left cerebellum and insula. Moreover, NMOSD patients presented increased SFC and TVFC of ECN versus HC in the right precuneus, cerebellum, and olfactory cortex and in left cuneus, precentral gyrus, and paracentral lobule. Reduced ECN SFC was associated with worse visual memory and fluency performances (r = range 0.36–0.45, $p <= 0.039$), while increased ECN TVFC was associated with better attention performances ($r = 0.54$, $p = 0.002$).

Conclusion: In NMOSD, abnormal SFC and TVFC of SN and ECN are associated with cognitive performances.

EPR-047 | Decision-Reinvestment differences in heart-rate variability contradicted in footballers, while mental-health correlates

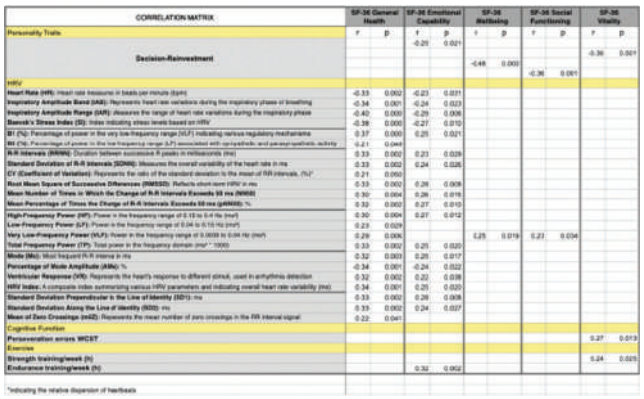
J. Pourhassan[1]; W. Hitzl[2]; B. Langenstein[1]; F. Erbguth[3]; K. Richter[4]
[1]*University Clinic for Internal Medicine, Institute for Sport Medicine, Paracelsus Medical University Nuremberg, Klinikum Nuernberg, Nuremberg, Germany;* [2]*Department Research and Innovation Management (RIM): Biostatistics and publication of clinical trial studies, Paracelsus Medical University Salzburg, Salzburg;* [3]*Department of Neurology, Paracelsus Medical University Nuremberg, Nuremberg, Germany;* [4]*Faculty for Medical Sciences, Goce Delcev University, Stip, North Macedonia*

Background and Aims: Decision-reinvestment behaviour leads to significant decrease in both motor-control, cognitive performance, and cardiac vagal activity. Heart-rate variability (HRV) is as a physiological marker reflecting modulation of the autonomic nervous system, and therefore implicate chances in athletes' regeneration, health, and performance status. This cross-sectional study examined the relationship between HRV and cognitive function, perceived health, as well as reinvestment strategies. The hypothesis was that trait-related HRV differences do not occur in athletes, perceived pain will be greater in reinvester athletes and correlate with cognitive function.

Methods: HRV of 88 football player was recorded with an HRV-analyser for 5 min. Participants then self-reported their mental and physical health (SF-36), decision-reinvestment strategy, and performed a set of cognitive tests to examine memory function (Backwards Corsi), selective attention (STROOP), and cognitive flexibility (Wisconsin Card Sorting Test, WCST). Spearman correlations with corresponding tests were used to analyse correlations between continuous variables, and a Two-Sample Test was performed to evaluate HRV differences between groups.

Results: Significant correlation occur in perceived health with multiple parameters of HVR (Table 1), as well as decision-reinvestment, and preservation errors. A positive correlation exist in regard of mental health with both hours of endurance (p 0.002) and strength training (p 0.024). There were no group differences in HRV ($p > 0.05$).

TABLE 1. Correlation Matrix – Overview of Decision Reinvestment, HRV, cognitive function and exercise parameters that correlate with physical and mental health.



Conclusion: Exercise induced vagal activity may inhibit trait-related changes in HRV, and boost mental health. Athletes with lower mental health scores have increased preservation errors during WCST, and greater tendency to ruminate.

Disclosure: ECG based HRV analyser was provided by Nilas MV GmbH, Germany.

EPR-048 | Neurobiological and psychological markers of reaction to extreme stress: A three-generation study of Holocaust survivors and their offspring. War stress in Ukrainian refugees

I. Rektor; M. Monika Fňašková; P. Říha; M. Gajdoš; M. Nečasová; S. Berezka; T. Evmenova; M. Preiss

Masaryk University, CEITEC – Neuroscience Centre, Brno, Czechia

Background and Aims: Ukrainian war stress: Acute and ongoing war stress has a significant neurobiological impact on refugees from war-torn Ukraine. The psychological tests showed stress, depression, and anxiety. The influence of ongoing stress is present in the thalamus connected with parts of the limbic circuitry – insula, orbitofrontal cortex, and para-hippocampal gyrus. The structural and connectivity data in this study reveal the characteristics of acute and ongoing stress.

Methods: We explored three generations of Holocaust survivors (HS). The target was to identify lifelong impact of extreme stress (TSC-40, PCL-C, SOS-10) and post-traumatic growth (PTGI). HS 44, median age 81 years, controls 31; 2nd generation 86, controls 62; 3rd generation 88, controls 64.

Results: Psychological testing: stress-positive in three generations versus controls; PTGI-positive in HS. The second and third generation are also stressed. Neuroimaging – MRI. IN HS, the grey matter (GM) was reduced in insulas, anterior cingulate, temporal pole. In the 2nd and 3rd generation there is a clear difference in MRI connectivity compared to controls.

Conclusion: Life-long psychological and brain structure changes in people who survived holocaust were identified more than 70 years after World War II. Extreme prenatal, childhood and young adulthood stress has an irreversible lifelong impact on the brain. The consequences of holocaust-related trauma are transmitted to the 2nd and 3rd generation.

Disclosure: Nothing to disclose.

EPR-049 | Macroscale structural covariance network reveals the biological mechanisms of neuropsychiatric symptoms

J. Jiang[1]; K. Zhao[2]; S. Jiang[1]; P. Zheng[2]; J. Xu[1]

[1]*Beijing Tiantan Hospital, Beijing, China, Capital Medical University, Beijing, China;* [2]*School of Artificial Intelligence, Beijing, China, Beijing University of Posts and Telecommunications, Beijing, China*

Background and Aims: The intricate and heterogeneous phenotypes associated with neuropsychiatric symptoms (NPSs) encumber exploration of their role in the neuropathology and underlying biological mechanisms of Alzheimer's disease (AD) continuum.

Methods: An individual-level Regional Radiomics Similarity Network (R2SN) for 487 patients with AD continuum (376 with NPSs vs. 111 without NPSs) were developed to refine the subtypes of NPS in the AD continuum. Distinct brain network dysfunction, multimodal neuroimaging burden, and clinical measures/progression of each NPS subtype were analyzed.

Results: Three NPS subtypes were identified based on 300 distinct key R2SN connections. Compared to those without NPS, the first NPS subtype (sNPS) and third NPS subtype (moNPS) exhibited significant opposite pattern of brain connectivity damage, while the second NPS subtype (miNPS) showed minimal differences (Figure 1). Both the sNPS and moNPS subtypes exhibited diminished baseline

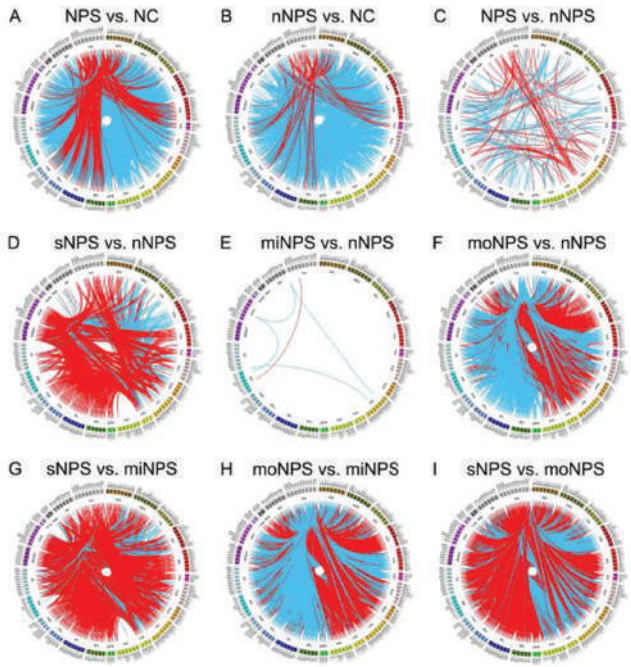


FIGURE 1. Characteristics of altered morphological connectivity in the R2SN profiles.

performance and rapid decline in the MMSE and MoCA scores, while no significant difference was discerned in miNPS. Both the sNPS and moNPS subtypes exhibited reduced regional grey matter volume, while miNPS subtype lacked significant structural brain changes but exhibited higher cerebral blood flow in some regions, suggesting early compensatory cerebral hyperperfusion (Figure 2). Gene set enrichment analysis (GSEA) elucidated each subtype's unique biological mechanisms associated with the contribution of NPS-related specific brain connectome dysfunctions to AD progression (Figure 3).

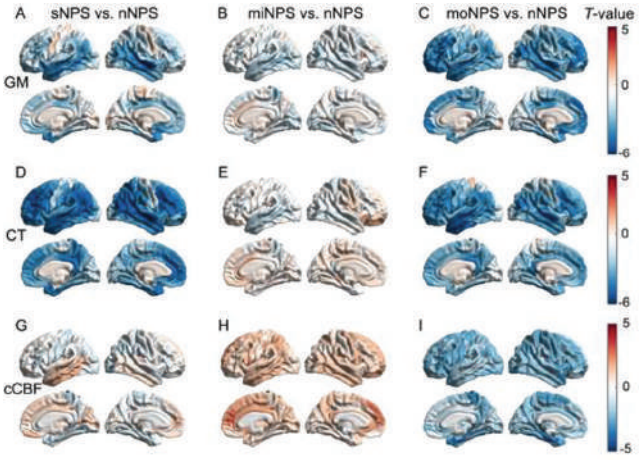

FIGURE 2. Differences in multimodal neuroimaging burden between three NPS subtypes in the AD continuum.

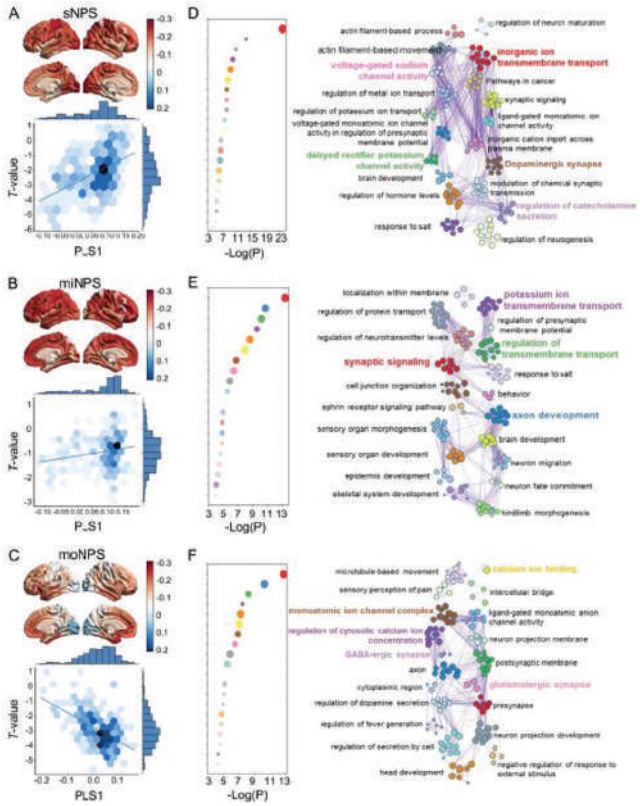

FIGURE 3. GSEA between three NPS subtypes and those without NPS in the AD continuum.

Conclusion: This is the first study to identify three distinct NPS subtypes on AD continuum through a data-driven approach, bridging the gap in the knowledge on the contributions of NPSs to AD continuum, and offering new insights into precise interventions for these patients.
Disclosure: Nothing to disclose.

EPR-050 | Decision-making, risk-taking, and divergent thinking differences between Italy and USA: Preliminary results

M. Crepaldi[1]; A. Cancer[2]; G. Fusi[1]; J. Gianni[1]; P. Iannello[2]; B. Colombo[3]; A. Antonietti[2]; A. Greco[1]; M. Rusconi[1]
[1]*Department of Human and Social Sciences, University of Bergamo, Bergamo, Italy*; [2]*Department of Psychology, Catholic University of the Sacred Heart, Milan, Italy*; [3]*Division of Education and Human Studies, Champlain College Burlington, Vermont, USA*

Background and Aims: Today's society is characterized by complexity and uncertainty. Risk dominates individual and social consciousness, increasing the challenge of answering the question, "How do people make decisions?" (Nyhlen and Liden, 2014). Several variables are known to influence decision-making (DM) process and styles, including uncertainty avoidance and tolerance (Hofstede, 2007) as well as creativity (particularly Divergent Thinking, DT), although the data are controversial (Collins & Koeklin, 2012; Crepaldi et al., in press). However, few studies consider cultural differences. Based on these premises, the study presents the cultural differences between Italians and the US in risk-taking, DM and DT.
Methods: 55 Italians (39 females; mean age: 22.4; SD 2.7) and 57 Americans (32 females; mean age 20.0; SD 1.5) were involved. Questionnaires investigating risk (DOSPERT), DM style (GDMS), and creativity (AUT) were administered.
Results: No significant differences emerge in DM styles, but initial analyses show significant differences in ethical risk-taking (ITA>US, $t = 2.63$; $p < 0.05$) and substantial differences in the DT task in fluency (US >ITA, $t = -7{,}28$; $p < .001$) and originality (US>ITA, $t = -2{,}47$; $p < 0.05$).
Conclusion: Living successfully means acting efficiently; a better DM process should help people achieve better life outcomes. Findings suggest that there are differences in risk-taking and DT, two components of DM, although no differences in DM styles emerge. Knowing the role of these variables in different cultures can help support the DM process. Therefore, extending the research in the lifespan and increasing the number of samples for comparison is useful.
Disclosure: The author declared no conflict of interest.

EPR-051 | Deep brain stimulation of the posterior hypothalamus in aggression management – A case series analysis

S. Poveda[1]; O. Bernal[1]; P. Arango[2]; M. Fonseca[3]; J. Diez[4]; S. Montoya[1]

[1]Neurology deparment, Militar Hospital, Bogotá, Colombia; [2]Clinica DESA, Cali, Colombia; [3]Instituto Roosevelt, Bogotá, Colombia; [4]Clínica Shaio, Bogotá, Colombia

Background and Aims: Pathological aggression, common in neurodevelopmental disorders, includes intellectual disability and motor/verbal aggression. Affecting over 50% of autistic children and up to 45% with intellectual disability, it jeopardizes safety. Surgical interventions like posterior hypothalamus DBS reduce aggression by 91% with fewer adverse effects than direct lesioning.

Methods: A cohort study of 13 patients with refractory aggression who received bilateral posterior hypothalamus DBS treatment was conducted. They were evaluated pre- and postoperatively using the MOAS. Clinical and psychometric assessments were conducted by a multidisciplinary team, with statistical analysis comparing pre- and postoperative scores.

Results: The analysis included 13 cases, predominantly male, all with a history of intellectual disability (Table1 and 2). At the 6-month follow-up, a median improvement of 58% was observed in the post-DBS MOAS score compared to the pre-DBS MOAS baseline, which was statistically significant ($p=0.002$) (Figure1). Improvement ranged between 43% and 73%, except for one case, a 12-year-old patient, whose benefit was only 18%.

TABLE 1. Qualitative clinical characteristics of patients treated with DBS for aggression.

Variable	n=13	%
Man	10	76.9
Epilepsy	8	61.5
Adverse effects	2	15.4
Hyporexia	1	7.7
Gait worse	1	7.7

TABLE 2. Quantitative clinical characteristics of patients treated with DBS for aggression.

Variable	Median	P25	P75	Min	Max
Age (years)	26	24	32	12	38
MOAS preDBS	14	12	15	7	18
MOAS posDBS 6 months	5	4	5	4	14
Follow-up time (months)	36	18	66	6	76

MOAS: Modified Overt Aggression Scale, pre: preDBS, pos: posDBS 6 months.

FIGURE 1. Boxplot MOAS pre and pos DBS

Conclusion: In our case series, posterior hypothalamus DBS proves highly effective for refractory aggression, surpassing conventional therapies. This intervention poses a low risk, yielding significant improvements in patients.

Disclosure: Nothing to disclose.

EPR-052 | Prediction of language and verbal fluency in Parkinson's disease patients undergoing Deep Brain stimulation (DBS)

S. Elsas[1]; M. Al Tawil[2]; U. Gschwandtner[2]; S. Hemm[3]; E. Taub[4]; P. Fuhr[2]

[1]Neurology and Research, Klinik Arlesheim AG, Arlesheim, Switzerland; [2]Department of Clinical Research and Department of Neurology, University Hospital Basel, Switzerland; [3]Institute for Medical Engineering and Medical Informatics, School of Life Sciences FHNW, Switzerland; [4]Department of Neurosurgery, University Hospital Basel, Switzerland

Background and Aims: Deep brain stimulation (DBS) is a common treatment for motor deficits in Parkinson's disease (PD). We studied the effects on speech capacity (phonematic and semantic fluency) after DBS.

Methods: Findings related to speech and cognition in patients with PD who underwent DBS ($N=31$, F=12, M=19; mean age 63.5±10.06 years, disease duration 12.5±5.38 years, preoperative UPDRS 20±13.12, postoperative UPDRS 14±9.16, preoperative LEDD 1150± 536.29, postoperative LEDD 482±336.81). Phonematic and semantic fluency were assessed before and 6 to 8 months after DBS with a semantic fluency test (animals), a phonematic test (s-words), Digit Span forward and backward, Wisconsin Card Sorting Test, Mini Mental State Examination (MMSE) and Trail Making Test. We used GLM for the statistics. Potential confounders were age, MMSE, MoCA, Wisconsin Card Sorting Test and Digit Span.

Results: Phonemic fluency (preoperative 0.056 ±1.04; postoperative −0.306 ±0.83, $p=0.034$) and semantic fluency (preoperative −0.356 ±1.004; postoperative −0.90 ±0.73, $p=0.009$) decreased after DBS. None of the potential confounders had a significant effect. However, pre-, and postoperative phonemic fluency were

significantly correlated ($r=0.54$, $p<0.009$), as were pre- and postoperative semantic fluency ($r=0.62$, $p<0.001$). Interestingly, pre-, and postoperative MoCA scores were not significantly correlated.

Conclusion: 1. In PD patients, the best predictors of verbal fluency after DBS are preoperative phonemic and semantic fluency scores, while other predictors of low verbal fluency after DBS could not be confirmed. 2. Poor and borderline preoperative verbal fluency may be a relative contraindication for DBS in patients with Parkinson's disease.

Disclosure: Nothing to disclose.

Background and Aims: X-linked adrenoleukodystrophy (ALD) is an inherited disorder in which more than half of the male patients develop inflammatory demyelinating lesions with high lethality (cerebral ALD, CALD). Lesions typically involve corpus callosum, corticospinal tracts (CST) and cerebellum on brain MRI. Hematopoietic stem cell transplantation (HSCT) is the standard of care, but many patients are not eligible, particularly in case of CST lesions which have a poor prognosis. This study evaluates the efficacy of a new treatment, leriglitazone, in CALD.

Methods: We treated 13 men not eligible or awaiting HSCT. Patients were assessed every 3 months by clinical scoring, plasma biomarkers (including Neurofilament Light Chain or NfL, reflecting disease activity) and brain imaging comprising FLAIR, diffusion tensor imaging (DTI) and post-contrast 3D T1 sequences. Total lesion load and corticospinal tracts lesion load were measured longitudinally after lesion segmentation on FLAIR sequence. DTI markers were automatically calculated in 19 regions of deep white matter (BrainQuant platform of BrainTale Care). Gadolinium enhancements were assessed visually.

Results: Ten patients showed an excellent clinical response. Lesion load was significantly correlated with NfL and DTI metrics (FA, MD) in total white matter, which remained globally stable in these patients. All lesions involving the corticospinal tracts turned gadolinium-negative and downsized in most patients. Regional variations of MD were in line with the volumetric evolution of lesions.

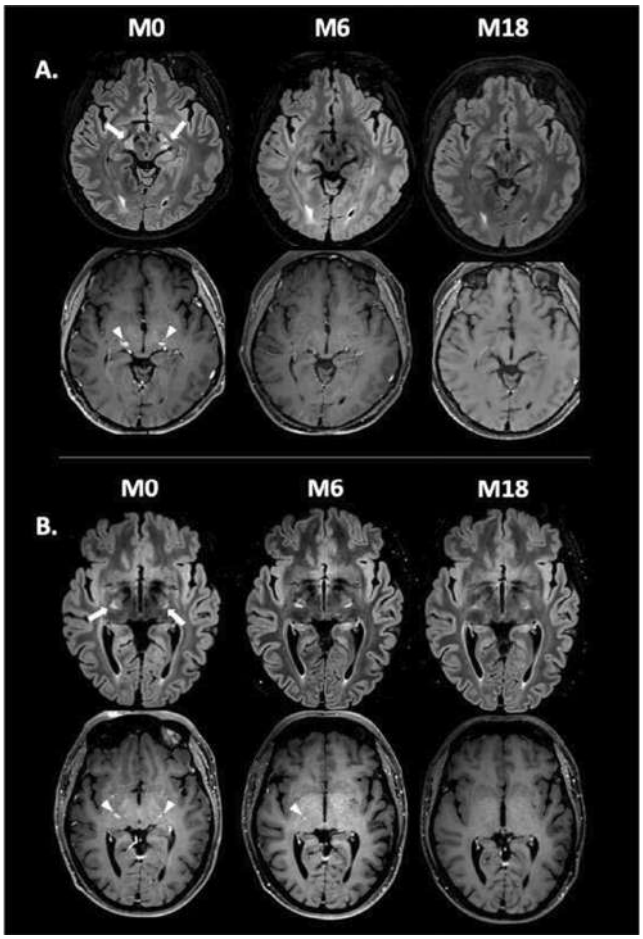

FIGURE 1. Evolution of CST lesion load on FLAIR (arrows) and gadolinium enhancements (arrowheads) in two CALD patients between baseline and M18.

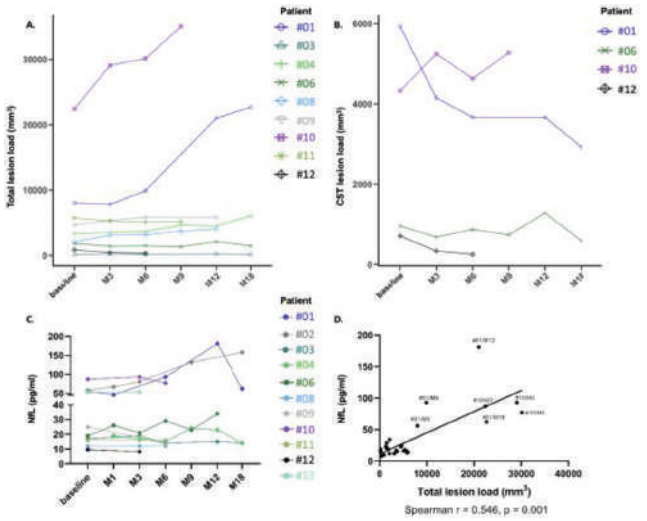

FIGURE 2. Evolution of total lesion load (A), CST lesion load (B) and NfL (C) over time, with correlation analysis between total lesion volume and NfL (D) showing a moderate significant correlation.

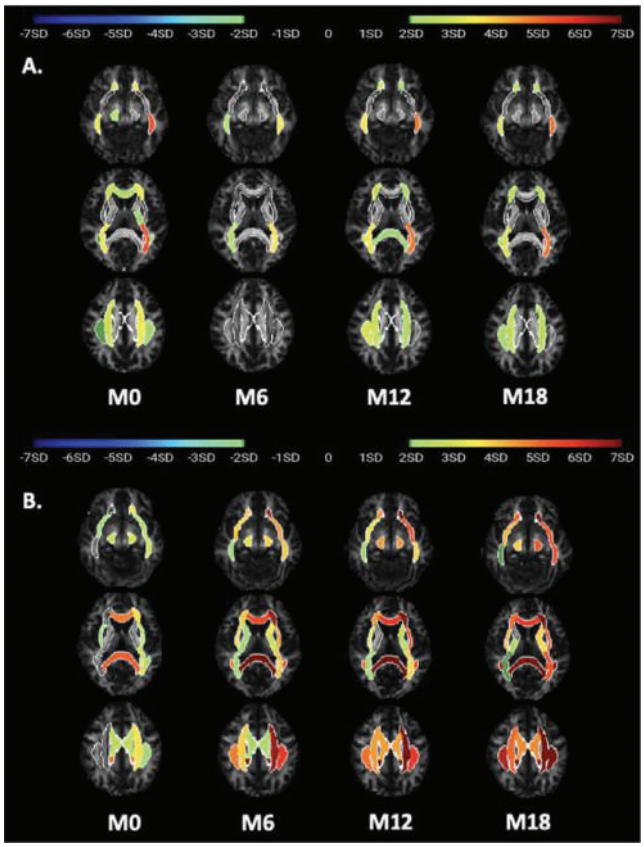

FIGURE 3. Evolution of the regional MD values (in standard deviations from healthy volunteers) in different regions of deep white-matter, in a patient with a positive evolution (A) and in a patient with deterioration (B).

Conclusion: These results show that leriglitazone can be an alternative treatment to HSCT in CALD, with a distinct action on the CST.

Disclosure: Nothing to disclose.

Background and Aims: Variants in ATP6V0C have been associated with neurodevelopmental disorders and seizures. In the present study we aim to delineate the ATP6V0C epilepsy phenotypes.

Methods: We retrospectively analyzed 33 cases from 27 families with ATP6V0C variants. Cases were identified by an international network of epileptologists/geneticists. SPSS was used for statistical analysis.

Results: ATP6V0C variants were predominantly missense (88%), often de novo (73%), and exhibited an average seizure onset at 19 months, with febrile seizures in 77% of cases. Generalized tonic-clonic seizures were the predominant type (82%), with other types such as myoclonic, absences, tonic, and focal seizures occurring in approximately 25%–35% of patients. Unspecified developmental and epileptic encephalopathy ($n=11$) and genetic epilepsy with febrile seizure plus (GEFS+) ($n=9$) were commonly observed. Developmental delay affected 76% of patients (evenly distributed between severe, moderate, and mild categories), with half experiencing drug-resistant epilepsy (DRE). Valproate showed >50% seizure reduction in 10 of 15 patients but was ineffective in those with DRE. MRI abnormalities were noted in seven severe cases, showing delayed myelination and corpus callosum agenesis. Thirteen cases with TMR-4 variants displayed a more severe phenotype, including higher rates of developmental delay ($n=13$), DRE ($n=8$), and abnormal neurological examination ($n=8$) with hypotonia and dysmorphic facial features. Logistic regression analysis highlighted the significance of affected amino acid position in predicting moderate or severe developmental delay (OR 1.018, $p=0.034$).

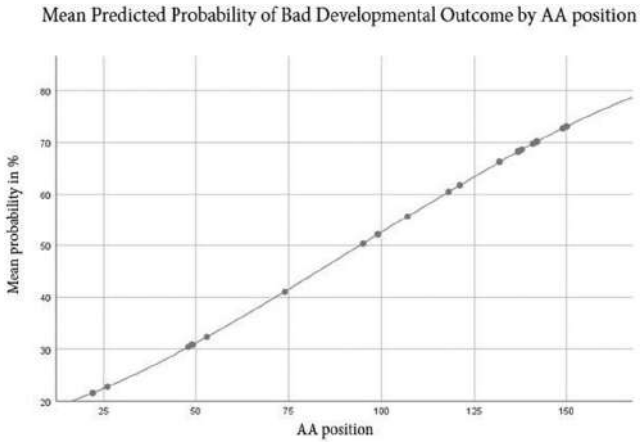

IMAGE 1. Logistic regression analysis.

Conclusion: ATP6V0C variants are linked to a spectrum of GEFS+ epilepsy phenotypes, underscoring a robust genotype-phenotype correlation.

Macdonald Foundation Department of Human Genetics, John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, USA; [4]Department of Brain and Behavioral Sciences, University of Pavia, 27100 Pavia, Italy; [5]Roy and Lucille Carver College of Medicine, University of Iowa, Iowa City, Iowa, USA; [6]Seattle Children's Hospital, University of Washington School of Medicine, Seattle, Washington, USA

Background and Aims: Despite the best efforts, over 50% of axonal CMT cases do not receive genetic confirmation. Notably, current short read technologies, including whole exome (WES) and whole genome sequencing (WGS), present major shortcomings in the study of structural variants and repeated regions, contributing to the missing heritability in CMT.

Methods: Here we leverage long read sequencing (LRS) and non-sequencing based optical genome mapping (OGM) to identify a large structural variant involving SORD and its pseudogene SORD2P, which disrupts SORD reading frame and causes SORD=CMT in multiple families.

Results: In three unrelated axonal CMT patients with high serum sorbitol and a heterozygous c.757delG SORD variant, LRS and OGM revealed a 200Kb inversion spanning two highly homologous SORD/SORD2P introns, undetectable by WES or WGS. Additionally, inverse PCR in 37 CMT cases with a heterozygous pathogenic SORD mutation identified this inversion in 4 (~10%) of them. This inversion occurred de novo in one family and was inherited from an asymptomatic parent in another. These cases resemble previously described SORD=CMT cases. Public data on 3D chromatin structure suggest SORD and SORD2P's proximity in the nucleus could facilitate such recombination events.

Conclusion: In conclusion, SORD/SORD2P inversion is key in axonal CMT cases with a single SORD mutation, especially when serum sorbitol is high. This study demonstrates LRS and OGM's effectiveness in identifying genetic causes in unresolved CMT cases, revealing a new mechanism by which structural variants in gene/pseudogene pairs (~3000 in the human genome) can cause genetic disease, often undetected by short-read sequencing technologies.

Disclosure: Nothing to disclose.

Background and Aims: Oculopharyngodistal myopathy (OPDM) is an inherited myopathy manifesting with a combination of ptosis, dysphagia, and distal weakness. Pathologically it is characterized by rimmed vacuoles and intranuclear inclusions on muscle biopsy. Recently, CGG/CCG repeat expansions in four different genes have been identified in OPDM patients of Asian ancestry. In this study we identified CCG expansions in ABCD3 in 35 OPDM cases from eight unrelated families and of European ancestry.

Methods: A combination of linkage studies, short-read whole genome sequencing and targeted long-read sequencing was employed for the gene discovery. Additional 68 patients with cranial myopathy or full OPDM were screened through repeat-primed PCR. ABCD3 expression on muscle and patients-derived fibroblast was quantified using RNA-sequencing, qPCR, and RNA FISH.

Results: CCG expansions in the 5'UTR of ABCD3 were independently identified in two large Australian OPDM families and through the 100,000 Genomics England Genome Project in three OPDM patients from two unrelated UK families. Targeted long-read sequencing confirmed the presence of mono-allelic CCG repeat expansions ranging from 118 to 694 repeats in all tested cases ($n=19$). Three additional ABCD3-positive patients were identified after PCR screening, for a total of 35 patients from eight unrelated families. ABCD3 transcript was upregulated in skeletal muscle and cells derived from affected OPDM individuals.

Conclusion: The study strengthens the association between the GCC/CCG repeat motif and a specific pattern of muscle weakness with prominent cranial involvement across different populations. The over-expression of ABCD3 transcript might play a role in the progressive skeletal muscle degeneration of this condition.

Disclosure: Nothing to disclose.

EPR-057 | Abstract withdrawn

EPR-058 | Evaluating outcome measures in ataxia in primary mitochondrial disease and spinocerebellar ataxia type 6

A. Moe[1]; J. Newman[2]; S. Del Din[2]; G. Gorman[2]; L. Alcock[2]; Y. Ng[3]
[1]Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, UK; [2]NIHR Newcastle Biomedical Research Centre, Newcastle University, Newcastle upon Tyne, UK; [3]NHS Highly Specialized Service for Rare Mitochondrial Disorders, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, UK

Background and Aims: Progressive ataxia is a common neurological feature reported in primary mitochondrial disease (PMD). However, there were limited clinical studies systematically assessing the severity of ataxia in patients with PMD. This study aims to delineate the ataxic features of patients with PMD by comparing to patients with Spinocerebellar Ataxia type 6 (SCA6).

Methods: In this cross-sectional study, adults with genetically confirmed PMD, patients with SCA6, and healthy controls were recruited. The following assessments were performed: Clinician-reported measures: SARA (Scale for the Assessment and Rating of Ataxia), ICARS (International Cooperative Ataxia Rating Scale), INAS (Inventory of Non-Ataxia Signs), etc. Patient-reported measures: ABC (Activities-Specific Balance Confidence Scale), FES1 (Falls Efficacy Scale-International), FSS (Fatigue Severity Scale), etc. Instrumented balance and gait analysis

Results: Seventy participants (PMD, $n=37$; SCA6, $n=11$; healthy controls, $n=22$) completed this study. The mean age of SCA6 patients was significantly older than PMD patients (61 vs. 46, $p=0.018$). The severity of ataxia, measured by SARA (9 vs. 8.7) and ICARS (17.3 vs. 14.8), was similar between patients with PMD and SCA6 ($p>0.05$). Patients with PMD had more non-ataxia signs (INAS) than SCA6 (3 vs. 1, $p<0.001$). Significant correlations were identified between clinician- and patient-reported measures in both patient groups. Patients with PMD had larger displacement of centre of pressure compared to healthy controls (Figure).

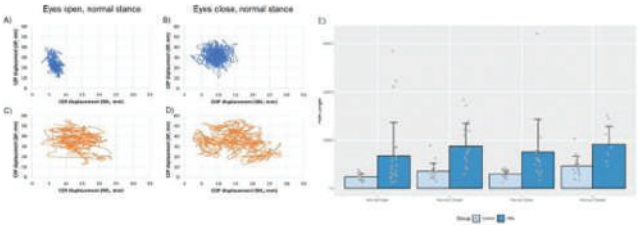

FIGURE. Force plate analysis. (A-B) age- & sex-matched healthy control and (C-D) a patient with a rare pathogenic mitochondrial DNA variant (m.7510T>C). (E) Comparisons of postural sway (path length) between age-matched controls and patients with PMD in D

Conclusion: Our findings show that the overall ataxic severity in PMD is comparable to SCA6. However, the impairment of balance and mobility in patients with PMD is also complicated by other additional neurological features.

Disclosure: The study was supported by Academy of Medical Sciences and Ataxia UK.

EPR-059 | Leber's hereditary optic neuropathy or Leigh syndrome—A digenic mechanism makes the difference

T. Klopstock[1]; B. Blickhäuser[1]; S. Stenton[2]; H. Prokisch[3]
[1]*Department of Neurology, Friedrich-Baur-Institute, University Hospital of the Ludwig-Maximilians-University, Munich, Germany,* [2]*Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA, USA,* [3]*Institute of Human Genetics, School of Medicine, Technical University of Munich, Munich, Germany*

Background and Aims: Leber's hereditary optic neuropathy (LHON) and Leigh syndrome (LS) represent in a way the opposite ends of the wide mitochondrial disease spectrum, with LHON being a relatively mild and tissue-specific disorder mostly in adolescents and young adults, and LS being a particularly severe and multi-systemic disorder mostly in children. Surprisingly, however, some cases of LS have been associated to genetic variants that in most instances cause LHON. We speculated that there must be an additional genetic cause leading to this huge phenotypic difference.
Methods: Five probands with LS harbouring the primary LHON variant m.11778G>A of the mitochondrial DNA (mtDNA) were investigated by whole exome sequencing.
Results: All five patients carried, in addition to the LHON-typical mtDNA variant, a heterozygous predicted loss of function or predicted deleterious missense variant in a nuclear-encoded Complex I subunit gene (NDUFS2 $n=3$, NDUFS7 $n=1$, NDUFS8 $n=1$).
Conclusion: Our findings provide an explanation for the longstanding enigma of severe LS being associated with primary LHON variants. While biallelic variants in nuclear-encoded Complex I subunit genes NDUFS2, NDUFS7 and NDUFS8 lead to recessive LS, a heterozygous variant in these genes (as for example in parents of recessive LS children) is not sufficient to cause disease. However, digenic inheritance of such a heterozygous nuclear variant in conjunction with a primary LHON variant leads to the extreme switch from LHON to LS phenotype.
Disclosure: Nothing to disclose.

EPR-060 | Preclinical development of a conjugate vaccine targeting poly-GA in C9orf72 ALS/FTD

T. Klopstock[1]; H. Kraan[2]; A. Spies[2]; J. Levin[1]; Q. Zhou[3]; D. Edbauer[3]
[1]*Department of Neurology with Friedrich-Baur-Institute, University Hospital of the Ludwig-Maximilians-University, Munich, Germany;* [2]*Intravacc, Bilthoven, The Netherlands;* [3]*German Center for Neurodegenerative Diseases (DZNE), Munich, Germany*

Background and Aims: A marked proportion of ALS and FTD patients carry a pathogenic (G4C2)n repeat expansion in C9orf72, which is translated into aggregating dipeptide repeat proteins, most abundantly poly-Glycine-Alanine. In mouse models, poly-GA aggregates promote neuroinflammation and secondary TDP-43 pathology, a key trigger of neuron loss, also in sporadic ALS/FTD. The GA-VAX consortium is developing a vaccine targeting poly-GA as a potential treatment for C9orf72 ALS/FTD by reducing poly-GA pathology and downstream toxicity through vaccine-induced antibodies.
Methods: Active immunization of mice; analysis of phenotype, biomarkers, and immunohistochemistry.
Results: Our initial studies demonstrated that active immunization with ovalbumin-conjugated (GA)10 significantly reduced poly-GA levels, neuroinflammation, and TDP-43 mislocalization in GA-CFP mice. Our latest data show that post-symptomatic immunization reduces serum neurofilament levels. To facilitate manufacturing of the vaccine, we optimized the formulation for solubility and immunogenicity. Our lead antigen (GA-VAX-01) shows high solubility, favourable immune response profiles, and improved motor function in GA-CFP mice. Next milestones are toxicology studies in rats and evaluation of additional efficacy parameters to support a clinical trial application.
Conclusion: The GA-VAX project represents a novel therapeutic approach for C9orf72-associated ALS and FTD. Recent developments, including promising pre-clinical results and ongoing studies, provide a strong basis for advancing our lead candidate GA-VAX-01 into clinical trials.
Disclosure: The GA-VAX consortium is funded by the EU Horizon Europe research and innovation programme, grant agreement No 101057649. HK and AS are employees at Intravacc BV. QZ and DE hold a patent application (PCT WO2020221937A1) describing anti-GA vaccination.

EPR-061 | Interim Results for Iluzanebart (VGL101) from IGNITE, the first interventional phase 2 study in patients with ALSP

D. Lynch[1]; J. Gelfand[2]; R. Kumar[3]; D. McLaren[4]; A. Meier[4]; R. Rajagovindan[4]; Z. Wszolek[5]
[1]*Department of Molecular Neuroscience, National Hospital for Neurology & Neurosurgery, Queen Square, and UCL Institute of Neurology, London, UK;* [2]*Department of Neurology, University of California, San Francisco, CA, USA;* [3]*CenExel RMCR, Englewood, CO, USA;* [4]*Clinical, Vigil Neuroscience, Inc., Watertown, MA, USA;* [5]*Department of Neurology, Mayo Clinic, Jacksonville, FL, USA*

Background and Aims: There are no licensed therapies for adult-onset leukoencephalopathy with axonal spheroids and pigmented glia (ALSP), a rare, fatal, autosomal-dominant neurodegenerative microgliopathy characterized by rapidly progressive cognitive decline, neuropsychiatric symptoms, and motor dysfunction due to CSF1R gene mutations, indicating a critical unmet medical need. Iluzanebart (VGL101), a fully human IgG1 monoclonal antibody TREM2 receptor agonist, was well tolerated in a phase 1 healthy volunteer study and demonstrated durable target engagement and pharmacological activity following multiple dosing.
Methods: IGNITE (NCT05677659), the first interventional clinical trial in ALSP, is an ongoing, phase 2, multicentre, open-label study assessing iluzanebart safety/tolerability and proof-of-concept,

targeting up to 15 eligible adults with documented CSF1R mutation and clinical and MRI findings consistent with ALSP for enrolment. Participants will receive intravenous iluzanebart every 28 ±7 days for a total of 13 doses over 48 weeks. Primary endpoint is safety/tolerability assessed by adverse events (AEs); other endpoints include volumetric MRI measures, fluid biomarkers, and clinical measures.

Results: The interim analysis of the first 6 patients in IGNITE who have received iluzanebart 20 mg/kg for >=6 months showed favourable safety and tolerability, with no treatment-related severe or serious AEs or discontinuations due to AEs. Iluzanebart demonstrated CNS target engagement and downstream pharmacological activity. Changes in individual-level MRI measures and disease-related fluid biomarkers were generally supportive of an impact on ALSP disease pathophysiology (Table).

TABLE. IGNITE phase 2 summary of biomarker changes (6-month interim analysis).

ALSP patient segment at baseline[a]	Patient	Baseline NfL (pg/mL)	Baseline MoCA	Change in trajectory[b]				Iluzanebart impact based on biomarker changes
				MRI ventricular[c]	MRI grey matter[c]	sCSF1R[d]	NfL[e]	
Progressive disease	A	80	17					Slowing progression
	B	159	21					Slowing progression
	F	54	25					Slowing progression
Cognitively normal	D	10	28					Stabilization
	E	12	28					Stabilization
Potentially converting	C	42	30					Variable impact

[a]"Progressive disease" defined as NfL significantly higher than age-normal range, MoCA <26, and significant neurodegeneration and ALSP symptom of cognitive impairment; "cognitively normal" defined as NfL within age-normal range, MoCA ≥26, and other ALSP symptoms except cognitive; "potentially converting" defined as NfL higher than age-normal range, MoCA ≥26, and evidence of neurodegeneration and other ALSP symptoms except cognitive impairment.
[b]Meaningful (dark) or limited (light) changes in a direction consistent with treatment benefit are indicated in green; meaningful (dark) or limited (light) changes in a direction not consistent with treatment benefit are indicated in yellow.
[c]MRI trajectories assessed for 0-6 months in IGNITE vs pre-IGNITE run-in data (from ILLUMINATE Natural History study) for each patient.
[d]sCSF1R levels from cerebrospinal fluid assessed at 6 months in IGNITE vs 0 months (IGNITE baseline) for each patient.
[e]NfL levels from serum assessed for 0-6 months in IGNITE vs pre-IGNITE run-in data (for patients B, D, E, F) or for 6-9 months in IGNITE vs 0-6 months in IGNITE (for patients A, C).
ALSP, adult-onset leukoencephalopathy with axonal spheroids and pigmented glia; MoCA, Montreal Cognitive Assessment; MRI, magnetic resonance imaging; NfL, neurofilament light chain; sCSF1R, soluble colony-stimulating factor 1 receptor.

Conclusion: These interim clinical trial results of iluzanebart support its continued development as a potential disease-modifying therapy for ALSP and TREM2 agonism as a potential therapeutic approach for this neurodegenerative disorder.

Disclosure: JMG receives research support to his institution for contracted research. Background and Aims: This study assessed the effectiveness and tolerability of adjunctive cenobamate (CNB) for the treatment of focal seizures in the context of real-world clinical practice.

Methods: This was a retrospective, multicentre study including subjects prescribed CNB at 21 centres in Italy within the frame of the national Expanded Access Program. Study outcomes included the 3-, 6-, and 12-month rates of seizure response, seizure-freedom, and treatment discontinuation. The change in the number of concomitant ASMs and the incidence of adverse events (AEs) were evaluated.

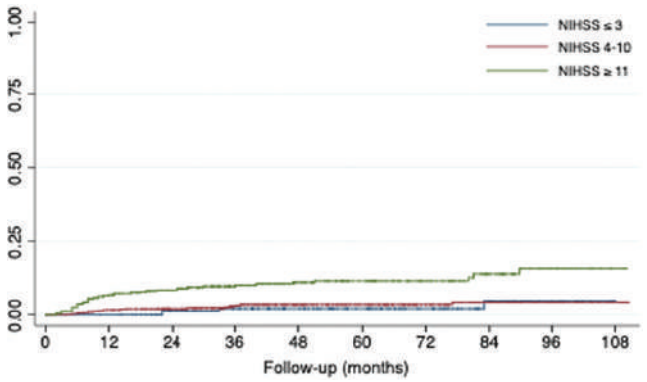
Results: The study included 236 subjects with a median age of 38 years. The median number of prior and concomitant antiseizure medications (ASMs) was 7 and 3, respectively. The median baseline seizure frequency was 15 seizures/month. The 3-, 6-, and 12-month responder rates were 47.9%, 52.1%, and 57.0%; the corresponding rates of seizure freedom were 9.7%, 12.2%, and 14.0%. At 12 months, 29.1% and 6.1% of the subjects were sustained seizure responder and sustained seizure free. A reduction in the number of concomitant ASMs occurred in 48.2% of the subjects who were on CNB treatment at 12 months. Treatment discontinuation rates were 5.1%, 9.1% and 21.2% at 3, 6, and 12 months. Adverse events occurred in 58.3% of the participants and the most common were somnolence and dizziness; no serious AEs were reported.

Conclusion: Adjunctive CNB was associated with the reduction in seizure frequency and the load of concomitant ASMs in a cohort of subjects with highly refractory epilepsy. Adverse events were common and mostly mild-to-moderate in intensity.
Disclosure: Nothing to disclose.

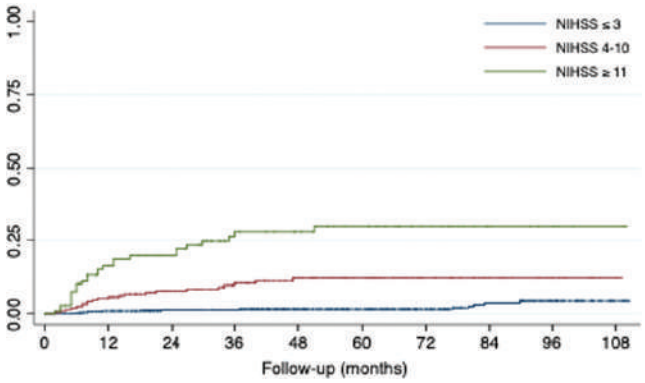
EPR-063 | Prediction of epilepsy after ischaemic stroke: can we do higher? The modified SeLECT 2.0 score

S. Lattanzi[1]; C. Cuccurullo[2]; N. Orlandi[3]; G. Borzi[3]; G. Bigliardi[3]; S. Maffei[3]; G. Giovannini[3]; S. Meletti[3]
[1]*Department of Experimental and Clinical Medicine, Marche Polytechnic University, Ancona, Italy;* [2]*University Federico II, Naples, Italy;* [3]*Neurology Unit, OCB Hospital, AOU Modena, Modena, Italy*

Background and Aims: The SeLECT 2.0 score is a prognostic model of unprovoked seizures after ischaemic stroke, but it does not consider the potential impact of revascularization. We aimed to explore whether replacing the severity of stroke at admission with the severity of stroke after treatment could improve the predictive accuracy of the score.
Methods: We retrospectively identified consecutive adults with acute first-ever ischaemic stroke who were admitted at the Stroke Unit of the Ospedale Civile Baggiovara and were treated with intravenous thrombolysis (IVT) and/or endovascular treatment (EVT). Study outcome was the occurrence of at least one unprovoked seizure presenting >7 days after stroke. The predictive power of the original and modified SeLECT 2.0 score was evaluated.
Results: Unprovoked seizures occurred in 65 (5.9%) out of 1094 subjects treated with IVT and/or EVT. The median values of the National Institutes of Health Stroke Scale at baseline and after treatment were 8 [5–14] and 1 [0–4]. The median values of the original and modified SeLECT2.0 scores were 3 [2–4] and 2 [1–3]. The modified SeLECT 2.0 score had higher values of Harrell's C and Somers' D parameters and lower values of Akaike's and Bayesian information criteria. The ROC curve for unprovoked seizures occurrence at 5 years was 0.663 and 0.851 for the original and modified scores.



Time to occurrence of unprovoked post-stroke seizures according to stroke severity at admission.



Time to occurrence of unprovoked post-stroke seizures according to post-treatment stroke severity.
Conclusion: Replacing baseline stroke severity with the stroke severity after treatment may improve the ability of the SeLECT 2.0 score to predict post-stroke epilepsy.
Disclosure: Nothing to disclose.

EPR-064 | Clinical and immunological studies in cryptogenic new-onset refractory status epilepticus

C. Milano[1]; C. Papi[2]; T. Iizuka[3]; E. Aguilar[4]; L. Sabater[4]; L. Naranjo[5]; R. Ruiz-Garcia[5]; F. Graus[4]; A. Consiglio[6]; J. Dalmau[4]; E. Martinez-Hernandez[7]
[1]*Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain; Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy;* [2]*Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain; Department of Neuroscience, Catholic University of the Sacred Heart, Rome, Italy;* [3]*Department of Neurology. Kitasato University School of Medicine, Japan;* [4]*Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain;* [5]*Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain; Department of Immunology, Hospital Clínic de Barcelona, University of Barcelona, Barcelona, Spain;* [6]*Department of Pathology and Experimental Therapeutics, Bellvitge University Hospital-IDIBELL, Hospitalet de Llobregat, Barcelona, Spain;* [7]*Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain; Department of Neurology, Hospital Clínic de Barcelona, University of Barcelona, Barcelona, Spain*

Background and Aims: New-onset refractory status epilepticus (NORSE) can develop during infectious or autoimmune encephalitis, but many cases remain without identifiable causes despite extensive investigations (cryptogenic NORSE, c-NORSE). In these patients, underlying inflammatory or antibody-mediated mechanisms are often considered. The aim of our study was to assess the presence of neuronal antibodies in patients with c-NORSE using comprehensive

antibody testing that also included a novel human-based neuronal immunofluorescence assay.

Methods: We included patients diagnosed with c-NORSE whose serum and cerebrospinal fluid (CSF) were neuronal antibody-negative using conventional techniques (brain immunohistochemistry, cell-based assays). Clinical information was reviewed and samples were tested with live neurons derived from human induced pluripotent stem cells (iPSCs).

Results: Twenty-four patients were studied (63% female, median age 33 years). In 21/24 patients, status epilepticus (SE) was preceded by fever. All patients required intensive care unit admission and treatment with anaesthetics. Initial brain MRI was abnormal in 42% of cases, showing DWI or T2/FLAIR temporal (60%), extratemporal (10%) or combined (30%) abnormalities. Repeat MRI identified 8 additional patients with abnormalities during SE. CSF showed inflammatory changes in 83%, while oligoclonal bands were always absent. All patients received first line immunotherapy, with resolution of SE only in one. Eight patients received second line immunotherapy, with partial improvement in two. Two patients had antibodies against neuronal surface proteins (pending to characterize) visible only with human iPSCs-derived neurons.

Conclusion: Most patients (92%) with c-NORSE did not have novel unknown neuronal antibodies reacting with human iPSC-derived neurons, indicating that underlying mechanisms are probably not antibody-mediated.

Disclosure: Nothing to disclose.

EPR-065 | Autopsies Conducted on Epilepsy Cases: Most of them are SUDEP

Background and Aims: Sudden unexpected death in epilepsy (SUDEP) is the most devastating complication of epilepsy. Recognizing clinical and autopsy findings pose challenges. This study aims to elucidate the pathogenesis and risk factors of SUDEP.

Methods: We analyzed epilepsy-related deaths between 2009 and 2019, evaluated by our Forensic Medicine Specialty Board, using demographic, autopsy data, and witness statements.

Results: For 108 cases (69% male), average age at death was 36.5±11.7 years, 94% had a diagnosed epilepsy, 66% were found deceased. Autopsies, conducted in 94% of cases, revealed the cause of death as SUDEP in 66%, non-SUDEP in 18%, possible SUDEP in 9%; SUDEP+ in 5%; and nearSUDEP in 2%. Among the 88 cases within the SUDEP spectrum, 80% had clues suggesting a pre-death seizure. Upon examining provoking factors, 38% of cases were found in the prone position, 13% had infections, 9% experienced sleep deprivation, 17% had medication nonadherence, and 3% had a history of alcohol&substance use. In 36% of cases, no antiepileptic drugs were detected in body fluids. Remarkably, 41% of SUDEP spectrum cases showed lividity on the body's front, contrasting with 7% in non-SUDEP cases, and 66.7% had residual urine in the bladder, contrasting with 25% ($p=0.011$, $p=0.047$ respectively).

Conclusion: The study shows most epilepsy-related deaths examined fall within the SUDEP spectrum, with findings like pre-death seizures, anterior lividity, and residual urine potentially serving as SUDEP indicators. Despite these correlations, no definitive autopsy features uniquely identify SUDEP, highlighting the need for further investigations.

Disclosure: This study has been presented in 59th Turkish National Neurology Congress.

EPR-066 | Prognostic factors in refractory and super-refractory status epilepticus: A retrospective review

J. Ferreira Maachado[1]; M. Seco[1]; Â. Fonseca[1]; H. Silva[2]; A. Ferreira[1]; C. Cruto[1]

[1]Neurology Service, Matosinhos Local Health Unit, Hospital Pedro Hispano, Porto, Portugal; [2]Neurophysiology Laboratory, Matosinhos Local Health Unit, Hospital Pedro Hispano, Porto, Portugal

Background and Aims: Refractory Status Epilepticus (RSE) and super-refractory (SRSE) are challenging to treat, posing complex management issues for patients.

Methods: Retrospective study with analysis of potential prognostic factors in patients with RSE and SRSE hospitalized from 2019 to 2023 with the objective of identifying prognosis-influencing factors.

Results: 47 patients were included, 55.3% female. The mean age was 63.3 (±18.9) years, with a mean pre-admission mRankin of 2 (±1.6). The mean score on the Status Epilepticus Severity Score (STESS) at admission was 4.6 (±1.4). Cerebrovascular disease was the leading etiology (21.3%). Overall mortality was 68.1%. 51.1% of patients underwent at least one burst-suppression (BS) cycle. The STESS scale score showed a linear correlation with mRankin at 3 months ($r=0.64$). The major predictors of death were age ($p=0.05$) and the presence of non-convulsive SE ($p=0.042$). Patients who underwent BS had a lower mortality rate (45.8% vs. 91.3%, $p<0.001$), even when age-adjusted ($p=0.05$). In patients undergoing anesthetic treatment, 11 had RSE and 13 SRSE; no significant mortality differences (36.4% vs. 53.8%, $p=0.39$) or mRankin variations at 3 months (2.14 vs. 2.17, $p=0.97$) were observed between groups.

Conclusion: This study shows that patients with lower STESS scores have lower mortality and disability. It also highlights that the implementation of BS reduces mortality, regardless of age. In patients undergoing anesthetic treatment, there were no significant differences between RSE and SRSE regarding morbi-mortality. We believe that the underlying etiology, age, and physical robustness of the patients with SRSE may have contributed to this outcome.

Disclosure: Nothing to disclose.

EPR-067 | Abstract withdrawn

EPR-068 | Epilepsy Trends in Kazakhstan: A Retrospective Longitudinal Study of Data from UNEHS 2014–2020

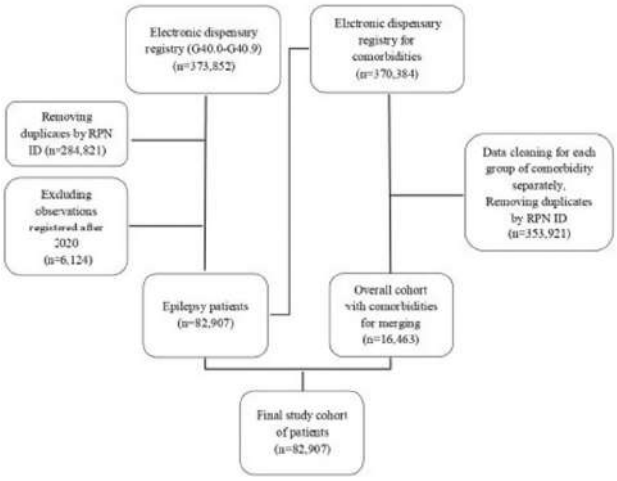
R. Akhmedullin[1]; Z. Utebekov[2]

[1]*Nazarbayev University School of Medicine, Astana, Kazakhstan;* [2]*RSE Medical Center Hospital of the President's Affairs Administration of the Republic of Astana, Kazakhstan*

Background and Aims: There is limited epidemiological data for Central Asia. Kazakhstan is the largest country in this region. The purpose of this study was to fill the gaps in examining the incidence, prevalence, DALYs, and mortality-associated factors of epilepsy

Methods: Using the Unified National Electronic Health System of Kazakhstan over a seven-year span, we explored epidemiology, DALYs, and all-cause mortality. Regression models using Cox proportional hazards were used to analyze the sociodemographic, mental, behavioral, and neurological factors affecting survival

Flow chart of the cohort selection process from the Unified National Electronic Health System (UNEHS).



Flow chart.

Results: The total cohort comprised 82,907 patients, with a significant increase in the incidence of epilepsy from 26.15 in 2014 to 88.80 in 2020. Similar trends were observed in the prevalence rates, which tripled from 26.06 to 73.10. The oldest (≥75) and youngest (0–5 years) age groups had the highest statistics. While mortality rates fluctuated, the elderly and children had the greatest rates of 9.97 and 2.98 per 1000 PY respectively. DALYs revealed a substantial disease burden, with 153,532 DALYs being lost during the study period. A few comorbidities, such as cerebral palsy (aHR 2.23) and central nervous system atrophy (aHR, 27.79), markedly elevated all-cause mortality. Furthermore, extrapyramidal and movement disorders (aHR 2.16, $p=0.06$) and demyelinating diseases of the CNS (aHR 6.36, $p=0.06$) showed a trend toward increased mortality risk. Notably, none of the mental or behavioral comorbidities was associated with mortality.

Association of comorbidities with all-cause mortality in epilepsy patients

Variables	Crude HR	p-value	Model 1. Adjusted HR and 95% CI	p-value	Model 2. Adjusted HR and 95% CI	p-value
Organic, including symptomatic, mental disorders (F00-F09)	1.10 (0.79-1.54)	0.55	0.83 (0.59-1.17)	0.30	0.83 (0.59-1.16)	0.28

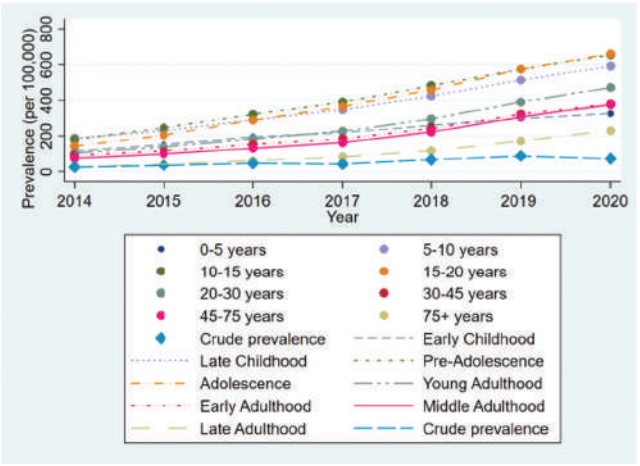
Demyelinating diseases of the central nervous system (G35-G37)	7.62 (1.07-54.25)	0.04	6.08 (0.85-43.47)	0.07	6.36 (0.89-45.53)	0.06
Episodic and paroxysmal disorders (G43-G47)	0.94 (0.23-3.77)	0.93	0.61 (0.15-2.45)	0.49	0.58 (0.15-2.37)	0.46
Diseases of myoneural junction and muscle (G70-G73)	7.58 (1.06-54.02)	0.04	6.48 (0.91-46.36)	0.06	5.57 (0.77-40.15)	0.08
Cerebral palsy and other paralytic syndromes (G80-G83)	1.23 (0.64-2.39)	0.53	2.10 (1.07-4.12)	0.03	2.23 (1.12-4.44)	0.02
Other disorders of the nervous system (G90-G99)	1.03 (0.51-2.08)	0.93	0.93 (0.46-1.87)	0.84	0.88 (0.43-1.79)	0.73

Association of comorbidities with all-cause mortality in epilepsy patients.



Prevalence 2014–2020.

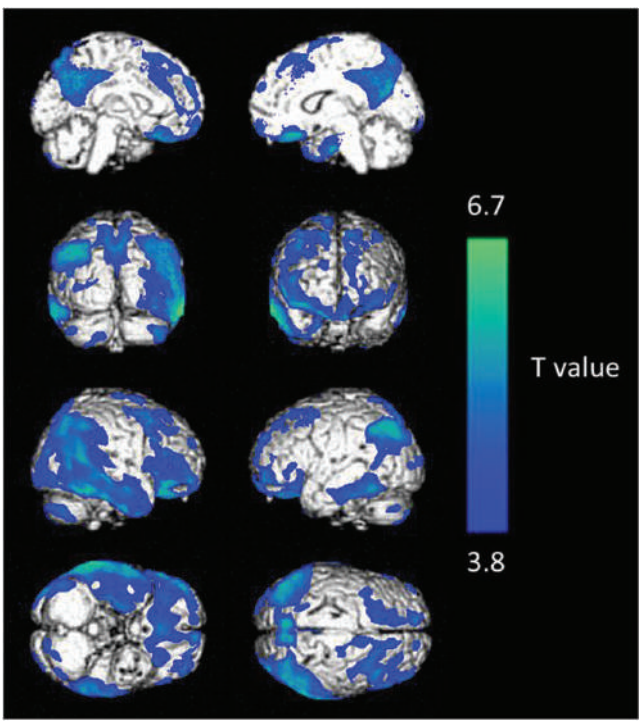
Conclusion: The findings highlight the significant burden, especially in younger age groups, and it was observed concerning comorbidity patterns, particularly the high prevalence of mental and behavioral conditions in the epilepsy cohort

Disclosure: Nothing to disclose.

EPR-069 | Brain 18F-FDG PET: an efficient tool at the initial diagnosis of non-lesional late-onset epilepsy

S. Puisieux[1]; S. Heyer[2]; M. Doyen[2]; L. Tyvaert[1]; A. Verger[2]
[1]*Department of Neurology, Hospital Center Regional And University De Nancy, France;* [2]*Department of Nuclear Medicine and Nancyclotep Imaging Platform, Hospital Center Regional And University De Nancy, France*

Background and Aims: This study evaluates the diagnostic performance and prognostic value of brain 18F-FDG PET at the initial diagnosis of patients with non-lesional late-onset epilepsy (NLLOE).
Methods: Eighty-seven, newly diagnosed NLLOE patients, >50 yo, with brain 18F-FDG PET scans, were prospectively included from June 2017 to January 2021 at the University Hospital of Nancy (maximum follow-up; 3 years) and categorized by clinical NLLOE subtype aetiology. Brain 18F-FDG PET scans were analysed using a combined visual and semi-quantitative approach at the individual level and a quantitative voxel-to-voxel comparison to sex- and age-matched controls at the group level.
Results: A normal 18F-FDG PET was observed in 46% of patients, with the final diagnosis of 88% of these patients excluding a neurodegenerative or inflammatory disorder. A normal 18F-FDG PET had a negative predictive value of 87% for a cognitive decline at follow-up. Moreover, a PET hypometabolic pattern suggestive of a neurodegenerative disorder had a 77% accuracy of identifying a cognitive decline at follow-up. At the group level, 18F-FDG PET identified a typical neurodegenerative pattern in patients with neurodegenerative disorders (p-voxel <0.001, corrected for cluster volume).



Statistical Z-score maps of brain 18F-FDG PET hypometabolism in the NDS-PET group represented in 3D rendered volume. The Z-score maps show the regions with significantly reduced metabolism compared to the normal database.
Conclusion: A 18F-FDG PET as part of the initial diagnosis of NLLOE patients has a significant impact on both NLLOE diagnosis and cognitive prognosis. For almost half of NLLOE patients, a normal 18F-FDG PET scan is able to exclude, neurodegenerative and inflammatory epilepsy aetiologies as well as a future cognitive decline, with a high level of certainty. In addition, 18F-FDG PET can identify neurodegenerative diseases with high diagnostic performances.
Disclosure: None.

EPR-070 | Psychosocial problems of epilepsy in Georgia – changes over the time (preliminary data)

T. Jishkariani[1,2,3]; K. Mamasakhlisi[1,2]; M. Megrelishvili[3]; S. Kasradze[1,2]
[1]*Cauasus International University (CIU), Tbilisi, Georgia;* [2]*Institute of Neurology and Neuropsychology (INN), Tbilisi, Georgia;* [3]*Ilia State University (Iliauni), Tbilisi, Georgia*

Background and Aims: The low quality of life in people with epilepsy (PWE) is largely determined by the problems of the patient's education, employment, social relations, family formation and other barriers, that were dramatically lower in the late 90s in Georgia (1). Since the beginning of the 21st century, many measures have been implemented to solve the psychosocial problems of people with epilepsy, although the actual results of these measures are unknown. Aim: To assess the dynamics of psychosocial problems of PWE in Georgia.
Methods: The study was conducted at the Institute of Neurology and Neuropsychology using the adapted survey QOL31, that was used in previous study (1). 305 PWE (Female – 171), aged 18–65 years, without severe cognitive dysfunctions were assessed. Indicators of patients' education, employment, marital status, satisfaction with their own health and social relationships were evaluated.
Results: Compared to the previous date indicators of the higher education (from 19.84% to 44.5%), employment (from 17% to 56%), general emotional well-being (from 9.39% to 80%) and in terms of social relations (from 15.1% to 88.9%) was significantly increased in PWE. The cases of satisfaction with one's own situation increased from 9.1% to 45%; As on marriage rate remained virtually unchanged (48.2% and 47%, respectively).
Conclusion: In general, the psychosocial problems of PWE have improved in Georgia, although some of the problems needs more active anti-stigma actions. Acknowledgments: The study was performed on the bases of Ph.D. educational programs grant funding from Sh. Rustaveli National Science Foundation of Georgia (PHDF-23-1911).

Jaimes Sánchez[4]; S. Campoy Díaz[2]; C. Romero del Rincón[3]; N. Fabregat Fabra[4]; Y. González Osorio[1]; S. Quintas Gutiérrez[3]; A. Guerrero Peral[1]
[1]Hospital Clinico Universitario de Valladolid, Valladolid, Spain; [2]Hospital Universitari de Bellvitge y Viladecans, Barcelona, Spain; [3]Hospital Universitario La Princesa/Madrid, Madrid, Spain; [4]Hospital Clinic Barcelona, Barcelona, Spain; [5]Fundación Jiménez Diaz/Madrid, Madrid, Spain; [6]Hospital Universitario de Donostia, Donostia, Spain; [7]Hospital Universitario Virgen del Rocio/Seville, Seville, Spain; [8]Hospital General Universitario Gregorio Marañon/Madrid, Madrid, Spain; [9]Hospital Universitario de A Coruña CHUAC, A Coruña, Spain; [10]Hospital Universitario de Basurto, Bilbao, Spain; [11]Hospital Universitario Reina Sofía/Córdoba, Córdoba, Spain; [12]Hospital Universitario de Cruces, Baracaldo, Spain; [13]Hospital Universitario de Albacete, Albacete, Spain; [14]Complejo Asistencial de Segovia, Spain

Background and Aims: We aimed to evaluate whether migraine patients with lack of response to a first anti-CGRP monoclonal antibody (mAb) respond to a second mAb. Thus, the effectiveness was evaluated between weeks 8–12 of treatment, compared to the month prior to the mAb onset.
Methods: Observational multicenter study with an ambisective cohort design. Adult patients with a confirmed diagnosis of migraine were included if they were treated with a mAb after the failure to a prior mAb. A structured questionnaire was administered, encompassing demographic and clinical variables. All consecutive patients were screened for eligibility. The endpoints recommended by the International Headache Society were evaluated. The study was approved by the Ethics review board (PI-22-2658) and the study protocol is public (NCT05785988).
Results: In 247 patients a second mAb was used, 48 discontinued due to inadequate tolerability: constipation ($n=17$), injection site reactions ($n=12$), lightheadedness ($n=10$); 10 withdrew the consent and 189 provided valid data. Patients were aged 49.8 (SD: 11.3) years and were female in 86.2% cases. Migraine subtype corresponded to chronic (85.2%), with aura (20.6%), with a median number of prior preventive drugs of 6 [IQR: 5–7]. Between weeks 8–12, 30%, 50% and 75% responses were achieved by 32.3%, 19% and 5.3% patients. The mean reduction of headache days per month was 3.6 (SD: 8.3).
Conclusion: Lack of efficacy to anti-CGRP mAbs does not preclude the lack of efficacy to a second mAb, albeit only a minority of patients respond. Predictors of response are needed to optimize the patients' selection.
Disclosure: Nothing to disclose.

EPR-072 | Assessing Migraine Stigma in Europe: Insights and Implications for Support

P. Goadsby[1]; E. RuizdelaTorre[2]; D. Pozo-Rosich[3]; D. Maassen van den Brink[4]; P. Irimia[5]; P. Mitsikostas[6]; P. Ashina[7]; P. Terwindt[8]; S. Bardají Ortiz[9]: A. Kelly[9]
[1]NIHR-King's Clinical Research Facility, King's College London UK; [2]European Migraine and Headache Alliance; [3]Headache Unit, Neurology Department, Vall d'Hebron University Hospital, Spain; [4]Department of Internal Medicine, Erasmus MC Medical Center, Rotterdam, The Netherlands; [5]Department of Neurology, Headache Unit, University Clinic of Navarra, Spain; [6]1st Department of Neurology, Aeginition Hospital, National and Kapodistrian University of Athens, Greece; [7]Danish Headache Center, Department of Neurology, Rigshospitalet Glostrup, University of Copenhagen, Denmark; [8]Department of Neurology, Leiden University Medical Center, Leiden, The Netherlands; [9]Prescient HealthCare Group

Background and Aims: Migraine is the most common cause of neurological referral in most practices. Stigma around migraine has been discussed broadly over some time. We sought to evaluate the stigma of migraine patients in Europe
Methods: The European Migraine & Headache Alliance (EMHA), a patient association umbrella alliance, collaborated with migraine experts to develop an anonymous and voluntary survey. Stigma Scale for Chronic Illness (SSCI) scales were used to assess migraine stigma and correlated with frequency, severity, and medication use. The survey was distributed through EMHA's European network. Data were analyzed in Excel.
Results: People with migraine ($n=4{,}210$) from around Europe completed the survey: Spain 22%, France 12%, Italy 11%, Germany 10%, Portugal 8%, and were predominantly women aged 25–64 years. Of respondents, 90% were migraine sufferers, with 50% considering themselves severe and 57% having ≥8 migraine days/month. Medical and workplace settings were identified as primary sources of stigma. Of responders, 74% felt medical professionals lacked an understanding of what it means to live with migraine, and 79% reported a negative impact on their careers. Migraine stigma was seen as more pronounced than for other neurological conditions but less than mental health conditions. Terms, such as severe, had no clear unifying definition, and diagnostic terminology, such as chronic migraine were poorly understood.
Conclusion: Migraine stigma impacts personal and professional lives. Broader education on migraine and changes in terminology used may limit stigma and improve quality of life people with migraine
Disclosure: Nothing to disclose.

EPR-073 | Prevalence and characteristics of women with menstrually-related migraine in the 2022 National Health & Wellness Survey

G. Terwindt[1]; M. Lewis[2]; A. Jenkins[3]; J. Cirillo[4]; K. Hygge Blakeman[5]; J. Yang[6]; L. Abraham[3]; J. Brown[2]
[1]*Department of Neurology, Leiden University Medical Centre, Leiden, NL;* [2]*Real World Evidence, Pfizer, New York, NY, USA;* [3]*HTA, Value & Evidence, Pfizer, Tadworth, UK;* [4]*HTA, Value & Evidence, Pfizer, New York, NY, USA;* [5]*Global Medical Affairs, Pfizer, Stockholm, Sweden;* [6]*Global Medical Affairs, Pfizer, New York, NY, USA*

Background and Aims: Menstrually related migraine (MRM) occurs in approximately 60% of women with migraine and is associated with attacks of longer duration, greater severity, and symptom burden than non-MRM attacks. There is a lack of evidence on the real-world utilization of migraine treatments among women with MRM.
Methods: This retrospective cross-sectional study used the five-country 2022 European National Health and Wellness Survey (NHWS, Cerner Enviza) to identify female participants who self-reported having a migraine diagnosis by a doctor and migraines related to menstruation. Respondents reported their migraine frequency, disability via the Migraine Disability Assessment Test (MIDAS), and current migraine treatments.
Results: Of 18.9 million women with diagnosed migraine, 10.6 million were pre-menopausal, and MRM was reported by nearly half (47.0%; mean age [SD], 35.5 [9.4] years). For women with MRM versus those without, 51.5% (vs. 42.4%) had moderate-to-severe migraine-specific disability, although monthly migraine (3.7 [5.0] vs. 3.5 [5.9] days) and headache frequencies were similar (7.1 [6.8] vs. 8.2 [7.5] days). Women with MRM had higher use of prescription migraine treatments (56.7 vs. 48.6%); non-steroidal anti-inflammatory drugs (60.4%), triptans (32.2%), and opioids (18.0%) were the most commonly used acute treatments. A smaller proportion of women with MRM used preventive treatments compared to women without MRM (16.6% vs. 19.1%).
Conclusion: The prevalence of MRM was 47.0% among pre-menopausal women. Women with MRM reported greater migraine-related disability and prescription medication use but had less preventive treatment use compared to their non-MRM counterparts.

EPR-074 | Long-term improvements following >=50% migraine response in eptinezumab-treated patients with migraine

M. Ashina[1]; S. Awad[3]; X. Lee[3]; L. Boserup[3]; B. Sperling[3]; R. Lipton[4]; J. Ailani[5]
[1]*Department of Neurology, Danish Headache Center, Copenhagen University Hospital- Rigshospitalet, Copenhagen, Denmark;* [3]*H. Lundbeck A/S, Copenhagen, Denmark;* [4]*Department of Neurology, Albert Einstein College of Medicine, Bronx, NY, USA;* [5]*Department of Neurology, Georgetown University Hospital, Washington, D.C., USA*

Background and Aims: The DELIVER trial examined long-term (72-week) patient response to eptinezumab preventive treatment. For eptinezumab-treated patients demonstrating an initial migraine response (i.e., response over the placebo-controlled period, Weeks [Wks] 1–12), changes from baseline in monthly migraine days (MMDs), 6-item Headache Impact Test (HIT-6) total score, presenteeism, and percentage of severe migraine attacks are reported.
Methods: DELIVER included patients with migraine and 2–4 prior preventive migraine treatment failures, with the long-term population ($n=865$) including those completing the 24-week placebo-controlled period and continuing into the 48-week dose-blinded period. Post hoc analysis followed eptinezumab-treated patients with a >=50% migraine response during the first dosing interval (Wks1–12) across subsequent 12-week dosing intervals for the 72-week trial duration.
Results: Over Wks1-12, 123/286 (43.0%, 100 mg) and 141/282 (50.0%, 300mg) eptinezumab-treated patients in the long-term full analysis set experienced >=50% migraine response. Eptinezumab-treated patients with initial >=50% migraine response showed sustained reductions in migraine frequency, with mean reductions of 7.8 (100 mg) and 8.1 (300 mg) MMDs over Wks1–12 and 8.2 (100 mg) and 8.6 (300 mg) over Wks61–72. Also shown were sustained improvements from baseline in headache-related impact (HIT-6 total score: baseline 66.1–66.5; reduction 13.3–15.1 [Wk12] and 14.1–15.9 [Wk72]); presenteeism-affected working time (baseline 52.2%–52.4%; reduction 35.7%–37.8% [Wk12] and 34.7%–35.4% [Wk72]); and percentage of severe migraine attacks (baseline 45.0%–47.9%; reduction 28.7%–29.5% [Wks1–12] and 29.6%–33.4% [Wks61–72]).
Conclusion: Patients with >=50% migraine response following one eptinezumab dose experienced improvements over Wks1–12 in MMDs, headache-related impact, presenteeism, and percentage of severe migraine attacks. Benefits of eptinezumab (100mg and 300mg) were maintained for 72 weeks.

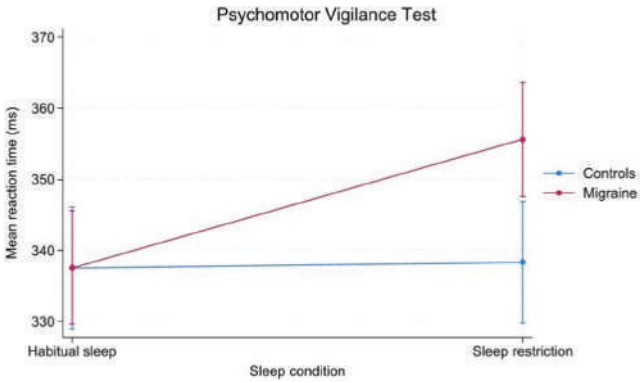
EPR-075 | Insufficient sleep cause cognitive impairment in interictal migraine patients

M. Mykland[1]; J. Neverdahl[1]; M. Uglem[2]; T. Sand[3]; P. Omland[3]
[1]*Norwegian Headache Research Centre (NorHEAD), Norwegian University of Science and Technology, Trondheim, Norway;* [2]*Department of Neurology and Clinical Neurophysiology, St. Olavs Hospital, Trondheim, Norway;* [3]*Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, Norwegian University of Science and Technology, Trondheim, Norway*

Background and Aims: There is a well-known, but unexplained connection between migraine and sleep. Whether migraine patients are more prone to cognitive effects of insufficient sleep between attacks is not known. We aimed to investigate attention as a measure of cognitive function after insufficient sleep, both in migraine patients and healthy controls.

Methods: We collected data from two studies with a corresponding study design. A total of eighty-five interictal migraine patients and sixty-three controls were examined after both two nights of eight-hour habitual sleep (HS) and two nights of four-hour restricted sleep (SR). All subjects performed a 10-min psychomotor vigilance test (PVT) the morning after the second sleep-controlled night. Sleep time was measured with actigraphy and a sleep diary. We applied linear mixed models to evaluate if the effect of sleep condition/measured sleep time differed between patients and controls.

Results: We found a significant effect of the interaction diagnosis x sleep condition for mean reaction time during PVT ($p=0.001$). Mean reaction time was increased after SR in the migraine group (estimated marginal mean; HS 337.6 ms, SR 355.6 ms), but not in the control group (estimated marginal mean; HS 337.6 ms, SR 338.4 ms). The corresponding interaction was also significant when exchanging sleep condition with measured sleep time ($p=0.016$).



Mean reaction time in milliseconds (ms) during a 10-min psychomotor vigilance test.

Conclusion: Insufficient sleep cause greater cognitive impairment in form of reduced attention in migraine patients compared to healthy controls.

Disclosure: Nothing to disclose.

EPR-076 | CGRP levels in peripheral blood in patients with idiopathic intracranial hypertension and migraine

N. Celebisoy[1]; A. Kisabay AK[2]; Y. Inalkac Gemici[2]; M. Batum[2]; B. Karakas[2]; E. Yildirim Özmen[3]; F. Gokcay[1]
[1]*Ege University Department of Neurology;* [2]*Celal Bayar University, Department of Neurology;* [3]*Ege University Department of Clinical Biochemistry*

Background and Aims: Calcitonin gene-related peptide (CGRP) plays a dominant role in migraine. This prospective study was designed to investigate CGRP levels in patients with idiopathic intracranial hypertension (IIH) and compare the results of migraine patients and healthy controls (HC). As a second objective, CGRP levels obtained from IIH patients defining sustained headache after the resolution of papilledema were compared with those not defining post-IIH headache.

Methods: Thirty-six patients with IIH, 36 with episodic migraine (EM), 18 with chronic migraine (CM), and 36 HC were included in the study. CGRP levels were studied from blood samples obtained from the antecubital vein by using a commercial ELISA kit.

Results: Serum CGRP levels of the patient groups were significantly higher than the HC ($p<0.001$). As compared with controls, both CM (p Adj <0.001) and IIH (p Adj $=0.039$) had significantly increased levels of CGRP. Levels recorded from EM patients did not differ from the HC (p Adj $=0.661$). In 16 IIH patients, persistent headache was reported after the normalization of intracranial pressure (ICP). Twenty patients did not report post-IIH headaches. Comparison of serum CGRP levels of these two groups revealed significantly higher CGRP levels in patients with sustained headaches obtained from blood samples both at the initial and control visit (p Adj <0.001).

Conclusion: CGRP levels of the patient groups were higher than the HC. High levels recorded in patients with IIH indicates the role

of CGRP in IIH-related headache and even higher levels in patients with sustained headache after normalization of ICP strengthens this finding.

Disclosure: Nothing to disclose.

EPR-077 | Sexuality and sexual function in females with migraine versus controls

J. Rothrock[1]; L. Peterlin[2]; R. Lipton[3]

[1]Inova Health/University of Virginia, Fairfax, VA USA; [2]Pennsylvania Headache Center and Penn State Health, Camp Hill, PA USA; [3]Albert Einstein University, New York, USA

Background and Aims: For females, migraine traditionally has been assumed to convey a relative decrease in libido. We compared the level of sexuality and various aspects of sexual function in two female migraine populations relative to a matched female population without migraine.

Methods: A consecutive series of heterosexually self-identifying and sexually active female patients ages 25–45 receiving care at a university-based headache clinic for migraine were asked to complete anonymously a set of surveys that included the Female Sexual Function Inventory (FSFI), From a general population sample we recruited females similar to the migraine group in age, race/ethnicity, marital status, educational background and socioeconomic status and asked them to complete the same surveys.

Results: In addition to 150 clinic-based migraine subjects (group 1) we evaluated 150 matched migraine-free controls (group 2) and 67 individuals with migraine from the general population (group 3). Relative to the control subjects (group 2), the clinic-based migraine group recorded a significantly higher mean FSFI score ($p < 0.05$). Patients with EM reported a higher monthly frequency of intercourse and a higher likelihood of intercourse resulting in orgasm. The mean FSFI score for the clinic-based migraine subjects did not differ significantly from the score for the 67 migraine patients from the general/non-clinic population (group 3). Mean FSFI scores from all three groups were above the level considered indicative of sexual dysfunction.

Conclusion: We found that heterosexually self-identifying and sexually active females with migraine reported a higher level of self-perceived sexuality and more positive sexual function than matched controls free of migraine.

Disclosure: None

EPR-078 | Corticosteroids and Galcanezumab in medication overuse headache: A three-arm head-to-head prospective cohort study

S. Braca; R. De Simone; A. Miele; A. Stornaiuolo; G. Cretella; C. Russo

Department of Neuroscience, Reproductive Sciences and Odontostomatology, University of Naples Federico II, Naples, Italy

Background and Aims: Medication Overuse Headache (MOH) is a condition where pain relief medications cause chronic headaches due to excessive use. Recent advancements highlight the effectiveness of preventive treatments like anti-CGRP monoclonal antibodies. Current strategies combine medication withdrawal and preventive treatments, with corticosteroids traditionally used to ease withdrawal symptoms.

Methods: This is a prospective three-arm observational cohort study comparing the effectiveness and safety of galcanezumab alone, galcanezumab plus prednisone and prednisone alone for the treatment of MOH. We enrolled 75 patients. Prednisone was administered at an initial dose of 50 mg daily, and then tapered off over 28 days. Duration of follow-up was 3 months.

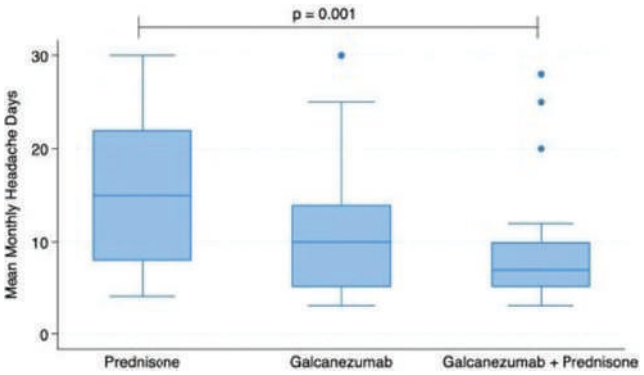
Results: All treatments proved effective ($p < 0.001$). We found a significant reduction of mean monthly days with headache in the Galcanezumab plus Prednisone group (baseline: 25, IQR: 20–30; after 3 months: 7, IQR: 5–10), in the Galcanezumab group (baseline: 25, IQR: 20–30; after 3 months: 10, IQR: 5–14) and in the Prednisone group (baseline: 20, IQR: 20–28; after 3 months: (median: 15 days, IQR: 8–22 days). Patients treated with Prednisone reported a higher incidence of side effects ($p = 0.002$).

Table 1 - Patients characteristics

	Overall (n = 75)	Group 1 (n = 25)	Group 2 (n = 25)	Group 3 (n = 25)	p-value
Age (years)					
Median	48	48	46	49	0.846
25th-75th	38-56	37-57	38-62	39-55	
Disease Duration (months)					
Median	23	24	26	22	0.957
25th-75th	13-33	12-34	9-33	17-30	
Sex, n (%)					
Female	58 (77.3)	18 (72.0)	21 (84.0)	19 (76.0)	0.694
Male	17 (22.7)	7 (28.0)	4 (16.0)	6 (24.0)	
Comorbidities, n (%)	42 (56.0)	13 (52.0)	15 (60.0)	14 (56.0)	0.931
Baseline Values					
Migraine days	25 (20-30)	25 (20-28)	25 (20-30)	25 (20-30)	0.788
MIDAS	65 (55-78)	66 (58-72)	64 (59-81)	65 (53-81)	0.914
Days of Acute Medication Intake	38 (25-60)	43 (25-55)	35 (25-55)	30 (30-60)	0.991
Medication Type, n (%)					
FANS	58 (77.3)	18 (72.0)	21 (84.0)	19 (76.0)	0.752
FANS + Triptans	1 (1.3)	1 (4.0)	0 (0.0)	0 (0.0)	
Opiates	1 (1.3)	0 (0.0)	0 (0.0)	1 (4.0)	
Triptans	15 (20.0)	6 (24.0)	4 (16.0)	5 (20.0)	

Legend. Group 1 = Prednisone; Group 2 = Galcanezumab; Group 3 = Prednisone + Galcanezumab

Demographic and Baseline Features.



Mean Monthly Days Reduction of Headaches.

Conclusion: Our study indicates that both Galcanezumab and Prednisone effectively decrease the frequency of headaches in patients with MOH. The combined usage of these treatments showed the highest reduction in mean monthly headache days. However, treatment with Prednisone determined a significant rate of adverse events, therefore we suggest its use only in unresponsive patients. In all other patients Galcanezumab appears to be a safe and effective option.

Disclosure: Nothing to disclose.

EPR-079 | Repeated onabotulinum Toxin A injections towards the sphenopalatine ganglion in chronic cluster and chronic migraine

L. Simmonds[1]; I. Aschehoug[2]; S. Hara[2]; T. Meisingset[2]; M. Matharu[1]; E. Tronvik[2]; D. Bratbak[2]

[1]Headache and Facial Pain Group, University College London Queen Square Institute of Neurology and National Hospital for Neurology and Neurosurgery, UK; [2]Norwegian Headache Research Centre, Trondheim, Norway

Background and Aims: This study explores onabotulinum toxin A (BTA) injections towards the sphenopalatine ganglion (SPG) in treatment-resistant chronic migraine (CM) and chronic cluster headache (CCH).

Methods: We included patients who had received at least one injection and completed headache diaries. We administered 25 units of BTA with navigated injections towards the SPG in local anaesthesia. Safety data were gathered from prior pilot trials and clinical records.

Results: The study involved 12 CM patients and 31 CCH patients. After a single injection, 81% of CM and 69% of CCH achieved a 50% reduction. Between weeks five and eight after injection, CM patients experienced a significant decrease of 9 moderate-to-severe headache days per month, while CCH patients saw an 8.9-attack reduction per month ($p < 0.001$). The 50% response rates persisted consistently over four consecutive injections in both groups, ranging between 67 and 81% in CM and 69%–89% in CCH. In the safety analysis, we evaluated 261 injections, and 123 linked adverse events (AE). One serious AE was reported with hospitalisation for investigation of facial weakness. The most frequent AEs was jaw pain/weakness ($n = 35$), localized pain/swelling the injection site ($n = 22$), and mild intermittent visual disturbances ($n = 28$). Four patients experienced facial weakness, and five reported transient diplopia. All these side effects resolved, with most resolving within 12 weeks, and none resulted in patients refusing further treatment.

Conclusion: This open-label study demonstrates that BTA injections targeting the SPG effectively treat both resistant CM and refractory CCH, providing sustained relief for at least three months.

Disclosure: Dr Bratbak and Prof Tronvik may benefit financially from a commercialization of a proposed treatment targeting the SPG and the intervention device used to perform the treatment through intellectual properties rights and has consulted for Man & Science within the past 12 months.

Movement disorders 1

EPR-080 | The phase 3 PROOF-HD trial demonstrates efficacy in Huntington disease participants without antidopaminergic medications

M. Geva[1]; R. Reilmann[2]; A. Feigin[3]; A. Rosser[4]; S. Kostyk[5]; M. Mehra[6]; M. Hayden[1]

[1]Prilenia Therapeutics B.V., Naarden, The Netherlands; [2]George Huntington Institute, Muenster, Germany; [3]NYU Langone Health, New York, NY USA; [4]University of Cardiff, Cardiff, Wales, UK; [5]Ohio State University College of Medicine, Columbus, OH, USA; [6]Biometrics Department, Tigermed-BDM Inc, Somerset, NJ

Background and Aims: The PROOF-HD trial evaluated the safety and efficacy of pridopidine (45mg bid) in patients with early HD (TFC>7).

Methods: Primary and key secondary endpoints were change to week 65 in total functional capacity (TFC) and clinical progression (cUHDRS)(respectively). Other endpoints included cognition (SWR), motor (Q-Motor) and Quality-of-Life (HD-QoL). Prespecified subgroup analyses excluded participants on antidopaminergic medication (ADMs)(neuroleptics and anti-chorea medications).

Results: Pridopidine was well tolerated with a safety profile comparable to placebo. The primary and key secondary endpoints were not met in all patients. Nominal p-values are reported. In analyses excluding participants on ADMs (placebo $n = 99$, pridopidine $n = 79$), the placebo group showed an expected decline in all measures. Pridopidine shows improvement from baseline in cUHDRS at week 26 (Δ0.46, $p = 0.006$), week 39 (Δ0.60, $p = 0.003$), and week 52 (Δ0.43, $p = 0.04$) with sustained benefit to week 78 (Δ0.50, $p = 0.08$). Pridopidine demonstrates an improvement from baseline in SWR at week 26 (Δ3.32, $p = 0.03$), week 39 (Δ4.14, $p = 0.02$), and week 52 (Δ4.22, $p = 0.02$) and maintained to week 78 (Δ2.82, $p = 0.2$) never falling below baseline. In Q-Motor measures, including finger tapping, pridopidine shows improvement from baseline at week 26 (Δ-31.96msec, $p = 0.00008$), week 39 (Δ-22.84msec, $p = 0.04$), and to

week 78 (Δ-34.23msec, $p=0.005$). Pridopidine preserved quality-of-life (HD-QoL) through week 78.

Conclusion: Pridopidine showed improvement over placebo on all endpoints, at every timepoint in participants off ADMs. PROOF-HD is the first trial to demonstrate consistent, meaningful, and sustained benefits on clinical progression in HD.

Disclosure: The PROOF-HD study was sponsored by Prilenia Therapeutics.

EPR-081 | The impact of antidopaminergic medication on longitudinal clinical progression in early Huntington disease (HD)

J. Long[1]; M. Geva[2]; K. Chen[2]; R. Hand[2]; H. Schuring[2]; Y. Goldberg[2]; M. Hayden[2]

[1]Departments of Psychiatry & Biostatistics, University of Iowa, Iowa City, USA; [2]Prilenia Therapeutics B.V., Naarden, The Netherlands

Background and Aims: Antidopaminergic medications (ADMs), comprised of anti-chorea medications (VMAT2 inhibitors (VMAT2i)) and neuroleptics (off-label), are used for the symptomatic treatment of HD. No prospective, double-blind studies have assessed the long-term effects of ADMs on disease progression in HD.

Methods: Rates of progression up to six years were assessed in an early manifest population (TFC >=7, DCL=4) from ENROLL-HD using the inclusion criteria of the PROOF-HD study. Each comparison involved a matching group On and Off the medication of interest (On vs. Off). The four comparisons were ADMs ($n=853$ per group), neuroleptics ($n=495$ per group), VMAT2i ($n=198$ per group), and antidepressants ($n=331$ per group). Pairs were matched at baseline using a propensity score constructed with 12 covariates.

Results: Participants on ADMs had faster disease progression across multiple measures including total functional capacity (TFC) ($p<0.001$), symbol digit modalities test (SDMT) ($p<0.001$), Stroop Word test (SWR) ($p<0.001$), and the composite UHDRS (cUHDRS) ($p<0.001$). Similar results were observed, when assessing neuroleptics and VMAT2i alone. On TMS subscales, ADM use was associated with improvement of chorea and, with worsening of bradykinesia ($p=0.001$). Participants on antidepressants showed no difference in progression rate.

Conclusion: ADMs use may be associated with adverse effects that alter disease progression, including cognition and function. Additional analyses will assess the impact of specific ADM medications/doses to identify treatments with minimal impact on disease progression. These observations have important implications for the design, conduct, and interpretation of investigational studies of disease-modifying agents in HD.

Disclosure: Prilenia Therapeutics sponsored this study.

EPR-082 | Subgroup analyses of a phase 3, randomized study of levodopa/carbidopa infusion (ND0612) for Parkinson's patients

W. Poewe[1]; N. Lopes[2]; J. Ferreira[3]

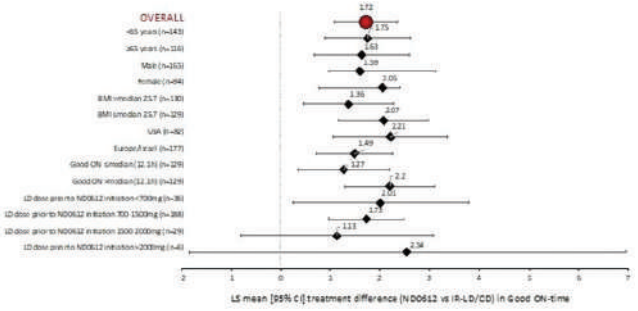
[1]Department of Neurology, Medical University Innsbruck, Innsbruck, Austria; [2]NeuroDerm Ltd., Rehovot, Israel; [3]Laboratory of Clinical Pharmacology and Therapeutics, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal

Background and Aims: Primary analyses from this Phase 3 study (NCT04006210) showed that treatment with an investigational, subcutaneous infusion of levodopa/carbidopa (ND0612, doses up to 720/90mg/day) supplemented with oral levodopa, provided an additional 1.72h [95%CI: 1.08h, 2.36h] of ON-time without troublesome dyskinesia (Good-ON) compared with immediate-release levodopa/carbidopa (IR-LD/CD; $p<0.0001$) at week 12. We present efficacy and safety findings for different patient subgroups categorized according to their baseline characteristics.

Methods: This was a randomized, double-blind, active-controlled trial in patients with Parkinson's disease experiencing motor fluctuations. Subgroups were analyzed separately for Good-ON using ANCOVA on multiply imputed data, with additional fixed factors for the subgroup variable and interaction term between the treatment group and subgroup variable. The influence of each subgroup factor was investigated by the interaction terms using Type III p-value combined for multiple imputation.

Results: The adjusted mean [95%CI] treatment effect of ND0612 for Good-ON was homogeneous across the different analyzed subgroups (Figure). Occurrence of adverse events (AEs) and serious AEs were generally consistent across subgroups (age, gender, region, and BMI). Consistent with the data for the full safety population, the most common AEs with ND0612 treatment across all subgroups were infusion site reactions. Overall, no relevant differences between subgroups were observed for AEs of particular interest, including dyskinesia, hallucinations, or falls.

Conclusion: The overall treatment effect was homogenous across different analyzed subgroups. Findings from these analyses support improved Good ON time, consistent with the overall effect of 1.72h, and no relevant differences in safety or tolerability were observed.



Subgroup analyses of Good ON time (primary endpoint).

EPR-083 | Onset of efficacy with levodopa/carbidopa infusion (ND0612) for Parkinson's patients

F. Stocchi[1]; N. Lopes[2]
[1]*University San Raffaele Roma and Institute for Research and Medical Care IRCCS San Raffaele, Rome, Italy*; [2]*NeuroDerm Ltd., Rehovot, Israel*

Background and Aims: Primary results from this Phase 2 study (NCT02577523) demonstrated that 28 days of treatment with 24h subcutaneous levodopa/carbidopa infusion (with investigational ND0612) increased ON-time with no/mild dyskinesia (Good ON) by a LS mean of 3.7 [1.9, 5.6]h ($p < 0.001$) in levodopa-treated patients with Parkinson's disease experiencing motor fluctuations. We report data from a secondary analysis which evaluated the onset of efficacy for the 24h ND0612 regimen ($N = 19$) as rated by patients and clinicians.

Methods: This was a 28-day, open-label study in patients with ≥2.5h/day of OFF-time despite optimized treatment. Patients treated with 24h ND0612 infusion received a daily levodopa/carbidopa dose of 720/90 mg plus adjunct oral levodopa/carbidopa as needed.

Results: Significant improvements versus baseline in daily Good ON-time (LS mean change: 1.83 [0.30, 3.35]h, $p = 0.02$) and ON-time with moderate-severe dyskinesia (LS mean change: −1.36 [−2.29, −0.42] h, $p = 0.006$) were observed at Day 3, as were improvements in Unified Parkinson's Disease Rating Scale motor scores (reduced from 37.4 to 26.6 at 8AM and from 28.3 to 19.2 at 4PM). Overall, 73.7% of patients self-reported an improvement (including 36.8% very much/much improved) in their global impression of health on Day 3. By day 7 of treatment, the proportion of patients who reported achieving a full ON at 9AM increased from 31.6% at baseline to 72.2%.

Conclusion: Results of this analysis demonstrate that significant and clinically relevant improvements in ON-time can be detected as early as Day 3 after ND0612 initiation that further improved by Day 28.

Disclosure: Funded by NeuroDerm, a Mitsubishi Tanabe Pharma Group Company. Nelson Lopes is employed by NeuroDerm. Fabrizio Stocchi is an investigator in the study and he/his institution received fees for participation, and is a consultant for NeuroDerm.

EPR-084 | Characterization of infusion site reactions with 24-hour subcutaneous infusion of ND0612

W. Poewe[1]; N. Lopes[2]; R. Pahwa[3]
[1]*Department of Neurology, Medical University Innsbruck, Innsbruck, Austria;* [2]*NeuroDerm Ltd., Rehovot, Israel;* [3]*University of Kansas Medical Center, Kansas City, KS, USA*

Background and Aims: ND0612 is an investigational, subcutaneous infusion of levodopa/carbidopa (max dose 720/90mg/day), supplemented with oral therapies, delivered via 2 cannulas to reduce skin burden. Here, we characterize infusion site reactions (ISRs) reported as adverse events (AEs) in clinical studies.

Methods: Integrated analysis of ISRs reported as AEs in patients with Parkinson's disease treated with a 24h regimen of ND0612 in two Phase 2 studies (NCT02577523 and NCT02726386) and one Phase 3 (NCT04006210) study. 'Grouped preferred terms' were defined for infusion site reactions including nodules, haematoma, swelling, eschar, erythema, infection, and pain.

Results: This analysis included 419 patients with a mean ± SD exposure of 395 ± 471 days [max 6.2 years]. Overall, 369 (88.1%) patients reported at least one ISR-AE, including 15 (3.6%) patients with serious ISR-AEs; 49 (11.7%) patients discontinued due to an ISR. Of 2461 ISRs-AEs, the most common were nodules (1065 events, 43.3%), haematoma (815 events, 33.1%), pain (141 events, 5.7%), and infection (134 events, 5.4%). Most ISR-AEs were mild (2079 events, 84.5%); 347 (14.1%) and 34 (1.4%) were moderate or severe, respectively. Most (88.1%) cases of infusion site infection were mild-moderate in severity, with a median time to resolution of 15 days. Infusion site infection led to discontinuation in only 12 (2.9%) patients.

Conclusion: While ISRs were commonly reported as AEs, 99% of ISR AEs were mild or moderate in severity and resolved with or without treatment. Despite the incidence of ISR events, most patients continued in the trials.

Disclosure: Funded by NeuroDerm, a Mitsubishi Tanabe Pharma Group Company. Werner Poewe is an investigator in the study and he/his institution received fees for participation, and is a consultant for NeuroDerm. Nelson Lopes is employed by NeuroDerm. Rajesh Pahwa is an investigator in the study and he/his institution received fees for participation, and is a consultant for NeuroDerm.

EPR-085 | Neural correlates of bradykinesia in Parkinson's disease: A kinematic and fMRI study

E. Sarasso[1]; A. Gardoni[2]; L. Zenere[2]; D. Emedoli[3]; A. Grassi[2]; S. Basaia[2]; R. Balestrino[4]; D. Corbetta[3]; F. Agosta[5]; M. Filippi[6]
[1]*Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute; and Vita-Salute San Raffaele University, Milan, Italy; Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics and Maternal Child Health, University;* [2]*Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [3]*Department of Rehabilitation and Functional Recovery, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [4]*Neurorehabilitation Unit, Neurosurgery and Gamma Knife Radiosurgery Unit, IRCCS Ospedale San Raffaele, and Vita-Salute San Raffaele University, Milan, Italy;* [5]*Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy;* [6]*Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy*

Background and Aims: Bradykinesia defines a "complex" of motor alterations including reduced movement amplitude and/or speed and tendency to reduce them with task repetition (sequence effect). We aimed at investigating the neural correlates of bradykinesia during a hand-tapping performance in people with Parkinson's disease (pwPD) relative to healthy controls.
Methods: Twenty-five pwPD and 25 age/sex-matched healthy controls were included. Subjects underwent brain functional magnetic resonance imaging (fMRI) including a hand-tapping task: alternatively opening and closing the right hand as fast and ample as possible. Hand-tapping speed and amplitude were measured during fMRI task using an optical fiber data glove.
Results: During the fMRI hand-tapping task, pwPD showed reduced hand-tapping amplitude (hypokinesia) and a greater sequence effect. PwPD relative to healthy controls showed reduced activity of frontoparietal areas, supplementary motor area, middle cingulum, parahippocampus, pallidum, thalamus, and motor cerebellar areas. PwPD showed an increased activity of cognitive areas: superior temporal gyrus, posterior cingulum, and cerebellum crus I. The decreased activity of cerebellum IV-V-VI, vermis IV-V, inferior frontal gyrus, and cingulum correlated with hypokinesia and with the sequence effect.
Conclusion: PwPD showed a worse hand-tapping performance relative to healthy controls. Interestingly, a reduced activity of areas involved in motor planning and timing correlated both with hypokinesia and with the presence of the sequence effect in pwPD. This study has the major strength of collecting objective motor parameters and brain activity simultaneously, providing a unique opportunity to investigate the neural correlates of the "bradykinesia complex".

Background and Aims: Subtle signs in isolated REM sleep behavioral disorder (iRBD) patients may predict conversion to parkinsonisms. We aimed at assessing motor, non-motor, and magnetic resonance imaging (MRI) characteristics in iRBD patients.
Methods: Thirty-eight polysomnography-confirmed iRBD patients and 28 age/sex-matched healthy controls (HC) underwent neurological, cognitive, and motor functional evaluations including Nine-Hole Peg Test (9HPT), 5-Time Sit-To-Stand (5TSTS), Timed Up and Go test (TUG) and 4-Meter Walking Test (4MWT) with and without cognitive dual-task (TUG-COG;4MWT-COG). Spatio-temporal gait parameters during 4MWT(-COG) and TUG(-COG) were collected using a stereophotogrammetric system. We obtained functional connectivity (FC) maps of the main resting-state networks, brain structural alterations using whole-brain voxel-based morphometry, deep grey matter volumes using FIRST, cortical thickness and brainstem volumes using Freesurfer. Analyses were corrected for age, sex and education.
Results: IRBD patients relative to HC showed worse performance during 9HPT and 5TSTS, higher asymmetry of arm-swing amplitude (4MWT) and higher stride length variability (4MWT-COG). Dual-task significantly worsened walking performance of iRBD more than HC. IRBD patients showed non-motor symptoms, worse memory, abstract reasoning and visuo-spatial abilities. IRBD patients showed decreased FC of pallidum and putamen within the basal ganglia network and of occipital and temporal areas within the visuo-associative

network, and reduced volume of the supramarginal gyrus. Structural/functional alterations correlated with clinical changes.

Conclusion: We found subtle motor and non-motor alterations together with structural/functional MRI changes that may represent initial manifestations of neurodegeneration in iRBD patients. Longitudinal data will help developing a conversion prediction model.

EPR-087 | Real-world clinical outcomes for Duchenne muscular dystrophy patients in Europe: results from a multi-national survey

V. Merla[1]; N. Posner[1]; J. Cappelleri[1]; A. Talaga[1]; S. Dukacz[1]; Z. Aslam[1]; E. Morton[2]; E. Chatterton[2]; H. Iqbal[2]; N. Hatchell[2]
[1]Pfizer Inc. New York, NY, USA; [2]Adelphi Real World, Bollington, UK

Background and Aims: Duchenne muscular dystrophy (DMD) is associated with progressive loss of muscle function, resulting in loss of ambulation and use of extremities. As data surrounding real-world outcomes for patients with DMD (pDMD) is limited, we aimed to outline clinical outcomes for these patients in Europe.

Methods: Neurologist-reported data were drawn from the Adelphi DMD Disease Specific Programme™, a cross-sectional survey with retrospective data collection in France, Germany, Italy, Spain, and the UK from October 2022–September 2023. Neurologists reported demographics and clinical characteristics of their pDMD. Analyses were descriptive.

Results: 90 neurologists provided data for 564 male pDMD. Mean (standard deviation; SD) age was 15.2 (7.9) years, mean (SD) time since symptom onset was 9.0 (7.5) years, 38% were non-ambulatory, and 21% had ≥1 diagnosed comorbidity. Difficulty climbing stairs (53%), and fatigue (41%) were the most frequently reported motor and non-motor symptoms, respectively. Mean (SD) North Star Ambulatory Assessment (NSAA) and Brooke upper extremity scale scores were 11.8 (9.6) and 2.8 (1.4), respectively. Difference in mean NSAA and Brooke upper extremity scores between ambulatory and non-ambulatory pDMD was 13.4 (16.6 vs. 3.2), and 1.9 (2.1 vs. 4.0), respectively. Mobility/support aids and respiratory aids were used by 73% and 32% pDMD, respectively.

Conclusion: Motor and non-motor symptoms were common, use of supportive aids/devices was high, and clinical testing scores suggested depletion of functional skills in pDMD. This indicates a high disease burden, which was greater for non-ambulatory pDMD. Additionally, this highlights a need for new therapies to address the high clinical burden of DMD.

EPR-088 | Impact of Duchenne muscular dystrophy on caregiver employment and quality of life: A real-world survey in Europe

V. Merla[1]; N. Posner[1]; J. Cappelleri[1]; A. Talaga[1]; S. Dukacz[1]; Z. Aslam[1]; E. Morton[2]; E. Chatterton[2]; H. Iqbal[2]; N. Hatchell[2]
[1]Pfizer Inc. New York, NY, USA; [2]Adelphi Real World, Bollington, UK

Background and Aims: Duchenne muscular dystrophy (DMD) has a degenerative nature whereby patients often rely on caregiver assistance. As little is known about the effect of caregiving for people with DMD (pDMD), this study aims to understand the impact on caregiver quality of life (QoL) and employment.

Methods: Data were drawn from the Adelphi DMD Disease Specific Programme™, a cross-sectional survey with retrospective data collection conducted in France, Germany, and Spain from October 2022–September 2023. Caregivers reported demographics, employment status and completed EQ-5D-5L (German tariff), EQ-5D Visual Analogue Scale (VAS) and the Work Productivity and Activity Impairment (WPAI) questionnaire. Analyses were descriptive.

Results: Overall, 99 caregivers had a mean (standard deviation; SD) age of 44.0 (9.9) years, 82% were women and 86% were parents of pDMD. pDMD had a mean (SD) age 12.9 (8.0) years; 68% were ambulatory. Overall, 42% of caregivers were employed (full/part-time) and provided care for a mean (SD) of 50.5 (33.4) hours per week. Caregivers (35%) changed their pattern of work due to caring. In the last seven days, caregiver overall work impairment was 46.6%, percentage impairment while working was 42.9%, work time missed was 5.6%, and activity impairment was 49.4%. Caregiver EQ-5D-5L and EQ-VAS scores were 0.88 (0.1) and 76.0 (15.9), respectively.

Conclusion: Over half of caregivers were not employed, and those who were employed experienced impairment while working. Caregivers also experienced an impact on ability to perform activities of daily living and QoL. This highlights a significant caregiver burden that needs addressing within the treatment and management of pDMD.

Disclosure: VM, NP, JCC, AT, SD, ZA are paid employees/stockholders of Pfizer. EM, EC, HI, and NH are paid employees of Adelphi Real World.

Background and Aims: We recently described increased D- and L-serine concentrations in the putamen of parkinsonian monkeys and the striatum and cerebrospinal fluid of Parkinson's disease (PD) patients compared to controls. However, data regarding peripheral D-serine levels in PD are scarce. Here, we assessed whether the serum levels of serine enantiomers and the other N-methyl-D-aspartate receptor (NMDAR)-related aminoacids (i) differ between PD patients and controls and (ii) correlate with clinical features and levodopa equivalent daily dose (LEDD) in PD.

Methods: We recruited 83 PD patients and 41 healthy controls (HC). PD cohort underwent an extensive motor, cognitive and quality of life characterization. The serum levels of D- and L-serine, L-glutamate, L-glutamine, L-aspartate, L-asparagine and glycine were determined using High Performance Liquid Chromatography.

Results: In age- and sex-adjusted analyses, no differences emerged in the serum levels of D-serine, L-serine or the other aminoacids between PD and HC. D-serine and D-/Total serine positively correlated with age in PD ($r=0.313$, $p=0.004$ and $r=0.311$, $p=0.004$) but not in HC. Moreover, we found that (i) D-serine and D-/Total serine increase with older age at PD onset ($r=0.379$, $p<0.001$ and $r=0.325$, $p=0.003$) (Fig. 1); (ii) LEDD negatively correlate with D-serine ($r=-0.248$, $p=0.027$) and the other excitatory aminoacids (Fig. 2). Finally, the addition of LEDD as covariate disclosed higher D-serine in PD compared to HC (Table).

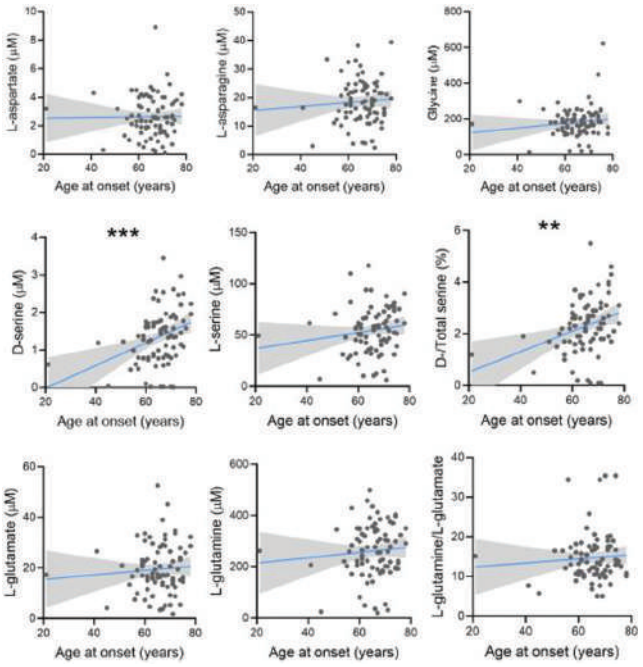

FIGURE 1. Scatterplots representing correlations between age at onset and serum neuroactive amino acid levels in PD group. $^{**}p<0.01$; $^{***}p<0.001$, Spearman's correlation. Blue lines and grey shadows represent the best fit line and its 95% CI.

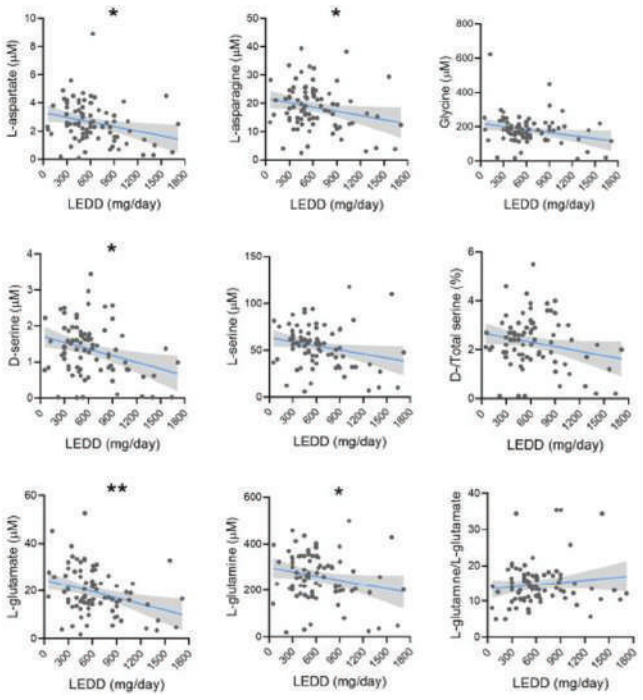

FIGURE 2. Correlations between LEDD and serum neuroactive amino acid levels in PD. $^{*}p<0.05$; $^{**}p<0.01$; age-, sex- and disease duration-adjusted partial correlations. Blue lines and grey shadows represent the best fit line and its 95% CI.

Table. Estimated serum levels of neuroactive amino acids in PD and HC extracted from ANCOVA models adjusted for the effect of age, sex and LEDD. Data are shown as estimated mean (standard error) of amino acids concentration. Significant p-values are shown in bold.

	HC (n = 41)	PD (n = 83)	p[a]
L-aspartate (μM)	2.7 (0.3)	2.9 (0.2)	0.724
L-asparagine (μM)	16.4 (1.6)	19.5 (1.0)	0.159
Glycine (μM)	155.2 (23.5)	194.8 (14.3)	0.206
D-serine (μM)	1.1 (0.1)	1.5 (0.1)	**0.038**
L-serine (μM)	48.9 (4.8)	57.2 (2.9)	0.192
D-/Total serine (%)	2.0 (0.2)	2.4 (0.1)	0.116
L-glutamate (μM)	20.3 (2.2)	21.0 (1.3)	0.792
L-glutamine (μM)	238.4 (22.0)	272.4 (13.5)	0.246
L-glutamine/L-glutamate	13.5 (1.3)	14.2 (0.8)	0.663

[a] PD compared to HC. Two-way ANCOVA with diagnosis and sex as factors; age and LEDD as covariates

Estimated serum levels of amino acids in PD and HC extracted from ANCOVA models adjusted for the effect of age, sex and LEDD. Data are shown as mean (standard error). a, Two-way ANCOVA with diagnosis and sex as factors, age as covariate.

Conclusion: Increased serum D-serine levels represent a putative biochemical signature of PD. The positive correlation between D-serine and age at PD onset supports the hypothesis that D-serine may play a neuroprotective role in PD.

Disclosure: This study was financially supported by Cariplo Foundation (Call 2017 – Scientific Research "Biomedical research on aging-related diseases", grant no. 2017-0575).

Background and Aims: The aims of this study were to develop a 3D Convolutional Neural Network (CNN) based on multimodal MRI to distinguish controls and PD patients and to employ CNN to predict the progression of PD.

Methods: Three cohorts were selected: (1) 86 mild, 62 moderate-to-severe PD patients and 60 controls; (2) 56 mild-PD subjects and 20 controls from PPMI database and (3) 91 mild-PD subjects and 38 controls. All participants underwent an MRI scan at baseline and a clinical evaluation at baseline and at 2-years follow-up. All the mild-PD subjects were classified stable or worsening using a k-means clustering based on baseline and follow-up UDPRS-III value. CNN were applied.

Results: CNN model demonstrated the capability to differentiate moderate-to-severe PD subjects from controls, achieving a good level of performance. Considering moderate-to-severe PD patients relative to controls, the accuracy rate on the test dataset reached nearly 75%, only relying on MRI data for classification. However, considering mild-PD versus controls, the accuracy rate was around 65% on the test set, highlighting challenges in the extraction of discriminative features during the initial stages of the disease. In the differentiation between stable and worsening PD, CNN reached over 70% accuracy rate on the test set by combining raw MRI and clinical data.

Conclusion: By integrating MRI data with clinical and demographic information, our CNN demonstrated promising results and offers a valuable tool for early diagnosis and personalized treatment planning for PD patients. Background and aims: Previous research has shown that inflammatory immune biomarkers including peripheral white blood cell subpopulations differ between Parkinson's disease (PD) patients and healthy controls (HC), with idiopathic PD patients exhibiting higher neutrophil to lymphocyte ratio (NLR). The aim of our present report was to assess the peripheral immune profile in patients harboring the p.A53T alpha-synuclein (SNCA) mutation.

Methods: Data regarding 30 p.A53T SNCA PD patients and 194 HCs were obtained from the database of the Parkinson's Progression Markers Initiative (PPMI). Focus was placed on peripheral immune blood cells subpopulations during the initial study assessment.

Results: NLR, Absolute Neutrophil cell count and Neutrophil to total Leukocytes ratio were increased in the p.A53T SNCA PD group as compared to HCs [2.74 vs. 2.18 ($p < 0.001$), 4.328 x 10^3 cells/μL vs. 3.674 x 10^3 cells/μL ($p = 0.001$), 65.47% vs. 59.55% ($p < 0.001$) respectively]. Absolute Lymphocyte cell count and Lymphocyte to total leukocytes ratio showed a trend towards being decreased in p.A53T PD. Monocyte to total Leukocytes ratio was lower in p.A53T PD ($p = 0.007$) and Neutrophil to Monocyte ratio (NMR) was increased as compared to HCs ($p < 0.001$). Differences in NLR were mainly driven by the male patient subgroup.

Conclusion: Our current study provides evidence of a specific pattern of peripheral immune response in the p.A53T SNCA PD group which aligns well with literature data in idiopathic and other genetic PD forms. Furthermore, given former evidence that alpha-synuclein represents an immune target in PD, we can speculate a putative underlying inflammatory pathway in this archetypal form of genetic synucleinopathy.

Disclosure: Christos Koros, Athina-Maria Simitsi, Nikolaos Papagiannakis, Roubina Antonelou, Ion Beratis and Leonidas Stefanis have received funding from Michael J. Fox Foundation for their participation in the Parkinson's Progression Markers Initiative study.

EPR-092 | Safety and efficacy of sublingual apomorphine in Parkinson's patients with or without concomitant dopamine agonists use

D. Santos Garcia[1]; W. Jost[2]; M. José Martí[3]; M. Fonseca[4]; C. Denecke Muhr[4]; I. Pijuan[4]

[1]Department of Neurology, Complejo Hospitalario Universitario de A Coruña, A Coruña, Spain; [2]Parkinson Klinik-Ortenau, Wolfach, Germany; [3]Parkinson's Disease & Movement Disorders Unit, Neurology Service, Hospital Clínic Universitari de Barcelona, IDIBAPS, CIBERNED, ERN-RND, Institut Clínic de Neurociències UBNeuro, Universitat de Barcelona, Barcelona, Spain; [4]Bial – Portela & Ca, S.A., Coronado, Portugal

Background and Aims: In Study CTH-301, apomorphine sublingual film (SL-APO) was generally well tolerated and efficacious over the long term as treatment for OFF-episodes in patients with Parkinson's disease. This post-hoc analysis assessed SL-APO in patients from Study CTH-301 with or without concurrent dopamine agonists (DA) use at baseline.

Methods: Study CTH-301 included a dose-optimisation (DO) and long-term safety (LTS) phase. Safety/tolerability assessments included incidence of treatment-emergent adverse events (TEAEs)/DA-related TEAEs, discontinuation rates due to adverse events (AEs), and time to discontinuation due to TEAEs. Efficacy assessments included optimized SL-APO dose, discontinuation rate due to lack of efficacy, changes in Movement Disorder Society-Unified Parkinson's Disease Rating Scale (MDS-UPDRS) Part III scores from pre- to post-dose and percentage of patients with a full-ON response within 30 minutes post-dose at weeks 24, 36 and 48.

Results: DA versus non-DA users demonstrated lower incidence of most common (>5%) TEAEs, including DA-related TEAEs, and lower discontinuation rates due to TEAEs in both the DO and LTS phases, and remained longer in the study (median 148.0 vs. 114.0 days; LTS phase) (Table 1). Non-DA users had a lower SL-APO mean dose (18.0 vs. 21.2 mg) and lower discontinuation rate due to lack of efficacy (4.8 vs. 7.2%). For both groups, a clinically meaningful reduction in MDS-UPDRS Part III was reached (Figure 1) and the percentage of patients reporting full-ON response was >75% at all visits (Figure 2).

TABLE 1. Safety/tolerability summary in DA users and non-DA users during the dose-optimisation and long-term safety phases*

Table 1. Safety/tolerability summary in DA users and non-DA users during the dose-optimisation and long-term safety phases*

EPR-093 | Exploring implication of dysfunctional cellular pathways in Parkinson's disease: Lysosomal-PD and mitochondrial-PD

G. Di Rauso[1]; F. Pirone[2]; G. Franco[2]; F. Arienti[2]; E. Frattini[2]; I. Trezzi[2]; F. Cavallieri[3]; F. Valzania[3]; E. Monfrini[2]; A. Di Fonzo[2]
[1]Clinical and Experimental Medicine PhD Program, University of Modena and Reggio Emilia, Modena, Italy; [2]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Neurology Unit, Milan, Italy; [3]Neurology Unit, Neuromotor & Rehabilitation Department, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy

Background and Aims: Lysosomal and mitochondrial dysfunction are possible pathogenetic mechanisms in Parkinson's disease (PD). The aim of this study is to examine phenotypic differences between mutated-PD patients according to the dysfunctional cellular pathway underlying the disease: the mitochondrial (mito-PD) or endolysosomal (lyso-PD) pathways.

Methods: PD patients carrying pathogenetic variant in different PD-associated genes (LRRK2, GBA1, PRKN, PINK1, DJ-1, RAB39B, POLG, TWNK, OPA1, mtDNA) were included in this retrospective observational study. We collected data about demographic characteristics, clinical features (presence of motor/non-motor symptoms, levodopa-induced dyskinesias (LID) and motor fluctuation (MF)) and Total Levodopa Equivalent Daily Dose (LEDD) at disease onset, 5- and 10-years follow-up. Patients were split in mito-PD (PRKN, PINK1, DJ-1, TWNK, POLG, OPA1, mtDNA) or lyso-PD (GBA1, LRRK2, RAB39B) groups depending on the cellular pathway most affected by the mutated gene.

Results: 135 PD patients were included: 99 lyso-PD (male: 65, age at onset: 55 years), and 36 mito-PD (male: 19, age at onset: 41 years). Mito-PD had higher prevalence of dystonia, while lyso-PD of bradykinesia and rigidity. Non-motor symptoms other than psychiatric and sleep disorders (namely dysautonomia, hyposmia, cognitive impairment, hallucinations, urinary symptoms, sialorrhea) had higher prevalence in lyso-PD, as well as MF and LID. LEDD was lower in

mito-PD (5y: 358 mg; 10y: 480 mg) than lyso-PD (5y: 500 mg; 10y: 645 mg) at 5-($p=0.05$) and 10- years ($p=0.06$) follow-up.

Conclusion: This study showed that lyso-PD patients had more frequently non-motor symptoms, MF and LID, whereas mito-PD patients had a prolonged response to low doses of levodopa.

Disclosure: The authors have no conflicts of interest to declare that are relevant to the content of this abstract.

EPR-094 | Opicapone effect on sleep disorders in fluctuating Parkinson's disease patients: Findings from the OASIS trial

J. Ferreira[1]; M. Gago[2]; R. Costa[3]; M. Fonseca[3]; J. Almeida[3]; J. Rocha[3]; J. Holenz[3]; C. Trenkwalder[4]

[1]CNS -Campus Neurológico, Torres Vedras, Portugal and IMM – Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina, Universidade Lisboa, Lisbon, Portugal; [2]Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal; [3]BIAL – Portela & Ca S.A., Coronado, Portugal; [4]Paracelsus-Elena Klinik, Kassel, Germany

Background and Aims: Motor fluctuations (MF) and associated sleep disorders are common in Parkinson's disease (PD) patients receiving levodopa/dopa decarboxylase inhibitors, negatively affecting their quality of life. Opicapone (OPC) proved to be effective in reducing end-of-dose MF in patients with PD. The OASIS study evaluated OPC's effects on sleep disorders in PD patients with MF.

Methods: In the exploratory, open-label, single-arm pilot OASIS trial, all patients ($N=16$) received OPC 50 mg once-daily as add-on to levodopa therapy for 6 weeks. Primary endpoint was change from baseline in PD Sleep Scale-2 (PDSS-2). Secondary endpoints included tolerability, functional motor and non-motor assessments (Movement Disorder Society [MDS]-Unified Parkinson's Disease Rating Scale [UPDRS], MDS-Non-motor Scale [NMS], 8-item PD Questionnaire [PDQ-8], 16-item PD Fatigue Scale [PFS-16], ON/OFF home diary), and Clinical and Patient Global Impression of Change (CGI-C; PGI-C).

Results: At week 6, there was a significant reduction of −7.9 points (95% CI −13.6, −2.2; $p=0.0099$) in total PDSS-2 score. Significant reductions were also observed in PFS-16 (−9.6 [95% CI −17.5, −1.7; $p=0.0211$]), MDS-NMS total score (-28.9 [95% CI −44.7, −13.2; $p=0.0052$]), MDS-UPDRS-III and IV (-6.3 [95% CI −11.6, −0.9; $p=0.0253$] and −1.2 [95% CI −2.0, −0.4; $p=0.0044$], respectively) and PDQ-8 (-14.2 [95% CI −23.3, −5.0; $p=0.0051$]). Absolute OFF-time was reduced (-142.1 mins), while ON-time without dyskinesia was increased (+127.1 mins). Most patients (93.3%) and most clinicians (80.0%) reported an improvement as evaluated by the PGI-C and CGI-C, respectively. OPC 50 mg was well tolerated.

Conclusion: Adding OPC to levodopa therapy improved sleep disturbances and other non-motor symptoms, supporting OPC's potential to treat MF in patients with PD-related sleep disorders.

Disclosure: Supported by Bial.

Background and Aims: Opicapone (OPC) demonstrated efficacy in reducing OFF-time in levodopa/dopa decarboxylase inhibitor (DDCi)-treated patients with Parkinson's disease (PD) and end-of-dose motor fluctuations (MF) and is generally well-tolerated. The EPSILON study explored OPC's potential to enhance the clinical benefit of levodopa/DDCi in PD patients without motor complications.

Methods: In this double-blind, multicentre, randomized, placebo-controlled study, 355 PD patients without MF treated with levodopa/DDCi and other anti-PD medications were randomized (1:1) to OPC 50 mg once-daily or placebo. A 4-week screening period was followed by a 24-week maintenance phase. Primary efficacy endpoint was change from baseline to week 24 in Movement Disorder Society-Unified PD Rating Scale (MDS-UPDRS)-III. Secondary endpoints included tolerability, Clinical and Patient Global Impression of Improvement/Change (CGI-I/PGI-C) and MDS-UPDRS-IV.

Results: At week 24, mean (standard error[SE]) change from baseline in MDS-UPDRS-III score for the OPC group was −6.5(0.7) versus −4.3(0.7) for the placebo group, with a significant −2.2(0.9) difference favouring OPC ($p=0.010$). Compared with placebo-treated patients, significantly more OPC-treated patients reported improvements on PGI-C (58% vs. 46%), with a similar trend observed for CGI-I (50% vs. 46%; p = not significant). Motor complications (MDS-UPDRS-IV items 1–6 score ≥1) were reported in fewer patients in the OPC than the placebo group (5.5% vs. 9.7%), with mean scores of 0.3 and 0.4 points, respectively. Frequency and types of adverse events were similar between the two groups; no dyskinesia was reported in either group.

Conclusion: Adjunct OPC significantly improved motor impairment in levodopa-treated PD patients without motor complications, with no dyskinesia reported as adverse event.

Background and Aims: Opicapone (OPC) has proven efficacy for treating end-of-dose motor fluctuations in levodopa/dopa decarboxylase inhibitor (DDCi)-treated patients with Parkinson's disease (PD). The Korean and European ADOPTION studies explored the efficacy of OPC 50 mg versus an additional 100 mg levodopa dose to treat early wearing-off in patients with PD.

Methods: Patient-level data from matching treatment arms in the two ADOPTION studies were combined. Trials had similar designs, eligibility criteria and methods. Both were prospective, multicentre, randomized, active-controlled, 4-week studies that recruited patients on stable regimen of immediate-release levodopa/DDCi (3–4 daily intakes, maximum 600 mg of levodopa, for ≥4 weeks pre-screening). Patients with an average daily OFF-time >5 hours while awake were excluded. Primary endpoint was change from baseline in absolute OFF-time. Secondary endpoints included tolerability, Movement Disorder Society-Unified PD Rating Scale (MDS-UPDRS), 8-item PD Questionnaire (PDQ-8), Clinical Global Impression of Improvement (CGI-I) and Patient Global Impression of Change (PGI-C).

Results: At week 4, mean (standard error[SE]) change from baseline in absolute OFF-time was −68.1 min(7.8) for OPC 50 mg and −33.6 min (9.7) for levodopa 100 mg, resulting in a significant difference of −34.6 min ($p=0.0056$). Numerically greater differences in favour of OPC were observed for MDS-UPDRS-III and IV, and PDQ-8. OPC-treated patients tended to show greater improvements on CGI-I and PGI-C. OPC was generally well-tolerated.

Conclusion: OPC 50 mg was superior to an increased daily levodopa dose in reducing wearing-off, suggesting that adding OPC may also be considered as first-line therapeutic option in PD patients with early/less severe motor fluctuations.

EPR-097 | sGFAP – A possible hint for cerebellar neurodegeneration in essential tremor?

L. Gattermeyer-Kell[1]; M. Khalil[1]; P. Opriessnig[1]; D. Kern[1]; S. Franthal[1]; M. Kögl[1]; P. Katschnig-Winter[1]; R. Schmidt[1]; C. Enzinger[1]; P. Schwingenschuh[1]

[1]Department of Neurology, Medical University of Graz, Graz, Austria

Background and Aims: Essential tremor (ET) is considered a heterogeneous syndrome and a possible neurodegenerative process has been debated. Diffusion tensor imaging (DTI) studies consistently revealed microstructural alterations in cerebellar regions like the cerebellar peduncles. In a pilot study, we found higher serum glial fibrillary acidic protein (sGFAP) in elderly, late-onset compared to younger, early-onset ET-patients. Higher sGFAP-levels have previously been found in other neurological disorders, inlcuding Parkinson's disease. We therefore aimed to investigate associations of sGFAP with cerebellar microstructural tissue damage in ET-patients.

Methods: 34 ET-patients underwent blood sampling and 3-Tesla cerebral MRI including DTI-sequences at the same visit. sGFAP was quantified by single-molecule-array. FA- and MD-values of inferior (ICP), middle (MCP) and superior (SCP) cerebellar peduncles were obtained from DTI-sequences.

Results: Higher sGFAP-levels correlated with lower FA-values in right (rs=-0.465, $p=0.006$) and left (rs=-0.563, $p<0.001$) ICP, right SCP (rs=-0.397, $p=0.020$) and right (rs=-0.375, $p=0.029$) and left (rs=-0.421, $p=0.013$) MCP. Increased sGFAP-levels correlated with increased MD in right (rs=0.468, $p=0.005$) and left (rs=0.376, $p=0.028$) ICP and right SCP (rs=0.347, $p=0.044$). Patients with sGFAP-levels above median (124.2 pg/mL) demonstrated significantly lower FA in bilateral ICP and MCP and right SCP and higher MD in right ICP compared to patients with sGFAP-levels below median.

Conclusion: Higher sGFAP-levels were associated with cerebellar microstructural white matter damage in ET. Together with our finding of elevated sGFAP-levels in elderly, late-onset ET-patients, these results support the hypothesis of a neurodegenerative process contributing to ET-pathophysiology at least in a subgroup of patients. Larger, prospective studies including MRI control groups are warranted.

Disclosure: Nothing to disclose.

EPR-098 | Impact of serum neurofilament-light on clinical decision making in a tertiary multiple sclerosis clinic

M. Wessels[1]; Z. van Lierop[1]; W. Lektranty[1]; B. Moraal[2]; B. de Jong[1]; B. van Oosten[1]; Z. van Kempen[1]; E. Strijbis[1]; B. Uitdehaag[1]; J. Killestein[1]; C. Teunissen[3]

[1]*Department of Neurology, Amsterdam UMC, Vrije Universiteit Amsterdam, MS Center Amsterdam, Amsterdam Neuroscience, The Netherlands;* [2]*Department of Radiology and Nuclear Medicine, Amsterdam UMC, Vrije Universiteit Amsterdam, MS Center Amsterdam, Amsterdam Neuroscience, The Netherlands;* [3]*Neurochemistry Laboratory, Department of Clinical Chemistry, Amsterdam UMC, Vrije Universiteit Amsterdam, Amsterdam Neuroscience, The Netherlands*

Background and Aims: Serum neurofilament light (sNfL) is an established biomarker for neuro-axonal damage in multiple sclerosis (MS). Clinical implementation remains relatively limited. We investigated the impact of sNfL implementation on clinical decision making in a tertiary MS clinic for different contexts.

Methods: sNfL measurements were added to routine practice between August 2021 and December 2022 for context 'differential diagnosis'(17%), 'new symptoms in MS'(18%), 'disease-modifying treatment (DMT) monitoring'(55%), and 'DMT baseline'(11%). Physicians filled in questionnaires on clinical decision making, expectations of MRI-activity, certainty regarding decision making, and how this changed after disclosure of the sNfL results. Characteristics associated with changes in scores and the perceived value of sNfL were investigated.

Results: 166 Questionnaires were completed (157 unique MS-patients, age 41±12 years, 68% female). Adding sNfL to the diagnostic tools influenced clinical decisions in 19.3% of cases. Clinicians' certainty significantly increased after disclosure of the sNfL result ($p = 0.004$), lower sNfL levels were associated with higher levels of certainty ($p = 0.044$). Expectation of activity on follow-up brain-MRI significantly decreased after the sNfL disclosure ($p = 0.008$), in accordance with significantly lower sNfL levels in those cases. Urgency and perceived value of the sNfL result was highest in the context of 'new symptoms' ($p = 0.017$), the motivation to measure sNfL was highest in the context of 'differential diagnosis' ($p < 0.001$).

TABLE 1.

Baseline[1] characteristics	Total (n=166)[2]	DMT efficacy (n=82, 49%)	New MS symptoms (n=29, 18%)	Differential diagnosis (n=28, 17%)		Screening DMT (n=27, 16%)

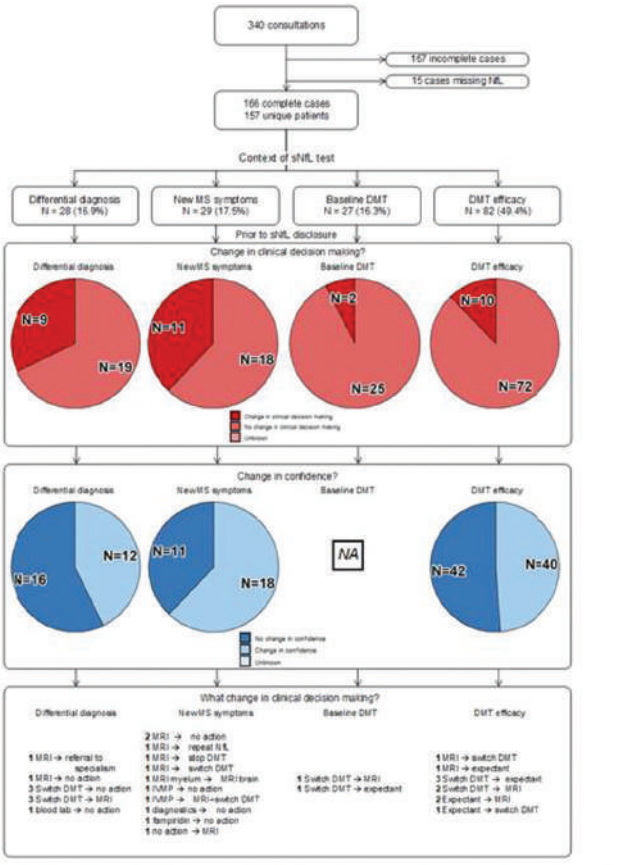
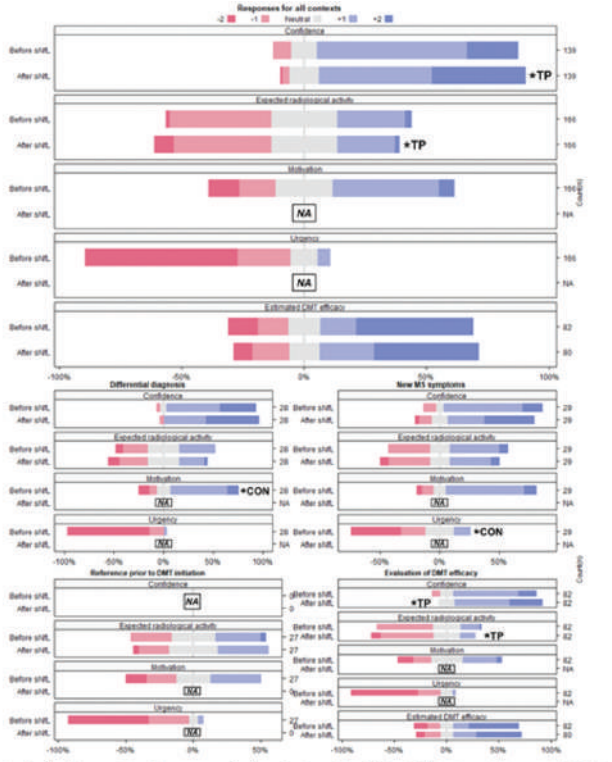
>95th percentile	23 (14)	9 (11)	4 (14)	5 (25)	3 (38)	2 (7)

Baseline characteristics for the 166 included cases.
1 The date of the blood draw for sNfL measurement was defined as baseline time point.
2 This included 157 unique patients, for sNfL were measured in 3 separate consultations by 1 patient, and 2 separate consultations in 7 patients.
3 Calculated using the NIL interface for physicians.17 For patients with CIS or MS, we calculated age corrected percentiles based on a reference cohort of patients with MS. For some age groups of patients with MS (below 20 and above 62 years), age corrected percentiles are technically unknown because of insufficient data. In this study, we therefore extrapolated age corrected percentiles based on the available data for MS patients7. For patients without MS, we calculated age corrected percentiles based on a reference cohort of controls (i.e. without a neurological diagnosis).



Flowchart with piecharts depicting inclusions, divisions into contexts of use, change in confidence and changes in clinical decision making after sNfL disclosure. sNfL = serum neurofilament light chain, DMT = disease modifying treatment, MS = multiple sclerosis, NA = not applicable.

FIGURE 1.



Likert-scale showing questionnaire response for all contexts combined (A) and different context separately (B-D). The median scores of questionnaire items were compared before and after sNfL disclosure, significant differences ($p<0.05$) are indicated with *TP. The median scores were furthermore compared between contexts, significant differences ($p<0.05$) are indicated with *CON. Three Likert-scale items (level of confidence, estimated DMT efficacy and expected radiological activity) were repeated in part 2 of the questionnaire. Median scores for these three items were compared between part 1 (prior to sNfL disclosure) and part 2 (after sNfL disclosure) of the questionnaire, and significant differences (p-value <0.05) are indicated in bold and by two asterisks (**). sNfL = serum neurofilament light, DMT = disease modifying treatment, MS = multiple sclerosis.

FIGURE 2.

Conclusion: sNfL implementation may have considerable impact on clinical decision making and certainty herein, depending on different contexts. Standard and regular implementation of sNfL in clinical practice and daily analysis may complement patient management; particularly in patients with new symptoms or suspicion of disease activity.

Background and Aims: Wearing-off symptoms (WoS) are reported by more than 50% of people with multiple sclerosis (MS) during treatment with natalizumab. Biomarkers of neuro-axonal damage (serum neurofilament light (sNfL) and glial fibrillary acidic protein (sGFAP)) could provide insight in the etiology of wearing-off symptoms with natalizumab. We investigated the association between these biomarkers and the occurrence of WoS in natalizumab treated MS patients, and the predictive value of these biomarkers on the occurrence of WoS during further treatment.

Methods: We performed longitudinal measurements of sNfL and sGFAP, using Simoa, in 364 participants (79.1% female, median age 40 years, median Expanded Disability Status Scale (EDSS) 3.0)

treated with natalizumab who participated in the NEXT-MS trial and completed a questionnaire about WoS. Association of sNfL and sGFAP levels with experiencing WoS were assessed, both cross-sectional at timepoints and longitudinal during follow-up. In addition, the predictive value of baseline sNfL and sGFAP for first time WoS occurence was investigated.

Results: 55.5% of patients treated with natalizumab experienced WoS. EDSS scores at baseline were higher in patients with WoS. Repeated analysis showed that sNfL and sGFAP levels were not associated with WoS at any timepoint. No association was found between changes in biomarker levels and first time WoS occurrence, neither were baseline sNfL and sGFAP levels predictive of first time WoS occurrence.

Conclusion: sNfL and sGFAP levels were not associated with natalizumab WoS, underpinning that acute and chronic neuro-axonal damage are most likely not the underlying cause of experiencing WoS.

TABLE 1. Baseline characteristics of included participants.

Ever experienced WoS	No (N=162)	Yes (N=202)	Total (N=364)	P-value
Sex, n (%)				
Male	33 (20.4%)	43 (21.3%)	76 (20.9%)	.93

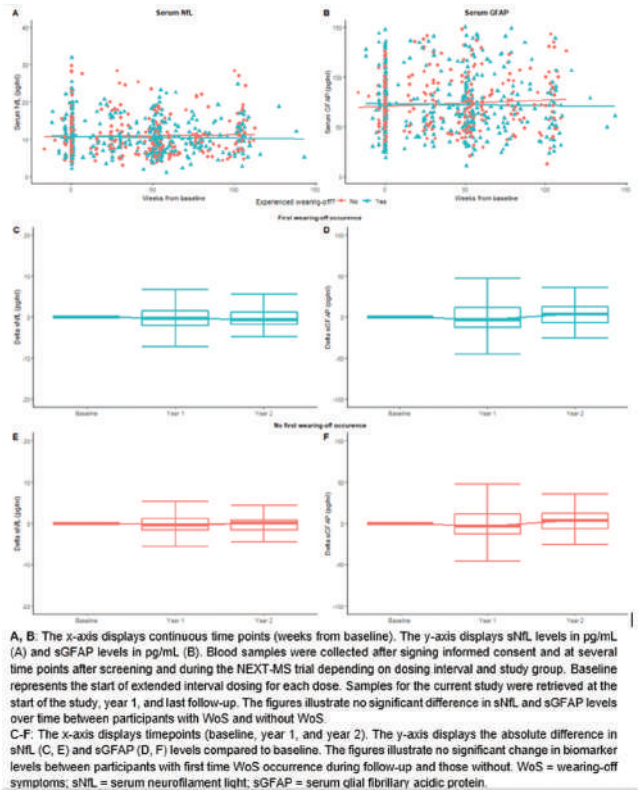
Duration NTZ treatment, years (IQR)	4.22 (1.31 - 8.71)	3.98 (1.67 - 7.50)	4.05 (1.50 - 8.20)	.85
NfL at baseline, pg/mL (IQR)	9.51 (7.17 - 13.02)	10.22 (7.40 - 13.16)	9.81 (7.22 - 13.1)	.5
GFAP at baseline, pg/mL (IQR)	66.86 (50.95 - 90.83)	70.75 (53.41 - 94.36)	68.03 (51.70 - 92.71)	.71
First time WoS occurrence during follow-up[b], n (%)	0 (0%)	33 (16.4%)	33 (9.09%)	<0.001

Values are depicted as medians with interquartile ranges or frequencies with percentages. Clinical characteristics were compared between groups using the Chi-Square test for categorical variables, the t-test for normally distributed continuous variables, and the Mann-Whitney U test for non-normally distributed continuous variables. WoS = Wearing-off symptoms; BMI = Body Mass Index; JCV = John-Cunningham Virus; sNfL = serum neurofilament light; sGFAP = serum glial fibrillary acidic protein; EDSS = Expanded Disability Status Scale; NTZ = natalizumab; SID = standard interval dosing (treatment every 4 weeks); EID10 = extended interval dosing with an aim drug trough concentration of 10 µg/mL; EID5 = extended interval dosing with an aim drug trough concentration of 5 µg/mL.[8]

[a]Baseline MRI scan of the NEXT-MS trial

[b]Participants that did not experience WoS at baseline, but reported WoS during follow-up.



A, B. The x-axis displays continuous time points (weeks from baseline). The y-axis displays sNfL levels in pg/mL (A) and sGFAP levels in pg/mL (B). Blood samples were collected after signing informed consent and at several time points after screening and during the NEXT-MS trial depending on dosing interval and study group. Baseline represents the start of extended interval dosing for each dose. Samples for the current study were retrieved at the start of the study, year 1, and last follow-up. The figures illustrate no significant difference in sNfL and sGFAP levels over time between participants with WoS and without WoS.

C-F. The x-axis displays timepoints (baseline, year 1, and year 2). The y-axis displays the absolute difference in sNfL (C, E) and sGFAP (D, F) levels compared to baseline. The figures illustrate no significant change in biomarker levels between participants with first time WoS occurrence during follow-up and those without. WoS = wearing-off symptoms; sNfL = serum neurofilament light; sGFAP = serum glial fibrillary acidic protein.

FIGURE 1. sNfL and sGFAP levels over time.

[1]*Department of NEUROFARBA, University of Florence, Florence, Italy;* [2]*IRCCS Don Carlo Gnocchi Foundation, Florence, Italy*

Background and Aims: Abnormalities of gait are present in 50%–80% of people with multiple sclerosis (pwMS), particularly in more disabled patients and during dual task (DT) conditions. The aim of this study, performed on a cohort of very early stage and non-disabled pwMS, was to evaluate cross-sectionally the relationship between gait and cognitive performance and longitudinally between the cognitive-motor interference (CMI) and disease progression.

Methods: 70 pwMS (age 36.5 ±11 years; female $n=49$, 70%) with disease duration <3 years and EDSS </=1.5 performed a 1-minute overground walking trial in a hallway in single and DT conditions at comfortable speed; spatio-temporal gait parameters were evaluated with two optoeletronic bars. Patients underwent also a neuropsychological assessment with Rao's battery. 38 pwMS completed the same evaluation after 1 year (T1). We performed Spearman correlation analysis of gait and cognitive parameters at baseline (T0) and a Mann–Whitney *U*-test to compare them in worsened (either MRI activity, EDSS >1, relapse) and non-worsened patients after 1-year follow-up.

Results: At T0 we found a relationship between symbol digit modalities test (SDMT) and the main spatio-temporal parameters of gait (step length, velocity) in single ($r=0.369$, $p=0.007$; $r=0.342$, $p=0.012$) and dual task conditions ($r=0.392$, $p=0.004$; $r=0.284$, $p=0.039$). 11/38 pwMS worsened at T1; greater DT costs of cadence (9.97 vs. 6.03; $p=0.017$) and velocity (0.176 vs. 0.088; $p=0.013$) were significantly related to disease worsening.

Conclusion: Even in very early and non-disabled pwMS gait performance is related to cognitive function. Dual task performance could reveal pwMS at greater risk of disease progression.

EPR-101 | Evaluation of brain atrophy in multiple sclerosis patients. Comparison between manual and volumetric measures

M. Pasca[1]; L. Marchi[2]; A. Mariottini[2]; A. Farina[2]; L. Massacesi[2]
[1]*Department of Neurology, "F. Ferrari" Hospital, Casarano, Lecce, Italy;* [2]*Department of Neurosciences, Drug and Child Health, University of Florence, Florence, Italy*

Background and Aims: manual measures such as corpus callosum index (CCI), normalized central corpus callosum area (CCAc), normalized mean corpus callosum area (CCAm), corpus callosum index (CCI) are potential biomarkers for brain atrophy. We investigate their suitability to assess the neurodegenerative component of multiple sclerosis (MS) by comparing them to volumetric measure (nBV) and expanded disability status scale (EDSS).

Methods: Fifty-three patients were included in this observational retrospective study. For each patient clinical and radiological data (nBV, CCAm, CCAc, CCI) were collected at two-time points, baseline (T0) and last follow-up (TX). All the MRi scans were performed with the same acquisition protocol.

Results: Inter-rater reliability between 2 examiners was excellent (0.98 inter-class correlation coefficient with absolute agreement (95% confidence interval, p-value <0.001)) for all the manual measures analyzed; Manual and volumetric measures showed statistically significant correlation between them, and with clinical measure (EDSS) at cross-sectional analysis. Manual measures showed better correlation with clinical measure (EDSS) compared with volumetric measure (ρs=-0,288 for NBV, ρs=-0,473 for CCAm, ρs=-0,490 for CCAc, ρs=-0,425 for CCI). At longitudinal analysis manual and volumetric (anBV) measures showed statistically significant correlation between them; aNBV was superior to manual measures in reducing the required sample size required to detect pre-specified treatment effects.

N = 53	T0	TX
EDSS (range)	1,5 (0,0 – 6,5)	2,0 (0,0 – 7,5)
Age (median years, range)	33,3 (22 – 64)	38,77 (24 – 69)
Gender (female %)	36 (67,9)	
Normalized Brain Volume (nBV), *median, range*	1577575 (1336697 – 1820497)	1537315 (1285398 – 1712687)
Annualized Normalized Brain Volume loss (aNBV loss) *Mean (2SD)* *Median (range)* *Coefficient of Variation (CV)*	 -0,27 (0,36) -0,24 (-0,65, -0,01) 0,67	
mean Corpus Callosus Area (mCCA), *median %, range*	2,71 (1,59 – 4,05)	2,55 (1,34 – 4,00)
Annualized mean Corpus Callosum Area loss (aCCAm loss) *Mean (2SD)* *Median (range)* *Coefficient of Variation (CV)*	 -1,27 (2,34) -0,89 (-5,19, -0,03) 0,92	
central Corpus Callosus Area, (eCCA), *median %, range*	2,89 (1,60 – 4,25)	2,63 (1,24 -3,93)
Annualized central Corpus Callosum Area loss (aCCAc loss) *Mean (2SD)* *Median (range)* *Coefficient of Variation (CV)*	 -1,36 (2,42) -1,01 (-7,6, -0,02) 0,89	
Corpus Callosus Index (CCI); *median, interval range*	0,29 (0,16 – 0,41)	0,268 (0,136 – 0,41)
Annualized Corpus Callosus Index (aCCI loss) *Mean (2SD)* *Median (range)* *Coefficient of Variation (CV)*	 -1,23 (2,28) -0,99 (-5,21, -0,03) 0,93

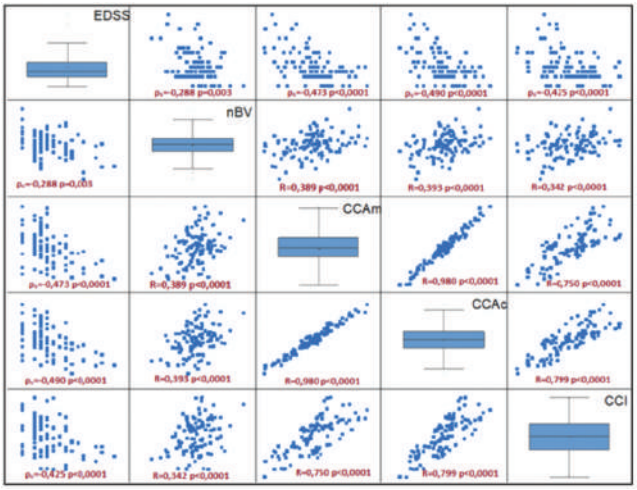
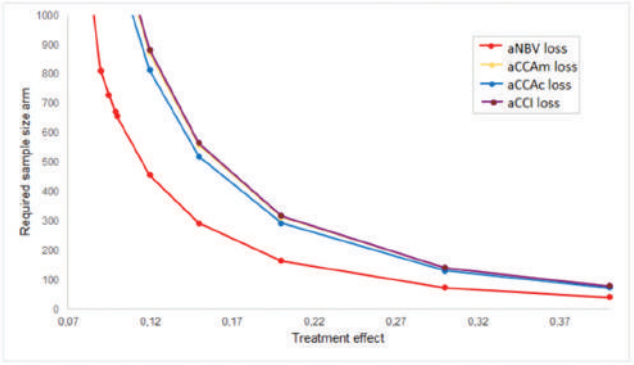
Abbreviations: Normalized Brain Volume (nBV); Annualized Normalized Brain Volume loss (aNBV loss); mean Corpus Callosus Area (mCCA); Annualized mean Corpus Callosum Area loss (aCCAm loss); central Corpus Callosus Area (eCCA); Annualized central Corpus Callosum Area loss (aCCAc loss); Corpus Callosus Index (CCI); Annualized central Corpus Callosum Area loss (aCCAc loss)

Demographic, clinical and MRi data at baseline (T0) and at follow-up (TX).



Correlation matrix of clinical, MRi manual and volumetric measures cross-sectional data. I MRi measures showed statistically significant correlation with EDSS, with manual measures showing better correlation compared with volumetric measure.



The required sample size per arm for each measure, for varying treatment effects with fixed power of 80% and 0.05 significance level. aNBV was superior to manual measures in reducing the required sample size required.

Conclusion: This study provides a direct comparison between manual and volumetric measurements, with the former being easy to use and showing better correlation with EDSS. Volumetric measure (nBV) have less variability in the sample size analysis, and are mostly recommended for clinical trials.

Disclosure: Nothing to disclose.

EPR-102 | Safety and efficacy of frexalimab in relapsing multiple sclerosis: 48-week results from the phase 2 open-label extension

P. Vermersch[1]; C. Granziera[2]; Y. Mao-Draayer[3]; G. Cutter[4]; O. Kalbus[5]; I. Staikov[6]; M. Dufek[7]; S. Saubadu[8]; R. Bejuit[8]; B. Djukic[9]; P. Truffinet[8]; E. Wallstroem[9]; G. Giovannoni[10]

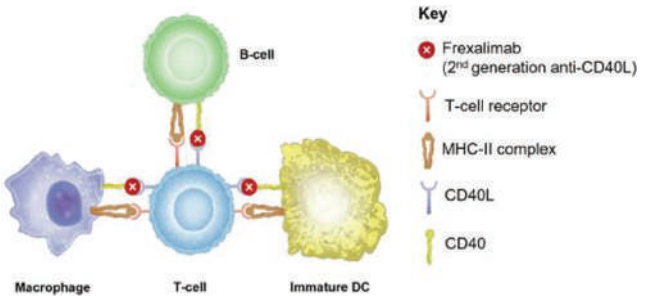
Background and Aims: Frexalimab, a second-generation anti-CD40L monoclonal antibody, blocks the costimulatory CD40/CD40L pathway, which is important for activation and function of adaptive and innate immunity. In the 12-week (W) double-blind-period (DBP) of a Phase 2 trial (NCT04879628), frexalimab demonstrated safety and efficacy with high-dose treatment showing an 89% reduction in new gadolinium-enhancing (Gd+) T1-lesions in participants with relapsing multiple sclerosis (RMS). Efficacy and safety were further

sustained over W24 in the open-label extension (OLE). Here, we report W48 results.



Inhibition of the CD40/CD40L interaction with frexalimab.

Methods: In the DBP, participants were randomized to frexalimab-high ($N=52$), frexalimab-low ($N=51$), or matching placebo (placebo-high, $N=12$; placebo-low, $N=14$). At W12, participants receiving placebos switched to respective frexalimab arms. Key assessments during the OLE included safety and efficacy (number of Gd+ T1-lesions and new/enlarging T2-lesions).

Results: 125/129 (97%) participants completed the DBP and entered the OLE; 112 (87%) remained in the study at W48. At W48, the number of Gd+ T1-lesions (mean±SD) remained low in participants who continued receiving frexalimab and in those who switched from placebo to frexalimab at W12 (frexalimab-high: 0.0±0.2; frexalimab-low: 0.2±0.5; placebo-high/frexalimab-high: 0.2±0.6; placebo-low/frexalimab-low: 0.1±0.3). Furthermore, 96% of participants in frexalimab-high, 87% in frexalimab-low, 90% in placebo-high/frexalimab-high, and 92% in placebo-low/frexalimab-low were free of Gd+ T1-lesions at W48. New/enlarging T2-lesions and T2-lesion volume change remained low with frexalimab-high through W48. Lymphocyte counts were stable over W48. Overall, frexalimab was well-tolerated through W48.

Conclusion: Frexalimab continued to show favorable safety and efficacy in RMS participants through W48. These data support its further development as a potential high-efficacy, non-lymphocyte-depleting treatment option in MS.

Background and Aims: Assessing the environmental impact on adult multiple sclerosis (MS) is complex due to long disease latency and risk for recall bias, and especially for perinatal exposures. We aimed to investigate the association between parental smoking habit and the development of pediatric-onset MS (POMS).

Methods: As a part of the Italian multicenter case-control PEDIGREE Study, the PEQ-IT questionnaire for prospective data collection was used. Subjects aged less than 18 years with POMS (2013 Krupp's diagnostic criteria) and with disease duration of up to 5 years from onset, and matched controls were enrolled.

Results: The study included 116 participants with POMS and 116 controls. Among them, 76.7% of cases and 54.3% of controls were females with a mean (SD) age of 16.6 (2.9) and 13.4 (5.0) years, respectively. The mean (SD) age at MS onset was 13.9 (3.0) years, median EDSS score was 1.0 (range 0–4.0), and the mean (SD) disease

duration was 33.3 (28.3) months. The crude odds ratio (OR) for risk of POMS among subjects with fathers being current smokers was 2.05 (95%IC 1.17–5.58) and 2.70 (95%IC 1.15–6.35) having been smokers pre-pregnancy. The OR was 5.10 (95%IC 1.07–24.23) when both parents smoked before pregnancy. No significant association was found with maternal smoking or children's smoking habits.

Table 1. Distribution of the main clinical and demographic characteristics of the study sample by status.

	Controls N=116	MS cases N=116	*p*

[a] investigated in subjects aged 10 to 17 years
[b] logistic regression: Odds Ratio (OR) adjusted for age at study time
[c] logistic regression: Odds Ratio (OR) adjusted for participant's smoking habit
[d] Fisher test

Association between active and passive cigarette smoking habit within families of MS cases and controls.

Conclusion: Our findings point to parental, and particularly paternal, smoking exposure, as a potential risk factor for POMS. The disparity in the impact of maternal versus paternal smoking could be attributed to a quantitative factor, social pressures and awareness influencing maternal smoking behaviors during and after pregnancy.

Background and Aims: Evaluating environmental influence on adult multiple sclerosis (MS) presents complexities, particularly with exposures during the perinatal period. This study aims to investigate how time spent outdoors, considered as a proxy for sun exposure, may contribute to the development of pediatric-onset MS (POMS).

Methods: As a part of the Italian multicenter case-control PEDIGREE Study, the PEQ-IT questionnaire for prospective data collection was used. Subjects aged less than 18 years with POMS and with disease duration of up to 5 years from onset, and matched controls were enrolled.

Results: The study included 117 participants with POMS and 123 controls. Among them, 76.9% of cases and 55.1% of controls were females with a mean (SD) age of 16.6 (2.9) and 13.4 (4.9) years, respectively. The mean (SD) age at MS onset was 13.9 (3.0) years, median EDSS score was 1.0 (range 0–4.0), and the mean (SD) disease duration was 29.3 (23.5) months. In our analysis, reduced (less than 60 minutes per week) time spent outdoors during spring in the first five years of life was associated with a significant risk of developing POMS (OR 2.26 (95%CI:1.25–4.07) (between 0 and 1 years: OR = 1.93(95%CI: 1.09–3.39); between 1 and 2 year: OR = 2.22 (95%CI:1.005–4.84); between 3 and 5 years: OR 4.82 (95%CI: 1.02–22.85). Less time spent outdoors resulted to be associated with a 2–3 times increased risk of POMS even when considering other seasons in the first 5 years of life ($p < 0.05$).

Conclusion: Spending more time in the sun in the first 5 years of life is associated with a reduced risk of developing POMS.

Disclosure: Pilotto S. has received compensations for research activities from FISM – Fondazione Italiana Sclerosi Multipla. Other authors have nothing to disclose in relation to this work. EPR-105 | Functional connectivity modifications in monoaminergic circuits underpin fatigue development in MS patients

M. Rocca[1]; M. Margoni[2]; P. Valsasina[3]; A. Bacchetti[3]; D. Mistri[3]; N. Tedone[3]; M. Filippi[4]

[1]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy; [2]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; [3]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: In multiple sclerosis (MS), monoaminergic network dysregulation may contribute to fatigue pathogenesis. Here, we investigated changes over time in monoaminergic-related resting state (RS) functional connectivity (FC) and its association with fatigue development in MS.

Methods: Eighty-nine right-handed MS patients and 49 healthy controls underwent neurological, fatigue and 3.0T RS functional MRI assessment at baseline and after 1.3-year median follow-up (interquartile range = 1.01–2.01 years). Fatigue was evaluated using the modified fatigue impact scale (MFIS) score. Patients were considered as fatigued if MFIS was >38. Independent component analysis constrained to PET atlases for dopamine, noradrenaline and serotonin transporters estimated monoaminergic-related RS FC.

Results: At baseline, 24 (27%) MS patients were fatigued (F) and 65 were non-fatigued (NF). Of these, 22 (34%) developed fatigue (devFAT) at follow-up and 43 remained NF (noFAT). At baseline, F-MS patients showed increased monoaminergic-related RS FC in hippocampal, postcentral and temporo-occipital cortices, as well as decreased insular RS FC. During the follow-up, devFAT MS patients showed increased dopamine-related hippocampal RS FC, significant at time-by-group interaction analysis. NoFAT patients showed decreased noradrenaline-related RS FC over time in superior frontal regions, while both devFAT and F-MS patients showed increased RS FC in the same regions; this divergent behavior was significant at time-by-group interaction analysis. DevFAT MS patients presented increased serotonin-related RS FC over time in the angular and middle occipital gyri; this latter region showed decreased serotonin-related RS FC at follow-up versus baseline in F-MS.

Conclusion: Specific monoaminergic networks changes over time characterized MS patients according to fatigue status.

Disclosure: MA Rocca received consulting fees from Biogen, Bristol Myers Squibb, Eli Lilly, Janssen, Roche; speaker honoraria from AstraZaneca, Biogen, Bristol Myers Squibb, Bromatech, Celgene, Genzyme, Horizon Therapeutics Italy, Merck Serono SpA, Novartis, Roche, Sanofi and Teva; research support from MS Society of Canada, Italian Ministry of Health, Italian Ministry of University and Research, and FISM. EPR-106 | Evaluation of sleep disorders in neuromyelitis optica spectrum disorder

E. Özlem Tiryaki; S. Türe; Y. Beckmann

Neurology Department, İzmir Katip Çelebi University, İzmir, Turkey

Background and Aims: We aimed to investigate the structure of sleep, sleep disorders, and the relationship between abnormalities and brain lesions in neuromyelitis optica spectrum disorder(NMOSD).

Methods: 26 patients with NMOSD and 20 healthy individuals were enrolled. Questionnaires were used to evaluate sleep quality, daytime sleepiness, restless legs syndrome(RSL). Night polysomnography (PSG) and multiple sleep latency tests(MSLT) were performed.

Results: Diencephalic lesions were present in 23.1% of patients, and infratentorial lesions were observed in 84.6%. NREM1 percentage, general AHI, REM-AHI, and NREM-AHI averages were higher in NMOSD patients. The obstructive sleep apnea syndrome(OSAS) and were more common in NMOSD patients ($p = 0.001$; $p < 0.001$). Mild obstructive apnea (OA) was detected in general AHI, and moderate OA was found in REM-AHI ($p = 0.002$; $p = 0.001$). Hypersomnia was detected in 30.8% of patients, narcolepsy in 11.5% and neither was observed in the control group. Sleep latency was shorter, and SOREM was higher in the NMOSD group ($p = 0.001$; $p = 0.001$). High REM-AHI was associated with short sleep latency and hypersomnia ($p = 0.010$; $p = 0.012$). No relationship was found between sleep changes and the presence of diencephalic lesion/infratentorial lesion. Epworth Sleepiness Scale, Beck Depression Scale, and

Pittsburgh Sleep Quality Index were higher in the patient group. There was a relationship between PSQI general score and EDSS ($p=0.023$). RLS were observed more frequently in the NMOSD group ($p=0.031$; $p<0.001$).

Conclusion: REM-related OA and hypersomnia are common in NMOSD patients. Therefore, NMOSD patients need objective evaluations such as PSG and MSLT. Our study is the first study conducted with MSLT in addition to PSG and shows the importance of quantitative examinations in NMOSD patients.

MS and related disorders 2

EPR-107 | Landscapes of gut microbiome and blood metabolomic signatures in relapsing-remitting multiple sclerosis

J. Feng[1]; S. Tang[2]; X. Yang[1]; M. Zhang[1]; Z. Li[1]; S. Zhang[1]; Y. Han[3]; Y. Li[3]; P. Monnier[4]; G. Yu[1]; P. Zheng[1]; K. Xu[1]; X. Qin[1]

[1]Department of Neurology, The First Affiliated Hospital of Chongqing Medical University, Chongqing 400016, China; [2]Department of Neurology, The People's Hospital of Tongliang District, Chongqing 402560, China; [3]Department of Radiology, The First Affiliated Hospital of Chongqing Medical University, Chongqing 400016, China; [4]Krembil Research Institute, University Health Network, Toronto, ON M5S 1A8, Canada

Background and Aims: Gut microbiome disturbances have been implicated in multiple sclerosis (MS), little is known about the changes and interactions between gut microbiome and blood metabolome, and how these changes affect the disease-modifying therapy (DMT) drugs in preventing the progression of MS.

Methods: The structure and composition of the gut microbiota were evaluated using 16S rRNA gene sequencing while an untargeted metabolomics approach was also used to compare the serum metabolite profiles from patients with relapsing-remitting MS ($n=154$) and healthy controls (HC; $n=81$).

Results: MS is characterized by increased α-phylogenetic diversity and significantly disturbed serum glycerophospholipid metabolism. Compared to MS patients in the acute phase (AMS), α-phylogenetic diversity in MS patients in the chronic phase (CMS) was significantly decreased. Serum glycerophospholipid metabolism also differed significantly between AMS and CMS. Moreover, a combination of two increased genera (Slackia, Lactobacillus) and five glycerophospholipid metabolism-associated metabolites (four increased: GPCho(22:5/20:3), PC(18:2(9Z,12Z)/16:0), PE(16:0/18:2(9Z,12Z)), PE(18:1(11Z)/18:2(9Z,12Z)); one decreased: PS(15:0/22:1(13Z))) in MS patients would enable distinguishing MS from HC; and a biomarker panel consists of four microbial genera (three decreased: Lysinibacillus, Parabacteroides, UBA1819; one increased: Lachnoanaerobaculum) and two glycerophospholipid metabolism-associated metabolites (one increased: PE(P-16:0/22:6); one decreased: CL(i-12:0/i-16:0/i-17:0/i-12:0)) in CMS patients would discriminate CMS from AMS in both the training and testing sets. Furthermore, DMT drugs inhibit the development of AMS via downregulating UBA1819 and upregulating CL(i-12:0/i-16:0/i-17:0/i-12:0).

Conclusion: We provide a deep insight into understanding the roles of microbiome and metabolome in MS and explore potential biomarkers, therefore further development of promising therapeutic targets for MS based on gut microbiota and metabolites.

Disclosure: All of the authors report no disclosures relevant to this research.

EPR-108 | Autologous hematopoietic stem cell transplantation in aggressive multiple sclerosis – a 25-year monocentric experience

A. Mariottini[1]; C. Nozzoli[2]; A. Repice[3]; C. Innocenti[2]; R. Boncompagni[2]; A. Barilaro[3]; I. Cutini[2]; A. Gozzini[2]; R. Saccardi[2]; L. Massacesi[1]

[1]Department of Neurosciences, Drug and Child Health, University of Florence, Florence, Italy; [2]Cell Therapy and Transfusion Medicine Unit, Careggi University Hospital, Florence, Italy; [3]Department of Neurology 2, Careggi University Hospital, Florence, Italy

Background and Aims: Autologous haematopoietic stem-cell transplantation (AHSCT) is a treatment option in aggressive relapsing-remitting (RR-) multiple sclerosis (MS) refractory to conventional disease-modifying treatments (DMTs). Here we report long-term outcomes from our 25-year experience.

Methods: Monocentric retrospective study including relapsing (R-) MS patients (primary-progressive MS excluded) treated with AHSCT in Florence between 1998 and 2023 with the same AHSCT protocol (mobilization: cyclophosphamide 4 g/sqm and G-CSF; conditioning: BEAM/ATG). Variables are reported as median (range) or number (frequency). Efficacy outcomes include survival free from relapses (RFS), disability worsening (PFS) and clinical-radiological disease activity (NEDA-3). The primary safety endpoint was 100-days transplant-related mortality (TRM).

Results: Ninety-three R-MS patients were included (Table 1). Follow-up duration was 57 months (1 – 262). PFS at 3, 5 and 10 years was 71%, 69% and 62%, respectively, being higher in RR-MS than in secondary-progressive (SP-)MS (at year 5: 88% vs. 48%; $p<0.0001$; Fig. 1a-b). RFS was 98% and 90% at year 3–5 and 10, respectively. NEDA-3 survival at 3, 5 and 10 years was 70%, 68%, and 52%, respectively, being higher in RR-MS than in SP-MS (at year 5: 86% vs. 48%; $p<0.0001$; Fig. 1c-d). NEDA-3 failure was mostly caused by disability worsening, with sparse events of new focal inflammatory activity, being 6 events observed over 575 patient-years of follow-up. TRM was 0%.

TABLE 1. Baseline clinical-demographic characteristics of the R-MS patients included.

	MS overall (n=93)		RR-MS (n = 50)		SP-MS (n = 43)	
	median	(range)	median	(range)	median	(range)
Age, y	36	(20 – 57)	36	(20 – 53)	40	(27 – 57)
Disease duration (onset), y	11	(1 – 33)	9.5	(1 – 29)	13	(6 – 33)
Number of previous DMTs	3	(0 – 7)	3	(0 – 7)	3	(1 – 6)
ARR in the prior 2 y	1	(0 – 4.5)	1.25	(0 – 4.5)	0.5	(0 – 2)
EDSS	5.0	(1.0 – 7.5)	3.0	(1.0 – 7.0)	6.0	(3.5 – 7.5)
			n	(%)	n	(%)
Gender, female	70	(75%)	37	(74%)	33	(77%)

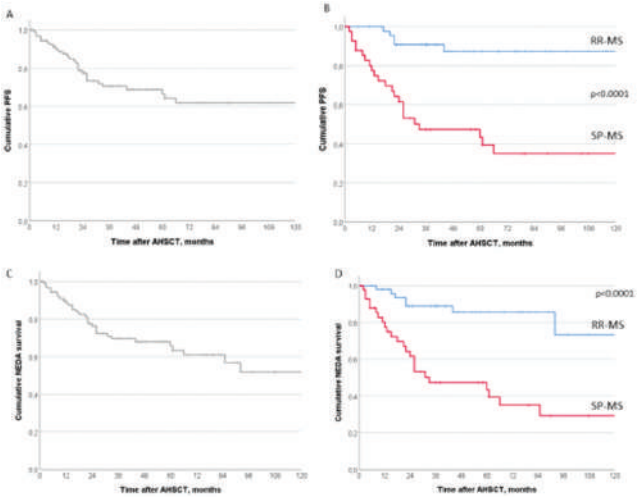

FIGURE 1. Cumulative proportion of patients free from EDSS worsening (PFS; A, B) and evidence of clinical-radiological disease activity (NEDA-3; C, D) over follow-up. RR-MS patients showed lower rates of treatment failure compared to SP-MS both for PFS an.

Conclusion: AHSCT is an effective treatment for patients with aggressive R-MS, with an acceptable safety profile, likely more effective than high-efficacy (HE-)DMTs over long-term. Definite evidence on this issue is awaited from ongoing randomized trials with HE-DMTs.

Disclosure: Nothing to disclose.

EPR-109 | Spinal cord gray matter atrophy predicts disability progression in multiple sclerosis

M. Azzimonti[1]; P. Preziosa[1]; E. Pagani[2]; A. Meani[2]; M. Rubin[1]; M. Gueye[1]; M. Filippi[3]; M. Rocca[1]

[1]*Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy;* [2]*Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [3]*Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy*

Background and Aims: Cervical spinal cord (cSC) gray matter (GM) damage is associated with more severe disability in multiple sclerosis (MS), but its relevance in predicting disability worsening is unclear. Here, we investigated whether cSC GM damage predicts disability progression in MS patients.

Methods: Eighty MS patients and 33 healthy controls (HC) underwent brain and cSC MRI scans at baseline, and neurological evaluations at baseline and after a median follow-up of 1.35 years. Global and GM cSC lesions were identified on axial T2-weighted sequences. Whole and GM cSC cross-sectional area (CSA) were manually quantified at C3–C4 level on phase-sensitive inversion recovery images. Brain T2-hyperintense lesion volume, normalized brain, thalamic and cortical volumes were also obtained. At follow-up, disability worsening was defined as progression on >=1/3 components of the Expanded Disability Status Scale (EDSS)-plus (EDSS worsening or >=20% threshold change for timed 25-foot walk or 9-hole peg test).

Results: Compared with HC, MS patients showed significantly higher brain and cSC lesions ($p < 0.001$), and lower normalized brain, thalamic and cortical volumes, and whole and GM cSC CSA ($p <= 0.03$). At follow-up, 34/80 (43.6%) MS patients showed EDSS-plus worsening. At univariate analysis, baseline predictors of disability worsening were cSC GM CSA ($\beta = -0.71$, $p = 0.02$) and NBV ($\beta = -0.01$, $p = 0.04$); at multivariate analysis, only cSC GM CSA was retained in the model ($\beta = -0.70$, $p = 0.02$, Nagelkerke-R^2=0.358).

Conclusion: cSC GM atrophy emerged as the only independent predictor of disability progression in MS, highlighting its clinical relevance in identifying patients at higher risk of disease worsening at short term.

Disclosure: M Azzimonti received travel grants from Novartis. P Preziosa received speaker honoraria from Roche, Biogen, Novartis, Merck Serono, Bristol Myers Squibb, Genzyme, Horizon and Sanofi, and research support from Italian Ministry of Health and Fondazione Italiana Sclerosi Multipla (FISM). EPR-110 | Ocrelizumab and ofatumumab comparison: an Italian real-world propensity score matched study

E. D'Amico[1]; G. Borriello[2]; S. Bonavita[3]; E. Signoriello[4]; R. Fantozzi[5]; S. Barone[6]; G. Abbadessa[3]; M. Cellerino[7]; V. Ziccone[8]; G. Miele[3]; G. Lus[4]; P. Valentino[6]; S. BUCELLO[8]; M. Inglese[7]; D. Centonze[5]; C. Avolio[1]; A. Zanghì[1]

[1]University of Foggia, Italy; [2]University of ROME; [3]University of Campania, Luigi VanVitelli; [4]FEDERICO II NAPLES; [5]NEUROMED POZZILLI; [6]CATANZARO MAGNA GRECIA; [7]University of Genoa; [8]Augusta Hospital

Background and Aims: The management of Multiple Sclerosis (MS) has undergone transformative evolution with the introduction of high-efficacy disease-modifying therapies (DMTs), specifically anti-CD20 monoclonal antibodies such as ocrelizumab (OCR) and ofatumumab (OFA).

Methods: This is an independent retrospective cohort study in Relapsing MS (RMS) patients followed at eight Italian MS centres who initiated treatment with OCR or OFA in the participating centres and with at least 12 months on therapy. A generalized linear regression model inverse probability of treatment weight (IPTW) PS-adjusted was performed to evaluate the relationship between annualized relapse rate (ARR) and treatment groups. No evidence of disease activity-NEDA3 at 12-months score was also collected. Safety profile of the investigated DMTs was recorded.

Results: A total cohort of 396 RMS patients fulfilled the required criteria and were enrolled in the study. Out of them, 216 had a prescription of OCR and 180 of OFA. The mean follow-up was 13.2±1.9 months. The estimated means for ARR did not show differences between the two groups, 0.059 for patients on OCR and 0.038 for patients on OFA ($p=0.185$). The generalized regression model IPTW PS-adjusted did not reveal differences between patients on OCR and OFA (ExpBOFA 0.974, 95%CI 0.934–1.015, $p=0.207$). NEDA-3 at 12-months was experienced by 199(92.1%) patients on OCR and 170(94.4%) patients on OFA ($p=0.368$). Generally, both therapies exhibit good tolerability.

Conclusion: The treatment with OCR and OFA resulted in comparable control of disease activity with good safety profile. Our results need further validation in larger multicentre studies with long-term follow-up.

Disclosure: Nothing to disclose.

EPR-111 | Secondary progression in a 30 years cohort from Italian MS registry

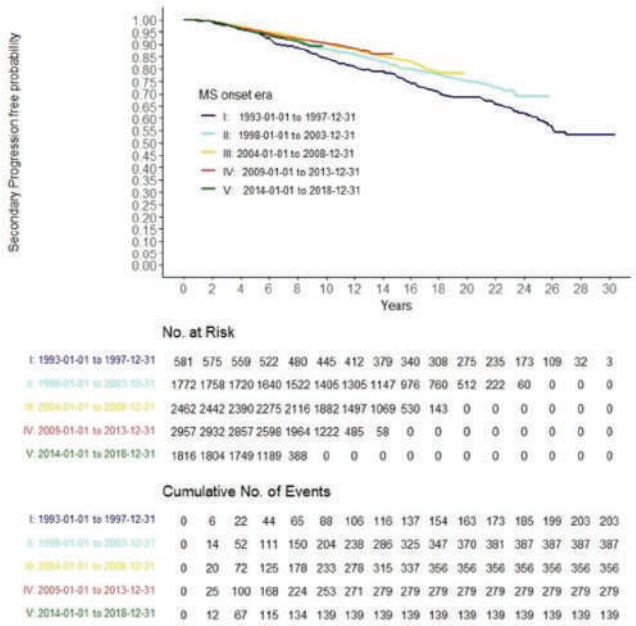
E. D'Amico[1]; C. Avolio[1]; A. Zanghì[1]; I.[2]

[1]University of Foggia; [2]ITALIAN MS REGISTRY

Background and Aims: Contemporary research in MS field emphasizes strategies to prevent or delay secondary progression advocating for early and aggressive interventions. Precision medicine, tailored to individual characteristics such as genetic profiles and biomarkers, holds promise in optimizing treatment outcomes.

Methods: This cohort study using prospectively acquired data from the Italian MS register (IMSR) extracted in November 2023. At the time of data extraction, longitudinal data of 73.564 patients from 120 MS centers were available in the IMSR. Secondary progressive Multiple Sclerosis (SPMS) was defined according to Lorscheider criteria. Conversion to SP was analysed along a 30 years epoch from 1993 to 2023. Five therapeutic era are considered: from 1993 to 1998, 1999 to 2004, 2005 to 2009, 2009 to 2014, and 2015 to 2018. Normalized SP incidence at 5 and 10 years will be analyzed.

Results: A total cohort of 1364 patients, with at least 2 years of follow-up, converted to SPMS (see Figure 1). Generally, patients converting to SPMS during the first eras were younger and with lowest therapeutic coverage all over the investigated follow-up (respectively, first epoch 60.7 (3.7–78.5) vs. last epoch 71.5 (47.4–86.3) (median, Q1–Q3).



MS onset among therapeutic era and SP conversion.

Conclusion: During a 30-year era, the SP conversion rate changed significantly and also the therapeutic overall coverage.

Disclosure: Nothing to disclose.

EPR-112 | Disability progression is a question of definition – a methodological reappraisal in the AMSTR

G. Bsteh[1]; N. Krajnc[2]; S. Marti[3]; R. Hoepner[3]; M. Guger[4]; F. Di Pauli[5]; J. Kraus[6]; C. Enzinger[7]; T. Berger[1]

[1]*Department of Neurology, Medical University of Vienna, Vienna, Austria;* [2]*Comprehensive Center for Clinical Neurosciences and Mental Health, Medical University of Vienna, Vienna, Austria;* [3]*Department of Neurology, Inselspital, Bern University Hospital and University of Bern, Switzerland;* [4]*Department of Neurology, Pyhrn-Eisenwurzen Hospital Steyr, Austria;* [5]*Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria;* [6]*Neurologist, Zell am See, Austria;* [7]*Department of Neurology, Medical University of Graz, Graz, Austria*

Background and Aims: It is unclear whether different definitions of disability progression influence frequency of disability progression overall as well as regarding relapse associated disability worsening (RAW) and progression occurring independent of relapses (PIRA).

Methods: Using data from the Austrian MS treatment registry, we compared event frequency and time to event for 672 definitions of disability progression using a) different cut-offs for minimal EDSS increase, b) different definitions for required confirmation of EDSS increase (unconfirmed, confirmed after 12/24/48 weeks, sustained) and c) use of fixed versus roving baseline score models. Then, we classified each event as either RAW or PIRA using the two described definitions of minimal interval to last relapse (>30 or >90 days).

Results: We analyzed data from 6646 RMS patients (mean age at baseline 35.2 years [SD 10.2], 73.2% female, median baseline EDSS 2.5 [IQR 2.5 – 6.0], median follow-up duration 2.7 years [IQR 2.6 – 8.9]). Rates of disability progression ranged from 71.7% with the most sensitive definition to 6.7% with the least sensitive definition. Classification as RAW or PIRA varied from a distribution percentage of 87:13 to 31:69 depending on the definition of progression used. The >90 days threshold decreased PIRA events by a mean 54.3% (vs. >30 days, $p < 0.001$) over all progression definitions. Comparing roving versus fixed baseline, progression rates increased by a mean 111.8% with the mean proportion of PIRA increasing from 36.1% to 54.3%.

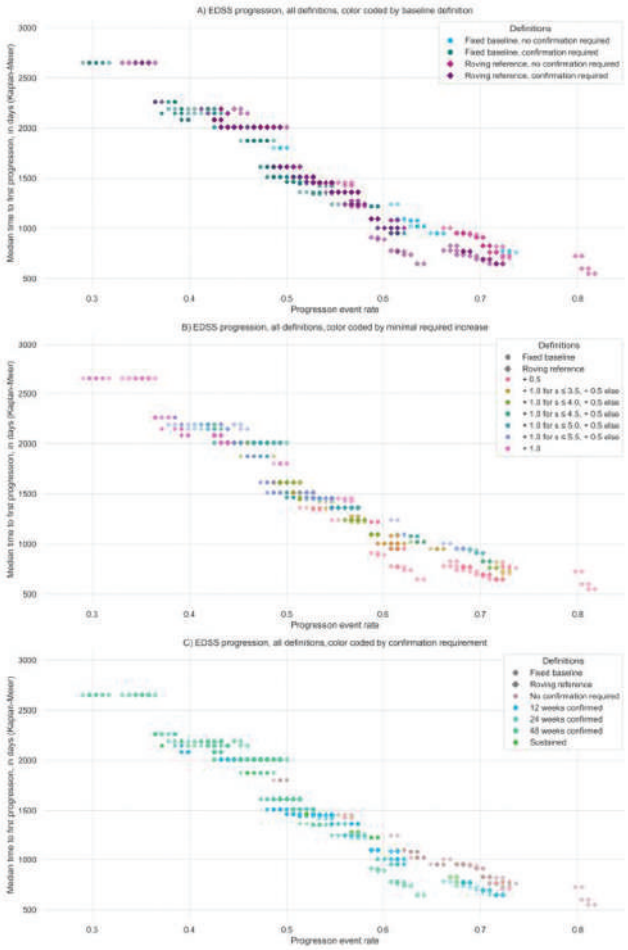


FIGURE 1. Impact of definition options on progression event rate versus time to progression.

Conclusion: The definition of disability progression strongly impacts rates of progression as well as observed proportions of RAW/PIRA.

[1]Department of Neurology, Medical University of Vienna, Austria; [2]Medical University of Vienna, Comprehensive Center for Clinical Neurosciences & Mental Health, Vienna, Austria; [3]Department of Neurology, Medical University of Innsbruck, Austria; [4]Department of Statistics, Faculty of Economics and Statistics, University of Innsbruck, Innsbruck, Austria; [5]Department of Neuroradiology, Medical University of Vienna, Austria; [6]Department of Neurology 2, Med Campus III, Kepler University Hospital GmbH, Linz, Austria; [7]Department of Neurology, Medical University of St. Pölten, St. Pölten, Austria; [8]Department of Neurology, Inselspital, Bern University Hospital and University of Bern, Bern, Switzerland; [9]Department of Neuroradiology, Medical University of Innsbruck, Austria

Background and Aims: Isolated value of MRI metrics in relapsing multiple sclerosis (RMS) as surrogate marker of response to disease-modifying treatment (DMT) is still a matter of debate.

Methods: We included RMS patients aged ≥18 years who i) had started moderately-effective DMT, ii) were clinically stable (no relapses/progression) on DMT for 12 months, iii) had MRI at DMT-start and after 12 months, and iv) had clinical follow-up for ≥2 years after the second MRI. The primary endpoint was occurrence of relapse during follow-up. Cox regression was employed including the number of new T2 lesions (T2L) as well as DMT strategy (continuing moderate DMT vs. escalating DMT) as independent covariates adjusting for age and sex.

Results: A total of 131 RMS patients (median age 36 [IQR 29–43] years, 73% females) were included and observed over a median 6 (5–9) years after second MRI. Sixty-two (47%) had relapse. Patients who continued moderate DMT had a three-fold increased risk of relapse given 2 new T2L and a four-fold increased risk given ≥3 new T2L. Escalation of DMT lowered the risk of relapse in patients with 2 new T2L by approximately 80% and with ≥3 new T2L by 65%. In case of only 1 new T2L, the increased risk of relapse as well as the treatment effect did not reach statistical significance of 5%.

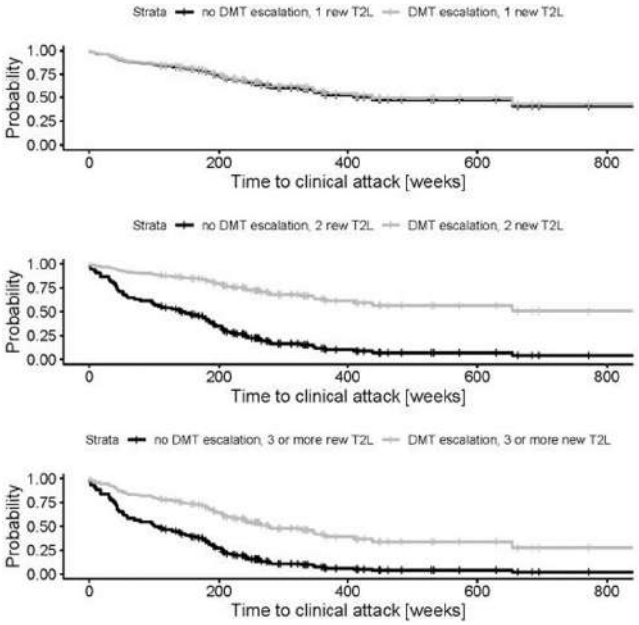

FIGURE 1. Probabilities for freedom of relapse depending on new T2 MRI lesions and DMT escalation.

Conclusion: In our real-world cohort of patients clinically stable under moderately effective DMT, escalation of DMT based on isolated MRI activity decreased risk of further relapse when ≥2 new T2L had occurred.

Disclosure: Gabriel Bsteh: has participated in meetings sponsored by, received speaker honoraria or travel funding from Biogen, Celgene/BMS, Janssen, Lilly, Merck, Novartis, Roche, Sanofi-Genzyme and Teva, and received honoraria for consulting Biogen, Celgene/BMS, Janssen, Merck, Novartis, Roche, Sanofi-Genzyme and Teva. He has received unrestricted research grants from Celgene/BMS and Novartis.

EPR-114 | Headache disorders in multiple sclerosis: Is there an association? A systematic review and meta-analysis

P. Gklinos[1]; D. Mitsikostas[1]

[1]1st Neurology Department, Eginition Hospital, National and Kapodistrian University of Athens, Athens, Greece

Background and Aims: The prevalence of headache disorders has been found to be increased in people with MS (pwMS), however, an association has not been established. Existing studies have provided conflicting results mostly because of methodological differences.

Methods: PubMed, Embase and Scopus were searched to identify eligible studies. Studies were included if they were cross-sectional, case-control or cohort. Newcastle-Ottawa Scale (NOS) was used to assess the risk of bias of the included studies. Meta-analysis was conducted using StatsDirect by calculating the overall prevalence of headache disorders in pwMS as well as the Odds Ratio (OR) of headache disorders in pwMS versus controls.

Results: Twenty-three studies were included yielding a total of 5,440 MS patients and 28,0958 controls. The majority of them scored a NOS score between 5 and 6 (max 9), which indicates that they did not rank high in terms of quality, because most studies were cross-sectional and uncontrolled, and only one was prospective, controlled, and longitudinal, but with small population size. Pooled prevalence for all headache disorders, migraine and tension-type headache (TTH) in pwMS was 58%, 30% and 19% respectively. A significant association between migraine and MS was found (OR = 2.02, 95% CI = 1.14–3.57).

Figure 6. (A) Odds ratio forest plot for migraine in pwMS vs controls. **(B)** Funnel plot for odds ratio meta-analysis for migraine.

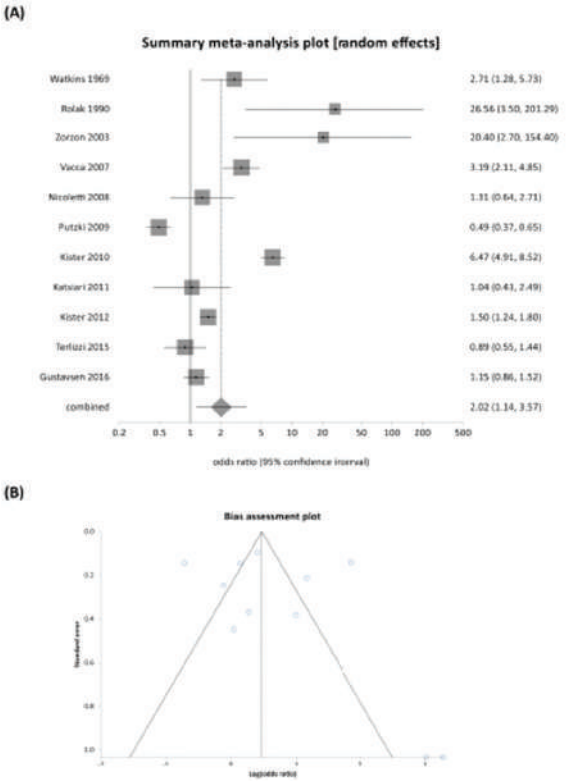

FIGURE 1. Odds ratio meta-analysis for migraine in multiple sclerosis versus controls.

Figure 3. (A) Forrest plot for overall migraine prevalence in pwMS **(B)** Funnel plot for migraine prevalence in pwMS

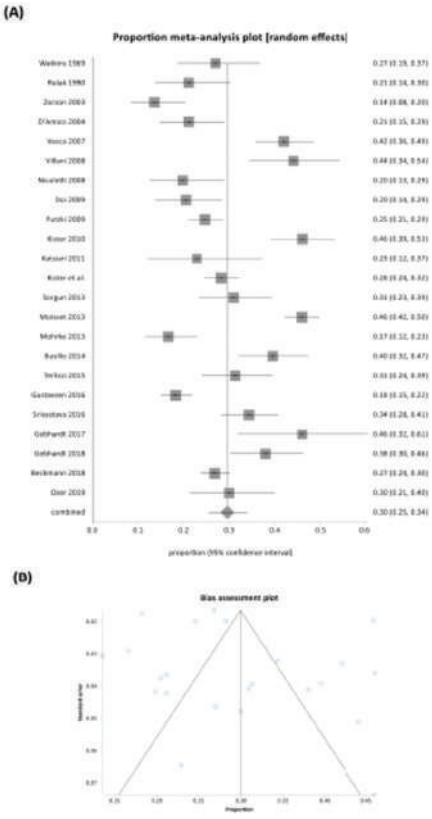

FIGURE 2. Prevalence meta-analysis for migraine in people with multiple sclerosis.

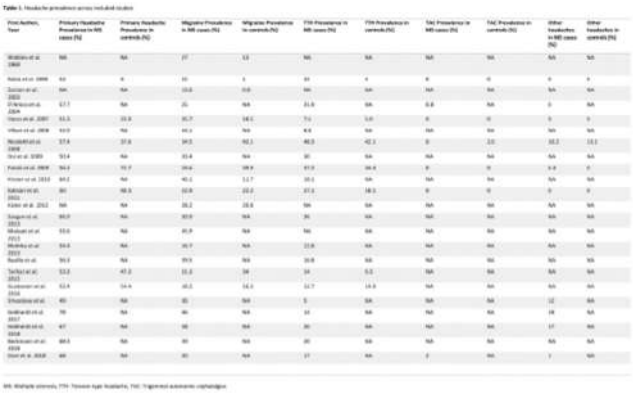
TABLE 1. Headache prevalence across included studies.



Conclusion: PwMS are twice as likely to experience migraine as controls, but the results need to be translated with caution since most of the studies included in the meta-analysis were of low or moderate quality. Larger prospective cohort, controlled, longitudinal studies are needed to confirm whether there is indeed an association between MS and migraine.

Disclosure: Nothing to disclose.

EPR-115 | Metabolomics of cerebrospinal fluid as a new potential source of biomarkers in early stages of multiple sclerosis

M. Zido[1]; D. Kacer[2]; K. Vales[2]; D. Zimova[1]; I. Stetkarova[1]
[1]*Department of Neurology, Third Faculty of Medicine, Charles University and Faculty Hospital Kralovske Vinohrady, Prague, Czechia;* [2]*National Institute of Mental Health, Klecany, Czechia*

Background and Aims: Multiple sclerosis (MS) is a chronic autoimmune disease affecting predominantly the white matter of the CNS. The exact cause of MS is still unknown and its pathophysiology is very complex. Metabolomics is a systematic study that profiles endogenously small metabolites present in the examined substrate. Comparison of the metabolomic profiles represents an important strategy to understand the pathophysiology of the disease at the molecular level. The main goal of this study was to determine significant differences in the metabolome of the CSF of patients in the initial stage of MS compared to the controls, and to explain these differences from a pathophysiological point of view.
Methods: We collected CSF samples from 40 MS patients and 33 controls. The analysis was performed using high-performance liquid chromatography with tandem mass spectrophotometry with a high-resolution detector. After that, we correlated these findings with EDSS values at the time of examination, after 1 and 2 years.
Results: Statistically significant changes (p-value <0.05) were observed in arginine, histidine, spermidine, glutamate, choline, tyrosine, serine, oleic, stearic and linoleic acid. Additionally, we observed a significant negative correlation with the EDSS values at the time of examination and after 1 year in the case of histidine.

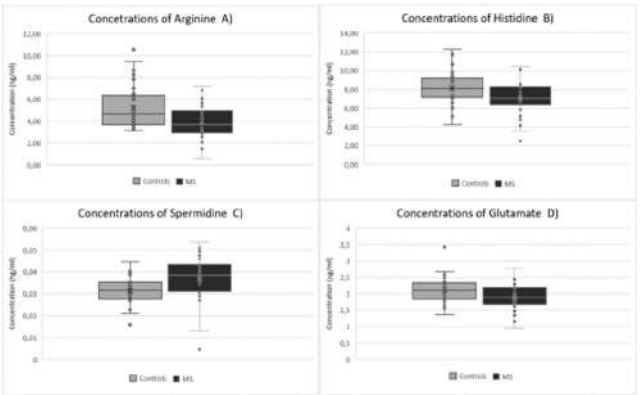


FIGURE 1. Comparison of concentrations between patients after the first clinical symptoms of MS and the control group in (A) arginine; (B) histidine; (C) spermidine; (D) glutamate.

Conclusion: In conclusion, we demonstrated significant differences in the concentrations of several metabolites in the CSF of patients in the early stages of MS, which could be used as new biomarkers of MS. These metabolites can potentially serve as prognostic indicators in the early stages of MS, markers of inflammation, ongoing demyelination or neurodegeneration.
Disclosure: Nothing to disclose.

Background and Aims: Nipocalimab is a fully human, effectorless IgG1 anti-neonatal Fc receptor (FcRn) monoclonal antibody evaluated in a pivotal phase 3 study in generalized myasthenia gravis (gMG). Nipocalimab may ameliorate disease by selectively targeting FcRn IgG recycling and lowering circulating IgG, including pathogenic autoantibodies in gMG.
Methods: Seropositive (anti-AChR/MuSK/LRP4) or seronegative adult gMG patients (MGFA Class II-IV) with insufficient response (MG-ADL ≥6) to ongoing standard-of-care (SOC) therapy were enrolled in a 24-week double-blind placebo-controlled study. Randomization was 1:1 to SOC+ nipocalimab (30 mg/kg IV loading dose followed by 15mg/kg every two weeks) or SOC+ placebo. The primary endpoint was mean change in MG-ADL score from baseline over weeks 22, 23 and 24 in seropositive patients. Secondary endpoints included change in QMG score. Safety and tolerability were also assessed.
Results: Of 199 patients enrolled, 153 were seropositive. Baseline demographics were balanced across arms (77 nipocalimab, 76 placebo). Nipocalimab showed statistically significant improvement in clinical efficacy with mean change in MG-ADL score of -4.70 (SE 0.329) from baseline over weeks 22-24 on nipocalimab vs. -3.25 (SE 0.335) on placebo (difference of LS means -1.45; p=0.002). Statistically significant improvement was seen in mean change in QMG score of -4.86 (SE 0.504) from baseline over weeks 22-24 on

nipocalimab vs. -2.05 (SE 0.499) on placebo (difference of LS means -2.81, p<0.001). Nipocalimab was well-tolerated with incidence of adverse events comparable to placebo.

Conclusion: The efficacy and safety results of this pivotal phase 3 study of nipocalimab in gMG will be presented at the EAN 2024 Congress.

EPR-117 | Minimal symptom expression in generalized myasthenia gravis: A post hoc analysis of MycarinG and open-label studies

C. Antozzi[1]; A. Drużdż[2]; J. Grosskreutz[3]; R. Pascuzzi[4]; K. Utsugisawa[5]; S. Sacconi[6]; J. Vissing[7]; M. Boehnlein[8]; B. Greve[8]; F. Grimson[9]; T. Tarancón[10]; V. Bril[11]

[1]Fondazione Istituto di Ricovero e Cura a Carattere Scientifico, Istituto Nazionale Neurologico Carlo Besta, Milan, Italy; [2]Department of Neurology, Municipal Hospital, Poznań, Poland; [3]Precision Neurology of Neuromuscular Diseases, Department of Neurology, University of Lübeck, Lübeck, Germany; [4]Neurology Department, Indiana University School of Medicine, Indiana University Health, Indianapolis, IN, USA; [5]Department of Neurology, Hanamaki General Hospital, Hanamaki, Japan; [6]Université Côte d'Azur, Peripheral Nervous System & Muscle Department, Pasteur 2 Hospital, Centre Hospitalier Universitaire de Nice, Nice, France; [7]Department of Neurology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [8]UCB Pharma, Monheim, Germany; [9]UCB Pharma, Slough, UK; [10]UCB Pharma, Madrid, Spain; [11]University Health Network, Toronto, ON, Canada

Background and Aims: High rates of Myasthenia Gravis Activities of Daily Living (MG-ADL) and Quantitative Myasthenia Gravis response were observed with rozanolixizumab across MycarinG (NCT03971422) and its open-label extension (OLE) studies in adults with generalized myasthenia gravis (MG). Attainment of minimal symptom expression (MSE; MG-ADL score: 0 or 1) is a stringent measure of therapeutic efficacy and a treatment goal in MG. A post hoc analysis of MSE is reported.

Methods: In MycarinG, patients received once-weekly placebo, rozanolixizumab 7mg/kg or 10mg/kg for 6 weeks. Patients could subsequently enrol in OLEs MG0004 (NCT04124965) then MG0007 (NCT04650854), or MG0007 directly. MG0004 comprised once-weekly rozanolixizumab 7mg/kg or 10mg/kg for <=52 weeks. In MG0007, after an initial 6-week cycle (rozanolixizumab 7mg/kg or 10mg/kg), cycles were administered on symptom worsening. Data were pooled across MycarinG, MG0004 (first 6 weeks) and MG0007 (data cut-off: 08 July 2022) for patients with >=2 symptom-driven cycles. The proportion of patients achieving MSE (MG-ADL score: 0 or 1) at any time in each cycle was analysed. Post hoc analysis of MSE rate was conducted based on achievement of MSE in Cycle 1.

Results: At data cut-off, 127 patients had >=2 symptom-driven cycles. MSE rates were 27.6% (35/127), 26.8% (34/127) and 25.5% (25/98) in Cycle 1, 2 and 3, respectively. For patients who achieved MSE in Cycle 1 and had further cycles, MSE rate was high over subsequent cycles (Cycle 2: 77.1% [27/35]; Cycle 3: 81.8% [18/22]).

Conclusion: The majority of patients achieving MSE in Cycle 1 continued to achieve MSE in subsequent rozanolixizumab treatment cycles.

Disclosure: This study was funded by UCB Pharma. Marion Boehnlein, Bernhard Greve, Fiona Grimson and Thaïs Tarancón are employees and shareholders of UCB Pharma. Full disclosure of all industry relationships will be made during congress presentation if accepted.

EPR-118 | DNTH103, a potentially safer and more convenient novel therapy for generalized myasthenia gravis

J. Vissing[1]; S. Peric[2]; L. Lewis[4]; J. Stavenhagen[5]; S. Gokhale[5]

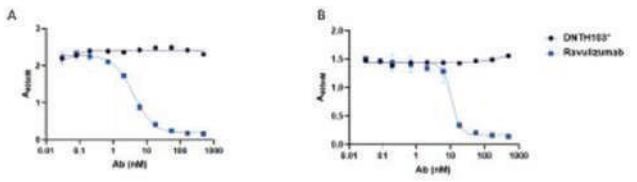
[1]Copenhagen Neuromuscular Center, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [2]University of Belgrade, Belgrade, Serbia; [4]Division of Infectious Diseases and Immunology, Department of Medicine, University of Massachusetts Chan Medical School, Worcester, MA, USA; [5]Dianthus Therapeutics, New York City, USA

Background and Aims: Complement inhibition is an effective treatment pathway of generalized myasthenia gravis (gMG).1,2 DNTH103 is a fully human, potent, monoclonal antibody with a long half-life. It selectively binds to active human C1s to block only the classical complement pathway (CP), with the aim of maintaining complement mediated bacterial killing.

Methods: Three preclinical studies evaluated the efficacy or safety of DNTH103. Study 1: DNTH103 functional activity was characterized with Human-on-a-Chip Neuromuscular Junction (NMJ) System using healthy iPSC-derived motoneurons and skeletal muscle myotubes and sera from 3 healthy and 3 acetylcholine receptor-positive

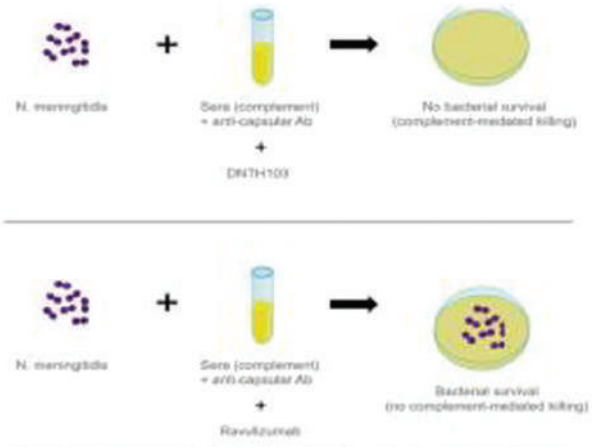
(AChR+) gMG patients. Fatigue index was calculated using continuous electrical stimulation of NMJs with or without DNTH103 or anti-C5. Study 2: complement assays using anti-C1s antibody (DNTH103*) and anti-C5 antibody (ravulizumab) evaluated their ability to inhibit the lectin and alternative pathways. Study 3: serum bactericidal assays with DNTH103, ravulizumab, or control were performed with 80% normal human sera and anti-capsular antibodies that mimic vaccination against Neisseria meningitidis.

Results: Treatment with DNTH103 at 0.1 and 1 μM reduced muscle fatigue index in AChR+ gMG samples by 24.8% and 27.8% respectively; similar results were observed with anti-C5. DNTH103* did not inhibit the lectin or alternative pathways or impede bacterial killing (similar to untreated control); ravulizumab inhibited all pathways and blocked bacterial killing by complement.



DNTH103* is an analogue and precursor to DNTH103 and differs in the N-terminal acid of the IgG4 heavy chain. Both have been shown to exhibit indistinguishable biophysical and functional properties.
Note: Data points represent mean (N=3) ± SD.
SD, standard deviation

FIGURE 1. Effect of Complement Inhibitory Antibodies on the Complement Lectin and Alternative Pathways in 1% Human Serum (mean ± SD).



*Serum bactericidal assay performed with 80% NHS and anti-capsular antibodies

FIGURE 2. High serum bactericidal assay to evaluate the effect of DNTH103 on N. meningitidis killing.

Conclusion: The ability of DNTH103 to improve neurotransmission and muscle contraction and selectively inhibit the CP makes it an attractive research candidate for gMG while potentially reducing the risk of severe infection seen with current gMG therapies.

Disclosure: This study was funded by Dianthus Therapeutics. The authors declare no conflicts of interest.

EPR-119 | Long-term safety outcomes of rozanolixizumab treatment in patients with generalized myasthenia gravis: A pooled analysis

J. Vissing[1]; J. Grosskreutz[2]; A. Habib[3]; K. Utsugisawa[4]; T. Vu[5]; M. Boehnlein[6]; M. Gayfieva[7]; B. Greve[6]; T. Tarancón[8]; F. Woltering[6]; V. Bril[9]

[1]Department of Neurology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [2]Precision Neurology of Neuromuscular Diseases, Department of Neurology, University of Lübeck, Lübeck, Germany; [3]MDA ALS and Neuromuscular Center, University of California, Irvine, Irvine, CA, USA; [4]Department of Neurology, Hanamaki General Hospital, Hanamaki, Japan; [5]Department of Neurology, University of South Florida Morsani College of Medicine, Tampa, FL, USA; [6]UCB Pharma, Monheim, Germany; [7]UCB Pharma, Slough, UK; [8]UCB Pharma, Madrid, Spain; [9]University Health Network, Toronto, ON, Canada

Background and Aims: The long-term safety of rozanolixizumab across MycarinG (NCT03971422) and ongoing open-label extension study MG0007 (NCT04650854) in adults with generalized myasthenia gravis has been previously presented (AANEM 2023). Here, predefined treatment-emergent adverse events (TEAEs) are evaluated.

Methods: In MycarinG, patients received one 6-week cycle of once-weekly placebo, rozanolixizumab 7mg/kg, or rozanolixizumab 10mg/kg. In MG0007, after an initial 6-week cycle (rozanolixizumab 7mg/kg or 10mg/kg), cycles were administered based on symptom worsening. Data were pooled across MycarinG and MG0007 (data cut-off: 08 July 2022) for patients receiving >=1 rozanolixizumab treatment cycle with a <=8-week follow-up period. Based on the mechanism of action of rozanolixizumab and pre-defined Medical Dictionary for Regulatory Activities search criteria, TEAEs including headaches, infections, hypersensitivity, anaphylactic reactions and gastrointestinal disorders were evaluated.

Results: Overall, 188 patients received >=1 rozanolixizumab treatment cycle (mean [standard deviation] cycles initiated: 3.6 [2.2]). TEAEs occurred in 89.9% (169/188) of patients (rozanolixizumab 7mg/kg: 77.4% [103/133]; 10mg/kg: 91.6% [120/131]). Incidence of pre-defined TEAEs was similar across repeated treatment cycles except for headaches and gastrointestinal disorders (more frequent in Cycle 1; Table); most were mild or moderate in intensity. Eight (4.3%) patients each experienced severe headaches and serious infections. One patient experienced serious aseptic meningitis which led them to discontinue the study. No serious hypersensitivity or anaphylactic reactions occurred. No potential risk for hepatotoxicity or renal toxicity or clinically meaningful changes in lipid or albumin levels were identified.

TABLE. Occurrence of pre-defined TEAEs by cycle in patients with at least one rozanolixizumab treatment cycle.

Category,* n/N (%)	Cycle	RLZ 7mg/kg	RLZ 10mg/kg	RLZ total
Headaches†	1	37/94 (39.4)	35/94 (37.2)	72/188 (38.3)

EPR-120 | Safety and effectiveness of ravulizumab in generalized myasthenia gravis: Evidence from a global registry

P. Narayanaswami[1]; S. Macwan[2]; J. Winkley[3]; A. Gordon[4]; M. Pulley[5]; E. Greene[6]; L. Zeinali[7]; E. Rodrigues[7]; A. Yegin[7]; J. Howard; Jr.[8]

[1]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA, USA; [2]Eisenhower Health Center, Rancho Mirage, CA, USA; [3]Baptist Health Medical Group Neurology, Lexington, KY, USA; [4]Northwest Neurology, Ltd., Lake Barrington, IL, USA; [5]University of Florida College of Medicine, Jacksonville, FL, USA; [6]Houston Methodist, Houston, TX, USA; [7]Alexion, AstraZeneca Rare Disease, Boston, MA, USA; [8]The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC, USA

Background and Aims: Complement C5 inhibitor therapies (C5ITs) eculizumab and ravulizumab are approved in the US and EU for anti-acetylcholine-receptor-antibody-positive (AChR+) generalized myasthenia gravis (gMG). The ongoing, global MG-SPOTLIGHT Registry is assessing ravulizumab safety and effectiveness in patients with gMG in routine clinical practice using the MG Activities of Daily Living (MG-ADL; includes minimum symptom expression [MSE] outcome) and MG Foundation of America clinical class (MGFA-CC) assessments.

Methods: This interim analysis includes ravulizumab-treated patients with MG-ADL total scores or MGFA-CC data for >=2 time points (before and after initiating C5IT). Descriptive statistics were performed and presented as mean (SD). Safety was assessed by frequency of serious adverse events (SAEs).

Results: Of 70/204 enrolled patients (63% male; aged 60.4 [19.0] years at MG diagnosis), 17 received ravulizumab only and 53 transitioned to ravulizumab from eculizumab; ravulizumab treatment averaged 3–4 months. In ravulizumab-only patients, MG-ADL score decreased from 5.8 (3.4) to 3.4 (3.3) after ravulizumab initiation (Table 1); in ravulizumab-switch patients, MG-ADL scores remained stable from 3.7 (4.2) to 3.4 (3.2) following ravulizumab initiation (Table 2). In ravulizumab-only pts, the 66.7% with MGFA-CC 0-II increased to 88.9% after ravulizumab initiation; in ravulizumab-switch patients, the 92.0% with MGFA-CC 0-II remained stable at 96.0% following ravulizumab initiation. Similar patterns were observed in patients achieving MG-ADL MSE. SAEs were similar to previous findings. Limitations included no adjustment for confounders and small sample sizes.

TABLE 1. Outcomes in patients treated with ravulizumab only. Data shown as mean (SD) unless otherwise indicated.

EPR-121 | Pozelimab and cemdisiran combination therapy in patients with myasthenia gravis: Phase 3 NIMBLE trial design

S. Jacob[1]; U. Chaudhari[2]; K. Mohan[2]; L. Perlee[2]; R. Pavani[2]; C. Lum[2]; J. Howard Jr[3]
[1]*Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, UK;* [2]*Regeneron Pharmaceuticals, Inc., Tarrytown, NY, USA;* [3]*Department of Neurology, The University of North Carolina at Chapel Hill, Chapel Hill, NC, USA*

Background and Aims: Generalized myasthenia gravis (gMG) is a rare autoimmune disease of the neuromuscular junction predominantly due autoantibodies that bind to the acetylcholine receptor (AChR). IgG1 AChR (and less commonly anti-lipoprotein receptor-related protein 4, LRP4) antibodies are likely responsible for neuromuscular junction damage via terminal complement activation, in most patients with gMG. Pozelimab and cemdisiran are investigational agents for gMG that both inhibit the terminal complement. Cemdisiran is an N-acetylgalactosamine-conjugated small interfering RNA that suppresses liver production of C5, while pozelimab is a monoclonal antibody inhibitor to C5. We describe the design of the ongoing phase 3 NIMBLE trial (NCT05070858), which aims to evaluate the efficacy and safety of pozelimab plus cemdisiran in patients with symptomatic gMG.

Methods: This is a multinational, randomized, double-blind, placebo-controlled trial in patients with clinically confirmed gMG (seropositive for anti-AChR or anti-LRP4 antibodies). The study includes 5-week screening period; 24-week double-blind placebo-controlled treatment period; 28-week double-blind extension treatment period, 68-week open-label long-term treatment period; and a 52-week post-treatment follow-up period (Figure 1). On Day 1, patients will be randomized to one of four treatment arms (Figure 1). This study will enroll approximately 235 patients. The primary and secondary study endpoints are summarized in Table 1.

Results: The first patient was enrolled on December 14, 2021.

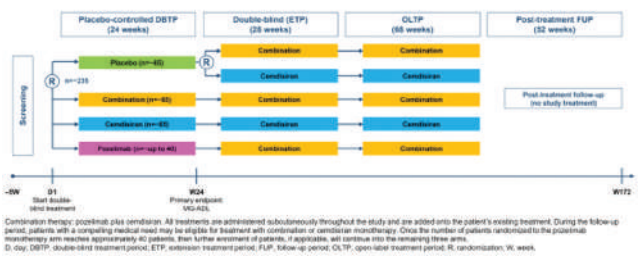
TABLE 1.

Table 1. Primary and secondary study endpoints of the NIMBLE trial

Endpoint
Primary endpoint
Change in MG-ADL total score from baseline to Week 24
Key secondary endpoint
Change from baseline in QMG score at Week 24
Other secondary endpoints
Proportion of patients:
• Responding on the MG-ADL, with a responder defined as one with a ≥3-point improvement from baseline to Week 24
• Responding on the QMG, with a responder defined as one with a ≥5-point improvement from baseline to Week 24
• With consistent response on the MG-ADL, defined as patients with ≥2-point MG-ADL improvement on ≥2 consecutive assessments spanning ≥4 weeks during the double-blind period
• With minimal symptom expression (defined by a score of 0–1 on the MG-ADL) at Week 24
• With improvement point thresholds of ≥2, 4, 5, 6, 7, 8, 9, or 10 on MG-ADL at Week 24
• With improvement point thresholds of ≥3, 4, 6, 7, 8, 9, or 10 on QMG at Week 24
Change from baseline in:
• MGC total score at Week 24
• MG-QOL15r total score at Week 24
• Incidence and severity of TEAEs, SAEs, and AESIs through Week 24
Concentrations of:
• Total pozelimab in serum at nominal time-points
• Cemdisiran and its metabolites in plasma at nominal time points
Incidence of:
• Treatment-emergent ADAs to pozelimab after repeated doses over time
• Treatment-emergent ADAs to cemdisiran after repeated doses over time
Change and percent change in CH50 over time

ADA, anti-drug antibody; AESI, adverse event of special interest; CH50, total complement hemolysis activity assay; MG-ADL, myasthenia gravis-activities of daily living; QMG, quantitative myasthenia gravis; SAE, serious adverse event; TEAE, treatment-emergent adverse event.

Figure 1. Study design



Combination therapy: pozelimab plus cemdisiran. All treatments are administered subcutaneously throughout the study and are added onto the patient's existing treatment. During the follow-up period, patients with a compelling medical need may be eligible for treatment with combination or cemdisiran monotherapy. Once the number of patients randomized to the pozelimab monotherapy arm reaches approximately 40 patients, then further enrollment of patients, if applicable, will continue into the remaining three arms.
D, day; DBTP, double-blind treatment period; ETP, extension treatment period; FUP, follow-up period; OLTP, open-label treatment period; R, randomization; W, week.

FIGURE 1.

Conclusion: This ongoing study (open for recruitment) is designed to evaluate the effect of pozelimab plus cemdisiran on daily functioning and other MG efficacy measures (including quality of life), as well as safety in patients with symptomatic gMG.

EPR-122 | Rozanolixizumab in generalized myasthenia gravis: Patient-reported outcomes in the randomized, Phase 3, MycarinG study

S. Sacconi[1]; A. Drużdż[2]; J. Grosskreutz[3]; A. Habib[4]; R. Mantegazza[5]; K. Utsugisawa[6]; J. Vissing[7]; M. Boehnlein[8]; A. Hareendran[9]; B. Greve[8]; T. Tarancón[10]; F. Woltering[8]; V. Bril[11]

[1]Université Côte d'Azur, Peripheral Nervous System & Muscle Department, Pasteur 2 Hospital, Centre Hospitalier Universitaire de Nice, Nice, France; [2]Department of Neurology, Municipal Hospital, Poznań, Poland; [3]Precision Neurology of Neuromuscular Diseases, Department of Neurology, University of Lübeck, Lübeck, Germany; [4]MDA ALS and Neuromuscular Center, University of California, Irvine, Irvine, CA, USA; [5]Department of Neuroimmunology and Neuromuscular Diseases, Fondazione IRCCS, Istituto Nazionale Neurologico Carlo Besta, Milan, Italy; [6]Department of Neurology, Hanamaki General Hospital, Hanamaki, Japan; [7]Department of Neurology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [8]UCB Pharma, Monheim, Germany; [9]UCB Pharma, Slough, UK; [10]UCB Pharma, Madrid, Spain; [11]University Health Network, Toronto, ON, Canada

Background and Aims: The five Myasthenia Gravis Symptoms Patient-Reported Outcome (MGSPRO) scales, developed to evaluate changes in severity of patient-relevant symptoms, were used to assess efficacy of rozanolixizumab in patients with generalized myasthenia gravis (gMG) in the MycarinG study.

Methods: The randomized, double-blind, placebo-controlled, Phase 3, MycarinG (NCT03971422) study enrolled adults with Myasthenia Gravis Foundation of America Disease Class II–IVa acetylcholine receptor or muscle-specific tyrosine kinase autoantibody-positive gMG. Patients were randomized 1:1:1 to weekly subcutaneous rozanolixizumab 7mg/kg, rozanolixizumab 10mg/kg, or placebo for 6 weeks. Primary endpoint was change from baseline (CFB) to Day 43 in Myasthenia Gravis Activities of Daily Living (MG-ADL) score. CFB to Day 43 in the five MGSPRO scale scores was assessed (secondary endpoints: Muscle Weakness Fatigability, Physical Fatigue, Bulbar Muscle Weakness; other endpoints: Respiratory and Ocular Muscle Weakness) . Safety was also assessed.

Results: Overall, 200 patients received rozanolixizumab 7mg/kg ($n=66$), 10 mg/kg ($n=67$) or placebo ($n=67$). At Day 43, least squares mean CFB in MG-ADL score was clinically meaningful and statistically significantly improved with rozanolixizumab versus placebo (Table). Improvements in MGSPRO Muscle Weakness Fatigability, Physical Fatigue and Bulbar Muscle Weakness scores were also statistically significant versus placebo, and improvements were observed in mean CFB to Day 43 for MGSPRO Respiratory and Ocular Muscle Weakness scores versus placebo (Table). Treatment-emergent adverse events occurred in 52 (81.3%), 57 (82.6%) and 45 (67.2%) patients in the rozanolixizumab 7 mg/kg, 10 mg/kg and placebo groups.

		Placebo (n=67)	RLZ 7mg/kg (n=66)	RLZ 10mg/kg (n=67)
MG-ADL (primary endpoint)	LS mean (SE)	−0.8 (0.5)	−3.4 (0.5)	−3.4 (0.5)
	LS mean difference vs placebo (95% CI)		−2.6 (−4.1, −1.2)	−2.6 (−4.0, −1.2)
	p-value		<0.001	<0.001
Muscle Weakness Fatigability	LS mean (SE)	−10.6 (3.0)	−23.0 (3.0)	−25.8 (3.1)
	LS mean difference vs placebo (95% CI)		−12.4 (−21.8, −4.1)	−15.2 (−23.6, −6.5)
	p-value		<0.001	<0.001
Physical Fatigue	LS mean (SE)	−10.6 (3.1)	−19.3 (3.0)	−25.5 (3.1)
	LS mean difference vs placebo (95% CI)		−8.7 (−18.1, −0.1)	−14.8 (−23.8, −5.9)
	p-value		0.012	<0.001
Bulbar Muscle Weakness	LS mean (SE)	−3.5 (2.4)	−14.8 (2.4)	−14.2 (2.5)
	LS mean difference vs placebo (95% CI)		−11.3 (−19.0, −5.0)	−10.7 (−17.8, −4.0)
	p-value		<0.001	<0.001
Respiratory Muscle Weakness*	Observed mean (SD)	−2.1 (22.5)	−12.5 (21.6)	−11.8 (16.5)
	Mean difference vs placebo		−10.4	−9.7
Ocular Muscle Weakness*	Observed mean (SD)	−3.4 (18.2)	−9.6 (16.8)	−11.9 (14.0)
	Mean difference vs placebo		−6.2	−8.5

*Results for these endpoints are descriptive.

CFB, change from baseline; CI, confidence interval; LS, least squares; MG-ADL, Myasthenia Gravis Activities of Daily Living; MGSPRO, Myasthenia Gravis Symptoms Patient-Reported Outcome; RLZ, rozanolixizumab; SD, standard deviation; SE, standard error.

CFB to Day 43 in MG-ADL score (primary endpoint) and MGSPRO scale scores

Conclusion: Rozanolixizumab demonstrated greater improvements in all five patient-relevant symptoms scales versus placebo, including Physical Fatigue, an important symptom for patients with gMG

Disclosure: Due to space constraints, full disclosures will be provided separately by email and will be included in the presentation if accepted. This study was funded by UCB Pharma. Sabrina Sacconi and Artur Drużdż have nothing to disclose. Marion Boehnlein, Asha Hareendran, Bernhard Greve, Thaïs Tarancón and Franz Woltering are employees and shareholders of UCB Pharma. The other authors' disclosures will be provided separately.

EPR-123 | Quality of life in generalized myasthenia gravis: Results from a global registry of eculizumab and ravulizumab treatment

C. Scheiner[1]; N. Jiang[2]; G. Cutter[2]; P. Narayanaswami[3]; R. Tandan[4]; L. Zeinali[5]; E. Rodrigues[5]; A. Yegin[5]; A. Gordon[6]
[1]*University of Tennessee Medical Center, Knoxville, TN, USA;* [2]*University of Alabama at Birmingham, Birmingham, AL, USA;* [3]*Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA, USA;* [4]*University of Vermont Medical Center, Burlington, VT, USA;* [5]*Alexion, AstraZeneca Rare Disease, Boston, MA, USA;* [6]*Northwest Neurology, Ltd., Lake Barrington, IL, USA*

Background and Aims: Complement C5 inhibitor therapies (C5ITs) eculizumab and ravulizumab are approved in the US and EU for anti-acetylcholine receptor antibody-positive (AChR+) generalized myasthenia gravis (gMG). The global MG SPOTLIGHT Registry enrolled patients receiving C5ITs in clinical practice to assess eculizumab and ravulizumab safety and effectiveness in patients with gMG. This analysis examined quality of life (QOL) changes after C5IT initiation using Myasthenia Gravis Quality of Life 15-revised (MG-QOL15r) scores.

Methods: Enrolled registry patients were included if they had MG-QOL15r assessments before and after C5IT initiation. Descriptive statistics were performed and are presented as mean (SD). Safety was assessed by evaluating frequency and type of serious adverse events.

Results: The 47/204 (23%) enrolled registry patients with available data were 60% male (aged 46.5 [20.3] years at MG diagnosis). In eculizumab-only-treated patients ($n=30$), the MG-QOL15r score before eculizumab initiation, 18.2 (6.9), improved to 12.2 (8.5) after 30.9 (16.1) months of eculizumab treatment. Among eculizumab-to-ravulizumab switched patients ($n=10$), the MG-QOL15r score of 18.2 (7.9) before C5IT initiation improved to 11.2 (10.6) after 29.6 (25.4) months of eculizumab and to 8.7 (9.0) after 4.6 (3.1) months of ravulizumab. The C5IT safety profile within this patient cohort was similar to previous analyses, including clinical trial data. Limitations include the lower number of patients with MG-QOL15r data in routine clinical use and lack of adjustment for potential confounders.

Conclusion: These initial results underline clinically meaningful QOL improvements in patients with AChR+ gMG treated with C5ITs in clinical practice. Patients transitioned from eculizumab experienced further slight QOL improvements with ravulizumab.

Disclosure: CAS, NJ, GC, PN, RT, and AG, or their institutions, have received compensation from research and funding organisations and/or pharmaceutical companies for speaking, consulting, and contracted research. LZ, ER, and AY are employees of Alexion, AstraZeneca Rare Disease and hold stock options in AstraZeneca.

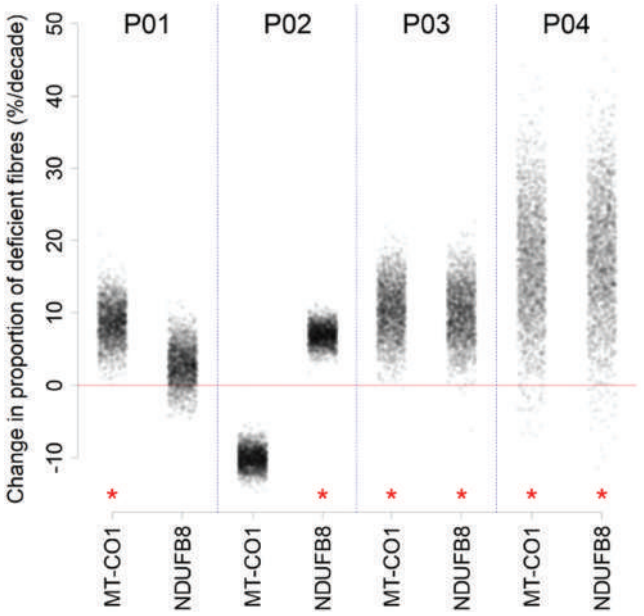
EPR-124 | Measuring change in OXPHOS-deficiency in skeletal muscle of patients with mitochondrial myopathy

T. Bernardino Gomes; J. Childs; D. M Turnbull; G. Gorman; C. Lawless; A. E Vincent
Wellcome Centre for Mitochondrial Research, Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, UK

Background and Aims: Mitochondrial diseases affect ~1 in 5,000 adults and often cause skeletal muscle disease (i.e., weakness, fatigue, and exercise intolerance). Disrupted oxidative phosphorylation (OXPHOS), a hallmark of mitochondrial disease, is a commonly used surrogate of impaired muscle bioenergetics. However, standard immunofluorescence (IF) OXPHOS markers have not been systematically demonstrated to detect changes and predict disease progression in longitudinal studies.

Methods: So far, we selected 4 participants with progressive myopathy due to mitochondrial DNA (mtDNA) single, large-scale deletions (SLSD). We used IF to measure changes in proportions of muscle fibres deficient in the standard OXPHOS markers, MT-CO1 and NDUFB8, between muscle biopsies at two time points (>3.6 years apart). Fibre status per marker was determined using a Bayesian Inference and reference fibre data from healthy controls. We plan to extend our cohort to 20 participants.

Results: We detected an increase deficiency for both markers, except for participant 2, who shown a decrease in MT-CO1 deficiency (Fig.1). Rate of change was estimated, using sampling interval, and varied substantially between participants and markers. This variability is unsurprising because deletion size, position, and proportion vary and differentially affect OXPHOS markers, and compensatory overexpression is well documented.



Rate of change in proportions of OXPHOS-deficient fibres between time points per participant. Dots are Bayesian Inference simulations of fibre OXPHOS status capturing uncertainty of the analysis. (*) statistically significant increasing deficiency.

Conclusion: Standard IF protocols seem to detect changes in markers of OXPHOS deficiency in skeletal muscle tissue over time. We now aim to increase our cohort and study the effect of deletion size, position, and proportion on the trajectory of these biomarkers. We hope that our findings will support future studies into disease progression and clinical trials in mitochondrial diseases.

Disclosure: Nothing to disclose. Work funded by Wellcome.

Ageing and dementia 2

EPR-125 | **Predictive efficacy of atrophy rating scales and volumetric analysis for Aβ-CSF status and anti-Aβ treatment eligibility**

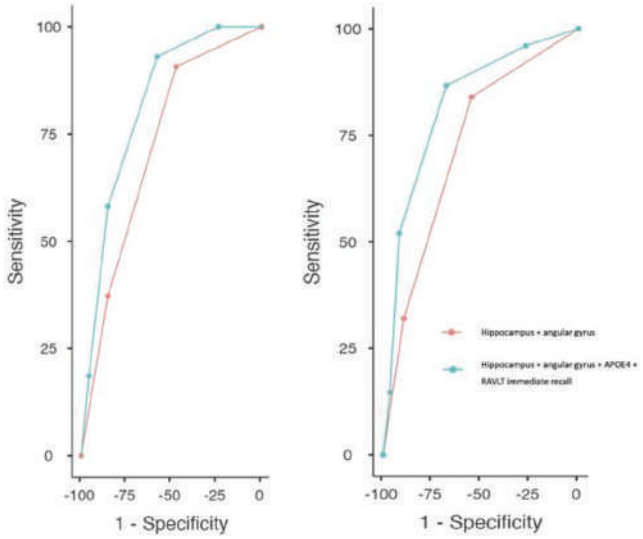
A. Zilioli[1]; A. Rosenberg[2]; R. Mohanty[3]; A. Matton[3]; G. Hagman[3]; M. Kivipelto[3]; E. Westman[3]

[1]*Department of Neurology, University-Hospital of Parma, Parma, Italy;* [2]*Population Health Unit, Finnish Institute for Health and Welfare, Helsinki, Finland;* [3]*Division of Clinical Geriatrics, Center for Alzheimer Research, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Huddinge, Stockholm, Sweden*

Background and Aims: Establishing tools that enable the prediction of amyloid status is of primary importance, especially considering the forthcoming availability of disease-modifying therapies and the need to identify eligible patients with Alzheimer's disease. We aim to predict CSF-amyloid status and eligibility for anti-amyloid treatment in a memory clinic by (I) comparing the predictive performances of visual, automated rating scales and volumetric analysis, and (II) combining MRI volumetric data with neuropsychological tests and Apoε4 status.

Methods: From the initial pool of 592 consecutive patients, 290 patients underwent a comprehensive assessment. Amyloid status was determined using data-driven CSF biomarker cutoffs (Ab42/Ab40 ratio). To assess eligibility for anti-Aβ treatment, we adhered to recent appropriate use recommendations published after the FDA approval of the anti-Aβ drug Aducanumab.

Results: The automated rating scales and volumetric analysis demonstrated higher performance compared to visual assessment in predicting Aβ status, particularly for parietal-GCA (AUC=0.699), MTA (AUC=0.663) scores, hippocampal (AUC=0.681), and angular gyrus (AUC=0.689) volumes. Combining hippocampal and angular gyrus volumes, with RAVLT immediate recall and Apoε4 status reached the highest accuracy (AUC=0.821), which remained high even in predicting anti-Aβ treatment eligibility (AUC=0.818).



ROC curves for the model combining hippocampus and angular gyrus volumes, and the comprehensive model adding neuropsychological and ApoE4 data. On the left in the global cohort, while the right in the prediction of the eligibility for anti-Aβ treatment.

Conclusion: Our study underscores the importance of employing automated neuroimaging assessment to quantify brain atrophy in a tertiary memory clinic. The integration of volumetric data with neuropsychological and genetic information results in a high level of accuracy for predicting amyloid-CSF status and anti-Aβ treatment eligibility, within the naturalistic and heterogeneous context of a memory clinic.

Disclosure: Nothing to disclose.

EPR-126 | 18F-fluorodeoxyglucose levels in cerebrospinal fluid are driven by glucose demand of the brain in Alzheimer's disease

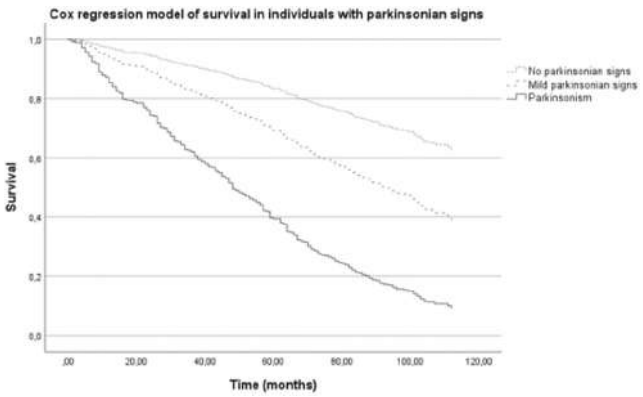
C. Motta[1]; A. Chiaravalloti[2]; C. Bonomi[1]; A. Martorana[1]
[1]*UOSD Centro Demenze, University of Rome "Tor Vergata", Italy;* [2]*Department of Biomedicine and Prevention, University of Rome "Tor Vergata", Italy*

Background and Aims: Glucose delivery to the brain requires transport across blood-brain-barrier (BBB) through glucose transporters (GLUT). It has been suggested that GLUT downregulation may be linked to neuronal deficits in Alzheimer disease (AD), but it remains unclear whether it is caused by reduced demands in affected tissues or whether reduced glucose availability, linked to altered BBB, could induce neuronal degeneration. The study aimed to investigate, for the first time to our knowledge, the relationships between cerebrospinal fluid (CSF) [18F]fluorodeoxyglucose (18F-FDG), cortical and subcortical glucose metabolism and most relevant CSF parameters in a population of AD patients.
Methods: A total of 224 biologically defined AD patients underwent a complete clinical investigation, structural MRI, 18F-FDG PET/CT and CSF analysis 2 weeks before the PET/CT scan. Core AD biomarkers, glycorrhachia and Albumin Quotient (QAlb) were evaluated. 18F-FDG in CSF and in brain was quantified using WFUpickatlas toolkit implemented in statistical parametric mapping (SPM12). Normalization was performed using the pons as reference.
Results: 18F-FDG in CSF was positivley related to glucose metabolism in gray matter ($r=0.37$; $p<0.0001$) and white matter ($r=0.44$; $p<0.0001$). Instead, higher BBB permeability (Qalb) was associated with lower glucose uptake in gray matter ($r=-0.16$; $p=0.018$), white matter ($r=-0.14$; $p=0.040$) and 18F-FDG in CSF($r=-0.16$; $p=0.018$). The mediation analysis confirmed a significant total effect of 18F-FDG in CSF on glucose metabolism in gray matter ($p<0.001$) although not mediated by QAlb values ($p=0.104$).
Conclusion: The presence of 18F-FDG in CSF could be indicative of glucose uptake to meet energy demands of AD brains, independent of BBB permeability.
Disclosure: Nothing to disclose.

EPR-127 | Increased mortality in older adults with parkinsonian signs – A longitudinal study from the Good Aging in Skåne-cohort

C. Algotsson[1]; S. Elmståhl[2]; A. Siennicki-Lantz[3]
[1]*Department of Clinical Sciences in Malmö, Lund University, Skane University Hospital, Malmö, Sweden;* [2]*Division of Geriatric Medicine, Department of Clinical Sciences in Malmö, Lund University, Skane University Hospital, Malmö, Sweden;* [3]*Division of Geriatric Medicine, Department of Clinical Sciences in Malmö, Lund University, Skane University Hospital, Malmö, Sweden*

Background and Aims: Mild parkinsonian signs (MPS) are highly prevalent in older adults. The aim of this study was to investigate the associations between parkinsonian signs and mortality, risk factors and underlying cause of death in older adults.
Methods: Community-dwelling older adults without any previously diagnosed movement disorder ($n=480$, median age 85, range 80–101 years) were examined using United Parkinson's Disease Rating Scale (UPDRS) during 2010-2012. Data regarding mortality were collected until 2020-09-22 from the Swedish cause of death registry.
Results: MPS were present in 49.4% and parkinsonism in 28.6% of the cohort (missing UPDRS-score in 79 participants). Mortality rates were significantly increased in individuals with MPS (HR 2.0, CI 1.2–3.4, p-value 0.008) and parkinsonism (HR 5.1, CI 3.0–8.5, p-value <0.001). Preliminary results imply that the main causes of death were neoplasms, vascular disease, and neurologic disease.



Survival of individuals above 80 years of age with mild parkinsonian signs and parkinsonism. A follow-up of 480 individuals, mild parkinsonian signs present in 49.4% and parkinsonism in 28.6%.
Conclusion: In a population of older adults above 80 years, parkinsonian signs are associated with an increased mortality rate. Further research regarding pathophysiology of parkinsonian symptoms in older adults with MPS is needed to increase knowledge and provide adequate treatment.
Disclosure: The authors have nothing to disclose. The Good Aging in Skåne (GÅS-SNAC) project, part of the Swedish National Study on Aging and Care, was supported by the Swedish Ministry of Health and Social Affairs, the county Region Skåne, the Medical Faculty at Lund University, and the Swedish Research Council (grant number 2013-8604, 2017-01613, 2021-01437).

EPR-128 | Age of onset moderates the effects of Vascular Risk Factors in Alzheimer's disease

C. Bonomi[1]; C. Motta[1]; M. Di Donna[1]; M. Poli[1]; M. Nuccetelli[2]; N. Mercuri[3]; A. Martorana[1]

[1]*UOSD Memory Clinic, University of Rome "Tor Vergata" – Rome, Italy*; [2]*Department of Biomedicine and Prevention, University of Rome "Tor Vergata" – Rome, Italy*; [3]*Neurology Unit, University of Rome "Tor Vergata" – Rome, Italy*

Background and Aims: The role of Vascular risk factors (VRFs) in the progression of Alzheimer's disease (AD) is not cleared yet and could be influenced by age-specific mechanisms of resilience and vulnerability.

Methods: For 368 patients with AD, we computed eight risk factors in a cumulative measure (vascular score, VS). We regressed VS on CSF markers of amyloid deposition, neurodegeneration (t-tau), and blood-brain-barrier (BBB) permeability (Albumin-Quotient, Qalb), stratifying patients into early-onset (<65,EOAD), classic late-onset (65–75, cLOAD) and very late-onset (>75,vLOAD). Moreover, with bootstrapped mediation analysis we tested direct and indirect associations of VS with t-tau, using Qalb as mediator. In a subset of 105 patients, we performed multivariate backward regressions to assess the effects of Qalb, VS, and t-tau on ΔMMSE.

Results: Cumulative vascular risk (VS) was positively associated with t-tau in EOAD ($\beta = 0.256$, $p = 0.019$) and in vLOAD ($\beta = 0.007$, $p < 0.001$), but not in cLOAD ($\beta = 0.007$, $p = 0.925$). Conversely, VS was positively associated with Qalb only in cLOAD ($\beta = 0.173$, $p = 0.015$), where Qalb trends toward mediating the association between VS and t-tau. Longitudinally, ΔMMSE was not associated with VS in any of the subgroups. Instead, it was negatively associated with both CSF t-tau and Qalb in EOAD and vLOAD, while Qalb was the only determinant of cognitive decline in cLOAD.

Conclusion: VRFs do not influence cognitive decline in AD, but impact neurodegeneration differently depending on age-of-onset, and notably in patients with more aggressive progression (EOAD) or old age (vLOAD). Instead, in cLOAD, the modulation of BBB permeability could represent a resilience response to neurodegeneration, albeit causing relatively steeper cognitive decline.

Disclosure: Nothing to disclose.

EPR-129 | The role of astrocytes in vascular regulation along the Alzheimer's continuum: 18F-FDG-PET correlates

F. Bernocchi[1]; M. Assogna[2]; C. Bonomi[1]; G. Koch[3]; N. Mercuri[1]; A. Martorana[1]; C. Motta[1]

[1]*Department of Systems Medicine, University of Rome "Tor Vergata", Rome, Italy*; [2]*Non-Invasive Brain Stimulation Unit/Department of Behavioral and Clinical Neurology, Santa Lucia Foundation IRCCS, Rome, Italy*; [3]*Department of Neuroscience and Rehabilitation, University of Ferrara, Ferrara*

Background and Aims: Astrocytes in Alzheimer's disease (AD) exert a pivotal role in blood-brain barrier (BBB) integrity and neurovascular unit (NVU) releasing soluble factors like Vascular Endothelial Growth Factor (VEGF), Matrix Metalloproteinases (MMP)-9, MMP-2 and Endothelin-1 (ET-1), all involved in mechanisms of neuroprotection in AD. In addition, astrocytes contribute to brain energy metabolism through glucose consumption. Here, we aimed at exploring the possible associations between CSF levels of the above-mentioned vascular factors and regional hypometabolism, evaluated via 18F-fluorodeoxyglucose Positron Emission Tomography (18F-FDG-PET).

Methods: We recruited 61 patients that fulfilled NIA-AA diagnostic criteria for AD and performed a 18F-FDG-PET scan and CSF evaluation of VEGF, MMP2/9 and ET-1 levels.

Results: ET-1 was positively associated to 18F-FDG uptake in right Broadman area (BA)13, BA 6 and BA 27, and left BA 22, BA 47 and BA 13 (see Figure 1). We also observed a trend of positive association between 18F-FDG uptake and MMP-2 CSF levels in left BA 20 and BA 21 (See Figure 2). No association was found with neither CSF VEGF nor MMP-9 levels (see Table).

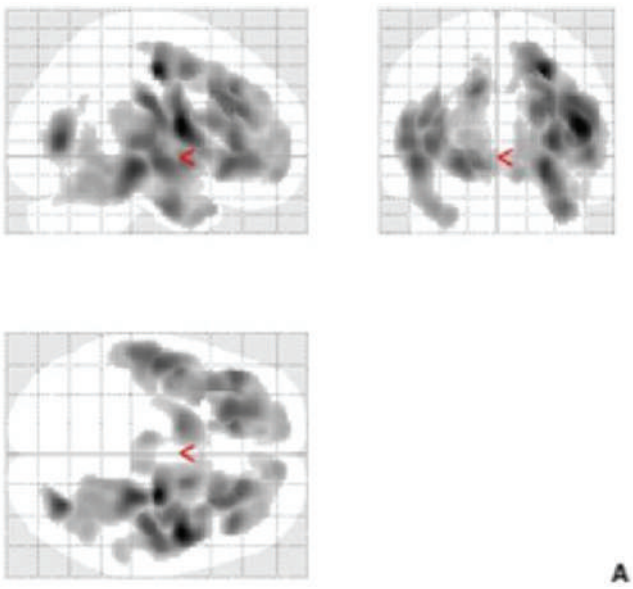


FIGURE 1. MNI projections showing cluster obtained in SPM regression analysis for the positive association between CSF ET-1 levels and glucose 18F-FDG uptake. The strength of correlation is represented in gray intensity scale.

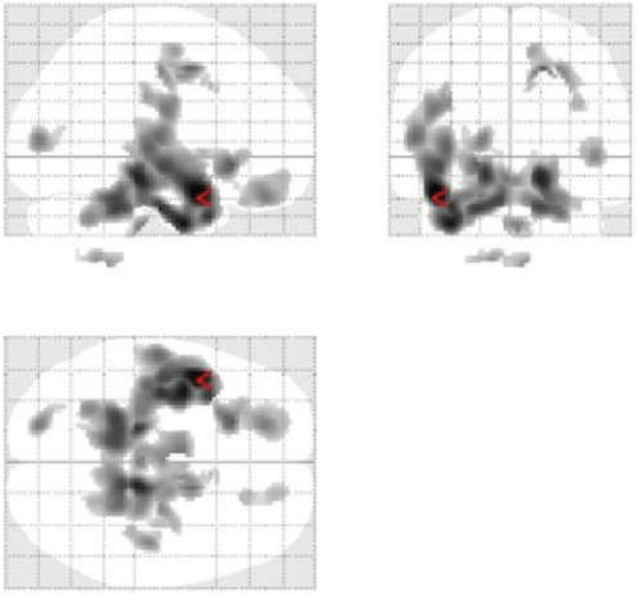

FIGURE 2. MNI projections showing cluster obtained in SPM regression analysis for the positive association between CSF MMP-2 levels and glucose 18F-FDG uptake. The strength of correlation is represented in gray intensity scale.

TABLE. Multivariate regression analysis showing associations between CSF vascular biomarkers and 18F-FDG uptake. L: left; R: right; FWE: Familywise error; FDR: False discovery rate; BA: Broadman Area; p unc: uncorrected p, n/a: not applicable.

Conclusion: The coexistence of positive associations between vascular factors and 18F-FDG uptake confirms that astrocytes can impact vascular regulation in a dynamic and heterogeneous process, where the positive association may represent a compensatory mechanism to counteract NVU dysregulation. This is in line with previous evidences that showed a positive correlation between CSF-GFAP and regional metabolism in key brain areas, suggesting a possible compensatory function of astrogliosis. To what extent such association can impact cognitive functions in AD remains elusive.

Disclosure: Nothing to disclose.

EPR-130 | Combined use of plasma p-tau181 and NfL chain in subjective cognitive decline and mild cognitive impairment

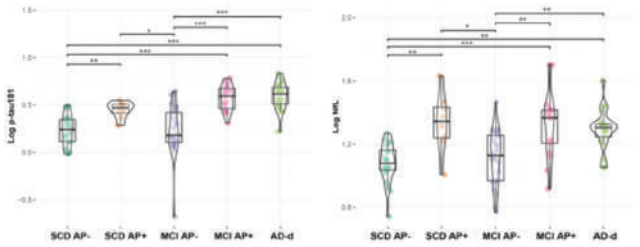
G. Giacomucci[1]; S. Mazzeo[1]; A. Ingannato[1]; C. Crucitti[1]; S. Bagnoli[1]; S. Padiglioni[2]; G. Galdo[1]; F. Emiliani[1]; D. Frigerio[1]; V. Moschini[3]; C. Morinelli[3]; S. Sorbi[1]; B. Nacmias[1]; V. Bessi[1]

[1]Department of Neuroscience, Psychology, Drug Research and Child Health, University of Florence, Florence, Italy; [2]Research and Innovation Centre for Dementia-CRIDEM, AOU Careggi, Florence, Italy; [3]SOD Neurologia I, Dipartimento Neuromuscolo-Scheletrico e degli Organi di Senso, AOU Careggi, Florence, Italy

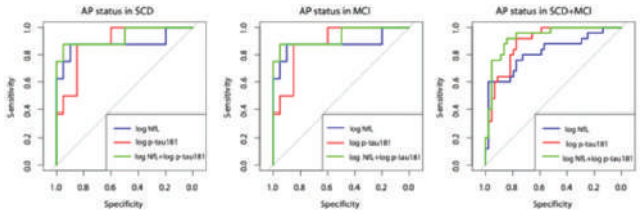
Background and Aims: We aimed to assess diagnostic accuracy of plasma p-tau181 and NfL separately and in combination in discriminating Subjective Cognitive Decline (SCD) and Mild Cognitive Impairment (MCI) patients carrying Alzheimer's disease (AD) pathology from non-carriers; to propose a flowchart for the interpretation of the results of plasma p-tau181 and NfL.

Methods: We included 43 SCD, 41 MCI and 21 AD-demented (AD-d) patients, who underwent plasma p-tau181 and NfL analysis. Twenty-eight SCD, 41 MCI and 21 AD-d patients underwent CSF biomarkers analysis (Aβ1-42, Aβ1-42/1-40, p-tau, t-tau) and were classified as carriers of AD pathology (AP+) it they were A+/T+ (regardless of N), or non-carriers (AP-) when they were A- (regardless of T and N), A+/T-/N-, or A+/T-/N+ according to the A/T(N) system.

Results: Plasma p-tau181 and NfL separately showed a good accuracy (AUC=0.88), while the combined model (NfL+p-tau181) showed an excellent accuracy (AUC=0.092) in discriminating AP+ from AP- patients. Plasma p-tau181 and NfL results were moderately concordant (Coehn's $k=0.50$, $p<0.001$). Based on a logistic regression model, we estimated the risk of AD pathology considering the two biomarkers: 10.91% if both p-tau181 and NfL were negative; 41.10% and 76.49% if only one biomarker was positive (respectively p-tau18 and NfL); 94.88% if both p-tau181 and NfL were positive.

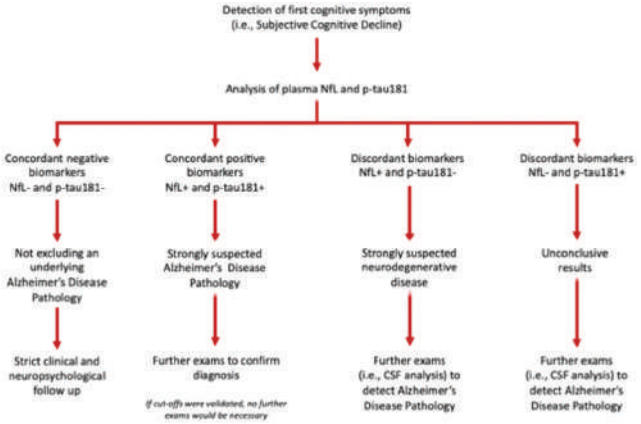


Plasma biomarkers levels across diagnosis/ATN groups.



ROC curves for accuracy of plasma p-tau181, NfL and the combined model (NfL+p-tau181) in distinguishing AP+ from AP- patients in SCD and MCI, considering both separately and together.

Conclusion: Considering the moderate concordance and the risk of presenting an underlying AD pathology according to the positivity of plasma p-tau181 and NfL, we proposed a flow chart to guide the combined use of plasma p-tau181 and NfL and the interpretation of biomarker results to detect AD pathology.



Flow chart for the potential use and interpretation of plasma biomarkers in clinical setting for the early detection of Alzheimer's disease

Disclosure: Nothing to disclose.

B. Rossi, Verona, Italy*

Background and Aims: Alpha-synucleinopathies, characterized by abnormal alpha-synuclein (a-syn) aggregates in the brain, exhibit varied clinical presentations, including distinct motor (Parkinson's Disease PD) and cognitive (Lewy Body Dementia DLB) forms. Pathological confirmation of a-syn-related pathology through minimally invasive techniques is crucial for neurodegenerative disease research. The Real-Time Quaking Induced Conversion assay (RT-QuIC) has been tested for a-syn detection in olfactory mucosa brushing (OMB) and cerebrospinal fluid (CSF), especially in PD patients. This study investigates dopamine transporter SPECT (DaT-SPECT) alterations' symmetry in DLB patients relative to RT-QuIC results in OMB.

Methods: Thirty-five DLB patients (27 males, 8 females) were enrolled, meeting McKeith's criteria. Mean age at OMB was 76 ±6 years, MMSE score 23.8 ±5. Patients were categorized into RT-QuIC-positive ($n=26$) and negative ($n=9$) groups. Thirty-one underwent DaT-SPECT; and BasGanV2 software was used for image post-processing, comparing them with normal controls to derive Z-scores. Non-parametric statistics assessed putamen and caudate Z-score asymmetry.

TABLE 1. Demographic characteristics of patients. Legend: DLB: Dementia with Lewy Bodies; pDLB: prodromal DLB; CCF: Core Clinical Features; VH: Visual Hallucinations; CF: Cognitive Fluctuations; Pk: Parkinsonism; RBD: Rem Sleep behavior Disorder; RWA: RE.

		Mean (SD)			CCF				
		Age, y	MMSE baseline	MMSE longitudinal	VH	CF	Pk	RBD_all	RWA
PDLB (n=18)		74.9 (5.3)	27 (1.9)	25.3 (4.3)	11/18 (61.1%)	9/18 (50%)	16/18 (88.9%)	12/18 (66.7%)	8/18 (44.4%)
	OMB +	74.7 (5.7)	26.9 (2.1)	25.6 (3.7)	10/14 (71.4%)	8/14 (57.1%)	12/14 (85.7%)	10/14 (71.4%)	7/15 (50%)
	OMB -	75.6 (4.5)	27.3 (1)	24.3 (6.8)	1/4 (25%)	1/4 (25%)	4/4 (100%)	2/4 (50%)	¼ (25%)
DLB (n=17)		77.6 (5.8)	20.5 (5)	13.8 (6.6)	12/17 (70.6%)	8/17 (47,1%)	15/17 (88.2%)	14/17 (82.4%)	9/17 (52.9%)
	OMB +	77.3 (6.2)	21.3 (5.5)	12.8 (7.2)	10/12 (83.3%)	5/12 (41.7%)	10/12 (83.3%)	10/12 (83.3%)	8/12 (66.7%)
	OMB -	78.6 (5.3)	18.6 (3.4)	16.8 (3.3)	2/5 (40%)	3/5 (60%)	5/5 (100%)	4/5 (80%)	1/5 (20%)

Results: Olfactory brushing was well tolerated by all participants. Statistically significant caudate asymmetry was found between RT-QuIC-positive and -negative OMB groups (positive: mean 0.1338 ±0.182, negative: mean 0.0337 ±0.187; $p=0.03$). No significant putamen difference was noted ($p=0.3$).

Conclusion: Our results confirm the frequent involvement of olfactory mucosa in DLB and validate RT-QuIC's diagnostic utility. OMB involvement can lead to a different spreading pattern of a-syn pathology. RT-QuIC in OMB is a novel diagnostic tool for alpha-synucleinopathies, well tolerated in DLB patients. Further research is needed to assess its prognostic value and correlations with other biomarkers.

Background and Aims: The discovery of meningeal lymphatic vessels in dura mater, also known as dural lymphatic vessels (dLVs) that depend on vascular endothelial growth factor-C (VEGF-C) expression has raised interest in their possible involvement in Alzheimer's disease (AD).
Methods: Here we induce sustained dLV atrophy or hyperplasia, by blocking or overexpressing VEGF-C in the APdE9 and 5xFAD mouse models of AD, resulting in impaired or improved macromolecular cerebrospinal fluid (CSF) drainage to cervical lymph nodes.
Results: In the AD mice, dLV morphology or function was not altered, dural amyloid beta accumulation was confined to blood vessels, and sustained manipulation of dLVs did not lead to significant changes in overall brain amyloid beta plaque load. Moreover, dLV atrophy did not alter the behavioral phenotypes of the AD mice but, interestingly, it improved CSF-to-blood drainage.
Conclusion: Our results indicate that sustained dLV manipulation does not affect amyloid beta deposition in the brain and that compensatory mechanisms promote CSF clearance.
Disclosure: Nothing to disclose.

EPR-133 | Exploring the association between frailty and Alzheimer's disease biomarkers

S. Buscarnera[1]; M. Canevelli[1]; F. Ribaldi[2]; G. Frisoni[2]; G. Bruno[1]
[1]*Department of Human Neuroscience, Sapienza University, Rome, Italy;* [2]*Centre de la Memoire, Département de réadaptation et gériatrie, Hopitaux Universitaires de Geneve, Geneve*

Background and Aims: The relationship between Alzheimer disease neuropathology and its clinical manifestation remains complex and it has been hypothesized that frailty, a measure of biological aging, could modify the association between them. We aimed to investigate the relationship between frailty and biomarkers of beta amyloid (A) and tau (T) pathology in a tertiary memory clinic population.
Methods: Data from 263 patients with dementia, mild cognitive impairment and cognitively unimpaired individuals were collected from the Memory Center of Geneva University Hospital. Frailty was measured using a 36-item frailty index (FI). We assessed A and T positivity through amyloid and tau PET or CSF. FI scores were compared between A- and T- versus A+ and T+ subjects. Linear regression models were used to explore the relationship between FI scores and the demographic and clinical features of participants. Longitudinal linear mixed models examined the impact of FI and biomarkers on cognitive decline.

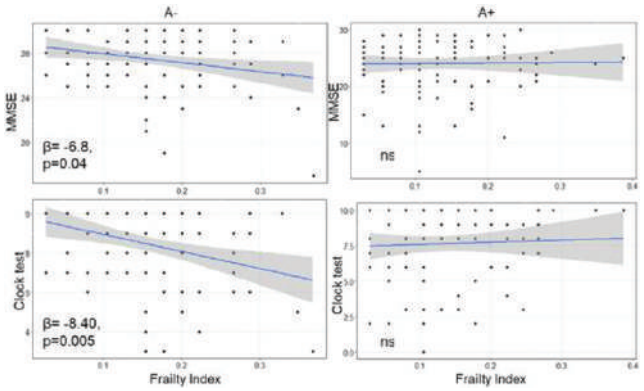
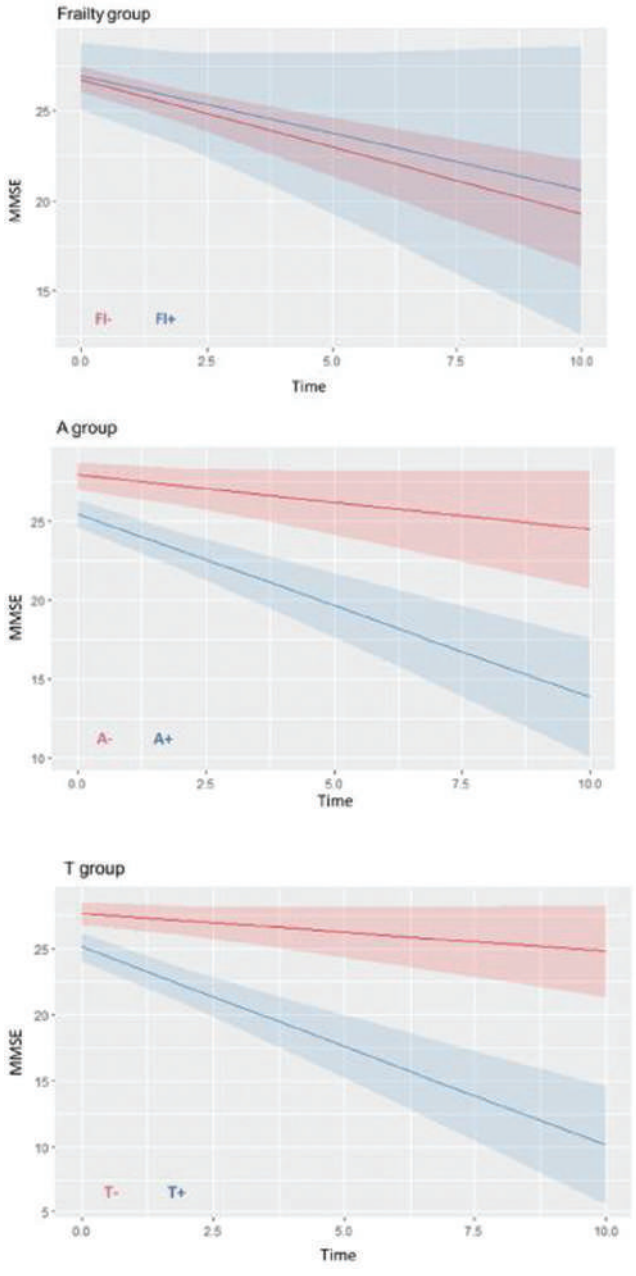
36	Pacemaker	0 no - 1 yes	

Frailty Index.

Results: The mean age was 70 (SD 8.6) years, and 52% were women. FI was positively correlated with age, depression and anxiety. FI was higher in A- and T- versus A+ and T+ ($p < 0.01$) separately; mean MMSE was higher in A-/T- than A+/T+ patients. In A- patients, FI correlated with MMSE ($\beta = -6.8$, $p = 0.04$) and Clock Test ($\beta = -8.40$, $p = 0.005$). Longitudinal models did not reveal statistically significant impact of FI on cognitive decline.



FI and neuropsychological tests in A subgroups.



Longitudinal models.

Conclusion: FI is higher in people with low levels of brain AD pathology. Next steps include to assess the prognostic value of FI in persons with or without AD biomarkers positivity.

EPR-134 | Cognitive and neuropsychological correlation with brain metabolism in C9Orf72 amyotrophic lateral sclerosis patients

F. De Marchi[1]; L. Mazzini[1]; M. Sarnelli[1]; L. Corrado[2]; R. Matheoud[3]; S. D'Alfonso[2]; R. Cantello[1]; G. Sacchetti[4]; C. Comi[5]; D. Perani[6]; G. Tondo[5]

[1]ALS Center, Neurology Unit, Department of Translational Medicine, University of Piemonte Orientale, 28100 Novara, Italy; [2]Department of Health Sciences, University of Eastern Piedmont, 28100 Novara, Italy; [3]Department of Medical Physics, Maggiore della Carità Hospital, Novara, Italy; [4]Department of Nuclear Medicine, Maggiore della Carità Hospital, Novara, Italy; [5]Department of Neurology, S. Andrea Hospital, University of Piemonte Orientale, Vercelli, Italy; [6]In Vivo Human Molecular and Structural Neuroimaging Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; Nuclear Medicine Unit, San Raffaele Hospital, Milan, Italy.

Background and Aims: C9ORF72 gene mutation accounts for a significant proportion of autosomal dominant ALS/FTD spectrum disorders. ALS patients' carriers of the C9Orf72 mutation (C9+) more commonly have an earlier disease onset, and a high frequency of severe cognitive impairment. In our preliminary report, we compared the 18F-FDG-PET imaging findings in a group of genetic patients, observing an extensive motor and prefrontal hypometabolism in fast progressors C9+ patients. This study aimed to expand the neuropsychological findings in C9+.

Methods: We included ten C9+ patients who underwent a complete neuropsychological evaluation and an 18F-FDG-PET scan at baseline. We obtained hypometabolism maps at a single-subject level following a validated voxel-based SPM procedure. The corresponding 18F-FDG-PET regional hypometabolism was extracted by anatomo-functional ROIs. Patients were divided into ALS-normal (ALS-no, $n=2$), ALS-behavior (ALS-bi, $n=2$), and ALS-cognitive (ALS-ci, $n=6$). The ROIs' hypometabolism was compared with scores in neuropsychological tests. Also, a mean hypometabolism map was derived in each cognitive group to underline brain metabolism differences between ALS-no, ALS-bi and ALS-ci.

Results: We observed several correlations between hypometabolism and anatomo-functional ROIs, such as, prefrontal areas and phonological fluency test (PFT) (r = -0.86, $p=0.03$), Frontal Assessment Battery (FAB) (r = -0.87, $p=0.002$) and Clock Drawing test (CDT) (r = -0.79, $p=0.01$); temporoparietal area and Short Story Test (0.73, $p=0.04$), CDT (r = -0.80, $p=0.001$). The ALS-no

have hypometabolism confined in motor regions; the ALS-bi group showed prominent hypometabolism in temporoparietal and limbic areas, and the ALS-ci group showed extended hypometabolism in motor/prefrontal regions.

Conclusion: The brain metabolism showed specific correlations with neuropsychological impairment in C9+ patients, and different hypometabolism maps based on the cognitive group.

Disclosure: Nothing to disclose.

EPR-135 | Single-center experience with nusinersen and risdiplam in spinal muscular atrophy types 2 and 3 in adults

L. Silva[1]; J. Moura[1]; D. Pereira[1]; L. Palhau[2]; T. Coelho[3]; M. Cardoso[3]; A. Sousa[3]

[1]Neurology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal; [2]Physical Medicine and Rehabilitation Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal; [3]Neurophysiology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal

Background and Aims: Spinal muscular atrophy (SMA) is an inherited neuromuscular disease with recent available genetic treatments. Risdiplam and nusinersen have shown significant benefits on motor function. We aim to analyze the evolution of our adult SMA cohort.

Methods: Retrospective single-center cohort study of adults with SMA. Demographic information, functional motor assessment scales and respiratory function tests were collected.

Results: We included 18 patients (10 SMA2 and 8 SMA3), 12(67%) men, median age of 32 (IQR = 14) years at the first treatment. The median follow-up time was 23 (IQR = 15) months. The median pre-treatment HFMSE and RULM scores were 4.5 (IQR = 17) and 16 (IQR = 22), respectively. Nusinersen was started in 8 patients (SMA3), 4 changed to risdiplam due to adverse events related to lumbar puncture. The median variation score for the other 4 patients [median age: 36.5 (IQR = 15) years] was 2.5 (IQR = 3.8) in HFMSE and 1 (IQR = 3.5) in RULM. The median change in the 6-minute walk test was −3.5 (IQR = 68) meters. Thirteen patients are treated with risdiplam [median age: 32 (IQR = 13) years], none with gait. The median changes in HFMSE and RULM scores were 0 (IQR = 1) and 0 (IQR = 2), respectively, with no differences between SMA types. The most reported subjective improvement was manual dexterity. The median FEV1/FVC ratio change was 1.5 (IQR = 4.5). One patient showed improved dysphagia.

Conclusion: In our cohort, there is clinical stabilization with those drugs counteracting the negative progression of the natural history of the disease.

Disclosure: Nothing to disclose.

EPR-136 | Prosaccadic alteration is associated with executive dysfunction in a cohort of ALS patients: A cross-sectional study

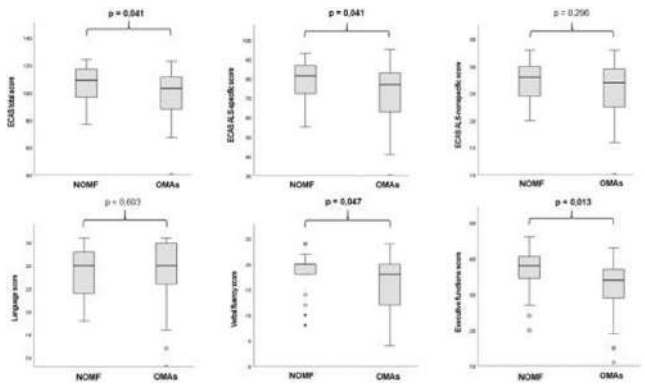
M. Olivero[1]; F. Verde[2]; A. Maranzano[2]; F. Scheveger[1]; F. Gentile[1]; E. Colombo[2]; C. Gendarini[1]; A. Cocuzza[1]; F. Girotti[2]; C. Morelli[2]; S. Messina[2]; V. Silani[2]; B. Poletti[2]; N. Ticozzi[2]

[1]Neurology Residency Program, University of Milan, Milan, Italy; [2]Department of Neurology and Laboratory of Neuroscience, IRCCS Istituto Auxologico Italiano, Milan, Italy

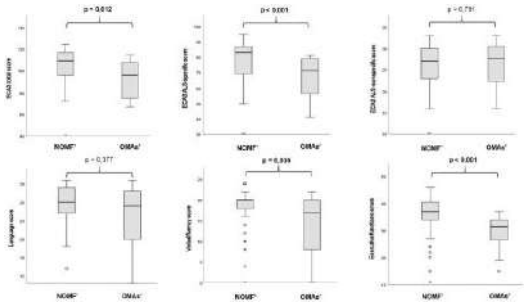
Background and Aims: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease affecting motor neurons, whose phenotype includes extramotor features, such as oculomotor abnormalities (OMAs) and cognitive-behavioral changes. The literature about OMAs, especially antisaccade alteration, detected by bedside neurological examination, is scarce. The aim of our study is to further investigate the characteristics of OMAs and to evaluate associations with clinical features in a cohort of ALS patients.

Methods: We enrolled a cohort of 80 inpatients with ALS. We assessed conjugate gaze, saccades, smooth pursuit and oculomotor praxia, testing for nystagmus. We evaluated cognitive-behavioral phenotype with the Edinburgh Cognitive and Behavioral ALS Screen (ECAS) – Italian version.

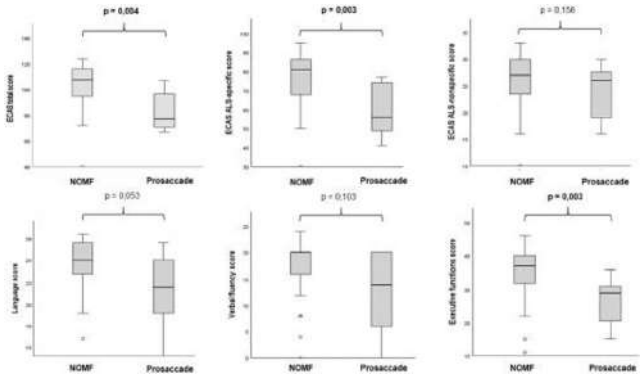
Results: We observed OMAs in 51.3 % and the most frequent was antisaccades dysfunction (82.9 %). We detected lower ECAS total score in ALS patients with OMAs versus normal oculomotor function (NOMF), predominantly in executive function subdomain. Afterwards, we excluded antisaccades variable from the analysis, creating OMAs' and NOMF' cohorts. We found a more significant difference in ECAS total score, mainly driven by executive function subdomain. Whereupon, we compared ECAS total score in patients with specific types of OMAs versus NOMF. We found lower scores in cases with pathologic prosaccades versus NOMF, mainly in executive function subdomain. Furthermore, we did not detect any difference in the frequency of behavioral symptoms in all cohorts analyzed.



Kruskal–Wallis analysis to compare ECAS total, domains and ALS-specific subdomains scores in OMAs versus NOMF ALS groups.



Kruskal–Wallis analysis to compare ECAS total, domains and ALS-specific subdomains scores in OMAs' versus NOMF' ALS groups.



Kruskal–Wallis analysis to compare ECAS total scores, domains and ALS-specific subdomains in prosaccadic alteration versus NOMF ALS groups.

Conclusion: We further confirm the association between cognitive impairment and OMAs in ALS. Prosaccades alteration strongly correlate with executive dysfunction, representing a promising clinical marker of neurodegeneration.

EPR-137 | Pridopidine for the treatment of ALS – results from the phase 2 Healey ALS platform trial

M. Geva[1]; J. Shefner[2]; B. Oskarsson[3]; Y. Cohen[1]; K. Chen[1]; M. Leitner[4]; S. Paganoni[5]; M. Cudkowicz[5]; M. Hayden[1]
[1]Prilenia Therapeutics B.V., Naarden, The Netherlands; [2]Barrow Neurological Institute, Phoenix, AZ; [3]Department of Neurology, Mayo Clinic, Jacksonville, FL; [4]Accelerating NeuroVentures, LLC, Needham, MA, USA; [5]Sean M. Healey and AMG Center for ALS and the Neurological Clinical Research Institute, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background and Aims: Pridopidine, a S1R agonist, was evaluated in the Phase 2 HEALEY ALS Platform Trial.

Methods: Participants had El Escorial possible, probable, or definite ALS, symptom onset <36mo and vital capacity >50%-predicted. Pridopidine 45 mg bid ($n=121$) was compared to a shared placebo ($n=164$). Primary endpoint was change from baseline through 24 weeks in ALSFRS-R. Secondary and exploratory endpoints included speech, respiration, and quality-of-life measurements. Nominal p-values are reported.

Results: Pridopidine was well tolerated, consistent with prior safety profile. Primary endpoint was not met in all participants. Statistically significant speech improvements were observed, including speaking rate (Δ0.19, $p=0.03$) and articulation rate (Δ0.21, $p=0.01$). Prespecified analysis of definite ALS and early participants showed lessening of decline in ALSFRS-R progression (Δ2.4, $p=0.19$), respiratory domain (Δ1.04, $p=0.18$), and improved dyspnea (Δ1.35, $p=0.014$). Less decline on the ALSAQ-40 quality-of-life scale (Δ-10.83, $p=0.018$), eating & drinking (Δ-19.18, $p=0.015$) and a trend in communication (Δ-13.04, $p=0.12$) were also observed. Post-hoc analysis of definite+probable ALS, early and fast progressors showed slowing of decline in ALSFRS-R (41% vs. placebo; Δ5.2, $p=0.04$), stability of dyspnea (Δ1.41, $p=0.02$) and speech (speaking rate; Δ1.08, $p<0.0001$ and articulation rate; Δ1.03, $p<0.0001$). A Kaplan-Meier survival analysis showed an increase of median survival time (~300 to 600 days) in definite+probable ALS and early participants ($n=37$) versus the delayed-start (168 days) placebo-to-pridopidine participants ($n=12$) (log rank $p=0.069$). The Cox Proportional Hazard Ratio, adjusted for baseline characteristics was 0.429 ($p=0.052$).

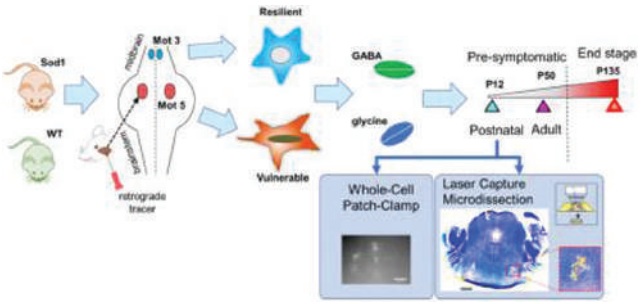
Conclusion: The beneficial effects of pridopidine were observed across multiple measures including survival benefits. These observations support conducting a Phase 3 study.

Disclosure: Prilenia Therapeutics is an industry partner of the HEALEY ALS Platform Trial. Full disclosures will be presented.

EPR-138 | Electrophysiological abnormalities in early stages of motor neuron pathology in G93A SOD1 mice

M. Wiedau[1]; X. Yang[2]; S. Chandler[2]; S. Venugopal[2]
[1]UCLA Neurology, Los Angeles, CA, USA; [2]UCLA Department of Integrative Biology and Physiology

Background and Aims: Motor neuron (MN) degeneration in ALS differs among neurons as MNs controlling extraocular and sphincter muscles remain resilient to degeneration. Efficient intracellular calcium buffering mechanism, enriched neurotrophic factors and genes involved in synaptic transmission including glutamate and GABA receptor subunits can affect neuronal resilience.
Methods: Utilizing transgenic SOD1G93A and wild type (WT) litter control mice at pre-symptomatic, adult and near end-stage, we compare longitudinal changes in pre-synaptic terminal proteins for GABA and glycine neurotransmitters of trigeminal jaw closer (JC) MNs (vulnerable MNs) and midbrain extraocular (EO) MNs (resilient MNs using in-vitro patch-clamp electrophysiology.



Methods Summary.
Results: GAD67 innervation in SOD1G93A trigeminal jaw closer MNs is reduced around age P12, relative to age-matched WT animals without significant difference around P50 and P135. Innate co-expression patterns of GAD67 and GlyT2 with co-dependency in EO MNs compared to JC in both SOD1G93A and WT mice at adult stages (P50 and P135) differ. Around P12 when GAD67 terminals expression was low in the mutant, in vitro patch-clamp electrophysiology showed that SOD1G93A JC MNs have reduced persistent GABA inhibition, relative to WT.
Conclusion: We show different innate co-expression patterns of GAD67 and GlyT2 with co-dependency in EO MNs compared to JC in both SOD1G93A and WT mice at adult stages and low GAD67 terminals expression in the P12 mutant with reduced persistent GABA inhibition in SOD1G93A JC MNs while pharmacological blocking of active GABA conductance disinhibited WT JC MNs and lowered their recruitment threshold, suggest a distinct pattern of intrinsic MN excitability.
Disclosure: Nothing to disclose.

EPR-139 | Risdiplam efficacy in spinal muscular atrophy patients: A single-center experience

O. Mihalache[1]; C. Vilciu[1]; M. Draghici[1]; A. Ene[1]; D. Petrescu[2]
[1]Department of Neurology, Fundeni Clinical Institute, Bucharest, Romania; [2]Department of Neurology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background and Aims: The study explores the outcomes of Risdiplam treatment in 20 adult Spinal Muscular Atrophy (SMA) patients, initiated between 2020 and 2023, in the Neurology II department, Fundeni Clinical Institute in Bucharest.
Methods: Regular evaluations were conducted every six months using the Hammersmith Functional Motor Scale Expanded (HFMSE), Revised Upper Limb Module (RULM), and 6-Minute Walk Test (6 MWT) assessment scales. Additionally, patients participated in structured interviews to capture subjective benefits reported by the individuals.
Results: Results revealed that 25% of patients improved on the assessment scales, while the remaining patients showed stabilization of motor functions. Notably, all patients reported subjective enhancements and an increased quality of life. Thirty-five percent of participants experienced improved swallowing and chewing, 45% reported increased strength in upper limbs, and 35% noted beneficial respiratory effects. Importantly, no adverse impact necessitating treatment interruption was observed.
Conclusion: The combination of quantitative assessments and patient-reported outcomes offers a comprehensive understanding of the multifaceted benefits associated with Risdiplam therapy.
Disclosure: Nothing to disclose.

EPR-140 | Genetics of amyotrophic lateral sclerosis (ALS): A population-based study in Serbia

A. Palibrk; I. Basta; S. Peric; I. Bozovic; V. Ivanovic; Z. Stevic
Neurology Clinic, University Clinical Center of Serbia, Belgrade, Serbia

Background and Aims: Although the pathogenesis of ALS is still unknown, the role of several genes in occurrence of this disease is known. Familial amyotrophic lateral sclerosis (FALS) accounts for 10%–20% of all ALS patients. The aim of our study was to examine the clinical characteristics of patients with FALS in Serbia.
Methods: This study included 171 patients with FALS, who were diagnosed between 2000 and 2022. Besides sociodemographic and clinical data, Revised Amyotrophic Lateral Sclerosis Functional Rating Scale (ALSFRS-r) was used. Level of significance was $p < 0.05$.
Results: Out of 1061 ALS patients diagnosed during this period, 171 patients had FALS (16%). Most common mutations were in SOD1 gene (63.7%), while 36.3% of patients had C9orf mutation. The average age at the disease onset was 53.94 $\pm$11.94, and FALS more commonly presented in male patients (54.1%). Patients with SOD1 mutation had more frequent spinal onset of the disease (86.1%),

objective sensory loss (46%) and sphincteric disorders (55%) compared to patients with C9orf mutation. While patients with C9orf mutation had a significantly later onset of the disease (59.4 ±8.9), more frequent presence of bulbar symptoms (86%), executive dysfunction (45%) and a higher degree of functional disability with an average value of the ALSFRS-r scale (34.7 ±7.1). Median survival time was significantly shorter in C9orf patients with 30 months, compared to 60 months in SOD1 patients.

Conclusion: Patients with C9orf mutation had significantly more severe clinical presentation, shorter survival time and a higher degree of functional disability compared to SOD1 patients.

Disclosure: Nothing to disclose.

EPR-141 | The relation between disease progression in amyotrophic lateral sclerosis and metabolic biomarkers

A. Motataianu[1]; B. Manescu[2]; L. Barcutean[1]; S. Andone[1]

[1]Department of Neurology, 'George Emil Palade' University of Medicine, Pharmacy, Science, and Technology of Targu Mures, Târgu Mures, Romania; [2]Department of Laboratory Medicine, 'George Emil Palade' University of Medicine, Pharmacy, Science, and Technology of Targu Mures, Targu Mures, Romania

Background and Aims: Amyotrophic lateral sclerosis (ALS), a progressive neurodegenerative disorder, has been extensively studied for its complex pathophysiology. In recent years, the relationship between metabolic biomarkers and the gut-brain axis has emerged as the new potential for therapeutic intervention.

Methods: This study investigates the relationship between metabolic biomarkers and the progression of ALS. We included a number of 44 ALS patients over 3 months followed for another 12 months. During this period, we collected blood samples to analyze various metabolic biomarkers and we also examined them using the ALS Functional Rating Scale (ALFSR). We also used DeltaFS (ΔFS) as a tool to analyze the disease's progression.

Results: The ALSFSR-Respiratory demonstrates positive associations with amylin and insulin while negatively correlating with MCP-1, indicating a potential link between respiratory symptoms and metabolic factors. Similarly, ALSFSR-Bulbar and ALSFSR-Fine motor subscores exhibit positive correlations with amylin, insulin, and leptin, unveiling potential connections between bulbar and fine motor symptoms and metabolic influences. Furthermore, the total ALSFSR score reveals positive correlations with amylin, GLP-1, and insulin, providing insights into the overall impact of these metabolic markers on the severity of ALS symptoms. Additionally, the study identifies GLP-1, glucagon, and MCP-1 as potential predictors for the time of diffusion and generalization of ALS symptoms. ΔFS values, indicative of accelerated disease progression, correlate inversely with amylin, C-peptide, insulin, and leptin.

Conclusion: Our study reveals a significant negative correlation between the progression rate and ALSFSR score in ALS and key metabolic biomarkers. This underscores the potential influence of metabolic dysregulation on the accelerated progression of ALS.

Disclosure: This work was supported by a grant of the Ministry of Research, Innovation and Digitization, CNCS – UEFISCDI, project number PN-III-P1-1.1-TE-2021-0960, within PNCDI III.

EPR-142 | Calculated maximal volume ventilation (cMVV) as a marker of early respiratory failure in ALS

U. Manera[1]; M. Torrieri[2]; C. Moglia[1]; A. Canosa[1]; R. Vasta[1]; F. Palumbo[1]; E. Matteoni[1]; S. Cabras[1]; M. Grassano[1]; A. Bombaci[1]; A. Mattei[3]; M. Bellocchia[4]; G. Tabbia[4]; F. Ribolla[4]; A. Chiò[1]; A. Calvo[1]

[1]'Rita Levi Montalcini' Department of Neuroscience, University of Turin, Turin, Italy; [2]Academic Neurology Unit, San Luigi Gonzaga University Hospital, Orbassano, Italy; [3]S.C. Pneumologia, S. Croce and Carle Hospital, Cuneo, Italy; [4]S.C. Pneumologia U, AOU Città della Salute e della Scienza di Torino, Turin, Italy

Background and Aims: Among the different pulmonary function tests (PFTs) used in ALS management, maximal voluntary ventilation (MVV) resulted to be able to capture early respiratory modification. In pulmonary disease, a calculated MVV (cMVV) is usually estimated by multiplying forced expiratory flow in first second (FEV1) or peak inspiratory flow (PIF) by a constant value. No study of cMVV in ALS has been performed yet.

Methods: We derived cMVV as prognostic biomarker in a center-based retrospective ALS population belonging to the Piemonte and Valle d'Aosta registry for ALS (PARALS). We collected the pulmonary function tests (PFTs) performed by ALS patients at diagnosis and during pulmonary assessment in the 1995–2015 period. According to current literature we derived cMVV using different methods. Correlation between cMVV other clinical variables were calculated and time-to-event analysis were performed evaluating both overall survival and time to NIV start.

Results: cMVV(40) significantly correlated with FVC% (0.626, $p < 0.001$), FEV1% (0.669, $p < 0.001$), ALSFRS-R total score (0.319, $p < 0.001$), PIF (0.693, $p < 0.001$), peak expiratory flow (PEF) (0.823, $p < 0.001$), pCO2 (-0.278, $p < 0.001$), HCO3- (-0.323, $p < 0.001$), BE (-0.318, $p < 0.001$) and pO2 (0.350, $p < 0.001$). Cox proportional hazard models adjusted confirmed that HRs for both survival and time to NIV decreased significantly with the increase of cMVV, especially in ALS patients with normal FVC% (≥80%).

Conclusion: cMVV is a marker of early respiratory failure in ALS, easily derivable from standard PFTs, especially for its identification in asymptomatic ALS patients with normal FVC measures.

Disclosure: Nothing to disclose.

Neuroepidemiology

EPR-143 | Decreasing number of deaths due to haemorrhagic stroke in Hungary: decreasing incidence or decreasing case fatality?

C. Hornyák[1]; T. Kovács[1]; A. Ajtay[2]; F. Oberfrank[3]; P. Vinnai[2]; D. Berecki[2]

[1]*Department of Neurology, Semmelweis University, Budapest, Hungary;* [2]*HUN-REN SU Neuroepidemiological Research Group, Budapest, Hungary;* [3]*Hungarian Academy of Sciences, Budapest, Hungary*

Background and Aims: Overall decrease in stroke mortality in the last decades in European countries are mostly explained by less severe strokes despite increasing or stable incidence. We tested if the decreasing annual number of deaths due to intracerebral haemorrhage (ICH) in Hungary is explained by a deceasing number of hospitalized cases or by less severe haemorrhagic strokes resulting in lower case fatality.

Methods: In the framework of the National Brain Research Program we evaluated claim forms submitted by hospitals of the whole country for a 17-year period of 2004–2020 using the NEUROHUN database. Case fatality for all cases with ICH (ICD-10 code of I61) was evaluated at 7 days, 30 days, 180 days and 1 year. As reporting neuroimaging was not always required for DRG reimbursement, in a sensitivity analysis we evaluated those cases where the reporting physician voluntarily declared that neuroimaging was performed.

Results: In the 17-year period, 61.732 patients had a discharge diagnosis of ICH. The annual number of hospitalized cases decreased from 4.520 in 2004 to 2.966 in 2020. Case fatality was 31.6% at 7 days, 45.9% at 30 days, 54.7% at 6 months and 57.6% at one year with only minor changes over the years. Similar case fatality rates were found in the sensitivity analysis of 31.069 cases (26.6%, 41.2%, 50.4% and 53.3% at the 4 time points).

Conclusion: the decreasing number of annual fatal cases due to ICH is explained mostly by decreased incidence and in a much smaller extent by a change in case fatality.

Disclosure: None.

EPR-144 | Epidemiology of late-onset multiple sclerosis: A population based-study

C. Cicero[1]; C. Chisari[1]; S. Toscano[1]; F. Manno[1]; G. Salafica[1]; R. Marziolo[2]; D. Maimone[2]; S. Lo Fermo[1]; M. Zappia[1]; F. Patti[1]; A. Nicoletti[1]

[1]*Department of Medical, Surgical Sciences and Advanced technologies G.F. Ingrassia, Section of Neurosciences, University of Catania, Via Santa Sofia 78, 95123, Catania, Italy;* [2]*Cannizzaro Hospital, Catania*

Background and Aims: Introduction: Multiple Sclerosis (MS) is defined as Late Onset Multiple Sclerosis (LOMS) when the onset occurs after 50 years. Across MS cohorts, the prevalence ranges from 0.6% to 12%, however little is known on the incidence of LOMS in the general population.

Methods: Methods: case ascertainment was conducted using the registries of all the MS centers of the province of Catania. Inclusion criteria for incident cases of LOMS were MS diagnosed according to McDonald criteria; patients older than 50 years at the disease onset; onset between 2005 and 2020; resident in the province of Catania at the time of the onset. Incidence rates (IR) have been calculated for the three quinquennia within the study period. Incidence rate ratios (IRR) have been computed to compare incidence rates.

Results: Results: 171 patients with LOMS were identified (104 women; 60.8%; mean age at onset 56 ±6 years). The average annual crude IR was 2.7/100,000 person-years (pyar) (95% Confidence Intervals, CI 2.31–3.13). Overall incidence risk was quite stable during the entire study period 2005–2020 (2.7/100,000 pyar). Nonetheless we observed an increased risk in the group aged 60–69 from 1.12/100,000 pyar during 2005 and 2010 to 3.12 during 2016–2020. When comparing the last quinquennum 2016–2020 to the first 2005–2010 the IRR was 2.79 (95%CI 1.13–7.81; *p*-value 0.01).

Conclusion: Conclusions: increasing MS incidence in older people may be due to a better accuracy in diagnosis as well as to the aging of the general population. However, possible role of environmental factors cannot be excluded.

Disclosure: Nothing to disclose.

EPR-145 | Incidence and mortality of ALS: A 42-year population-based nationwide study

H. Andersen

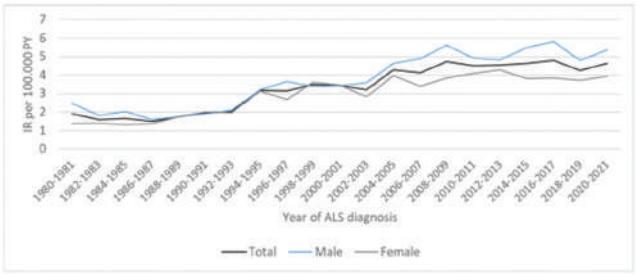
Department of Neurology, Aarhus University Hospital, Aarhus, Denmark

Background and Aims: Recent studies have suggested that the incidence rate (IR) of amyotrophic lateral sclerosis (ALS) and the rate of death (MR) from ALS are increasing. We aimed to examine 42-year trends in the incidence and mortality of ALS in Denmark.

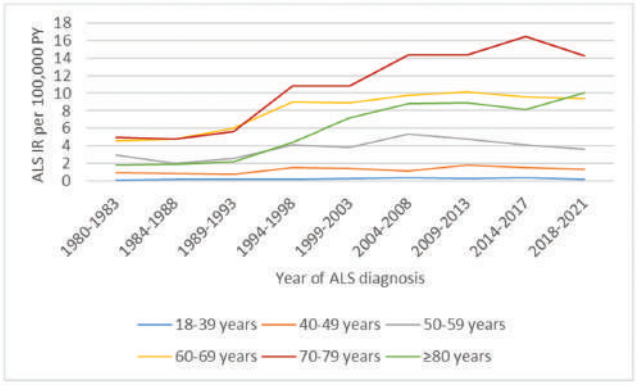
Methods: We retrieved individual-level data of all patients aged 18 and above with a first-time ALS. The IR and MR were calculated based on data from 1980 to 2021.

Results: We identified 5,943 patients with ALS and identified a total of 5,069 deaths among this nationwide population. The overall ALS IR was 3.4 per 100,000 persons per year (PY) (95% CI, 3.4–3.5). ALS incidence gradually rose with year of diagnosis, and the incidence rate ratio (IRR) was clearly higher (IRR, 2.8; 95% CI, 2.4–3.2) when comparing the latest period with the first. The incidence increase was primarily in patients aged ≥70 years. Incidence was associated with male gender compared with females (IRR, 1.3; 95% CI, 1.2–1.3) and rose with age at diagnosis in both genders and peaked in the age-group 70–79 years (IR, 10.9; 95% CI, 10.4–11.4). Parallel to the IR, the MR increased over time and particularly in patients aged

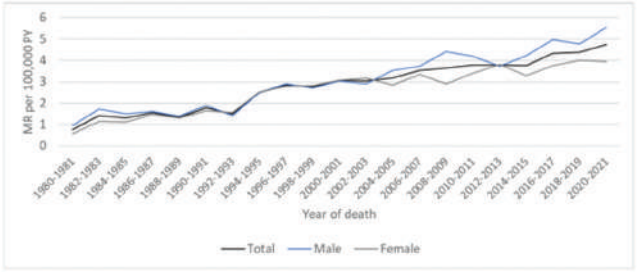
70 years and above. MR rose with age at diagnosis and peaked at the age of 75 years.



ALS incidence rates per 100,000 from 1980 to 2021 in males and females.



ALS incidence rate; age groups and year of diagnosis.



ALS mortality rates per 100,000 from 1980 to 2021 in males and females.

Conclusion: In Denmark the IR and MR of ALS steadily increased over a 42-year period, with important risk increase related to higher age. Thus, the number of elderly patients with ALS can be expected to increase considerably.

Disclosure: Nothing to disclose.

EPR-146 | Validation of the ICD-10 code DG61.8 for chronic inflammatory demyelinating polyneuropathy in Western Denmark

H. Haahr-Lillevang; L. Kjøbsted Markvardsen; H. Andersen
Department of Neurology, Aarhus University Hospital, Aarhus, Denmark

Background and Aims: Chronic inflammatory demyelinating polyneuropathy (CIDP) is an autoimmune disorder leading to muscle weakness and sensory loss. Identification of patients with CIDP for epidemiological studies is challenging. CIDP is diagnosed with ICD-10 code DG618, however the positive predictive value (PPV) is unknown. We aimed to determine the PPV of DG618 for CIDP and thereby calculate the incidence of CIDP in Denmark.

Methods: A complete list of patients diagnosed with DG618 in Denmark from 01.01.1996 to 31.12.2020 ($n=1856$) were obtained from the Danish Healthy Data Authority. Complete medical charts, biochemical workup and reports from imaging and neurophysiology were obtained for 352 patients from hospitals in Western Denmark. Records were validated using EFNS/PNS 2010 diagnostic criteria for CIDP; especially neurophysiology findings were revised meticulously.

Results: Only 91 (median age 60.4 years, 35 females) out of 352 patients fulfilled the criteria for CIDP resulting in a PPV of 25.9% for CIDP. Of confirmed CIDP patients 41 were typical and 50 atypical (20 distal, 16 asymmetrical, 6 pure motor and 3 sensory); 78 definite, 9 probable and 4 possible. The most frequent other diagnoses found were MGUS (Monoclonal Gammopathy of Undetermined Significance) and/or anti-MAG (Myelin Associated Glycoprotein) ($n=43$) and non-MGUS ($n=22$) demyelinating polyneuropathies not fulfilling CIDP criteria, Guillain-Barre syndrome ($n=39$), axonal ($n=21$) and neoplastic ($n=19$) polyneuropathies and spinal stenosis ($n=19$). Based on the PPV the incidence of CIDP is 0.35/100.000 person-years in Denmark.

Conclusion: The PPV of DG618 for CIDP is too low to use this code for epidemiological studies of CIDP using health registries.

Disclosure: This project was sponsored solely from resources from Aarhus University and Aarhus University Hospital. No company or interest organization was part of the study at any level. Helga Haahr-Lillevang, Lars Kjøbsted Markvardsen and Henning Andersen is currently undertaking another study sponsored by CSL Behring. Lars Kjøbsted Markvardsen participates in an advisory- or monitoring board for CSL Behring and furthermore have received payment for either lectures, presentations speaker's bureaus, manuscript writing or educational events from CSL Behring and Takeda Denmark.

EPR-147 | Prevalence, clinical profiles, and prognosis of Isaacs syndrome in Japanese nationwide survey

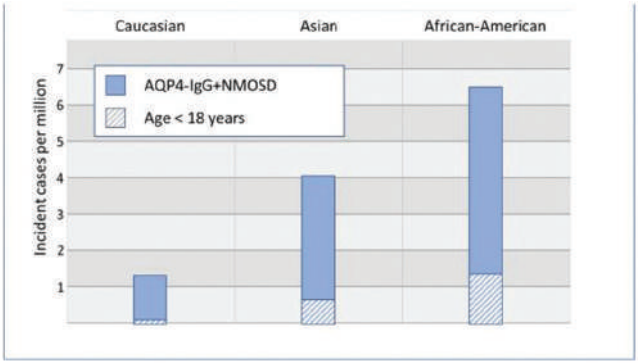
N. Matsui[1]; K. Tanaka[2]; Y. Sato[3]; S. Kuwabara[4]; Y. Izumi[1]
[1]*Department of Neurology, Tokushima University Graduate School of Biomedical Sciences, Tokushima, Japan;* [2]*Department of Animal Model Development, Brain Research Institute, Niigata University, Niigata, Japan;* [3]*Department of Preventive Medicine and Public Health, School of Medicine, Keio University, Tokyo, Japan;* [4]*Department of Neurology, Graduate School of Medicine, Chiba University, Chiba, Japan*

Background and Aims: To elucidate current epidemiological, clinical, and immunological profiles and treatments of Isaacs syndrome in Japan.
Methods: A nationwide mail survey was conducted using an established method. Data processing sheets were sent to neurology in hospitals and clinics throughout Japan to identify Isaacs patients who were seen between April 2018 and March 2021.
Results: The total estimated number of patients with Isaacs syndrome was 114 [95% confidence interval (CI): 89.63–138.92], and the estimated prevalence was 0.091 per 100,000 population. Detailed clinical profiles were available for 44 patients. The median age at onset was 40 years (range, 17–78 years), and 24 (55%) were female. The median time from symptom onset to diagnosis was 24 months (range, 1–372 months). Forty patients (91%) showed electrophysiological findings supporting peripheral nerve hyperexcitability. Antibodies to LGI-1 and CASPR2 in serum and/or CSF were examined for 28 patients by cell-based assay (CBA). Of these, 3 patients (11%) had both LGI-1 and CASPR2 antibodies and 3 patients (11%) had only LGI-1 antibodies. Thirty-six of 38 patients (95%) responded to immunotherapy. The median modified Rankin Scale (mRS) at baseline was 2, and median mRS at last follow-up was 1.5. The symptom severity was independent risk factors for poor outcome (mRS ≥3) in the Isaacs syndrome patients (Odds ratio, 10.33; 95% CI, 1.7–63.99).
Conclusion: This study provides the current epidemiological and clinical status of Isaacs syndrome in Japan. The outcome of Isaacs patients was similar to the previous studies, but more early diagnosis is needed.
Disclosure: Nothing to disclosure.

EPR-148 | Epidemiology of Aquaporin-4-IgG-positive NMOSD in Sardinia, Italy

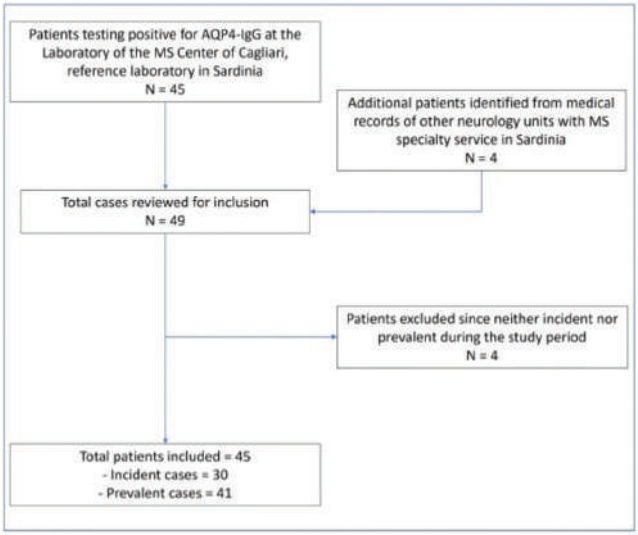
P. Zara[1]; M. Puci[1]; M. Pateri[2]; S. Othmani[1]; S. Sotgiu[1]; M. Saddi[3]; G. Fenu[4]; S. Leoni[1]; M. Melis[4]; G. Sotgiu[1]; P. Solla[1]; E. Cocco[2]; J. Frau[2]; E. Sechi[1]
[1]*Department of Medical, Surgical, and Experimental Science, University of Sassari;* [2]*Multiple Sclerosis Center, ASL Cagliari-University of Cagliari;* [3]*Ospedale San Francesco, ASL Nuoro;* [4]*Azienda Ospedaliera G. Brotzu, Cagliari*

Background and Aims: The Italian Island of Sardinia (population, 1,587,413) is well recognized as a high-risk area for multiple sclerosis (MS). It is unclear, however, whether other less common demyelinating diseases of the central nervous system (CNS) such as aquaporin-4-IgG-positive neuromyelitis optica spectrum disorder (AQP4-IgG+NMOSD) are similarly over-represented. We determined the incidence and prevalence of AQP4-IgG+NMOSD in Sardinia.



The bar graph shows the average reported incidence of AQP4-IgG+NMOSD per million person-years among Caucasians, Asians and African-Americans. Within each bar, the relative frequency of patients with pediatric onset (<18 years of age) is highlighted by diagonal lines.

Methods: Incidence was calculated between January 1, 2013 and December 31, 2022; while the prevalence day was December 31, 2022. Patients with AQP4-IgG+NMOSD were retrospectively identified using two sources: (1) Laboratory archives of the MS Center in Cagliari (reference and only laboratory for AQP4-IgG testing in Sardinia); and (2) medical records of the four Sardinian Units specialized in the treatment of MS and other CNS demyelinating disorders. Serum positivity for AQP4-IgG was assessed by cell-based assay.



The flow chart summarizes the steps towards identification of patients with AQP4-IgG+NMOSD.

Results: A total of 45 cases were included (incident, 30; prevalent, 41). The median age at disease onset was 51 (range, 6–78) years; 96% were Caucasian. The female to male ratio was 9:1. The crude incidence and prevalence were 1.9 (95% CI; 1.3-2.6)/million person-years and 2.6 (95% CI; 1.9-3.5)/100,000, respectively. After age-standardization to the World population, these estimates decreased to 1.3 (95% CI: 0.8-1.9)/million and 1.8 (95% CI: 1.2-2.5)/100,000, respectively.

Table 1 – Demographics and clinical characteristics for the full cohort of included cases with AQP4-IgG+NMOSD and for incident cases only; continuous and categorical variables are reported as median (range) and numbers (%)

	Full cohort (N=45)	Incident cases (N=30)
Age at disease onset	51 (6-78)	54 (17-78)
Onset age <18 years	3 (7%)	1 (4%)
Onset age 18-39 years	9 (20%)	4 (13%)
Onset age 40-64 years	21 (46%)	13 (43%)
Onset age 65+ years	12 (27%)	12 (40%)
Female sex	40 (89%)	28 (93%)
Ethnicity		
White	43 (96%)	29 (97%)
Black	1 (2%)	0 (0%)
Asian	1 (2%)	1 (3%)
Coexisting autoimmunity	23 (51%)	15 (50%)
Number of relapses	2 (1-15)	2 (1-6)
Presenting attack		
LETM	26 (57%)	21 (70%)
ON	13 (29%)	4 (13%)
Brain/brainstem attack	3 (7%)	3 (10%)
Combinations of the above	3 (7%)	2 (7%)
CSF-restricted OCB (≥2)	4/27 (15%)	3/19 (16%)
EDSS at last follow-up	4 (0-8.5)	3 (0-8.5)
Follow-up duration, years	6 (1-27)	3 (1-9)

Abbreviations – CSF = cerebrospinal fluid; EDSS n= expanded disability status scale-score; LETM = longitudinally extensive transverse myelitis; OCB = oligoclonal bands; ON = optic neuritis.

Demographics and clinical characteristics for the full cohort of included cases with AQP4-IgG+NMOSD and for incident cases only; continuous and categorical variables are reported as median (range) and numbers (%).

Conclusion: The incidence and prevalence of AQP4-IgG+NMOSD in Sardinia are comparable to those reported in other predominantly Caucasian countries (≈1/million and 0.8-3.3/100,000, respectively). The higher MS risk in the Island seems to be disease-specific and not paralleled by a higher risk for other CNS demyelinating diseases.

Disclosure: Nothing to disclose.

EPR-149 | The impact of patient factors on long-term institutionalization in Alzheimer disease

R. Manso Calderón[1]; M. Sevillano García[1]
[1]*Neurology Department, Complejo Asistencial Universitario de Salamanca, Salamanca, Spain*

Background and Aims: Our goal is to identify patient factors associated with institutionalization in Alzheimer disease (AD) in order to design interventions from which delay this step and reduce costs.

Methods: A descriptive study that prospectively recorded data of 479 consecutive patients who met NIA-AA criteria for AD (mean age 79.5 ±7.1 years, mean duration of dementia 4.1 ±3.9 years, 30.9% men) followed-up in a Dementia Unit.

Results: Overall, institutionalization occurred in 19.3% of participants. This was significantly more prevalent in housewives ($p=0.031$), patients with an older age ($p=0.02$) or a single or widowed status ($p<0.001$). Other factors associated with institutionalization were not only higher scores in Clinical Dementia Rating ($p<0.001$), Mini Mental State Examination ($p<0.001$), Barthel Index ($p<0.001$) and disease duration ($p=0.007$), but also the presence of delusions [OR=2.0-IC (1.3-3.1)-$p=0.003$], agitation [OR=3.1-IC (1.9–5.1)-$p<0.001$], epilepsy [OR=3.9-IC (1.5–10.4)-$p=0.004$], rapid progression [OR=1.9-IC (1.1–3.2)-$p=0.023$], antipsychotics [OR=3.7-IC (2.3–5.8)-$p<0.001$], anxiolytics [OR=1.8-IC (1.1–2.8)-$p=0.014$], no acetylcholinesterase inhibitors (AChEI) and/or memantine use [$p=0.022$] and multiple drug therapy ($p<0.001$). No differences were found in other neuropsychiatric symptoms, vascular risk factors, living in a rural or urban area, gender or education level.

Conclusion: A smaller family support network or being older than 80 years, the severity of disability, those symptoms related to dementia that cause more caregiver burden (psychosis) and no AChEI and/or memantine use predict institutionalization in AD. Identifying modifiable risk factors for institutionalization and, consequently, implementing appropriate measures can be an important step in AD care management.

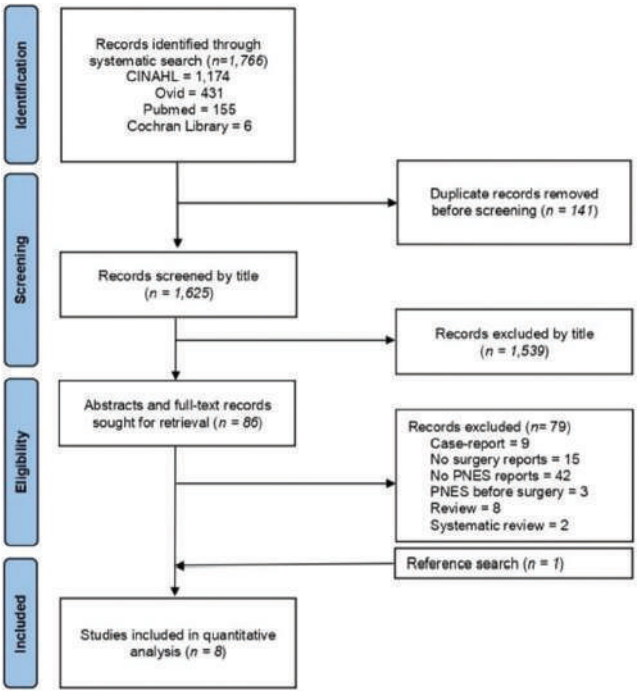
Disclosure: Nothing to disclose.

EPR-150 | New-onset psychogenic nonepileptic seizures after intracranial neurosurgery: A meta-analysis

R. Akhmedullin[1]; Z. Utebekov[2]; G. Kyrgyzbay[2]; D. Kimadiev[2]
[1]*Nazarbayev University School of Medicine;* [2]*RSE Medical Center Hospital of the President's Affairs Administration of the Republic of Kazakhstan*

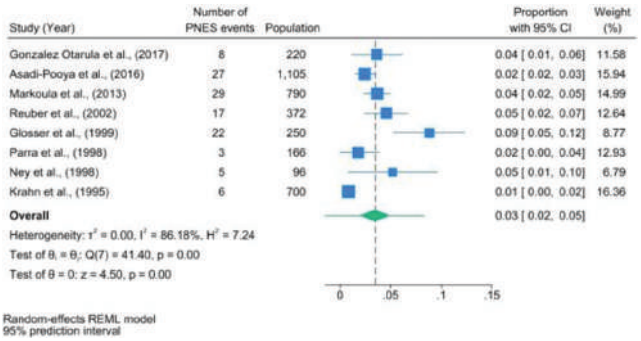
Background and Aims: PNES are among the most prevalent neurological conditions, its epidemiology and neurobiology remain unclear. Although approximately 14 million people need neurosurgical care annually, there is a dearth of thorough analysis on the PNES occurrence following surgery.

Methods: We conducted a comprehensive literature search of the PubMed, Ovid, CINAHL, and Cochrane Library databases until December 2023. We identified studies on the occurrence of PNES in patients underwent intracranial surgery, and confirmed diagnosis using video-EEG. Estimates are reported as both Freeman–Tukey transformed proportions and raw proportions using random effects models. We reported both 95% CIs and prediction intervals (PI). We assessed the risk of bias and identified the pooled odds ratio (OR) for mutually exclusive groups. The heterogeneity investigated using the I^2 statistic and significance determined using Cochran's Q-test p-value. Post-hoc Egger's regression test, and series of sensitivity analyses performed. This study was registered in PROSPERO.

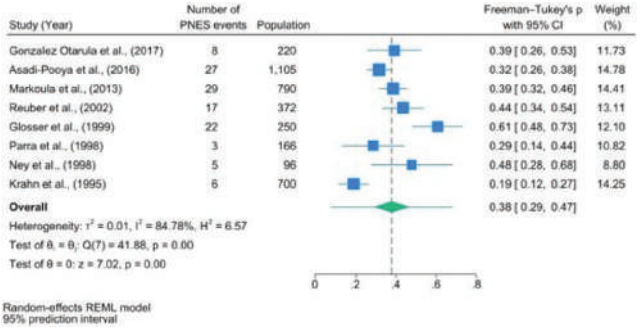


PRISMA.

Results: Of the 1766 studies identified, 86 were selected for the review. Eight studies ($n = 3,699$) were eligible for inclusion. Studies, spanning from 1995 to 2017, primarily focused on epilepsy surgeries. The pooled raw proportion was 3% (95% CI 2%-5%; 95% PI 0%-11%), Freeman-Tukey proportions were 0.38 (95% CI 0.29–0.47; 95% PI 0.08–0.68). Meta-analysis on surgery areas indicated two-fold increase in PNES following temporal resections (OR 2.05, 95%CI 0.81–5.19). Publication year and approximated reference population were associated with heterogeneity in estimates



Forest plot of raw proportions with prediction interval (inverse Freeman-Tukey's proportions).



Forest plot (Freeman-Tukey's transformed proportions).

Conclusion: These findings emphasize the importance of sustained video-EEG monitoring and psychiatric assessments. Careful assessments should become an essential component of care and integrated into clinical practice

Disclosure: Nothing to disclose.

EPR-151 | The prognosis of mild cognitive impairment: A systematic review and meta-analysis

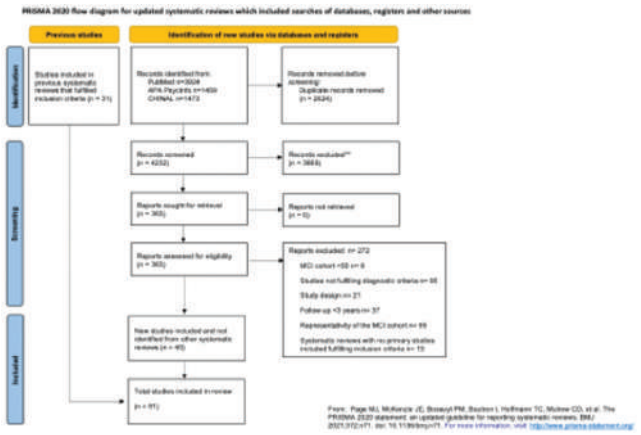
of Neuroinformatics, IRCCS Istituto Centro San Giovanni di Dio Fatebenefratelli, Brescia, Italy; [11]IUSS Cognitive Neuroscience (ICoN) Center, University School for Advanced Studies, Pavia, Italy; [12]Vita-Salute San Raffaele University, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; [13]President "Associazione Italiana Malattia di Alzheimer" – AIMA, Italy; [14]Department of Public Health and Infectious Diseases, Sapienza University, Rome, Italy

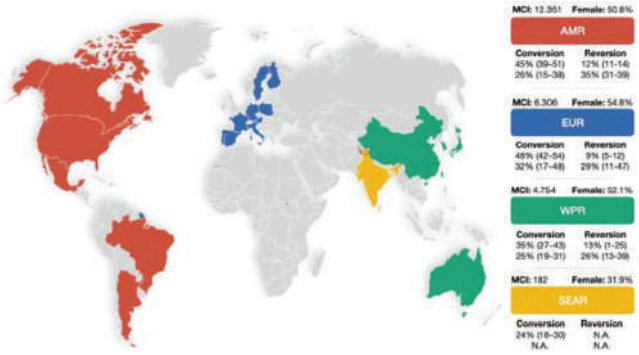
Background and Aims: Controversies persist on the prognosis of MCI: highly variable conversion rates have been described and reversion to normal cognition has only recently been analyzed. We updated the evidence on the risk of conversion to dementia integrating it with the recent data on reversion and stability rates. To our knowledge, this is the first systematic review that comprehensively evaluates the different cognitive trajectories of MCI.

Methods: All studies published up to June 2023 were retrieved by searching databases. We included studies evaluating the prognosis of MCI, with at least a 3-year follow-up. MCI and dementia diagnoses should align with established international criteria.

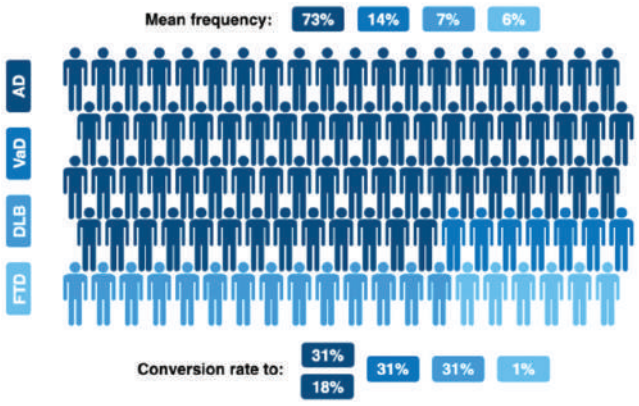


Prisma flow diagram

Results: We included 91 studies evaluating a total of 33.198 participants. Conversion and reversion rates were 43% (95%CI: 39%-46%) and 12% (95%CI: 7%-16%) in clinical-based studies and 28% (95%CI: 22%-35%) and 28% (95%CI: 17%-39%) in population-based studies. AD dementia was the most frequent diagnosis (72.0%) followed by VaD. FTD and DLB diagnoses showed higher mean frequencies in the clinical- compared with the population-based setting (7.0% vs. 4.9% and 6.1% vs. 3.4%, respectively).



World map of included studies by WHO regions.



Distribution of dementia subtypes.

Conclusion: We observed a probability of reverting to normal cognition three times higher in the population-based setting. Up to 50% of patients with MCI did not convert to dementia even in the studies with the longest follow-up (≥5 years) and annual conversion rates decreased with longer follow-ups. Our data might be helpful to improve clinical practice, provide context to ongoing and future studies on prognostic factors, and support the organization of sustainable and accessible dedicated care pathways.

Disclosure: Nothing to disclose.

Neurocritical care

EPR-152 | Periodic discharges and status epilepticus: A critical reappraisal

F. Misirocchi[1]; P. De Stefano[3]; I. Florindo[2]; P. De stefano[3]

[1]Unit of Neurology, Department of Medicine and Surgery, University of Parma, Parma, Italy; [2]Unit of Neurology, University Hospital of Parma, Parma, Italy; [3]EEG & Epilepsy Unit, Department of Clinical Neurosciences, University Hospital of Geneva, Geneva, Switzerland

Background and Aims: Periodic Discharges (PDs) in Status Epilepticus (SE) are historically related to negative outcome, and the Epidemiology-based Mortality Score in SE (EMSE) identifies PDs as

an EEG feature associated with unfavorable prognosis. However, supportive evidence is conflicting. This study aims to evaluate the prognostic significance of interictal PDs during and following SE.

Methods: All 2020–2023 non-hypoxic-ischemic SE patients with available EEG during SE were retrospectively assessed. Interictal PDs during SE (SE-PDs) and PDs occurring 24–72 h after SE resolution (post-SE-PDs) were examined. In-hospital death was defined as the primary outcome.

Results: 189 SE patients were finally included. SE-PDs were not related to outcome, while post-SE-PDs were related to poor prognosis confirmed after multiple regression analysis. EMSE global AUC was 0.751 (95%CI: 0.680–0.823) and for EMSE-64 cutoff sensitivity was 0.85, specificity 0.52, accuracy 63%. We recalculated EMSE score including only post-SE-PDs. Modified EMSE (mEMSE) global AUC was 0.803 (95%CI: 0.734–0.872) and for mEMSE-64 cutoff sensitivity was 0.84, specificity 0.68, accuracy 73%.

Conclusion: Interictal PDs during SE were not related to outcome whereas PDs persisting or appearing >24h after SE resolution were strongly associated to unfavorable prognosis. EMSE performed well in our cohort but considering only post-SE-PDs raised specificity and accuracy for mEMSE64 cutoff. This study supports the utility of differentiating between interictal PDs during and after SE for prognostic assessment.

Disclosure: Nothing to disclose.

EPR-153 | Prognostic value of signal abnormalities on brain MRI in post-anoxic super-refractory status epilepticus

F. Pasini[1]; S. Diamanti[2]; C. Capraro[3]; M. Patassini[3]; E. Bianchi[4]; M. Pozzi[5]; M. Normanno[5]; A. Coppo[5]; P. Remida[3]; L. Avalli[5]; C. Ferrarese[2]; G. Foti[5]; S. Beretta[2]

[1]Department of Neurology and Stroke Unit, ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy; [2]Epilepsy Center, Department of Neurology, Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy; [3]Neuroradiology Unit, Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy; [4]RCCS Mario Negri Institute for Pharmacological Research, Milan, Italy; [5]Department of Intensive Care, Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy

Background and Aims: Comatose patients following cardiac arrest experience refractory status epilepticus (SE) in about one-third of cases, potentially signaling an adverse prognosis. Nevertheless, the association between SE and hypoxic-ischemic brain injury (HIBI) radiological signs remains uncertain.

Methods: In this single-center retrospective study, we investigated the distribution of HIBI in post-anoxic super-refractory SE using brain MRI. Patients were classified into two groups based on cortical gray matter involvement. The study examined associations between these two patterns and outcomes, including neurological status at six months, SE resolution, consciousness recovery before discharge, and six-month mortality.

Results: From November 2012 to March 2023, 40 patients were included. HIBI distribution: basal ganglia (55%), cerebellum (46.2%), cerebral cortex (45%), hippocampus (28.7%), and thalamus (22.5%). HIBI was non-severe in 22 patients (55%, Group I) and severe in 18 (45%, Group II). Poor neurological outcome at 6 months was 27% in Group I and 83% in Group II (OR 13.3, CI 95% [2.81–63.11], $p < 0.001$). Consciousness recovery before discharge occurred in 73% of cases in Group I versus 22% in Group II (OR 9.3, CI 95% [2.1–39.9], $p = 0.003$). SE resolved in 95% of patients in Group I versus 67% in Group II (OR 10.5, CI 95% [1.1–97.9], $p = 0.032$). Mortality at 6 months was 40% in Group I versus 55% in Group II (OR 1.81, CI 95% [0.5–6.3], $p = 0.356$).

Secondary outcomes according to the severity of post-anoxic brain injury.

Conclusion: Severe HIBI was associated with increased chances of poor outcomes, reduced probabilities of consciousness recovery and SE resolution. Six-month mortality showed no significant difference between severe and non-severe HIBI patients.

Disclosure: Nothing to disclose.

EPR-154 | Mapping burst suppression and structural brain injury post-cardiac arrest

G. Velasquez[1]; P. Kandhare[1]; F. Jiang[1]; V. Jayabal[1]; M. Aghaeaaval[1]; B. Zhou[1]; J. Talbott[3]; E. Calabrese[2]; S. Gandhi[3]; J. Shih[1]; M. Otero[1]; C. Hemphill[1]; B. Westover[4]; S. Nagarajan[3]; J. Lee[5]; E. Amorim[1]

[1]Department of Neurology, University of California, San Francisco; [2]Department of Radiology, Duke University Medical Center; [3]Department of Radiology & Biomedical Imaging, University of California, San Francisco; [4]Department of Neurology Massachusetts General Hospital; [5]Department of Neurology, Brigham and Women's Hospital

Background and Aims: Burst suppression is a neurophysiological marker of severe hypoxic-ischemic brain injury post-cardiac arrest. This study's goal was to identify the neuroanatomical sources of burst suppression post-cardiac arrest.

Methods: MRI and EEG data from 86 comatose patients following cardiac arrest in two academic hospitals were retrospectively obtained. For EEG epochs with burst suppression detected, individual bursts were segmented and underwent whole brain source localization using the Champagne algorithm and mapped onto the Desikan-Killiany atlas. The eight regions with the highest EEG burst power (>90th percentile) were determined for each patient. Structural brain injury severity on MRI was measured using percent volume per ROI with apparent diffusion coefficient (ADC) $<650 \times 10^{-6}$ mm^2/s. The presence of brain injury on MRI was defined based on qualitative review of ADC maps.

Results: 39 (45%) patients had burst suppression and 23 (59%) had injury on MRI. Burst sources on EEG originated from bilateral lateral occipital lobes, pars triangularis, superior frontal regions, rostral middle frontal gyrus, and left middle temporal gyrus. Higher burst power was correlated with greater brain injury volume in bilateral lateral occipital lobes (Left: $r=0.209$, $p<0.01$; Right: $r=0.547$, $p<0.001$), bilateral pars triagularis (Left: $r=0.174$, $p=0.026$; Right: $r=0.413$, $p<0.001$), left superior frontal gyrus ($r=0.354$, $p<0.001$), and left middle temporal gyrus ($r=0.304$, $p<0.001$).

Table 1. Frequency of Regions Found in the Top 90th Percentile of EEG Burst Power

Hemisphere	Region	Frequency (Max n=39)	Mean Power Percentile (%)
Right	Inferiorparietal	20	96.27
Left	Lateraloccipital	19	96.40
Right	Lateraloccipital	16	96.84
Left	Middletemporal	20	95.76
Left	Parstriangularis	16	97.55
Right	Parstriangularis	15	97.81
Left	Rostralmiddlefrontal	14	95.66
Right	Rostralmiddlefrontal	12	96.94
Left	Superiorfrontal	13	95.81
Right	Superiorfrontal	19	94.20
Left	Superiorparietal	16	94.62

Figure 1. Correlation between EEG Burst Power & Percent Volume with ADC < 650

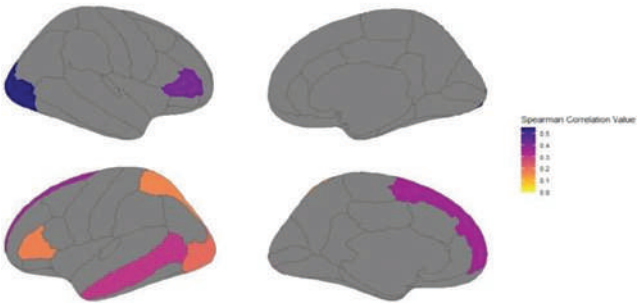

Table 2. Correlation between EEG Burst Power & Percent Volume with ADC < 650

Hemisphere	Region	Spearman Correlation	p-value
Left	Lateraloccipital	0.209	0.007
Right	Lateraloccipital	0.547	<.001
Left	Middletemporal	0.304	<.001
Left	Parstriangularis	0.174	0.026
Right	Parstriangularis	0.413	<.001
Left	Superiorfrontal	0.354	<.001
Left	Superiorparietal	0.167	0.033

Conclusion: Burst suppression post-cardiac arrest preferentially involves the lateral occipital lobes, pars triangularis, and superior frontal regions. Higher regional EEG burst power was associated with greater injury severity on MRI.

EPR-155 | Management of oral secretions following tracheostomy: A longitudinal prospective study from a Neurocritical Care Unit

A. M. Abu Baker[1]; S. Watve[2]; V. Devgire[2]; S. Eltringham[3]; A. Forrester[3]; K. P. S. Nair[2]
[1]University of Sheffield, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK; [2]Departments of Neurology and Neurorehabilitation, Directorate of neurosciences, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK; [3]Department of Speech and Language Therapy, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK

Background and Aims: Patients in Neurocritical Care Units (NCCU) who undergo tracheostomy may require interventions to manage oral secretions. This study reviewed the management of oral secretions and outcomes following tracheostomy among patients admitted to NCCU.

Methods: Longitudinal prospective study of patients requiring tracheostomy in NCCU.

Results: 54 (5.4%) of 999 patients admitted to NCCU required tracheostomy during the study period. The mortality among these patients was 11.1% ($n=6$). The tracheostomy tube could be removed in 59.3% ($n=32$). Tracheostomies were more common in males, low GCS at admission and those with cerebrovascular pathologies. 55.6% ($n=30$) of patients had oral secretion issues. 6 different types of drugs were used for secretion management; hyoscine hydrobromide was the most common among them, followed by glycopyrronium bromide and botulinum neurotoxin type-A. Presence of oral secretion management issues demonstrated significant associations with the total length of stay in NCCU, time taken for decannulation and need for recannulation, admission GCS, fibreoptic endoscopic evaluation of swallowing (FEES) referrals, pulmonary infections and oral candidiasis ($p<0.05$). Secretion issues were not significantly associated with seizures, delirium, hydrocephalus interventions, neurosurgical interventions and spasticity interventions ($p>0.05$). Incidence of chest infections was higher before the institution of secretion pharmacotherapies. Prevalence of oral candidiasis was higher among people who had oral secretion management.

Conclusion: This study highlights the impact of oral secretion management on outcomes following tracheostomy among patients in NCCU. It presents a case for early initiation of pharmacotherapy in managing oral secretions.

EPR-156 | Abstract withdrawn

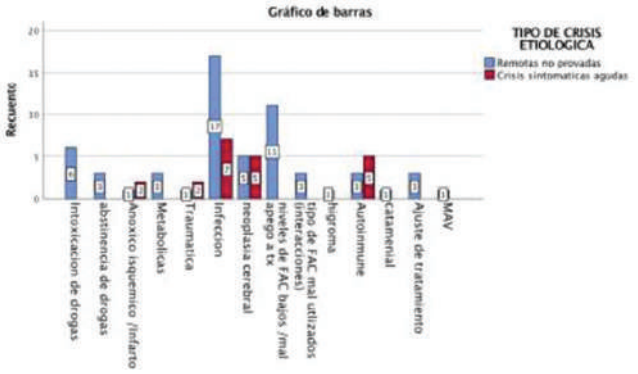
EPR-157 | Behavior of refractory status epilepticus in the Intensive Care Unit in Mexico: Case series

X. Vilchis; J. Cruz; M. Fernández González Aragón
National Institute of Neurology and Neurosurgery

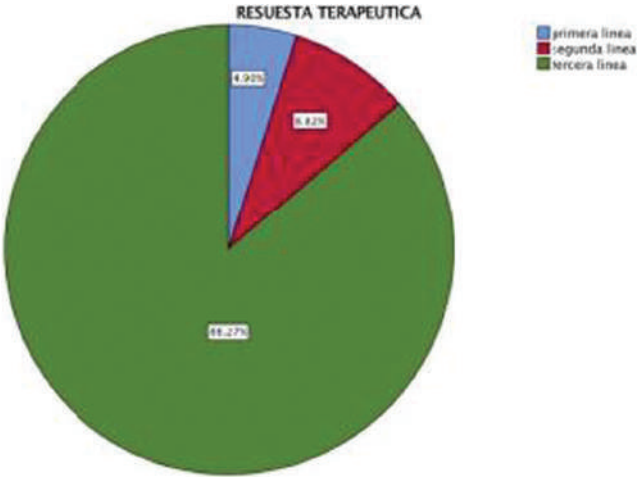
Background and Aims: Refractory status epilepticus has different characteristics with respect to established status epilepticus (SE).

Methods: A descriptive case series study. A total of 102 patients with SE in the ICU of the National Institute of Neurology and Neurosurgery (2010–2024) were evaluated. IBM SPSS statics was used for the descriptive statistical analysis.

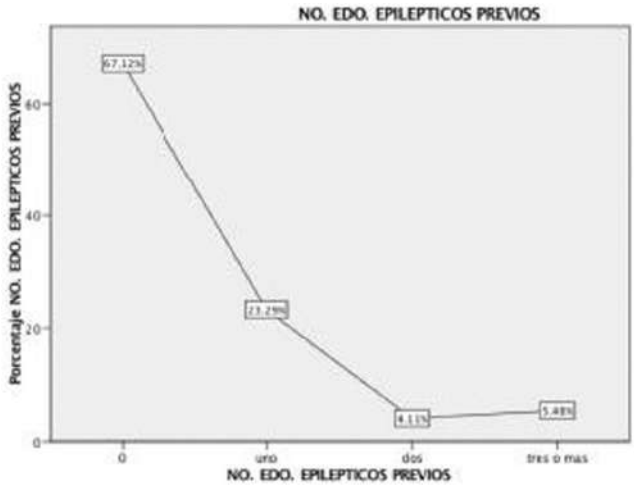
Results: The characteristics were female (53%), age 36.4+13.9 years with a diagnosis of epilepsy at 16.3+14.0 years in 73 patients of focal type (20/21) without severity (18/21) and of structural cause (51%), with encephalopathy (42/73), drug resistance (78%) and lack of control in the last month (44%), of which 24 had had at least one previous SE. Fifty-seven percent were admitted with stupor/coma (Glasgow 8.8+4.5 points) with infections identified as the major cause of exacerbation (30%) and serum levels of anti-seizures drugs decreased in 6%. EEG monitoring lasted 2.7+9.0 h, localizing severe (22%) frontal lobe activity (21%) and dysfunction (60%), identifying 21% of non-convulsive SE. Levetiracetam and valproate were the most used together with the use of IV anesthetics in 46% (midazolam 0.35+0.2 mg/kg/h or propofol 1.9+1.3 mg/kg/h) for 8.4+11.3 days (max 64); being that the use of mechanical ventilation was 12.8+15.2 days (max 91) with a final hospital days of 32.1+31.6(max 146). The 10.8% with extraordinary therapies including 11 patients who underwent surgery (partial callosotomy 3/11). The STESS scale of 2.4+0.8 points, leaving with major disability 35.3% (RANKIN 2.7+1.9) and a mortality of 13%.



Cause of status epilepticus.



Therapeutic response.



Number of previous status epilepticus.

Conclusion: SE in the UTI have demographic, clinical, neurophysiological, therapeutic and prognostic characteristics in the Mexican population.

Disclosure: Nothing to disclose.

EPR-158 | Efficacy of lumbar drains in reducing intracranial blood volume in patients with aneurysmal subarachnoid hemorrhage

R. Mertens[1;2]; M. Iqbal[1]; Z. Shaked[1]; K. Kersting[1]; K. Krantchev[1]; A. Janas[1]; P. Vajkoczy[1]; S. Wolf[1]

[1]*Department of Neurosurgery, Charité – Universitätsmedizin Berlin, Berlin, Germany;* [2]*Berlin Institute of Health at Charité – Universitätsmedizin Berlin, BIH Charité Junior Clinician Scientist Program*

Background and Aims: The utility of lumbar drainage (LD) in reducing unfavorable outcomes following aneurysmal subarachnoid hemorrhage (aSAH) has been established by the EARLYDRAIN trial(1). The underlying mechanism remains unelucidated. Here, we investigated the effect of LD on intracranial blood volume (IBV) in aSAH patients in comparison to no drainage or drainage via an external ventricular drain.

Methods: Different types of intracranial hemorrhage (basal SAH, cortical SAH, subdural hematoma, intracerebral and intraventricular hemorrhage) were manually segmented on longitudinal non-contrast enhanced CT scans of 68 patients treated at a single institution in the EARLYDRAIN trial using ITK-SNAP. Changes in IBV were analyzed and compared between patients treated with and without LD using generalized additive models.

Results: Twenty-eight patients were treated with and 40 without LD. No significant differences in demographic characteristics were observed. Total hemorrhage volume on admission was unevenly distributed among patients, with a median of 29.1 mL (range: 4.4-100.0 mL). No significant difference regarding initial hemorrhage volume was noted between the groups ($p=0.14$). LD was associated with a faster reduction of total IBV in the first 14 days following aSAH ($p=0.0003$), with a maximum difference observed between day 3 and 5. The reduction was most pronounced in the cortical SAH volume ($p=0.0027$), followed by the intraventricular ($p=0.069$) and basal SAH ($p=0.073$) components.

Conclusion: LD appears to contribute to a more rapid reduction of IBV measured by CT. This may indicate a potential mechanism serving as an explanation for the improved outcome by early application of LD in patients with aSAH. Further analysis is warranted.

EPR-159 | Deep peripheral blood mononuclear cell phenotyping aiming to separate early- and late-onset myasthenia gravis

J. Theorell[1]; A. Fower[2]; P. Ambrose[3]; V. Damato[4]; L. Handunnetthi[2]; S. Irani[5]; S. Brauner[6]; N. Wilcox[7]; A. Handel[2]; F. Piehl[6]

[1]*Department of Medicine, Huddinge, Karolinska Institutet, Stockholm, Sweden;* [2]*Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, UK;* [3]*Nottingham University Hospital Trust, Nottingham, UK;* [4]*Dipartimento di Neuroscienze, Psicologia, Area del Farmaco e Salute del Bambino, University of Florence, Florence, Italy;* [5]*Department of Neurology, Mayo Clinic, Jacksonville, Florida, USA;* [6]*Department of Clinical Neurosciences, Karolinska Institutet, Stockholm, Sweden;* [7]*Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, UK22*

Background and Aims: Myasthenia gravis (MG) is an autoimmune disorder of neuromuscular transmission, most commonly caused by autoantibodies towards the acetylcholine receptor (AChR+). The major MG subtypes without thymoma-association are early- and late onset MG (EOMG and LOMG). Divergences in age, sex ratio, HLA associations, autoantibodies and thymic hyperplasia suggest

different pathogeneses and potentially treatment needs for EOMG and LOMG patients. However, in clinical practice, the primary factor used for subgrouping is age. The main aim of the current project is to identify biomarkers by deep peripheral blood mononuclear cell (PBMC) phenotyping that could help to complement the separation of EOMG from LOMG by pathophysiologically sound criteria.

Methods: 1. Identification of cell populations and markers distinguishing EOMG from LOMG by single-cell trascriptomic, surface proteomic and B- and T-cell receptor analyses, in PBMC from 16 symptomatic patients, 8 each with EOMG or LOMG, all immunologically untreated, AChR+, plus a matched control set. 2. Checking the above screening hits by spectral cytometry in an independent replication cohort from Oxford of untreated AChR+ patients (13 with EOMG, 17 with LOMG) and 20 healthy controls.

Results: Initial screening identified populations of innate lymphoid/natural killer cells and CD4 T cells as most promising for separation of EOMG and LOMG. The replication analyses are ongoing and will be included in the presentation.

Conclusion: We have identified possible, biologically plausible, cell-surface biomarker candidates separating the two myasthenia patient subgroups, now being validated in an independent cohort. If confirmed, this may enable flow cytometry-based techniques to facilitate separation of the two MG subforms.

Disclosure: Funding for this study was received from the Swedish Wenner-Gren foundation, FT2021-0005, the Swedish MRC (grant no. 2020-02700) and EJPRD23-104 (OptiMyG) Jakob Theorell has received a fee for presenting at a Lundbeck-financed conference, not relating to this work. Susanna Brauner has received in non-restricted research grants from UCB Pharma and Janssen, not related to this study. Fredrik Piehl has received research grants from Janssen, Merck KGaA and UCB, and fees for serving on DMC in clinical trials with Chugai, Lundbeck and Roche, and preparation of expert witness statement for Novartis.

EPR-160 | The short chain fatty acid sodium butyrate protects for oxidative stress in the peripheral nervous system

C. Lohmann[1]; N. Rilke[1]; M. Shaygan Tabar[1]; B. Sarpong[1]; A. Blush[1]; M. Sgodzai[1]; X. Pedreiturria[1]; J. Motte[1]; T. Grüter[2]; R. Gold[1]; K. Pitarokoili[1]

[1]*Department of Neurology, St. Josef Hospital, Ruhr University Bochum, Bochum, Germany;* [2]*Department of Neurology, Evangelic Hospital Lippstadt gGmbH Wiedenbrücker Str. 33, 59555 Lippstadt, Germany*

Background and Aims: Butyrate is one of the short-chain fatty acids produced in the gut by bacteria during the anaerobic fermentation of indigestible fibers and is known for its immunomodulatory properties on T cells and macrophages through its binding to G-protein coupled receptors, free fatty acid receptors 2 and 3. This study describes for the first time the effects of butyrate in the peripheral nervous system via cultures of Schwann cells and dorsal root ganglia.

Methods: Survival of Schwann cells and outgrowth of dorsal root ganglia were evaluated after inducing oxidative stress with S-nitroso-N-acetyl-D-L-penicillamine treatment after pre-treatment with sodium butyrate. Furthermore, we performed an investigation of gene expression of the cell cultures after oxidative stress induction and sodium butyrate treatment as well as of the myelination of the nerve fibers under the influence of sodium butyrate in embryonic dorsal root ganglia and Schwann cell co-cultures.

Results: Coincubation of the Schwann cells with sodium butyrate 24 hours before induction of oxidative stress was able to protect the cells and reduce cellular death, visualized by microscopy and measured by propidium iodide staining. Furthermore, it modulated the gene expression of histone deacetylase 1 and 2, as well as the expression of the nuclear factor kB (NF-kB) and the protein kinase mammalian target of rapamycin (mTor).

Conclusion: We were able to demonstrate an anti-oxidative effect of sodium butyrate on Schwann cells through modulation of the expression of histone deacetylases. These effects might have therapeutical implications for patients with inflammatory and degenerative diseases of the peripheral nervous system.

Disclosure: Nothing to disclose.

EPR-161 | Evobrutinib ameliorates pathologies in a mouse model of neuromyelitis optica spectrum disorder

K. Chan[1]; H. Xue[1]; L. Yick[1]

[1]*Neuroimmunology and Neuroinflammation Research Laboratory, Department of Medicine, LKS Faculty of Medicine, the University of Hong Kong, Hong Kong, China*

Background and Aims: Neuromyelitis optica spectrum disorders (NMOSD) are autoimmune inflammatory demyelinating disorders of the central nervous system (CNS). Most NMOSD patients exhibit seropositivity for the pathogenic autoantibodies aquaporin-4-immunoglobulin G (AQP4-IgG). B cells play a crucial role in the mechanism underlying AQP4 autoimmunity. Bruton's tyrosine kinase (BTK) contributes to B-cell activation upon antigen recognition by B-cell receptor. The therapeutic potential of inhibiting BTK in NMOSD is unclear. We aim to study whether the BTK inhibitor evobrutinib ameliorates NMOSD-like pathologies in a mouse model of NMOSD with AQP4 autoimmunity [1].

Methods: Mice were immunized against AQP4 using in vivo electroporation [1]. Then mice received evobrutinib (oral gavage) or vehicle for 42 days. All mice were euthanized at day 42 for tissue harvesting. [1] Yick LW et al. JCI Insight 2023;e161003.

Results: AQP4 immunization triggered AQP4 autoimmunity and NMOSD-like spinal cord pathologies in mice. Immunofluorescence revealed prominent loss of AQP4 and GFAP, as well as patchy demyelination and axonal loss, in the spinal cord of AQP4 immunized mice compared to sham controls. Flow cytometry analysis demonstrated that AQP4 immunization caused the expansion of splenic memory B cells and plasma cells. Importantly, evobrutinib treatment improved

motor impairments, reduced AQP4 and GFAP loss, and decreased demyelination and axonal loss in AQP4 immunized mice. These were associated with reduction in the frequency of splenic antigen-presenting B cells. These results indicate that evobrutinib ameliorated NMOSD-like pathologies in mice with AQP4 autoimmunity.

Conclusion: Our findings suggest evobrutinib exerts therapeutic effect in NMOSD by modulating the function of B cells.

Disclosure: Nothing to disclose.

EPR-162 | CSF plasma cells produce highly specific autoantibodies in patients with LGI1/CASPR2 autoimmune encephalitis

L. Abrante[1]; D. Esser[1]; J. Dargvainiene[1]; G. Meyer zu Hörste[2]; M. Titulaer[3]; N. Melzer[4]; K. Wandinger[1]; F. Leypoldt[1]

[1]Institute of Clinical Chemistry, Christian-Albrecht University of Kiel and University Medical Center Schleswig-Holstein Kiel/Lübeck, Germany; [2]University of Münster, Münster, Germany; [3]Department of Neurology, Erasmus University Medical Center, Rotterdam, The Netherlands; [4]Department of Neurology, Heinrich-Heine-University Düsseldorf, Germany

Background and Aims: Autoimmune encephalitis (AE) are inflammatory diseases characterized by adaptive autoimmunity against synaptic proteins and receptors of the central nervous system (CNS). Autoantibodies targeting the neuronal proteins leucine-rich-glioma-inactivated-1 (LGI1) and contactin-associated protein-like 2 (CASPR2) define common subtypes of AE associated with cognitive dysfunction, epileptic seizures, and psychiatric syndromes. Although inflammatory changes of cerebrospinal fluid (CSF) are mostly absent and serologic findings have suggested primarily systemic autoantibody production, plasma cells in CSF and a strong HLAII restriction are hallmarks of these diseases.

Methods: To evaluate the role of clonally expanded plasma cells in the CSF of patients with LGI1 and CASPR2-AE, we analyzed the CSF of 5 untreated patients with AE (3 LGI1 and 2 CASPR2), using scRNA (10x, 5' and VDJ), and performed a comprehensive in silico analysis of their B cell repertoire. We synthesized recombinant antibodies (rHumAB) of the top 5-7 clonally expanded antibody-producing cells per patient and analyzed these rHumAbs for specificity, epitopes, affinity, and somatic hypermutation (SHM).

Results: Cell and tissue-based assays, and flow cytometry analysis, demonstrated that 10/10 rHumAbs from CASPR2 and 17/17 rHumAbs from LGI1 patients' CSF were indeed autoantigen reactive, with high avidity and affinity. These results were in line with an increased number of SHM and epitope complexity.

Conclusion: We conclude that patients with LGI1/CASPR2-AE harbor a high rate of intrathecally expanded, autoantigen-specific plasma cells in their CSF compartment, which suggests prominent local T-cells help driving the disease development. This finding needs to be considered for monitoring response to therapy and future therapy development.

Disclosure: "Nothing to disclose."

EPR-163 | Dysautonomia in anti-Hu paraneoplastic neurological syndromes

M. Villagrán-García[1]; A. Farina[1]; J. Arzalluz-Luque[2]; L. Campetella[1]; S. Muñiz-Castrillo[1]; M. Benaiteau[1]; E. Peter[1]; P. Dumez[1]; M. Rafiq[3]; B. Joubert[1]; J. Honnorat[1]

[1]French Reference Centre on Paraneoplastic Neurological Syndromes and Autoimmune Encephalitis, Hospices Civils de Lyon, Hôpital Neurologique, Bron 69677, France; [2]Department of Neurology, Hospital Universitario Virgen Macarena, Seville 41009, Spain; [3]Department of Neurology, University Hospital of Toulouse, Toulouse 31300, France

Background and Aims: Dysautonomia has been associated with paraneoplastic neurological syndrome (PNS)-related mortality in anti-Hu PNS, but its frequency and spectrum remain ill-defined. We describe anti-Hu patients with dysautonomia, estimate its frequency, and compare them to patients without dysautonomia.

Methods: Patients with anti-Hu antibodies diagnosed in the study centre (1990–2022) were retrospectively reviewed; those with autonomic signs and symptoms were identified.

Results: Among 477 anti-Hu patients, 126 (26%) had dysautonomia (the only PNS manifestation in 7/126, 6%); gastrointestinal (82/126, 65%), cardiovascular (64/126, 51%), urogenital (24/126, 19%), pupillomotor/secretomotor (each, 11/126, 9%), and central hypoventilation (10/126, 8%). Patients with isolated CNS involvement less frequently had gastrointestinal dysautonomia than those with peripheral (alone or combined with CNS) involvement (7/23, 30% vs. 31/44, 70% vs. 37/52, 71%; $p=0.002$); while more frequently central hypoventilation (7/23, 30% vs. 1/44, 2.3% vs. 2/52, 4%; $p<0.001$) and/or cardiovascular alterations (18/23, 78% vs. 20/44, 45% vs. 26/52, 50%; $p=0.055$). Median [95%CI] overall survival was not significantly different between patients with (37[17;91] months) or without dysautonomia (28[22;39] months; $p=0.78$). Cardiovascular dysautonomia (HR:1.57, 95%CI[1.05;2.36]; $p=0.030$) and central hypoventilation (HR:3.51, 95%CI[1.54;8.01]; $p=0.003$) were associated with a higher risk of death, and secretomotor dysautonomia a lower risk (HR:0.28, 95%CI[0.09;0.89]; $p=0.032$). Patients with cardiovascular dysautonomia dying ≤1 year from clinical onset had severe CNS (21/27, 78%), frequently brainstem (13/27, 48%), involvement.

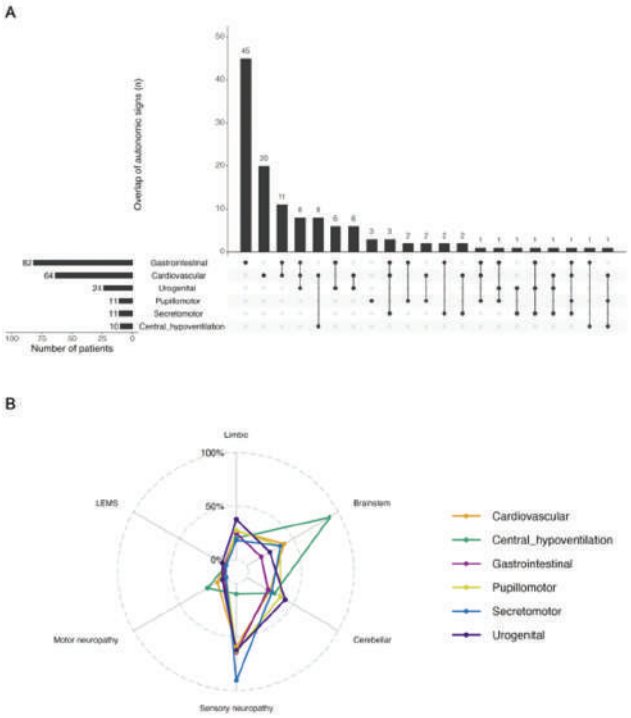

FIGURE 1. Characterisation of autonomic and extra-autonomic neurological involvement. (A) Upset plot presenting the numbers and different combinations of autonomic involvement in $n = 126$ patients with anti-Hu PNS. Each row represents an autonomic domain, th.

Abbreviations: n, number.

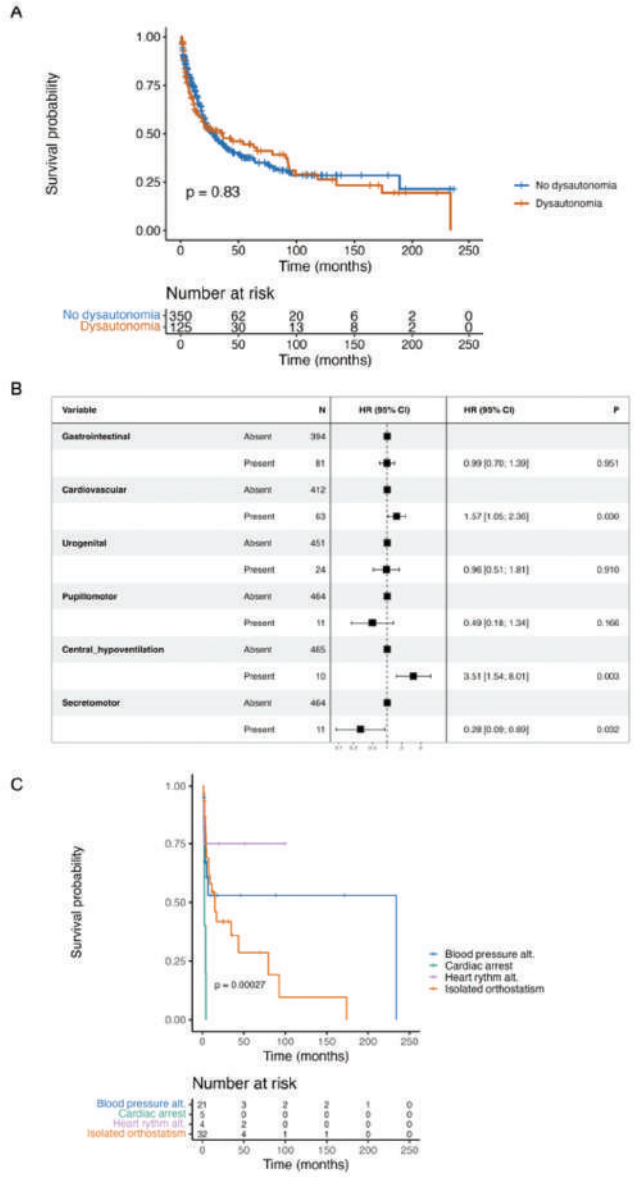

FIGURE 2. Survival analyses. (A) Kaplan-Meier curves according to the presence or absence of dysautonomia. Tick marks indicate censored patients, and the comparison was made using the Log-rank test. Two patients had to be excluded due to missing date of P.

Conclusion: Anti-Hu PNS dysautonomia is rarely isolated, frequently gastrointestinal, cardiovascular and urogenital. CNS dysfunction, particularly brainstem, associates with lethal cardiovascular alterations and central hypoventilation, while peripheral involvement preferentially associates with gastrointestinal or secretomotor dysautonomia, being the latest more indolent.

Box 7072, Kampala, Uganda; [3]Laboratory of Parasitic Diseases, National Institutes of Health, Bethesda, MD; [4]Ministry of Health, P.O Box 7272, Kampala, Uganda; [5]Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, L35QA, UK; [6]Medical Research Council/Uganda Virus Research Institute and London School of Hygiene & Tropical Medicine Uganda Research Unit, P.O Box 49, Entebbe, Uganda; [7]Centre for Tropical Medicine and Global Health, University of Oxford, Oxford, OX3 7FZ, UK; [8]Department of Psychiatry, St John's College, University of Oxford, St Giles, Oxford OX1 3JP; [9]Nuffield Department of Clinical Neurosciences, John Radcliffe Hospital, University of Oxford, Oxford, OX3 9TH, UK

Background and Aims: Nodding syndrome (NS) is a complex neurological disorder of unknown aetiology. Here we investigated the role of autoimmunity to neuronal antigens in NS patients.

Methods: We screened for the presence of leiomodin-1 and neuronal antibodies in plasma and CSF of 240 NS patients enrolled in a phase II trial of doxycycline for the treatment of NS. Plasma was tested for antibodies to Onchocerca volvulus (Ov16 and Ov3261) and leioimodin-1. Filarial worm infection was defined as a positive antibody test to any of the two Onchocerca volvulus antigens. CSF was tested by immunohistochemistry (IHC) on rodent brain sections and by antigen specific cell-based assays for neuronal proteins and leiomodin-1.

Results: A total of 232/240 (96.7%) plasma samples tested positive for Onchocerca volvulus. Leiomodin-1 antibodies were detected in 77/240 (32.1%) plasma samples and in 26/240 (10.8%) CSF samples. Circulating leioimodin-1 antibodies (76/232 [32.8%] Ov16/Ov3261 positive vs. 1/8 [12.5%] Ov16/Ov3261 negative, $p=0.044$) but not CSF leioimodin-1 antibodies (25/232 [10.8%] Ov16/Ov3261-positive vs. 1/8 [12.5%] Ov16/Ov3261-negative, $p=1.0$) was associated with Onchocerca volvulus infection. However, CSF leiomodin-1 antibodies were more likely to be present in patients with myoclonic seizures or drop attacks. Neuropilar staining by IHC was found in 28/240 (11.7%) NS CSFs. Among them, 2 had GABAbR antibodies and one had CASPR2 antibodies. Only 8/28 (28.6%) patients had both leiomodin-1 and neuropilar antibodies.

Conclusion: NS is associated with infection by Onchocerca volvulus and circulating antibodies to leioimodin-1. In addition, patients with CSF leioimodin-1 antibodies present with myoclonic seizures and drop attacks.

Disclosure: None

EPR-165 | Improvements in pain and quality of life after inebilizumab in attack-free NMOSD participants

O. Aktas[1]; F. Paul[2]; H. Hartung[3]; D. Sato[4]; J. Burton[5]; M. Smith[6]; W. Rees[6]; K. Patterson[6]; B. Cree[7]

[1]Department of Neurology, Medical Faculty, Heinrich Heine University Düsseldorf, Düsseldorf, Germany; [2]Experimental and Clinical Research Center, Max Delbrück Center for Molecular Medicine and Charité – Universitätsmedizin Berlin, Berlin, Germany; [3]Department of Neurology, Heinrich Heine University Düsseldorf Faculty of Medicine, Düsseldorf, Nordrhein-Westfalen, Germany; [4]School of Medicine, Pontifical Catholic University of Rio Grande do Sul (PUCRS), Port Alegre, Brazil; [5]Departments of Clinical Neurosciences and Community Health Sciences, University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [6]Amgen Inc, Thousand Oaks, CA, USA; [7]UCSF Weill Institute for Neurosciences, Department of Neurology, University of California San Francisco, San Francisco, CA, USA

Background and Aims: Chronic pain and disability contribute to decreased quality of life (QoL) in NMOSD. Previous analyses showed year-over-year improvements in pain and QoL with inebilizumab. Here we further evaluated Pain and QoL improvement in attack-free, inebilizumab participants over 3-years to determine improvements in non-attack-related pain and QoL.

Methods: N-MOmentum (NCT02200770) had 6-month-randomized-control-period (RCP) with an open-label-extension-period (OLP) of ≥2 years. Year-over-year changes in pain (SF-36-Bodily-Pain-Score [BPS]), QoL (SF-36-physical-component-summary[PCS]), and disability (Expanded-Disability-Status-Scale[EDSS]) were assessed for significance using mixed linear models in 95 participants who were attack-free with ≥3-years of inebilizumab. Sensitivity analysis was conducted in 72/95 participants who were attack-free for ≥6 months prior to inebilizumab treatment to control for acute attack-related recovery.

Results: At Baseline, 38% (36/95) participants reported an abnormal QoL score (SF36-PCS <40), 89% (32/36) of these reported increased pain (SF36-Bp <40) and 50% (18/36) reported significant disability (EDSS ≥5). After 3-years of inebilizumab, QoL scores improved in 89% (32/36) of attack-free participants with an abnormal baseline QoL score. 39% (37/95) of participants had abnormal pain scores (SF36-BPS <40) at baseline and improvements were reported in 78% (29/37) $p < 0.001$ after 3-years of inebilizumab. SF36-PCS and BPS scores also improved in participants with normal (≥40) baseline scores after 3-years of inebilizumab. Improvements in EDSS from baseline to 3-years of inebilizumab were observed in 44% (40/91) of participants including 36% (25/69) with less disability (<5 EDSS) and 68% (15/22) with greater disability (≥5 EDSS) at baseline. These results were consistent with the sensitivity analysis.

Conclusion: Year-over-year Improvements in Pain, QoL, and EDSS were observed in attack-free participants on inebilizumab. Interestingly, these improvements were independent of acute attack-related recovery.

EPR-166 | Bone marrow granulopoiesis instructs B cell-mediated neuroinflammation and autoimmunity

Q. Liu

Tianjin Medical University General Hospital, Tianjin 300052, China

Background and Aims: B cells are active participants in autoimmune etiology. Bone marrow hematopoietic stem and progenitor cells (HSPCs) are integrative hubs to sense immune activation and orchestrate inflammation. Yet the alterations of bone marrow HSPCs in B cell-mediated autoimmunity and their potential impact on disease progression remain unknown. Neuromyelitis optica spectrum disorder (NMOSD) is a B cell-mediated autoimmune neurological disease with autoantibodies to aquaporin-4 (AQP4-IgG) in 75% of patients.

Methods: We assessed bone marrow HSPC activity and B cell development using combined approaches of single cell sequencing and flow cytometry. We examined the safety and efficacy of belimumab in 14 patients with NMOSD and followed up for at least 52 weeks.

Results: In patients with NMOSD, we found remarkably augmented granulopoiesis in bone marrow, accompanied by expansion of B cell clones. This aberrant granulopoiesis is mediated by hyperactive JAK-STAT signaling, leading to a significant increase of neutrophils that produce BAFF to drive the generation of antibody-secreting cells and AQP4-IgG. Augmented neutropoiesis is also observed in NMOSD patients receiving rituximab who experienced a relapse. In an open-label, single-arm trial of belimumab, an anti-BAFF monoclonal antibody, in 14 NMOSD patients, belimumab prevented relapse and reduced the production of antibody-secreting cells and AQP4-IgG.

Conclusion: Thus, targeting bone marrow niche presents a new avenue to treat patients with NMOSD and perhaps other immune-mediated central nervous system diseases.

Disclosure: Nothing to disclose.

Neuro-oncology

EPR-167 | Primary meningeal melanocytic tumors (PMMT): A review from the Ultra Rare Brain Tumors domain of the EURACAN

A. Pellerino[1]; R. Verdijk[2]; L. Nichelli[3]; N. Andratschke[4]; A. Idbaih[5]; R. Goldbrunner[6]

[1]Division of Neuro-Oncology, Department of Neuroscience "Rita Levi Montalcini", University and City of Health and Science Hospital, Turin, Italy; [2]Department of Pathology, Section Ophthalmic Pathology, Erasmus MC University Medical Center Rotterdam, Rotterdam, The Netherlands; Department of Pathology, Leiden University Medical Center, Leiden, The Netherlands; [3]Department of Neuroradiology, Sorbonne Université, Assistance Publique-Hôpitaux de Paris, Groupe Hospitalier Pitié-Salpêtrière-Charles Foix, Paris, France; [4]Department of Radiation Oncology, University Hospital Zurich, University of Zurich, Zurich, Switzerland; [5]P-HP, Hôpitaux Universitaires La Pitié Salpêtrière-Charles Foix, Sorbonne Université, Inserm, CNRS, UMR S 1127, Institut du Cerveau-Paris Brain Institute, ICM, Service de Neurologie 2- Mazarin, Paris, France; [6]Center for Neurosurgery, Department of General Neurosurgery, University of Cologne, Cologne, Germany

Background and Aims: PMMT are ultra rare entities with distinct histological and molecular features as compared with other melanocytic or pigmented intracranial lesions.

Methods: The EUropean Network for RAre CANcers (EURACAN) Task Force on Ultrarare Brain Tumors (domain 10) has perfomed a literature revision from January 1985 to December 2023 regarding the evidence of epidemiologic and clinical characteristics, histological and molecular features, radiological findings, and activity of local and systemic therapies.

Results: Molecular analysis can detect specific mutations, including SF3B1, EIF1AX, BAP1, NRAS and BRAF, that are found in PMMT and not in other melanocytic lesions. Neuroimaging shows the leptomeningeal involvement with or without parenchymal lesions with meningeal base implant, delineate the extension with respect to adjacent structures, but cannot reveal the aggressiveness of the disease. Gross-total resection is the first choice in case of circumscribed meningeal melanocytoma and melanoma; conversely, meningeal biopsy may be reserved for patients with diffuse and multinodular leptomeningeal spread to achieve a definitive diagnosis. High-dose radiotherapy is rarely indicated in diffuse melanocytic tumors except as palliative treatment to alleviate symptoms. A definitive advantage of a specific systemic treatment over other could not be concluded, as most of the data available derive from case reports or small cohorts.

Conclusion: As PMMT are extremely rare, weak correlations between clinical characteristics, molecular profile, radiological findings at diagnosis and progression, and poor evidence on the best therapeutic approach are available thus far. There is the need to develop shared platforms and registries to capture more knowledge regarding these ultra rare entities.

Disclosure: The authors declare no conflict of interest.

EPR-168 | Severe myasthenia gravis and myositis overlap syndrome following CAR T cell therapy for B cell non-Hodgkin lymphoma

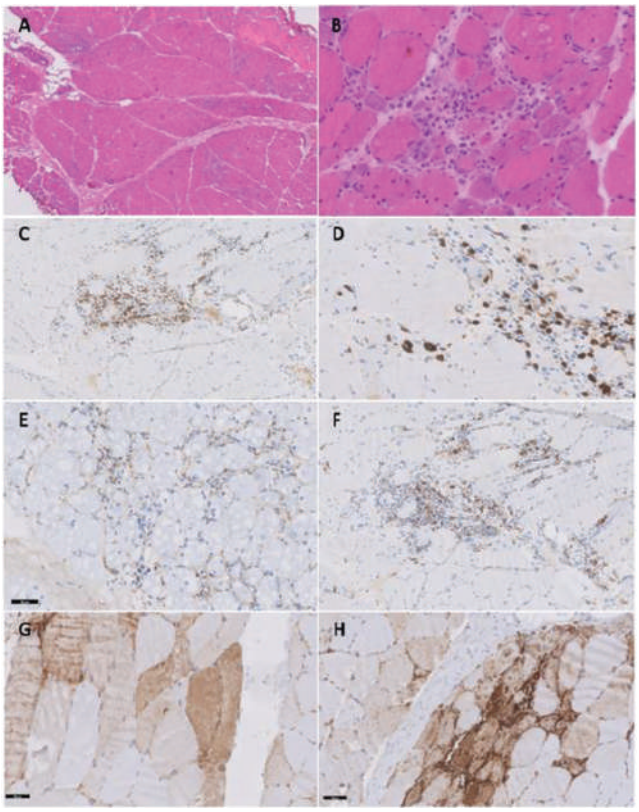
A. Llanes Ferrer[1]; R. Pariente-Rodríguez[2]; M. Palacios Berraquero[3]; C. García-Hoz[2]; A. Lario[3]; E. Rodríguez Martín[2]; I. García de la Torre[2]; F. Martín Moro[3]; P. Garay Albízuri[1]; B. Martínez García[1]; D. Pérez Gil[1]; S. Sainz de la Maza[1]; G. García Ribas[1]; A. Chinea Rodríguez[3]; M. Villar[2]; I. Corral[1]

[1]Neurology Department, Hospital Ramón y Cajal, Madrid, Spain; [2]Immunology Department, Hospital Ramón y Cajal, Madrid, Spain; [3]Haematology Department, Hospital Ramón y Cajal, Madrid, Spain

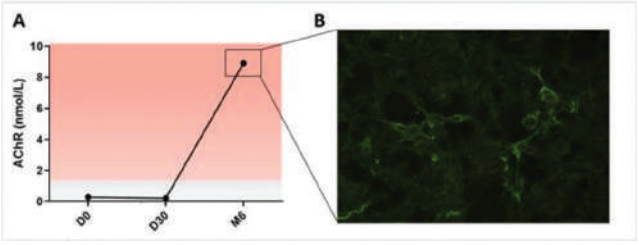
Background and Aims: Chimeric antigen receptor (CAR) T-cell therapy has significantly improved prognosis of relapsed/refractory B-cell lymphomas (DLBL). However, it can generate potential life-threatening complications. Reports of delayed immune-related adverse events (irAEs) are extremely rare. Here we describe the first case of neurological irAE following CAR-T therapy.

Methods: Case report.

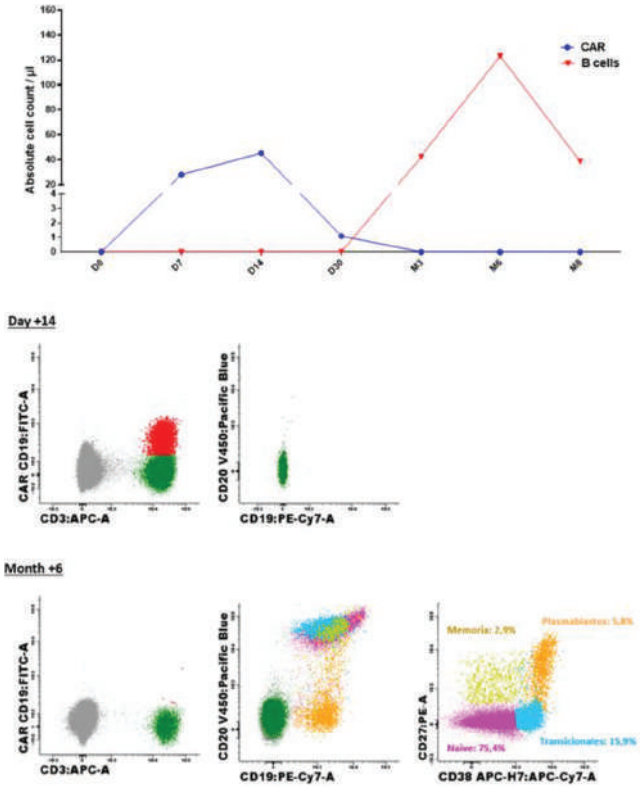
Results: A 68-year-old man with history of relapsed DLBL received CAR-T therapy (axicabtagene-ciloleucel), with complete metabolic response. Six months later he developed progressive proximal muscle weakness, dysphagia, and respiratory failure requiring invasive mechanical ventilation. DLBL relapse was ruled out by CT-scan and core-needle biopsy. Diagnostic workup showed elevated creatine kinase concentrations [1685 U/L (normal range 38-174)], myopathic signs on EMG, inflammatory TCD8+ infiltrates on muscle biopsy (Figure 1), pathological single-fibre EMG, and positive anti-acetylcholine-receptor (anti-AChR) antibodies. Anti-AChR antibodies were tested in two historical sera of the patient with negative results (Figure 2). Flow cytometry analysis showed undetectable circulating CAR-T cells, with complete reconstitution of B compartment (Figure 3). He was finally diagnosed with a severe myasthenia gravis (MG) and polymyositis overlap syndrome. Treatment with high-dose corticosteroids, intravenous immunoglobulins, support therapies, and prolonged physiotherapy were required for significant clinical improvement at one-month follow-up [modified Rankin Scale: 1; MG-Activities of Daily Living: 3/24 (12 points improvement)].



Deltoid muscle biopsy compatible with polymyositis: necrotic fibres (A-B), inflammatory aggregates of TCD8+ lymphocytes (C-D), scarce complement deposits (E), frequent macrophages CD68+ (F), and intense immunoreactivity in anti-HLA-1 staining (G-H).



(A) Evolution of anti-AChR antibodies titles, analysed with ELISA: immediately before CAR-T infusion (D0), on first month (D30), and on sixth month (M6) coinciding with symptom-onset. (B) shows cell-based assay (Euroimmun) positivity confirmation.



Expansion kinetics of anti-CD19 CAR-T cells and B-cell counts in peripheral blood, analysed by flow cytometry (A). Peak expansion of CAR-T cells (in red) on day 14 (B). Undetectable CAR-T cells with reconstitution of B compartment on month 6 (C).

Conclusion: To our knowledge, this is the first late-onset neurological irAE described with CAR-T. The cause of immune tolerance-breakdown is not yet identified. In our case, it occurred after CAR-T cells ceased to be detectable, coinciding with complete reconstitution of the B compartment. Further investigation of the mechanisms involved is warranted.

Disclosure: None.

EPR-169 | Neuronal injury and neurofilaments abnormalities in patients treated with anti-CD19 CAR-T cells

A. Vilaseca[1]; A. Zabalza[1]; G. Iacoboni[2]; C. Carpio[2]; M. Sánchez[2]; H. Ariño[1]; X. Montalban[1]; P. Barba[2]; Á. Vidal-Jordana[1]
[1]*Department of Neurology and MS Centre of Catalonia (Cemcat), Vall d'Hebron University Hospital, Barcelona, Spain;* [2]*Hematology Department, Vall d'Hebron University Hospital, Barcelona, Spain*

Background and Aims: Patients receiving anti-CD19 Chimeric Antigen Receptor (CAR) T-cell therapy may develop Immune Effector Cell-Associated Neurotoxicity Syndrome (ICANS) after infusion. Information regarding the occurrence of neuronal injury during ICANS is scarce. Our goal was to describe serum neurofilament light chain (NfLs) dynamics after anti-CD19 CAR T-cell therapy, comparing patients who developed ICANS with a control cohort who did not.

Methods: This was a nested case–control study within a prospective cohort that included all anti-CD19 CAR-T-treated patients at a single center. Cases manifested ICANS, with matched controls lacking ICANS. We assessed NfLs levels (normalized Z-scores) at baseline, Day 7, and Day 14 post CAR-T administration. Comparative risk analyses, linear mixed analysis with a split-plot design, and ROC analysis for optimal NfLs cut-off to differentiate ICANs presence and grade ≥2 were performed.

Results: We identified 32 cases and 24 controls. Yescarta use (OR6.6; 95%CI 2.0–21.7) and CRS occurrence (OR4.8; 95%CI 1.1–20.8) increased ICANS risk. Baseline NfL concentrations were elevated in both cases and controls versus normal expected values ($p=0.025$, $p=0.032$, respectively; Figure 1). In the Split-plot design, day 7 NfLs were significantly higher in ICANS grade ≥2 (means Z-score 2.19 and 1.60, respectively; $p=0.022$), with no differences at baseline and Day 14 (Figure 1). Patients lacking ICANS on Day 7, with NfLs exceeding Z-score >2.197, exhibited a higher incidence of ICANS grade ≥2 (38.5%vs. 4.6%, $p=0.01$).

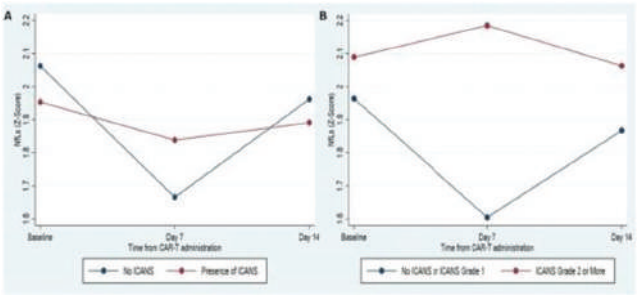


FIGURE 1. Linear Mixed Analysis by ICANS Presence (A) and ICANS Grade 2 or more (B).

Conclusion: Patients with ICANS grade 2 or higher exhibit an increase in NfLs compared to patients without ICANS or who only develop ICANS grade 1, being a Z-score ≥ 2.197 the best cut-off value to differentiate them.

Disclosure: Grant (CM22/00247).

EPR-170 | Neuroimaging and neuropsychological features of hypothalamic syndrome after craniopharyngioma

R. Balestrino[1]; F. Freri[2]; V. Castelnovo[2]; E. Canu[2]; B. Silvia[2]; L. Albano[1]; M. Losa[1]; L. Barzaghi[1]; A. Castellano[4]; A. Falini[4]; F. Agosta[2]; P. Mortini[1]; M. Filippi[2]

[1]Department of Neurosurgery and Gamma Knife Radiosurgery, IRCCS San Raffaele, Milano, Italy; [2]Neuroimaging Research Unit, Division of Neuroscience, IRCCS Ospedale San Raffaele, Milan, Italy; [4]Neuroradiology Unit, IRCCS Ospedale San Raffaele, Milan, Italy

Background and Aims: Hypothalamic obesity (HO) and neuropsychological deficits are common in craniopharyngioma (CP) patients, significantly impacting their quality of life. The study aimed to uncover shared pathogenetic pathways between obesity and psychological disturbances in individuals with HO following CP.

Methods: Fourteen CP patients (7 with HO, 7 without) underwent comprehensive assessments, including neuropsychological evaluations, functional magnetic resonance imaging (fMRI) tasks related to eating behavior and emotional recognition, and cortical thickness analysis. Correlations between cortical thickness and the expression of oxytocinergic pathway genes were explored.

Results: CP HO patients exhibited reduced bilateral insula cortical thickness correlating with eating behavior questionnaire scores. Increased insula activity, along with other hedonic network regions, was observed. CP patients showed greater anterior cingulate cortex activation during fMRI tasks. In emotional recognition tasks, CP HO subjects displayed increased prefrontal region activation. No correlation was found with oxytocin gene expression, but a significant correlation with oxytocin receptor gene expression was observed.

Conclusion: These findings align with obesity studies, indicating altered brain activation in CP HO resembling patterns associated with pleasurable food processing and lacking inhibitory control seen in CP. Oxytocin may offer therapeutic potential for reinstating physiological emotional processing in CP HO subjects post-CP, as suggested by gene expression correlations indicating conservation of areas expressing oxytocin receptors.

Disclosure: Nothing to disclose.

EPR-171 | IL6 blockade: An effective approach in steroid-refractory immune checkpoint inhibitor-related neuropathies

C. Baek[1]; N. Kramkimel[2]; M. Mongin[3]; T. Gendre[4]; T. Maisonobe[5]; D. Psimaras[1]; C. Birzu[1]

[1]Neuro-oncologie, Hôpital Pitié Salpêtrière APHP, Paris, France; [2]Dermatologie et vénérologie, Hôpital Cochin APHP, Paris, France; [3]Neurologie, Hôpital Avicenne APHP, Bobigny, France; [4]Neurologie, Hôpital Mondor APHP, Créteil, France; [5]Neurophysiologie, Hôpital Pitié Salpêtrière APHP, Paris, France

Background and Aims: Immune checkpoint inhibitor-related neuropathies (irAE-np) are generally responding to steroids and

intravenous immunoglobulin (IVIG), however little is known regarding the management of refractory cases. The use of tocilizumab (anti-receptor for interleukin 6R) in steroid-refractory immune-related adverse event (irAE) has already been documented as safe form oncological standpoint and efficient in tissue agnostic irAE. Our aim is to describe the clinical response of steroid-refractory irAE-np to Tocilizumab with or without synchronous ICI rechallenge.

Methods: We retrospectively collected the cases of steroid-refractory irAE-np referred to the French OncoNeuroTox network from 2021 to 2023. The inclusion criteria were (i) subacute onset of neuropathy less than three months after the last ICI infusion, (ii) after exclusion of alternative diagnoses, and (iii) refractory to corticosteroid therapy at 1 mg/kg or 3 boli of 1g + IVIG.

Results: Four cases of polyradiculoneuropathy under ICIs for melanoma were identified (anti-PD1 2/4; anti-PD1 + anti-CTLA4 2/4). The median time to irAE-np onset was 47 (10-300) days. All patients presented with a demyelinating electrophysiological phenotype and ¾ fulfilled the EFNS 2021 criteria. The CSF analysis showed an albumin-cytological dissociation with a proteins at 0.68 (0.42-2.4) g/L and 6 (2-13) cells/mm^3 and a subnormal IL6 level at 5 (3-9) pg/mL. Monthly Tocilizumab allowed a neurological improvement ($\Delta mRS = 1$) maintained even after ICIs rechallenge.

Conclusion: Little is known on the management and the ICI rechallenge in steroid-refractory irAE-np. Our series points to Tocilizumab to be an effective and secure treatment for steroid-refractory irAE-np in monotherapy or in combination with an anti-PD1.

Disclosure: Nothing to disclose.

EPR-172 | Management of glioblastoma (GBM) at recurrence: treatment modalities and predictors of response.

F. Bruno[1]; A. Pellerino[1]; E. Marchesani[1]; B. Raschio[1]; M. Borgognone[1]; L. Bertero[2]; F. Panico[3]; F. Rizzo[3]; A. Gastino[4]; M. Levis[4]; D. Garbossa[3]; R. Rudà[1]

[1]*Division of Neuro-Oncology, Department of Neurosciences, University and City of Health and Science Hospital, Turin, Italy;* [2]*Pathology Unit, Department of Medical Sciences, University of Turin, Turin, Italy;* [3]*Division of Neurosurgery, Department of Neurosciences, University and City of Health and Science Hospital, Turin, Italy;* [4]*Division of Radiotherapy, Department of Oncology, University of Turin, Turin, Italy*

Background and Aims: The choice of treatments at recurrence for glioblastoma (GBM) patients is challenging. We explored which factors affected the response to treatments at recurrence of an institutional real-life cohort.

Methods: We retrospectively included IDH-wildtype GBM patients treated from 2010 and 2023. We defined first progression-free survival (1st-PFS) from diagnosis to first recurrence, 2nd-PFS from first to second recurrence, overall survival (OS) from second recurrence to death/censoring.

Results: We included 109 GBM patients at recurrence. Treatments modalities were re-resection (16/109, 14.7%), re-RT (11/109, 10.1%), and 2nd-line CHT/antiangiogenic agents (98/109, 89.9%) – of those, 40/98 (40.8%) received regorafenib, 20/98 (20.4%) bevacizumab, 19/98 (19.4%) TMZ rechallenge, and 19/98 (19.4%) nitrosoureas. 2nd-PFS an OS were 6.0 and 11.0 months. Patients receiving TMZ had a longer median 2nd-PFS (17 months, vs. 5.0 for regorafenib, 5.0 for bevacizumab, and 5.0 for nitrosoureas, $p = 0.004$), and OS (32.0 months, versus 13.0 for bevacizumab, 9.0 for nitrosoureas, and 10.0 for regorafenib, $p < 0.027$). TMZ was predominantly given to MGMTp-methylated patients (16/17, 94.1%, vs. 50.0%, 68.4% and 52.6% for bevacizumab, nitrosoureas and regorafenib, $p = 0.016$), with longer 1st-PFS (35.0 months vs. 11.5, 11.0 and 11.0 for bevacizumab, nitrosoureas and regorafenib, $p < 0.001$). In a multivariate analysis on 2nd-PFS, age and use of regorafenib correlated with shorter 2nd-PFS. In a multivariate analysis on OS, MGMTp methylation was the only positive factor.

Conclusion: Selected GBM patients with favourable baseline characteristics (MGMTp methylation; prolonged 1st-PFS) benefited from TMZ rechallenge at recurrence. Except for those, we could not identify subgroups who took advantage from other strategies.

Disclosure: Nothing to disclose.

EPR-173 | Neurotoxicity using academic and commercial anti-cd19 cart therapy in patients with refractory hematologic diseases

J. Cabrera-Maqueda[1]; E. Fonseca[1]; V. Guerra[1]; T. Alba-Isasi[1]; M. Massons[1]; M. Guasp[1]; A. Calvi[1]; N. Martinez[2]; V. Ortiz-Maldonado[2]; J. Delgado[2]; M. Sepulveda[1]; S. Llufriu[1]; E. Martinez-Hernandez[1]; Y. Blanco[1]

[1]*Neuroimmunology and Multiple Sclerosis Unit and Laboratory of Advanced Imaging in Neuroimmunological Diseases (ImaginEM), Hospital Clinic Barcelona, Fundació de Recerca Clínic Barcelona-IDIBAPS, Barcelona, Spain;* [2]*Hematology Service, Hospital Clinic Barcelona, Fundació de Recerca Clínic Barcelona-IDIBAPS, Barcelona, Spain*

Background and Aims: CART therapy can associate cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). We aim to describe the incidence of CRS/ICANS and outcome of patients treated with two different anti-CD19 CART products.

Methods: Single-center retrospective study of consecutive patients treated with commercial Axicabtagene Ciloleucel or ARI-0001 (produced in-house) between 2019 and 2023. ARI-0001 was split into 3 fractions (10%, 30%, 60%) with full administration depending on the absence of CRS. We assessed demographic and clinical features, and toxicity-related complications.

Results: 84 patients (59.5% males), median age 60 years (interquartile range 47.5–67), 72.6% with ECOG = 0 were included. 44 patients received ARI-0001 (36.4% transformed follicular lymphoma). In 10 patients (22.7%) administration of ARI-0001 was partial, 9 due to CRS grade 1-2 and 1 by macrophage activation syndrome. Three cases developed ICANS grade 1-2. Of the 34 who completed

3 doses, CRS was observed in 25 (73.5%) patients, grade >3 in 3, and none developed ICANS. 40 patients received Axicabtagene Ciloleucel (65% diffuse large B-cell lymphoma). CRS was observed in 33 (82.5%) patients, achieving grade >3 in 1, and 23 (57.5%) patients developed ICANS, grade >3 in 6 (15%). No deaths were attributed to CRS or ICANS for any product.

Conclusion: Despite a similar frequency of CRS, the academic CART showed a lower incidence of ICANS than the commercial product, probably explained by different indications and fractionated administration.

Disclosure: Nothing to disclose.

EPR-174 | Zotiraciclib for newly diagnosed or recurrent glioblastoma: updated outcome and biomarker analysis

E. Le Rhun[1]; T. Gorlia[2]; J. Felsberg[3]; J. Jongen[4]; C. Maurage[5]; F. Ducray[6]; D. Gramatzki[7]; P. Hau[8]; O. Chinot[9]; M. Preusser[10]; S. Cartalat[6]; P. Roth[7]; M. van den Bent[4]; J. Furtner[10]; M. Collienne[2]; G. Reifenberger[3]; T. Weiss[7]; M. Weller[7]

[1]Neurosurgey, University Hospital Zurich, Zurich, Switzerland; [2]EORTC Headquarters, Brussels, Belgium; [3]Neuropathology, University Hospital Düsseldorf, Düsseldorf, Germany; [4]Neurology, Erasmus, Rotterdam, The Netherlands; [5]Neuropathology, University Hospital Lille, Lille, France; [6]Neurology, University Hospital Lyon, Lyon, France; [7]Neurology, University Hospital Zurich, Zurich, Switzerland; [8]Neurology, University Hospital Regensburg, Regensburg, Germany; [9]Oncology, University Hospital Marseille, Marseille, France; [10]Oncology, University Hospital Vienna, Vienna, Austria

Background and Aims: Standards of care for recurrent glioblastoma are poorly defined. The multi-cyclin dependent kinase inhibitor Zotiraciclib depletes short-lived survival proteins such as c-MYC and MCL-1 which are overexpressed in glioblastoma.

Methods: EORTC 1608 was a three parallel group phase Ib, non-randomized, multicenter study in IDH wildtype newly diagnosed glioblastoma or anaplastic astrocytoma. In groups A and B, the maximum tolerated dose (MTD) of Zotiraciclib in elderly patients, in combination with radiotherapy alone (group A) or temozolomide alone (group B), by O6-methylguanine DNA methyltransferase promoter methylation status, were determined. In group C, we explored single agent activity of TG02 at first relapse with a primary endpoint of progression-free survival at 6 months (PFS-6). Tumor expression of CDK-9, c-MYC and MCL-1 was determined by immunohistochemistry. Tumor-related extracellular vesicles were quantified according to the minimal information for studies of extracellular vesicles 2018 (MISEV2018) guidelines.

Results: Main toxicities of zotiraciclib were neutropenia, gastrointestinal disorders and hepatotoxicity. The MTD was 150 mg twice weekly in group A or bi-weekly in group B. PFS-6 in group C was 6.7%. The tumor expression of c-MYC and MCL-1 was moderately cross-correlated. High protein levels of MCL-1 were associated with inferior survival. The levels of tumor-related extracellular vesicles in the blood correlated with tumor volumes determined by MRI and increased from baseline to recurrence.

Conclusion: Zotiraciclib exhibits overlapping toxicity with alkylators and low single agent clinical activity. The role of c-MYC and MCL-1 as therapeutic targets and the diagnostic value of extracellular vesicles in peripheral blood in glioblastoma warrant further study.

Disclosure: This study was supported by an unrestricted research grant from Adastra Pharmaceuticals (San Diego, CA) to the European Organisation for Research and Treatment of Cancer (EORTC).

EPR-175 | High-grade gliomas with pleomorphic and pseudopapillary features (HPAP) are circumscribed tumors with long-term survival

A. Picca[1]; L. Nichelli[2]; L. Bertero[3]; B. Barka[4]; M. Bernier[5]; F. Bruno[6]; I. Coin[7]; K. Hoang-Xuan[1]; A. Idbaih[1]; M. Henri[8]; J. Masliah-Planchon[9]; B. Mathon[8]; R. Rudà[6]; M. Sanson[1]; M. Touat[1]; K. Mokhtari[4]; F. Bielle[4]

[1]Service de Neuro-Oncologie, Institut de Neurologie, DMU Neurosciences, AP-HP, Sorbonne Université, Inserm, CNRS, UMR S 1127, Paris Brain Institute (ICM), Hôpital Universitaire Pitié-Salpêtrière, Paris, France; [2]Service de Neuroradiologie, AP-HP, Hôpital Universitaire Pitié-Salpêtrière, Paris, France; [3]Pathology Unit, Department of Medical Sciences, University of Turin, Turin, Italy; [4]Service de Neuropathologie, AP-HP, Hôpital Universitaire Pitié-Salpêtrière, Paris, France; [5]Service d'Anatomie et Cytologie Pathologiques, Hôpital Foch, Suresnes, France; [6]Division of Neuro-Oncology, Department of Neuroscience, University and City of Health and Science Hospital, Turin, Italy; [7]Service de Neurologie, Hôpital Foch, Suresnes, France; [8]Service de Neurochirurgie, AP-HP, Hôpital Universitaire Pitié-Salpêtrière, Paris, France; [9]Department of Genetics, Institut Curie, Paris, France

Background and Aims: The taxonomy of primary CNS tumors is evolving. Recently, DNA methylation profiling has contributed to the identification of HPAP (high-grade glioma with pleomorphic and pseudopapillary features), a potential new tumor entity that harbors variable morphology, recurrent MAP kinase pathway activating events, and a significantly longer survival compared to glioblastoma. Our goal is to independently validate and further characterize this entity.

Methods: We retrieved prospective and retrospective cases with histological (pleomorphic xanthoastrocytoma, astroblastoma) or molecular (chromosome 13 loss) features compatible with the diagnosis of HPAP and performed tSNE dimensionality reduction on their methylome profile.

Results: We identified nine cases that clustered with previously reported HPAP cases. Median age was 42 years (range 23–66), and there was a female predominance (male/female ratio 0.5). Presenting symptoms included intracranial hypertension (44%), focal deficits (33%), and seizures (33%). The most common localization was the temporal lobe (50%). All cases were IDH1/2 wildtype. Recurrently mutated genes included TP53, ATRX, and RB1. Two cases (22%)

had activating BRAF V600E mutations. Upfront management was heterogeneous (Figure), and included surgery alone (22%), adjuvant radiotherapy (33%), or radiotherapy plus temozolomide (44%). After a median follow-up of 7.0 years (range 0.4–15.3, Figure), all patients but one were alive. The only observed death was due to intratumoral hemorrhage in a patient treated with bevacizumab. CDKN2A loss seemed to identify more aggressive tumor course.

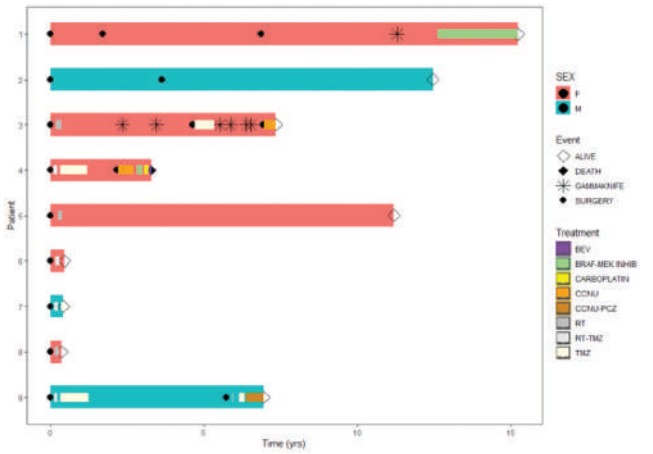

FIGURE 1. Swimmer plot of the nine cases indicating the received treatments.

Conclusion: HPAP is a novel entity of circumscribed gliomas with frequent high-grade histological presentation but excellent long-term survival. A proper identification could guide neuro-oncologist in appropriate treatment choices.

EPR-176 | Clinical and genetic characterization of a Hereditary spastic paraplegias cohort: Experience from the University of Pisa

A. Meli[1]; P. Lopriore[1]; V. Montano[1]; C. Bernardini[1]; G. Cecchi[1]; M. Caligo[2]; G. Siciliano[1]; M. Mancuso[1]
[1]*Neurological Institute, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy;* [2]*Laboratory of Molecular Genetics, University Hospital of Pisa, Pisa, Italy*

Background and Aims: Hereditary spastic paraparesis or paraplegias (HSPs) are a heterogeneous group of inherited neurodegenerative disorders caused by the degeneration of the pyramidal tracts. The present study aims to characterize the clinical features and molecular data of a cohort of patients diagnosed with HSP analyzing the baseline data from a continuous, prospective cohort.
Methods: Phenotype and genotype data of patients with clinical signs and symptoms indicative of pure or complicated HSP were collected from the TreatHSP Consortium's register. Disease severity was assessed using the Spastic Paraplegia Rating Scale (SPRS) at baseline, 6- and 12-months follow-up.
Results: A cohort of 40 patients was studied. Family history indicated dominant (40%), recessive (5%), and simplex (55%) inheritance. SPG4 was the major cause of HSP (22.5%). SPG7 and SPG10 were the second genetic cause (12.5%). Other genotypes were rarer (SPG3A, SPG11, SPG12, SPG17, SPG31, SPG84, CCDC88C, ANO5). Disease severity correlated with disease duration. The average duration of illness was 19.5 ± 16.3 years. The average disease duration before loss of the ability to walk independently was of 18.9 ± 18.3 years. Earlier onset (<25 years) was associate with longer diagnostic delay. SPRS baseline was available for 28 patients and reliably reflected disease severity. Follow-up (25) not showing minimal changes in an average follow-up of 6.1 months.
Conclusion: HSP has slowly progressive course. SPRS reliably reflects disease severity although it is unable to detect small differences within a short follow-up period. A future prospective study will confirm this baseline data on disease course over a long period.
Disclosure: The authors declare no conflicts of interest.

EPR-177 | Neurological manifestation and genetics of phacomatoses: A retrospective study from University of Pisa

C. Bernardini[1]; P. Lopriore[1]; A. Meli[1]; M. Caligo[2]; E. Manni[3]; V. Montano[1]; G. Siciliano[1]; M. Mancuso[1]
[1]*Neurological Institute, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy;* [2]*Laboratory of Molecular Genetics, University Hospital of Pisa, Pisa, Italy;* [3]*Unit of Dermatology, Azienda Ospedaliero Universitaria Pisana, Pisa, Italy*

Background and Aims: This study aimed to assess neurological presentations and genetic characterization in patients with phacomatoses at our adult neurological center.
Methods: This retrospective study examined a cohort of 40 patients (40% male, mean age 46, 3 years) clinically suspected or with a molecular diagnosis of Tuberous Sclerosis Complex (TSC) or Neurofibromatosis (NF). Genetic testing was performed using single gene or panel next-generation sequencing and Multiplex ligation-dependent probe amplification from DNA extracted from blood. Clinical and neuroradiological data were collected from the patient's medical records.
Results: Neurological symptoms were present in 50% of patients, with epilepsy (35%), pediatric intellectual/learning disability (25%), headache (20%), and adult mood disorders (10%) being the most common ones. A neuroradiological central nervous system involvement was present in 19/32 confirmed or suspected NF/Schwannomatosis and 7/7 confirmed or suspected TSC. Molecular diagnosis was established in 29 cases. Mutations in NF1, NF2, TSC1, TSC2, and LZTR1 led to molecular diagnosis of NFI (20), NFII (3), TSC1 (3), TSC2 (2) and Schwannomatosis (1). For NF1 mutations, single nucleotide variants were most common (70%).

Conclusion: Phacomatoses, complex genetic diseases with common neurological involvement, require a profound understanding for timely diagnosis and optimized management, especially considering the prevalence of NFI and the recent approval of drugs for TSC-associated manifestations. To enhance our initial findings next steps might include, in addition to expanding the cohort size and thoroughly examining non-neurological aspects, investigating correlations such as genotype-phenotype and phenotype-diagnostic yield.
Disclosure: No conflict of interests to declare.

EPR-178 | The prevalence of pathogenic and likely pathogenic CSF1R variants in the UK Biobank

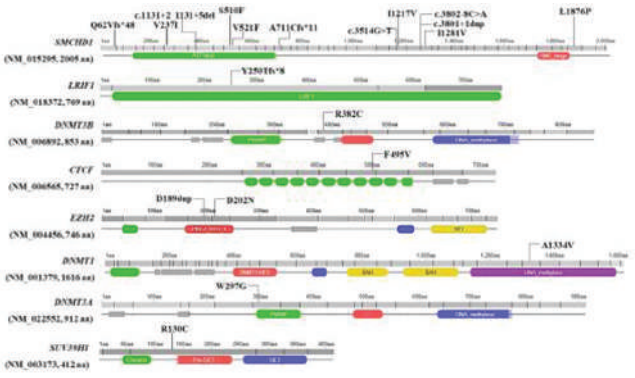
C. Wade[1]; K. Runeckles[2]; J. Chataway[1]; H. Houlden[3]; D. Lynch[4]
[1]*Queen Square Multiple Sclerosis Centre, Department of Neuroinflammation, UCL Queen Square Institute of Neurology, Faculty of Brain Sciences, University College London London WC1N 5EH;* [2]*University Health Network, Toronto, Ontario, Canada;* [3]*Department of Neuromuscular Disease, UCL Queen Square Institute of Neurology, London, UK;* [4]*National Hospital for Neurology and Neurosurgery, Queen Square, London WC1N 3B*

Background and Aims: CSF1R-related adult-onset leukoencephalopathy with axonal spheroids and pigmented glia (ALSP) is an autosomal dominant inherited white matter disorder, leading to a variable combination of dementia, movement disorders, upper motor neuron signs and ataxia. Though increasingly recognized, the true prevalence of CSF1R-related ALSP is unknown.
Methods: Pathogenic and likely pathogenic CSF1R variants (as classified by American College of Medical Genetics criteria) were identified in UK Biobank whole-exome sequencing data ($N = 470{,}000$). Available demographic and phenotypic data were also extracted and analysed to identify clinical manifestation of a disease state.
Results: We identified 18 unique CSF1R pathogenic variants present across 25 subjects (giving a prevalence of ~1 in 18,800), and 44 unique likely pathogenic mutations across 107 subjects (~1 in 4,400) – with a combined prevalence is 132 (~1 in 3,500). Individuals carrying a pathogenic CSF1R variant were significantly more likely to have a psychiatric diagnosis or a diagnosis of Parkinson's disease.
Conclusion: Pathogenic and likely pathogenic CSF1R variants are more common in the UK Biobank population than previously anticipated. Available clinical data points to possible clinical manifestation of the disease in those carrying pathogenic variants, and suggests that ALSP may be significantly underrecognized as a disease entity.
Disclosure: Nothing to disclose.

EPR-179 | Whole Exome Sequencing of 126 patients highlights variants in candidate genes associated with FSHD

C. Strafella[1]; D. Megalizzi[2]; G. Trastulli[2]; L. Colantoni[1]; E. Proietti Piorgo[1]; S. Bortolani[3]; E. Torchia[3]; M. Monforte[3]; C. Caltagirone[4]; E. Ricci[5]; G. Tasca[6]; E. Giardina[2]
[1]*Genomic Medicine Laboratory UILDM, IRCCS Santa Lucia Foundation, Rome, Italy;* [2]*Genomic Medicine Laboratory UILDM, IRCCS Santa Lucia Foundation; Medical Genetics Laboratory, Department of Biomedicine and Prevention, Tor Vergata University, Rome, Italy;* [3]*Unità Operativa Complessa di Neurologia, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome Italy;* [4]*Department of Clinical and Behavioral Neurology, IRCCS Fondazione Santa Lucia, Rome, Italy;* [5]*Unità Operativa Complessa di Neurologia, Fondazione Policlinico Universitario A. Gemelli IRCCS; Istituto di Neurologia, Università Cattolica del Sacro Cuore, Rome, Italy;* [6]*John Walton Muscular Dystrophy Research Centre, Newcastle University and Newcastle Hospitals NHS Foundation Trusts, Newcastle Upon Tyne, UK*

Background and Aims: Despite the progress made in the study of FSHD, the wide heterogeneity of disease complicates its diagnosis and the genotype-phenotype correlation. The present work employed Whole Exome Sequencing (WES) to investigate known and unknown genetic contributors that may be involved in FSHD and represent potential disease modifiers, even in presence of a D4Z4 Reduced Allele (DRA).
Methods: The study involved 126 patients with clinical signs of FSHD, which were characterized by D4Z4 sizing, methylation analysis, WES and segregation analysis. In-house protocols were employed for D4Z4 sizing and methylation analysis, whereas the Illumina® Next-Seq 550 system was utilized for WES.
Results: The WES data analysis highlighted 20 relevant variants (Figure 1), among which 14 were located in known genetic modifiers (SMCHD1, DNMT3B and LRIF1) and 6 in novel genes (CTCF, DNMT1, DNMT3A, EZH2 and SUV39H1) implicated in the DUX4-repressive machinery (Figure 2). Most of them were found together with a permissive short (4-7 RU) or borderline/long DRA (8–20 RU). The segregation and methylation analysis among family members, together with clinical findings, provided a more comprehensive picture of patients.



The variants identified in genes known to cause FSHD (SMCHD1, DNMT3B and LRIFI1) and candidate genes (CTCF, DNMT1, DNMT3A, EZH2 and SUV39H1).

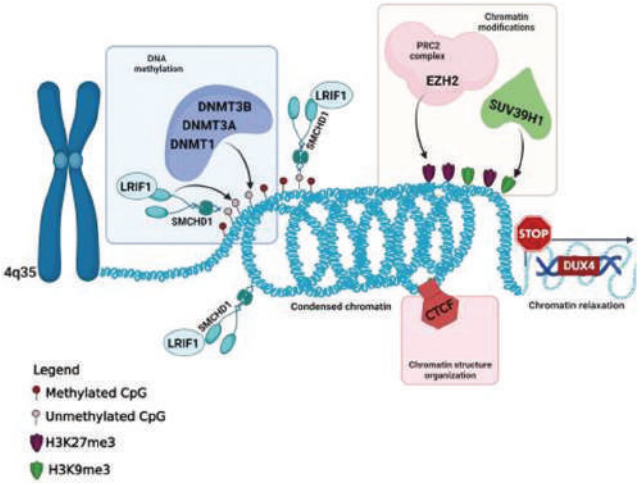


Illustration of the genes harboring the variants identified in FSHD patients and their role in the DUX4-repressive machinery.

Conclusion: Our results support FSHD as a genetically complex disease, in which variations in known and candidate genes could influence the phenotype, penetrance and severity of disease among patients as well as within the same family. Our results further emphasize the importance of extending the analysis of molecular findings within the proband's family, with the purpose of providing a broader framework for understanding single cases and allowing finer genotype-phenotype correlations in FSHD-affected families.

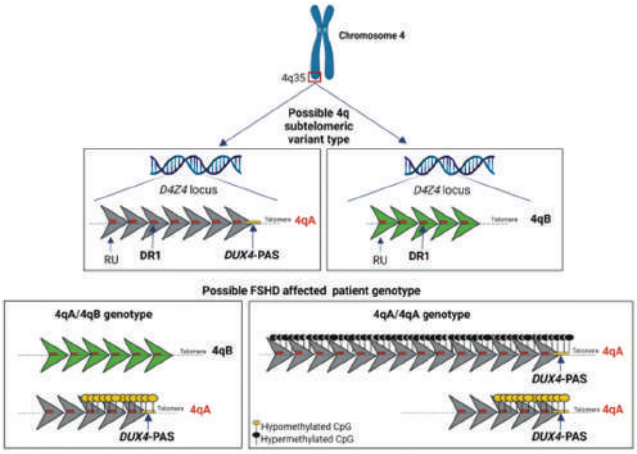
Disclosure: None.

EPR-180 | Validation of a machine learning tool for identifying FSHD patients: A one-year follow-up study

D. Megalizzi[1]; R. Cascella[2]; G. Trastulli[1]; L. Colantoni[3]; E. Proietti Piorgo[3]; M. Monforte[4]; G. Tasca[5]; E. Ricci[6]; C. Caltagirone[7]; C. Strafella[3]; E. Giardina[1]

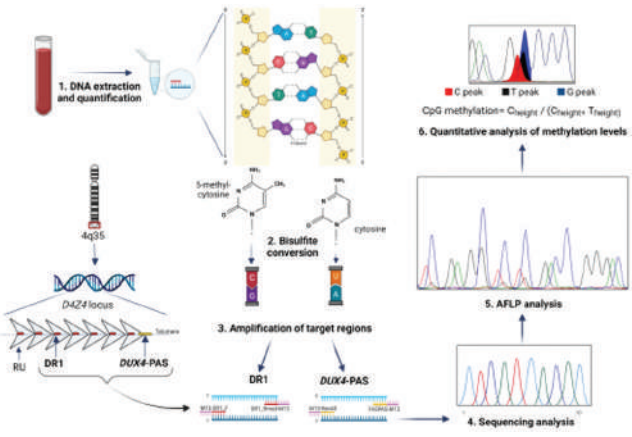
Gemelli IRCCS, Rome, Italy; Istituto di Neurologia, Università Cattolica del Sacro Cuore, Rome, Italy; [7]Department of Clinical and Behavioral Neurology, Santa Lucia Foundation IRCCS, Rome, Italy

Background and Aims: Facio-Scapulo-Humeral Dystrophy (FSHD) is a myopathy characterized by the loss of repressive epigenetic features affecting the D4Z4 locus (4q35) (Figure 1). The study aimed at validating a machine learning (ML) pipeline for discriminating FSHD subjects according to the DNA methylation profile of D4Z4.



4q35 D4Z4 locus, permissive 4qA allele and epigenetic landscape of FSHD.

Methods: 251 subjects with clinical signs of FSHD sent to our center during 2022–2023 were analyzed. The recruited subjects were tested for the 4q subtelomeric variant by means of specific PCR. Subjects carrying at least a 4qA allele underwent methylation levels analysis of two D4Z4 regions (Figure 2). The identification of methylation profiles compatible with FSHD was performed by running a ML algorithm based on methylation levels. The presence of a short D4Z4 allele and/or of pathogenic variants in FSHD genes was simultaneously evaluated.



D4Z4 methylation analysis workflow.

Results: Among the 251 subjects, the 4q variant type distribution was 41% 4qA/4qA, 51% 4qA/4qB and 8% 4qB/4qB. Of the 232 carriers of at least a 4qA allele, the ML model predicted 122 subjects as FSHD in line with the reduced methylation levels compatible with the disease. The remaining 110 subjects were predicted as non-FSHD and showed high methylation levels. By comparing the results of D4Z4 allele sizing, for 122 hypomethylated subjects the FSHD prediction was fully concordant with the presence of FSHD genetic signatures. Among the 110 subjects classified as non-FSHD, 85 were concordant with the absence of FSHD genetic alterations and 25 subjects displayed borderline methylation levels.

Conclusion: The present method emerges as a powerful tool to be implemented into the FSHD diagnostic practice.

Disclosure: Nothing to disclose.

EPR-181 | Predictors of survival in Friedreich's Ataxia: A prospective cohort study

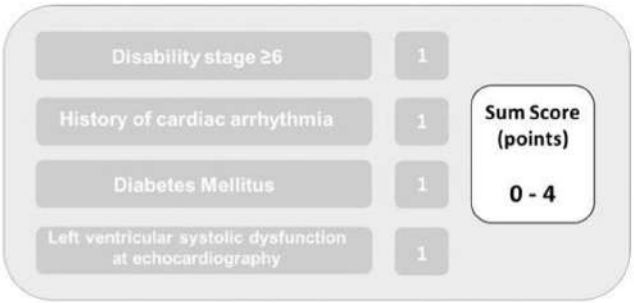
Background and Aims: Friedreich's ataxia (FA) is a rare multisystemic disorder which can cause premature death. We investigated predictors of survival in FA within a prospective registry established by the EFACTS (European Friedreich's Ataxia Consortium for Translational Studies, ClinicalTrials.gov Identifier NCT02069509).

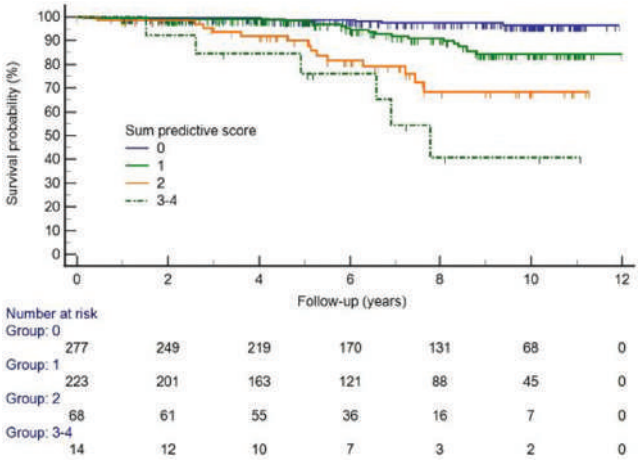
Methods: We enrolled genetically confirmed FA patients at 11 tertiary centres and followed them in yearly intervals. We investigated overall survival applying the Kaplan-Meier method, life-tables and log-rank test. We explored prognostic factors applying Cox proportional hazards regression and subsequently built a risk score which was assessed for discrimination and calibration performance.

Results: Between September 2010 and March 2017, we enrolled 631 FA patients. Median age at inclusion was 31 years (range 6–76). Until December 2022, 44 patients died and 119 terminated the study for other reasons. The 10-year cumulative survival rate was 87%. In a multivariable analysis, the disability stage (hazard ratio [HR] 1.51; 95% CI 1.08–2.12, $p=0.02$), history of arrhythmic disorder (HR 2.93; 95% CI 1.34–6.39, $p=0.007$) and diabetes mellitus (HR 2.31; 95% CI 1.05–5.10, $p=0.04$) were independent predictors of survival. GAA-repeat lengths did not improve the survival model. A risk score built on the previously described factors plus the presence of left ventricular systolic dysfunction at echocardiography enabled to distinguish four trajectories to prognosticate up to 10-year survival (log-rank test $p<0.001$).



Sum score	10-years cumulative survival rate	95% CI
0	96·4%	93·4%-99·4%
1	84·3%	77·4%-91·3%
2	69·6%	55·4%-83·8%
≥3	42·4%	10·7%-74·1%

EFACTS Survival Predictive Score (EFACTS-SPS).



Survival rates in the EFACTS cohort according to the developed prognostic score.

Conclusion: Arrhythmias, progressive neurological disability, and diabetes mellitus influence the overall survival in Friedreich's Ataxia. We built a survival prognostic score which identifies patients deserving closer surveillance and who may benefit from early invasive cardiac monitoring and therapy.

Disclosure: Nothing to disclose.

EPR-182 | Identifying p.P102L-associated Gerstmann-Sträussler-Scheinker syndrome phenotypes using machine learning clustering

E. Minerva[1]; A. Canosa[1]; S. Callegaro[1]; L. Tavaglione[1]; R. Vasta[1]; U. Manera[1]; M. Grassano[1]; F. Palumbo[1]; S. Cabras[1]; E. Matteoni[1]; F. De Mattei[1]; F. Di Pede[1]; G. Zocco[1]; G. Pellegrino[1]; C. Moglia[1]; A. Calvo[1]; A. Brusco[2]; D. Imperiale[3]; S. Gallone[4]; A. Chiò[1]

[1]*ALS Centre, "Rita Levi Montalcini" Department of Neuroscience, University of Turin, Turin, Italy*; [2]*Medical Genetics Unit, "Rita Levi Montalcini" Department of Neuroscience, University of Turin, Turin, Italy*; [3]*Neurology Unit, Prion Disease Regional Center, Maria Vittoria Hospital, Turin, Italy*; [4]*Neurogenetic Unit, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino, Turin, Italy*

Background and Aims: Gerstmann-Sträussler-Scheinker disease (GSS) is the second most common inherited prion disease, often associated with the PRNP variant p.P102L. Addressing its significant clinical heterogeneity, we proposed a new onset-based phenotypic classification, aiming at supporting diagnostic and prognostic assessments.

Methods: Clinical data from patients with confirmed p.P102L GSS, spanning 1987–2022, were collected from two Neurology Centres in Turin (Italy). Then we reviewed the literature for cases with p.P102L GSS. Original and literature cases were merged and a k-means clustering based on age and symptoms at onset was performed to define phenotypic groups, which were analysed for significant differences in clinical features and codon 129 polymorphism (Met/Val).

Results: We collected 253 patients (10 original cases + 243 literature cases), uncovering ataxia as the predominant onset symptom, followed by cognitive impairment. Codon 129 polymorphism (Met/Val) exhibited significant associations with age of onset and disease duration. K-means clustering resulted in four distinct groups: "Early onset and long survival", "Cognitive impairment and rapid progression" mimicking classic Creutzfeldt–Jakob disease, "Late onset with classic phenotype", and "Sensory/Motor onset".

Conclusion: Our findings confirm the phenotypic heterogeneity of p.P102L GSS, even within the same pedigree. This study, encompassing the largest cohort of Italian patients and the most extensive literature review assessed so far, identified four distinct clinical phenotypes that appear meaningful for the diagnostic approach and the prognostic evaluation of GSS. Preliminary data hint at a potential role of sex and codon 129 polymorphism in GSS phenotypic variability.

Disclosure: Nothing to disclosure.

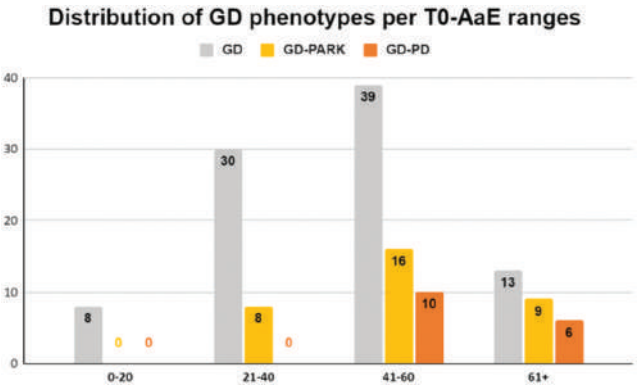
Hospital, Monza, Italy; [17]Department of Translational and Precision Medicine, Sapienza University, Rome, Italy

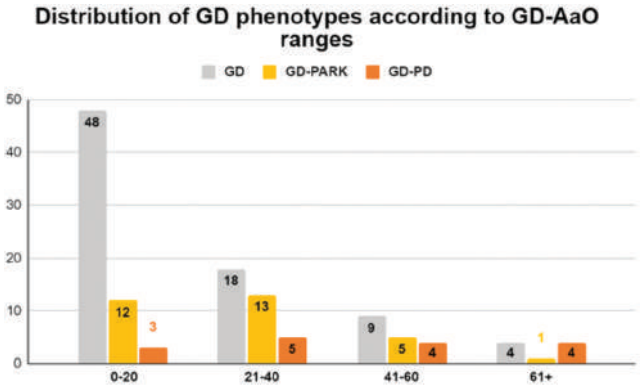
Background and Aims: Gaucher's disease (GD) is a lysosomal storage disorder caused by biallelic GBA1 mutations. GBA1 mutations are the major genetic risk factor for Parkinson's disease (PD) and dementia with Lewy bodies (DLB). The aim of the study was to investigate the prevalence of motor and non-motor clinical features of PD in a cohort of GD patients, and to identify possible predictors of phenoconversion to PD or DLB.

Methods: GD patients consecutively underwent neurological examination at baseline (T0) and after five years (T1) by movement disorders specialists. Patients with at least two non-motor symptoms or one motor and non-motor symptom were classified as patients with parkinsonian syndrome (GD-PARK).

Results: 147 GD patients were evaluated with a mean T0 age-at-examination (T0-AaE) was 47.3 ±15.9 y. 16 patients (10.9%) were diagnosed with PD with a mean age-at-onset (AaO) of 55.6 ±12.5 y. The occurrence of PD was higher according to AaE ($p=0.026$) and AaO of GD ($p=0.006$). The PD-AaO positively correlated with T0-AaE ($p=0.002$), GD-AaO ($p=0.001$), and age-at-GD therapy ($p=0.005$). 33 patients (22.4%) were classified as GD-PARK, displaying a higher burden of non-motor symptoms than GD patients ($p=0.006$). A subgroup of 32 patients (21.8%) underwent a second evaluation, where three patients phenoconverted to PD, six to DLB. Only urinary urgency resulted more frequent in phenoconverted patients ($p=0.049$).



Distribution of Gaucher's disease (GD) phenotypes according to ranges of age-at-examination at baseline (T0-AaE). GD-PARK = GD patients with parkinsonian syndrome; GD-PD = GD patients with diagnosis of Parkinson's disease (PD).



Distribution of Gaucher's disease (GD) phenotypes according to ranges of age-at-onset of GD (GD-AaO). GD-PARK = GD patients with parkinsonian syndrome; GD-PD = GD patients with diagnosis of Parkinson's disease (PD).

Conclusion: A high portion of GD patients display motor and, more frequently, non-motor symptoms of PD. This study highlights the potentialities of studying the GD population to identify specific biomarkers defining the prodromal phase and risk of conversion to PD.

Disclosure: Nothing to disclose.

Epilepsy 2

EPR-184 | Relation between SEEG parameters and tau pathology in patients with pharmacoresistant TLE

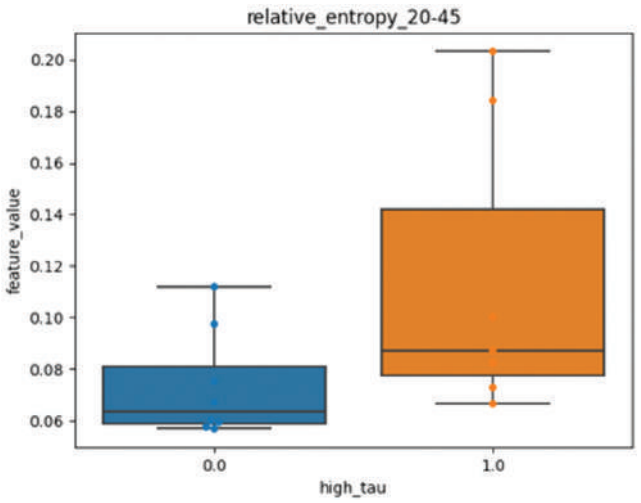
I. Ševčíková[1]; E. Zatloukalová[1]; M. Hendrych[3]; P. Klimeš[2]; B. Matoušková[2]; I. Doležalová[1]; M. Pail[1]; J. Kočvarová[1]; M. Brázdil[1]
[1]First Department of Neurology, St. Anne's Faculty Hospital, Brno, Czechia; [2]International Clinical Research Center, St. Anne's Faculty Hospital, Brno, Czechia; [3]St. Anne's Faculty Hospital, Brno, Czechia

Background and Aims: This study explores the association between hyperphosphorylated tau, commonly linked with neurodegenerative disorders like Alzheimer's, and temporal lobe epilepsy (TLE). TLE is the most prevalent form of pharmacoresistant epilepsy that profoundly affects patients' daily lives. The burden of tau pathology observed in the temporal lobe of young TLE patients is much bigger in comparison with the general population (Thom et al., 2011).

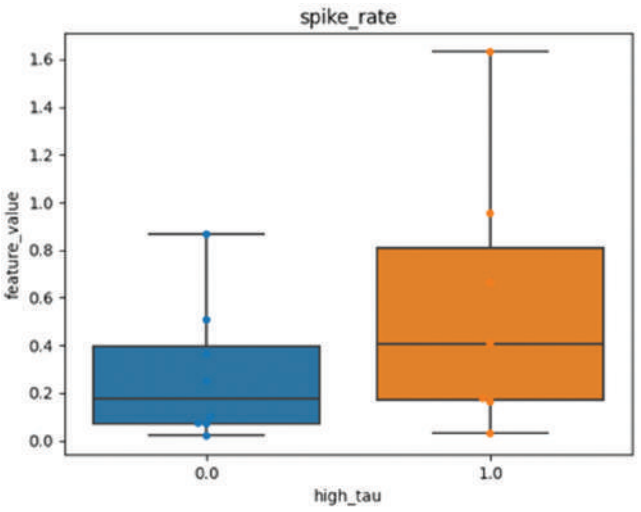
Methods: This study is focused on 15 patients who underwent anterior-mesial temporal resection between 2005 and 2022 for pharmacoresistant TLE with hippocampal sclerosis. It investigates the correlation between tau pathology and electrophysiological parameters in preoperative stereoelectroencephalography (SEEG) recordings. According to the immunohistochemically analysed resection samples were patients categorized into high ($n=8$) and low ($n=7$) tau burden groups.

Results: Although not statistically significant due to the sample size, patients with high tau burden displayed trends of increased spike count ($p=0.29$, medium effect size) and decreased functional

connectivity (higher relative entropy, $p = 0.07$, large effect size) compared to the low tau burden group.



Relative entropy



Spike rate

Conclusion: This study suggests a potential link between tau pathology and electrophysiological parameters in pharmacoresistant epilepsy, offering insights into epileptogenic mechanisms. Further validation on a larger sample size could aid in identifying patients at a higher risk of relapse post-epilepsy surgery and those prone to post-operative cognitive dysfunction. Additionally, it raises the prospect of targeting neurodegenerative proteins as therapeutic interventions and identifying novel prognostic biomarkers for personalized epilepsy care.

Disclosure: This work was supported by the project nr. LX22NPO5107 (MEYS): Financed by EU – Next Generation EU, and by the Ministry of Health of the Czechia, grant nr. NU22-04-00366.

EPR-185 | Poststroke epilepsy after mechanical thrombectomy: Voxel-based lesion symptom mapping

J. Gruber[1]; S. Ropele[2]; C. Enzinger[2]; H. Deutschmann[3]; R. Helbok[1]; M. Sonnberger[4]; T. von Oertzen[5]; T. Gattringer[2]

[1]*Departement of Neurology, Kepler University Hospital, Linz, Austria;* [2]*Department of Neurology, Medical University of Graz, Graz, Austria;* [3]*Division of Neuroradiology, Vascular and Interventional Radiology, Department of Radiology, Medical University of Graz, Graz, Austria;* [4]*Department of Neuroradiology, Neuromed Campus, Kepler University Hospital, Linz, Austria;* [5]*University Hospital Wuerzburg, Wuerzburg, Germany*

Background and Aims: Poststroke epilepsy (PSE) is an important complication of stroke. Data regarding the predictors of PSE in patients with large-vessel occlusion stroke receiving mechanical thrombectomy (MT) are scarce. Voxel-based lesion symptom mapping on MRI might be a valuable tool in risk prediction of PSE. This study aims to assess PSE risk after acute stroke treated with MT via voxel- and volumetric-based analyses.

Methods: In this bi-center study from two large tertiary stroke centers, we included stroke patients who had received MT between 2011 and 2017 and available post-interventional brain MRI as well as long-term-follow-up data. Lesion symptom mapping was done with FLAIR (Fluid Attenuated Inversion Recovery) scans. All lesion masks were registered to a FLAIR group template using FLIRT (FMRIB's Linear Image Registration Tool). Lesion symptom mapping was applied using the NiiStat software, with MATLAB. The analysis was confined to voxels showing a lesion overlap in at least 10 patients. Statistical significance was set at $p < 0.05$ corrected for familywise error.

Results: We analyzed 348 patients (median age: 67 years, 45% women) with follow-up of median 76 months. 32 patients (9.2%) developed PSE. Finally, lesion maps from 281 patients were considered for lesion symptom mapping including 28 patients with PSE. Analyses identified the area tempestas, the temporal pole and the precentral area independently related to PSE risk.

Conclusion: In our study, patients with large vessel occlusion stroke receiving MT showed an increased risk of developing PSE with infarction in the area tempestas, the temporal pole and the precentral area.

Disclosure: None related to this study.

EPR-186 | Efficacy of adjunctive cenobamate for patients with different epilepsy aetiologies: Results of an open-label study

J. Serratosa[1]; B. Majkowska-Zwolińska[2]; E. Alvarez-Baron[3]; J. Leach[4]; K. Thangavelu[5]; C. Brandt[6]

[1]Fundación Jiménez Díaz University Hospital, Madrid, Spain; [2]Epilepsy Diagnostic and Therapeutic Centre, Foundation of Epileptology, Warsaw, Poland; [3]Angelini Pharma España, Madrid, Spain; [4]Global Medical Department, Angelini Pharma S.p.A, Rome, Italy; [5]MeDaStats LLC, Tampa, FL, USA; [6]Bethel Epilepsy Centre, Mara Hospital, Bielefeld, Germany

Background and Aims: The aetiology of epilepsy can be a prognostic predictor for seizure recurrence. An open-label extension (OLE) of the international, double-blind, placebo-controlled clinical trial C017 (NCT01866111) evaluated long-term efficacy and safety of adjunctive cenobamate. This post-hoc analysis assessed cenobamate efficacy in different types of epilepsies.

Methods: The modified intent-to-treat population included 354 adults who completed the double-blind phase and entered the OLE. They were grouped according to 1 or more of the following definite or possible specific epilepsy aetiologies: viral/bacterial/parasitic infection; traumatic brain injury; stroke/intraventricular haemorrhage; hypoxic-ischemic encephalopathy; genetic/chromosomal developmental encephalopathies; cortical malformations; mesial temporal sclerosis; and other aetiologies (metabolic/toxic insults, neurocutaneous syndromes, inborn errors of metabolism, neoplasia, dementia, and other degenerative neurologic disease). Comparison of baseline and post-baseline seizure frequency (percentage reduction) in each group was conducted.

Results: The median baseline seizure frequency per 28 days ranged from 6 (traumatic brain injury) to 11.5 (cortical malformation/brain development). Median disease duration ranged from 17.3 years (viral/bacterial/parasitic infection) to 27 years (intraventricular haemorrhage/stroke). Long-term responders (≥50% seizure reduction) for the 5-year analyses were: viral/bacterial/parasitic infection, 60.7% (17/28); traumatic brain injury, 58.5% (24/41); stroke/intraventricular haemorrhage, 60.0% (9/15); hypoxic-ischemic encephalopathy, 73.3% (11/15); mesial temporal sclerosis, 64.7% (22/34); other aetiologies 59.1% (13/22); cortical malformation/brain development, 42.3% (30/71); and 69.7% of patients who had an unknown classification (122/175).

Conclusion: This post-hoc analysis further supports the efficacy of cenobamate by demonstrating a sustained response in patients with different epilepsy aetiologies.

Background and Aims: Gliomas are the most common primary tumor of the CNS parenchyma in adults, often with a poor prognosis. Brain-tumor-related epilepsy (BTRE) is a cause of high morbility and mortality in these patients. The aim of the study is to explore the prognostic power of EEG's qualitative and quantitative features.

Methods: Patients affected by brain glioma that underwent brain surgery (gross tumor resection) and at least one EEG after the surgery were enrolled at the IRCSS Ospedale Policlinico San Martino. Qualitative (slow and epileptiform abnormalities) and quantitative (spectra power and mean frequencies, at lesional and lobar level) EEG features in the lesionectomy zone were compared between patients with and without seizures after surgery, and between patients with and without tumor recurrence.

Results: 81 patients (52 males, mean age 54.40 yo, 53 glioblastoma multiforme, 19 astrocytoma, 9 oligodendroglioma) were enrolled. At qualitative analysis, slow abnormalities in post-surgical EEG were more frequent in patients having seizures after surgery ($p = 0.045$).

Quantitative analysis showed that in post-surgical EEGs, the alpha power spectrum at lesionectomy was lower in patients having seizures after surgery ($p=0.046$). Moreover, in pre-surgical EEGs, the delta spectrum at lesion level was lower in patients with tumor recurrence ($p=0.019$).

Conclusion: EEG may be a predictive-prognostic tool for seizure recurrence and for progression free survival, proving clues about the clinical trajectory in glioma patients. In particular, focal slowing and alpha power reduction was associated with seizures. Larger data are needed to confirm these preliminary results.

Disclosure: Nothing to disclose.

EPR-188 | Interim European outcomes for patients enrolled in the CORE-VNS registry

A. Sen[1]; M. Dibue[2]

[1]*Oxford Epilepsy Research Group, NIHR Biomedical Research Centre, Nuffield Department of Clinical Neurosciences, John Radcliffe Hospital, Oxford, UK;* [2]*LivaNova PLC (or a subsidiary), Houston, TX*

Background and Aims: The Comprehensive Outcomes Registry in Subjects with Epilepsy Treated with Vagus Nerve Stimulation (VNS) Therapy (CORE-VNS) is an ongoing prospective study in patients with drug-resistant epilepsy (DRE) in a real-world setting.

Methods: DRE patients receiving implantable VNS (new or replacement) were eligible for participation in the CORE-VNS. Seizure frequency (SF), maximum SF free periods, seizure severity, post-ictal severity, changes in quality of life and sleep, anti-epileptic drug and rescue drug use, and seizure-related hospital and emergency department visits were evaluated at baseline and at 3, 6, 12, 24 and 36 months. Interim results for the European cohort are presented.

Results: Across Europe, a total of 341 subjects signed informed consent with 327 included in the modified safety population across 6 different countries. The mean age at consent was 24.9 years and epilepsy types include combined (30.1%), focal (54%), and generalized (14.2%). Sixty-seven percent of subjects were naïve to VNS Therapy (43% < 18 years of age and 53.1% female). The responder rate (percent of subjects with >50% reduction in seizures) for subjects reporting at 24 months was 74.1% (all seizures). A median percent reduction in SF was 79.2% with a median seizure count of 9 (all seizures).

Age at Informed Consent (Years)	First Implant N=226	Re-Implant N=100	Total (N=338)
Mean (SD)	24.9 (17.2)	33.7 (16.1)	27.6 (17.3)
Median	21	31	25.5
Min, Max	1, 71	11, 73	1, 73
< 4 years (%)	15 (6.6%)	0 (0.0%)	15 (4.4%)
4 - 11 years (%)	46 (20.4%)	4 (4%)	52 (15.4%)
12 - <18 years (%)	37 (16.4%)	12 (12%)	50 (14.8%)
≥ 18 years (%)	128 (56.6%)	84 (84%)	221 (65.4%)
Female	120 (53.1%)	43 (43%)	170 (50.3%)
Male	106 (46.9%)	57 (57%)	168 (49.7%)

Demographics

Conclusion: At the 24-month visit, 74.1% of subjects reporting had experienced more than 50% SF reduction and nearly 60% had experienced >80% SF reduction.

Disclosure: AS is a primary investigator in the CORE-VNS prospective registry. MD is an employee of LivaNova PLC.

EPR-189 | Risk of post-stroke epilepsy following revascularization therapies: A 7-years single-center observational study

N. Orlandi[1]; C. Cuccurullo[3]; G. Borzì[4]; G. Giovannini[2]; L. Picchetto[2]; S. Maffei[2]; S. Lattanzi[5]; G. Bigliardi[2]; S. Meletti[2]

[1]*Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy;* [2]*Neurology Unit, Ospedale Civile, Azienda Ospedaliera-Universitaria di Modena, Modena, Italy;* [3]*Neurology and Stroke Unit, Ospedale del Mare Hospital, ASL Napoli 1, Naples, Italy;* [4]*Department of Neurology and Psychiatry, Policlinico Umberto I, "Sapienza" University of Rome, Italy;* [5]*Neurological Clinic, Department of Experimental and Clinical Medicine, Marche Polytechnic University, Ancona, Italy*

Background and Aims: To date, the incidence and risk factors for Post-Stroke Epilepsy (PSE) in patients receiving revascularization therapies have not yet been completely assessed.

Methods: Observational, single-center, retrospective study of prospectively acquired data in consecutive patients admitted to the Stroke Unit of Modena Academic Hospital (Italy) who received revascularization therapies (intravenous thrombolysis [IVT] and/or endovascular thrombectomy [EVT]) for first ever acute ischemic stroke from January 1st 2014 to December 31st 2021. Early (ES) and late (LS) post-stroke seizures were classified according to the ILAE definitions. The incidence of LS was assessed through a survival analysis, while a Cox regression model was used to identify outcome predictors.

Results: 1094 patients were included, 665 (61%) and 169 (15%) of whom were treated with IVT or EVT, respectively. In 260 cases, both treatments were performed. Overall, 28 patients (3%) developed ES, whereas LS occurred in 66 patients (6%). The highest risk of LS was observed within 12 months after stroke (3.1%) (mean follow-up: 53 months). Cortical involvement (HR 3.2 95% CI 1.6–6.6; $p = <0.01$) and NIHSS values at discharge suggestive of moderate (NIHSS 4–10)

(HR 3.2 95% CI 1.6–6.6; $p = <0.01$) or severe stroke (NIHSS ≥ 11) (HR 5.4, 95% CI 1.02–18.6; $p < 0.01$) were independently associated to the development of LS.

Conclusion: In our cohort of stroke patients receiving revascularization therapies the risk of LS was low. Cortical involvement and stroke severity (NIHSS score after treatment) were independently associated with the onset of LS.

Disclosure: Nothing to disclose.

EPR-190 | Theta burst transcranial magnetic stimulation in patients with generalized epilepsy: A TBS-hdEEG paradigm approach

P. Leahu; S. Groppa
State University of Medicine and Pharmacy "Nicolae Testemițanu", Chisinau, Republic of Moldova

Background and Aims: Transcranial theta burst magnetic stimulation (TBS) coupled with high-density electroencephalography (hd-EEG) is a continuously developing area of research with promising clinical application in the management of epilepsy patients. It aims to explore how targeted magnetic stimulation impacts neural networks and potential mechanisms of seizure control.

Methods: We hypothesized that multifocal cTBS could improve clinical outcomes compared to baseline by reducing seizure frequency/days, severity of seizures; improve quality of life with few adverse events. Patients received six cTBS stimulation sessions on consecutive days. Each session consisted of 3 cTBS trains with 10 min intertrain-interval. One cTBS train included 600 pulses delivered in bursts at theta frequency during 40s at 80% of RMT over Cz (covering bilateral motor cortices). Patients underwent follow-up assessments at 4, 8, and 12 weeks, spanning a 12-week period.

Results: Among fourteen enrolled generalized epilepsy patients, twelve completed the trial (age 33.1 ± 7.5; 10 females). Over 12 weeks, reduction of ≥50% compared to baseline in seizure frequency was achieved in 75% at 4 and 12 weeks ($p < 0.05$); seizure days 75% and 83.3% respectively ($p < 0.05$); seizure severity 66.6% and 75% ($p < 0.05$). Compared to baseline, changes in all clinical outcomes parameters were statistically significant during each follow-up visit ($p < 0.05$), nevertheless, inter-visit changes were not. A tendency towards the reduction of interictal EEG discharges and cortical excitability was observed. No significant adverse events were recorded.

Conclusion: Our research provides compelling evidence that novel cTBS-EEG approaches hold value in identifying meaningful biomarkers while simultaneously facilitating therapeutic improvements in generalized epilepsy patients.

Disclosure: Nothing to disclose.

EPR-191 | Abstract withdrawn

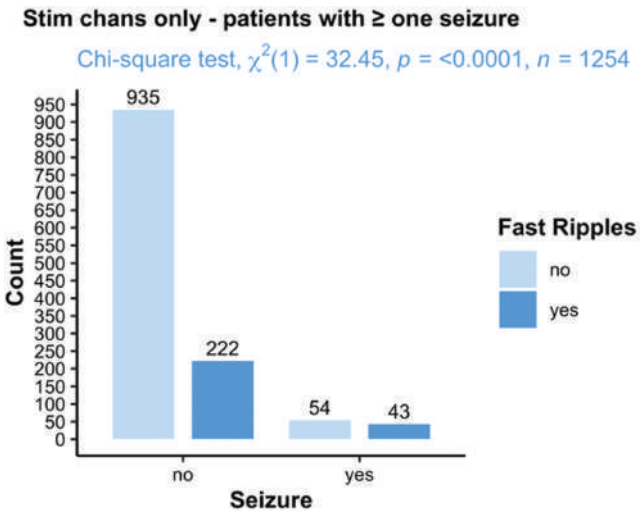
EPR-192 | Spikes, fast ripples and SEEG stimulated seizures: A common hyperexcitability mechanism?

R. Vicini; E. Garnier; M. Fratello; T. Biagioni; F. Bartolomei; F. Pizzo
Hôpital de la Timone, Marseille/Aix Marseille Université

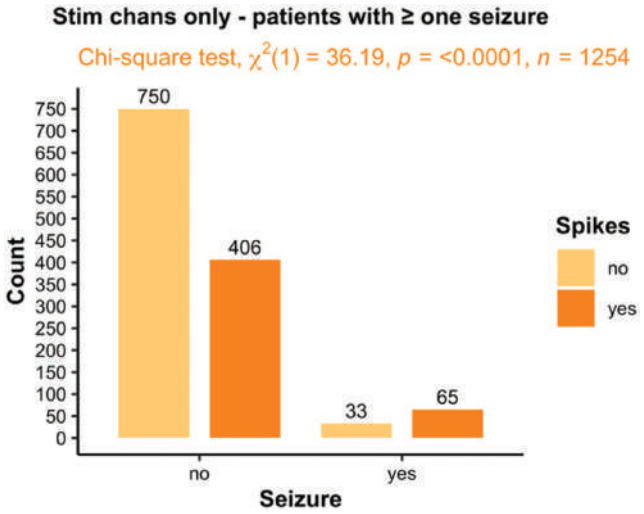
Background and Aims: Interictal spikes and High Frequency Oscillations are being studied as epileptogenicity/hyperexcitability biomarkers. We investigated the association between the presence of spikes and Fast Ripples (FR) during the interictal period and the probability of generating a seizure by stimulating a channel during the SEEG procedure.

Methods: We analyzed non-REM sleep SEEG recordings, sampled at 2048 Hz, of 49 patients, of whom 38 had at least one seizure during the SEEG stimulation procedure. We considered both stimulations by choc (1 Hz) and by train (50 Hz). FR (250–500 Hz) and spikes were automatically detected (Delphos detector). Channels were considered "spiky" or with a high rate of FR when above the 75° percentile after normalization. The statistical tests used are Chi-square and Wilcoxon test.

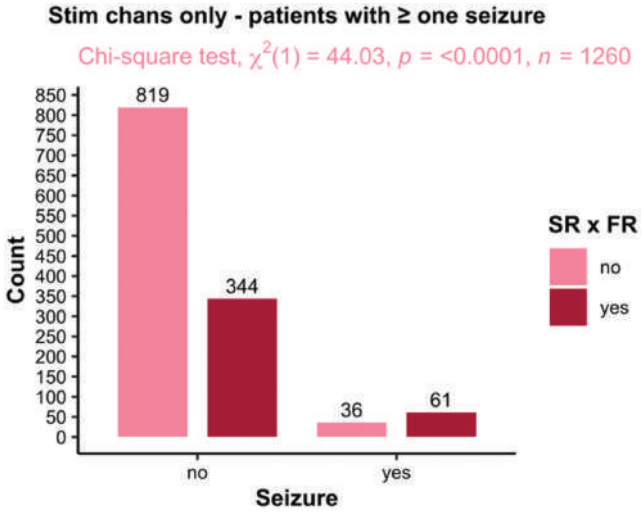
Results: In patients that experienced one or more seizures by stimulation, among the stimulated channels that generated a seizure: - 65% of channels were spiky, 33% were not (sensitivity 66.3%, specificity 64.9%). - 43% had FR, 54% did not (sensitivity 44.3%, specificity 80.8%). - 61% had spikes × FR, 35% did not (sensitivity 62.9%, specificity 70.4%). There is a statistically significant difference ($p = <0.0001$) in proportion of channels with spikes and with spikes × FR between the stimulations that generated a seizure and the ones that did not.



Seizures in stimulated channels with a high number of Fast Ripples.



Seizures in stimulated channels with a high number of spikes.



Seizures in stimulated channels with a high number of spikes × Fast Ripples.

Conclusion: Channels with a high rate of spikes and spikes × FR are more likely to generate a seizure if stimulated. These results can have a clinical utility: when trying to generate a seizure by stimulation (Trebuchon et al., 2020), it would be better to directly stimulate those channels.

Disclosure: Nothing to disclose.

Headache 2

EPR-193 | **Efficacy of atogepant in trial completers: A post hoc analysis of the 12-week ADVANCE and 52-week open-label trials**

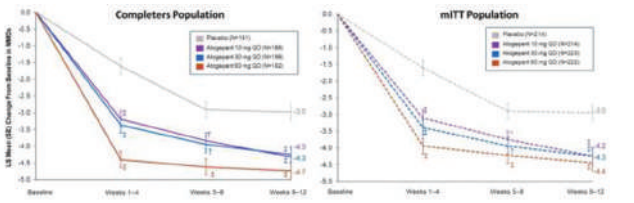
A. Blumenfeld[1]; U. Najib[2]; B. Savage-Edwards[3]; K. Carr[4]; P. Gandhi[5]; B. Dabruzzo[4]; D. Holle-Lee[6]

[1]The Los Angeles Headache Center, Los Angeles, CA, USA; [2]WVU Rockefeller Neuroscience Institute, Morgantown, WV, USA; [3]Rehabilitation & Neurological Services, Huntsville, AL, USA; [4]AbbVie, North Chicago, IL, USA; [5]AbbVie, Florham Park, NJ, USA; [6]Department of Neurology, West German Headache and Vertigo Center Essen, University of Essen, Essen, Germany

Background and Aims: Atogepant is an oral calcitonin gene–related peptide receptor antagonist approved for the preventive treatment of migraine in adults. This analysis evaluated efficacy of atogepant in participants who completed the ADVANCE or 52-week open-label trials.

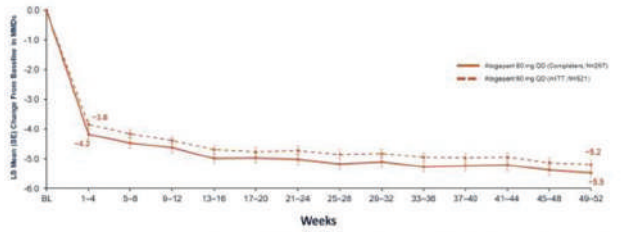
Methods: ADVANCE was a 12-week, double-blind, placebo-controlled trial that evaluated safety and efficacy of atogepant for preventive treatment of episodic migraine. A separate 52-week, open-label trial evaluated long-term safety and efficacy of atogepant. This analysis evaluated efficacy in participants who completed the trial with non-missing monthly migraine day (MMD) data for all visits. Change from baseline in MMDs and proportions of participants achieving ≥50% MMD decrease were evaluated.

Results: In ADVANCE, 765 participants completed the trial with non-missing MMD data (placebo: $n = 191$; atogepant 10 mg: $n = 186$; atogepant 30 mg: $n = 196$; atogepant 60 mg: $n = 192$). Among completers, similar decreases in MMDs compared with the mITT population were observed (Figure 1). A ≥50% decrease in MMDs was reported by 65.6% and 71.4% of atogepant 60 mg-treated completers at weeks 1–4 and 9–12, respectively. In the 52-week trial, 297 of 546 (54.4%) randomized atogepant 60 mg participants met completer criteria. LS mean changes in MMDs for completers were −4.2 during weeks 1–4 and −5.5 during weeks 49–52 (Figure 2). The proportions of completers who achieved ≥50% decrease in MMDs were 65.0% during weeks 1–4 and 84.5% during weeks 49–52 (Figure 3).



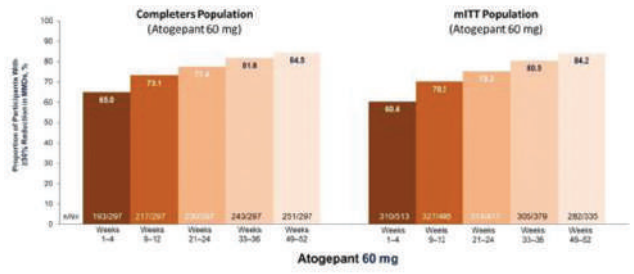
*P<0.05; †P<0.01; ‡P<0.001. Nominal P values were not tested in hierarchical order or adjusted for multiplicity.
LS = least squares; mITT = modified intent-to-treat; MMDs = monthly migraine days; QD = once daily; SE = standard error.

FIGURE 1. Changes in baseline in MMDs during the ADVANCE trial.



BL = baseline; LS = least squares; mITT = modified intent-to-treat; MMDs = monthly migraine day; QD = once daily; SE = standard error.

FIGURE 2. Changes in baseline in MMDs over time in the 52-week open-label trial.



mITT = modified intent-to-treat; MMDs = monthly migraine day.

FIGURE 3. Proportions of participants achieving ≥50% reduction in MMDs from baseline over time in the 52-week open-label trial.

Conclusion: Similar reductions in MMDs were observed with the 12- and 52-week trial completers and mITT populations, with the completer population demonstrating a trend towards greater reduction with atogepant over time.

Disclosure: This study was supported by AbbVie.

EPR-194 | Real-world effectiveness of switching to fremanezumab from other CGRP pathway mAbs: PEARL study 4th interim analysis

Background and Aims: According to the European Headache Federation guidelines for preventive migraine therapy use, switching from one monoclonal antibody (mAb) targeting the calcitonin gene-related peptide (CGRP) pathway to another may be beneficial in patients who experience adverse events or inadequate response; however, long-term, prospective effectiveness data supporting this approach are limited.

Methods: PEARL (EUPAS35111) is an observational, Phase 4 study evaluating the effectiveness of fremanezumab in adults with episodic or chronic migraine (EM, CM). The fourth interim analysis was conducted when all enrolled participants had completed ≥12 months of treatment. This sub-analysis explored reductions in monthly migraine days (MMD) in participants who switched to fremanezumab from another CGRP pathway mAb.

Results: Of 96 switch participants enrolled at baseline, 89 had data for full analysis (Table 1). During the first 6 months of treatment, 31 switch participants (34.8%) achieved ≥50% MMD reduction from baseline. Responses were numerically higher in participants who switched due to lack of efficacy than for 'other' reasons, while responses were similar for participants with EM and CM (Figure 1).

Over the same time period, 40 switch participants with CM (58.0%) achieved ≥30% MMD reduction. Mean change from baseline in MMD remained consistent through months 1 to 15 (Figure 2) in the switch cohort.

TABLE 1. Previous CGRP pathway mAb use.

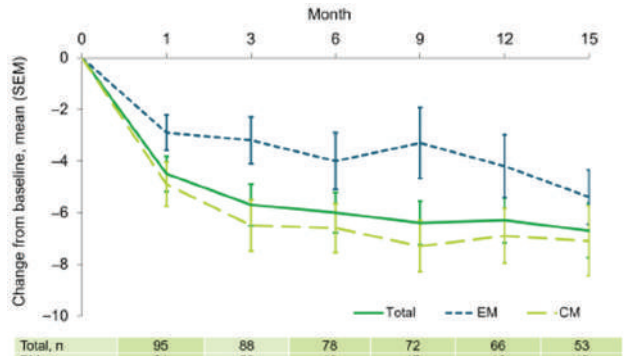
	Total participants (N = 89)	EM participants (n = 20)	CM participants (n = 69)
Reasons for switch*, n (%)			
Switch due to lack of efficacy	39 (43.8)	7 (35.0)	32 (46.4)
Switch due to reasons other than 'lack of efficacy'	50 (56.2)	13 (65.0)	37 (53.6)
Previous CGRP pathway mAb treatment, n (%)			
Galcanezumab only	1 (1.1)	0	1 (1.4)
Erenumab only	84 (94.4)	19 (95.0)	65 (94.2)
Galcanezumab and erenumab†	4 (4.5)	1 (5.0)	3 (4.3)
Mean duration of preventive therapy, months (SD)			
Galcanezumab	4.0 (1.8)	–	–
Erenumab	12.1 (11.4)	–	–

*As reported by the participant; †On separate occasions.
CGRP, calcitonin gene-related peptide; CM, chronic migraine; EM, episodic migraine; mAb, monoclonal antibody.

	All	EM	CM
Total participants, n	1043	346	697
Non-switch participants, n	954	326	628
Switch participants, n	89	20	69
Switch participants – 'other', n	50	13	37
Switch participants – 'lack of efficacy', n	39	7	32

CM, chronic migraine; EM, episodic migraine; MMD, monthly migraine days.
At cut-off, not all data for this endpoint were available and missing data have been excluded. The number of participants prematurely discontinuing the study and the number of participants that had not yet reached the relevant observation time-point increased (in addition to delays in data being entered into the electronic data capture system), thus contributing to the drop in n numbers.

FIGURE 1: Proportion of participants with ≥50% reduction from baseline in MMD during the 6 months after fremanezumab initiation, by migraine type.



Total, n	95	88	78	72	66	53
EM, n	21	20	18	17	16	13
CM, n	74	68	60	55	50	40

CM, chronic migraine; EM, episodic migraine; MMD, monthly migraine days; SEM, standard error of the mean.
Not all participants had data available for each time point and missing data have been excluded. The number of participants prematurely discontinuing the study and the number of participants that had not yet reached the relevant observation time-point increased (in addition to delays in data being entered into the electronic data capture system), thus contributing to the drop in n numbers.

FIGURE 2: Mean change from baseline in MMD in switch participants from Month 1 to Month 15, by migraine type.

Conclusion: This analysis demonstrates the long-term effectiveness of fremanezumab in participants who have not responded to, or tolerated, another CGRP pathway mAb for preventive migraine treatment. Switching to fremanezumab may therefore be a beneficial treatment option in this patient population.

Disclosure: Funded by Teva Pharmaceuticals.

EPR-195 | Real-world effectiveness of anti-CGRP monoclonal antibodies compared to OnabotulinumtoxinA (RAMO) in chronic migraine

D. Montisano[1]; R. Giossi[2]; M. Canella[1]; M. Marosano[3]; C. Altamura[3]; F. Vernieri[3]; L. Grazzi[1]

[1]Headache Center, Neuroalgology Dept., Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy; [2]Poison Control Center and Clinical Pharmacology Unit, Grande Ospedale Metropolitano Niguarda, Milan, Italy; [3]Fondazione Policlinico Universitario Campus Bio-Medico, Roma, Italy

Background and Aims: Anti-CGRP mAbs and BoNT-A are the only treatment specifically approved for CM prophylaxis. Direct comparisons between the two treatments are not available, so far.

Methods: We performed an observational, retrospective, multicenter study to compare the real-world effectiveness of anti-CGRP mAbs and BoNT-A. Patients with CM having received either treatment according to Italian prescribing regulations were extracted form available clinical databases. Efficacy outcomes included the change from baseline in monthly headache days (MHD), Migraine disability assessment test (MIDAS), and migraine acute medications (MAM) evaluated at 6 and 12 months of follow- up. The primary outcome was MHD change from baseline at 12 months. Safety outcomes included serious adverse events (SAE) and treatment discontinuation.

Results: 216 potentially eligible patients were screened and 183 (86 anti-CGRP mAbs; 97 BoNT-A) were included. Anti-CGRP mAbs resulted in a significant reduction in MHD compared to BoNT-A at 12 months of follow-up. Anti-CGRP mAbs showed a significant MIDAS and MAM reduction compared to BoNT-A at 6 and 12 months. No SAE were reported. Treatment discontinuations, mainly for inefficacy, were comparable between the two treatments.

Conclusion: Anti-CGRP mAbs seemed more effective than BoNT-A with comparable safety.

Disclosure: Nothing to disclose.

EPR-196 | Impact of fremanezumab cessation and reinitiation in migraine management: PEARL study 4th interim analysis

D. Mitsikostas[1]; M. Ashina[2]; F. Amin[3]; P. Kokturk[4]; C. Schankin[5]; G. Sahin[6]; P. Pozo-Rosich[7]; P. Dorman[8]; T. Nežádal[9]; I. Martins[10]; M. Sumelahti[11]; V. Ramirez Campos[12]; X. Ning[12]; H. Akcicek[4]; C. Tassorelli[13]

Mondino Foundation, Pavia, Italy

Background and Aims: Despite recent updates to the guidelines, some reimbursement authorities still mandate a pause in preventive treatment with calcitonin gene-related peptide (CGRP) pathway monoclonal antibodies (mAbs) after 1 year of continuous use. However, migraine symptoms frequently return following treatment cessation and treatment effectiveness can be reduced upon reinitiation.

Methods: PEARL (EUPAS35111) is a Phase 4 study evaluating the real-world effectiveness of fremanezumab in adults with episodic or chronic migraine. The fourth interim analysis was conducted when all participants completed ≥12 months of treatment; this subanalysis explored the impact of fremanezumab cessation and reinitiation on monthly migraine days (MMD).

Results: Of 220 participants with documented cessation of fremanezumab, 98 stopped treatment for reimbursement, and 192 reinitiated after a mean (SD) period of 2.6 (2.0) months (Table 1). Over 40% of participants experienced worsening of migraine (≥50% increase in MMD) at Months 1 and 2 post-cessation (Figure 1). Mean MMD decreased after reinitiation but remained higher than before cessation (Figure 2). The proportion of participants achieving ≥50% reduction in MMD at Month 1 and Month 3, respectively, was 49.0% and 58.9% in the first treatment period (before cessation) versus 35.7% and 45.5% in the second treatment period (after reinitiation).

TABLE 1: Participants with documented cessation and reinitiation of fremanezumab.

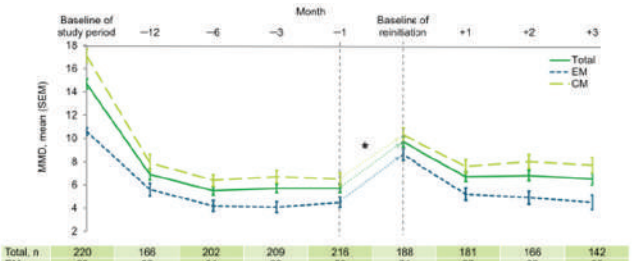
	Total	EM participants	CM participants
Participants with documented cessations	n = 220	n = 83	n = 137
Time from first dose to cessation, months (SD)	11.2 (3.6)	11.6 (2.6)	10.9 (4.1)
Reason for cessation, n (%)			
Reimbursement	98 (44.5)	47 (56.6)	51 (37.2)
Improvement of migraine	18 (8.2)	5 (6.0)	13 (9.5)
Other	80 (36.4)	26 (31.3)	54 (39.4)
Participants with documented reinitiation	n = 192	n = 72	n = 120
Time from cessation to reinitiation, months (SD)	2.6 (2.0)	2.6 (1.9)	2.6 (2.1)
Reason for reinitiation of fremanezumab, n (%)			
Worsening of migraine	77 (40.1)	40 (55.6)	37 (30.8)
Improvement of AE	3 (1.6)	–	3 (2.5)
Other	112 (58.3)	32 (44.4)	80 (66.7)

AE, adverse event; CM, chronic migraine; EM, episodic migraine; SD, standard deviation.

	Month 1	Month 2
Total, n	179	158
EM, n	66	54
CM, n	113	104

CM, chronic migraine; EM, episodic migraine; MMD, monthly migraine days.
At cut-off, not all data for this endpoint were available and missing data have been excluded. The number of participants prematurely discontinuing the study and the number of participants that had not yet reached the relevant observation time-point increased (in addition to delays in data being entered into the electronic data capture system), thus contributing to the drop in n' numbers.

FIGURE 1: The proportion of participants with a ≥50% increase in MMD from the time of cessation to Month 1 and 2 after cessation.



Total, n	220	166	202	209	216	188	181	166	142
EM, n	83	67	81	82	83	71	67	63	55
CM, n	137	99	121	127	133	117	114	103	87

CM, chronic migraine; EM, episodic migraine; MMD, monthly migraine days; SEM, standard error of the mean.
*Data for MMD during the cessation period are not captured in the graph. MMD at Month 1 following cessation of fremanezumab were 7.6, 6.8 and 8.0 for Total, EM and CM participants, respectively.
Not all participants had data available for each time point and missing data have been excluded. The number of participants prematurely discontinuing the study and the number of participants that had not yet reached the relevant observation time-point increased (in addition to delays in data being entered into the electronic data capture system), thus contributing to the drop in n numbers.

FIGURE 2: Mean MMD through the first treatment period up to 1 month prior to cessation and through the second treatment period from the baseline of reinitiation.

Conclusion: Post-fremanezumab cessation, a notable rise in MMD was observed, with reduced effectiveness upon reinitiation. This challenges the rationale behind mandated treatment pauses, underscoring the need for individualized patient management strategies.
Disclosure: This study was funded by Teva Pharmaceuticals.

EPR-197 | Number needed to treat and cost per responder analysis of anti-CGRP monoclonal antibodies for migraine prevention

D. Mitsikostas[1]; X. Lee[2]; L. Boserup[2]; R. Kongerslev[2]; R. Phul[2]; S. Sacco[3]
[1]*First Neurology Department, Aeginition Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece;* [2]*H. Lundbeck A/S, Copenhagen, Denmark;* [3]*Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy*

Background and Aims: Four monoclonal antibodies (mAbs) targeting calcitonin gene-related peptide (CGRP) are approved for migraine prevention, and they are commonly prescribed/reimbursed after failure of traditional oral medications. Patients achieving clinical response (e.g., ≥50% monthly migraine day [MMD] reduction) during an anti-CGRP mAb trial are likely to continue treatment. We compared number needed to treat (NNT) and quarterly cost per responder (CPR) across anti-CGRP mAbs.
Methods: Data were from randomized, double-blind, placebo-controlled phase 3b clinical trials that evaluated an anti-CGRP mAb (eptinezumab, erenumab, fremanezumab, or galcanezumab) for migraine prevention in adults with episodic or chronic migraine and 2–4 prior preventive treatment failures. NNT was calculated as 1 divided by absolute risk reduction (difference between active and placebo in proportion of patients with ≥50% MMD reduction over Weeks 1–12). CPR was calculated by multiplying NNT by the quarterly (3-month) drug acquisition cost per drug (2023 UK £).
Results: All anti-CGRP mAbs demonstrated higher rates of ≥50% MMD reduction over Weeks 1–12 than their respective placebos ($p < 0.05$; Figure 1). Corresponding NNTs were 3.4 with eptinezumab 100 mg, 6.3 with erenumab 140 mg, 4.0 for both fremanezumab 225 mg and 675 mg, and 4.0 with galcanezumab 120 mg. CPRs were £4,655 with eptinezumab 100 mg, £7247 with erenumab 140 mg, £5,400 for both fremanezumab 225 mg and 675 mg, and £5400 with galcanezumab 120 mg.

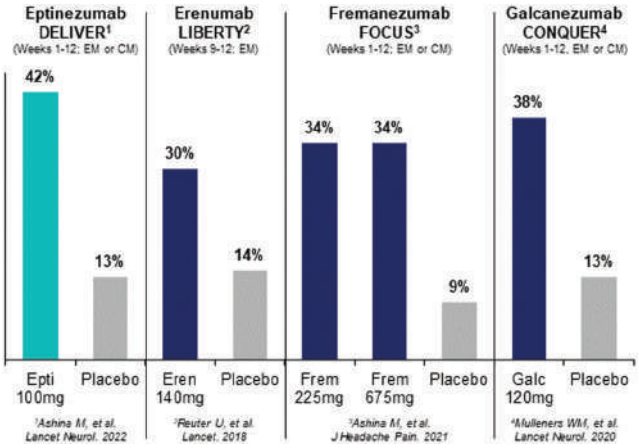


FIGURE 1: Percentage of patients with ≥50% reduction in MMDs from analyzed studies. Please note methodological differences between studies may preclude reliable comparison. CM, chronic migraine; EM, episodic migraine.

Conclusion: These results show a low number of patients with migraine need to be treated with an anti-GCRP mAb to achieve one patient with a ≥50% reduction in pre-treatment MMDs over Weeks 1–12, with eptinezumab showing the lowest NNT and CPR.

EPR-198 | Inflammatory profile and monocytes differentiation in migraine: Association with disease severity

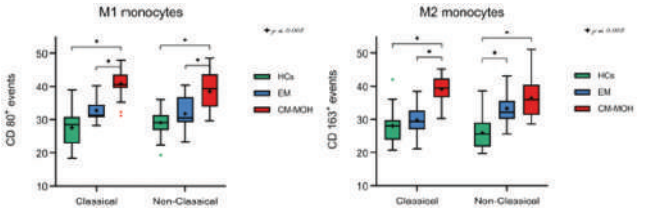
F. Bighiani[1]; R. De Icco[1]; R. Greco[2]; F. Cammarota[1]; M. Corrado[1]; G. Vaghi[1]; E. Mazzotta[1]; A. Antoniazzi[1]; G. Sances[2]; V. Grillo[1]; M. Francavilla[1]; A. Zanaboni[1]; E. Guaschino[2]; M. Allena[2]; N. Ghiotto[2]; C. Tassorelli[1]
[1]*Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; Headache Science & Neurorehabilitation Center, IRCCS Mondino Foundation, Pavia, Italy;* [2]*Headache Science and Neurorehabilitation Center, IRCCS Mondino Foundation, Pavia, Italy*

Background and Aims: Neuroinflammation has been considered in the pathogenesis of migraine. There is growing evidence of

aberrant cytokine production in migraine patients. The objective of the present study is to evaluate the expression levels of pro- and anti-inflammatory cytokines and the differentiation of monocytes in patients suffering episodic migraine (EM), chronic migraine with medication overuse headache (CM-MOH), and healthy controls (HCs).

Methods: In this cross-sectional study we assessed the gene expression of IL-1β, TNF-α and IL-10 (Relative Quantification – RQ) in peripheral blood monocytes. Monocyte differentiation was assessed by the number of events recorded using fluorescence-activated cell sorting. Pro-inflammatory M1 monocytes are defined as CD80+ whereas anti-inflammatory M2 monocytes are identified as CD163+. Monocytic subpopulations were differentiated in classical (CD14++/CD16−) and non-classical (CD14+/CD16++). All patients were studied in the interictal migraine phase.

Results: Demographic features were similar among 52 EM, 44 CM-MOH and 30 HCs. IL-1β and TNF-α expression levels were higher in CM-MOH patients compared to EM and HCs subjects ($p=0.001$ for all intergroup comparisons). IL-10 gene expression was lower in EM and CM-MOH when compared to HCs ($p=0.001$). Regarding monocyte profile, CM-MOH patients showed increased number of both M1 and M2 phenotypes when compared to EM and HCs (all $p \leq 0.005$).



Number of events recorded for the different monocytic subtypes among the three study groups.

Conclusion: Migraine patients exhibit a pro-inflammatory status with higher gene expression of IL-1β and TNF-α and reduced expression of IL-10. Monocyte phenotype distribution in migraine patients shows an overlap of increased pro-inflammatory and anti-inflammatory profiles. These alterations appear to be associated with the disease severity, being especially noticeable in patients with CM-MOH.

EPR-199 | Hypersensitivity to PACAP-38 in post-traumatic headache: A randomized clinical trial

H. Al-Khazali

Department of Neurology, Danish Headache Center, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark

Background and Aims: Pituitary adenylate cyclase-activating polypeptide-38 (PACAP-38), known for its role in migraine pathogenesis, has been identified as a novel drug target. Given the clinical parallels between post-traumatic headache (PTH) and migraine, we explored the possible role of PACAP-38 in the pathogenesis of PTH.

Methods: We conducted a randomized, double-blind, placebo-controlled, 2-way crossover trial involving participants diagnosed with persistent PTH resulting from mild traumatic brain injury. Participants were randomly assigned to receive a 20-min continuous intravenous infusion of either PACAP-38 (10 pmol/kg/min) or placebo (isotonic saline) on two separate experimental days, with a 1-week wash-out period in between. The primary outcome was the difference in incidence of migraine-like headache between PACAP-38 and placebo during a 12-h observational period post-infusion. The secondary outcome was the difference in the area under the curve (AUC) for baseline-corrected median headache intensity scores during the same 12-h observational period.

Results: During the 12-h observational period, 20 (95%) of 21 participants developed migraine-like headache after intravenous infusion of PACAP-38, compared with 2 (10%) participants after placebo ($p<0.001$). Furthermore, the baseline-corrected AUC values for median headache intensity scores during the 12-h observational period was higher after PACAP-38 than placebo ($p<0.001$).

Conclusion: These compelling results demonstrate that PACAP-38 is potent inducer of migraine-like headache in people with persistent PTH. Thus, targeting PACAP-38 signalling might be a promising avenue for the treatment of PTH.

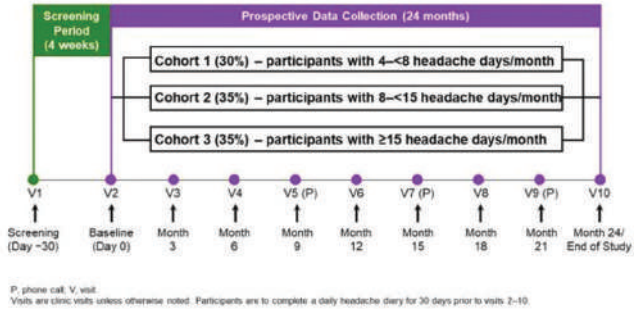
Background and Aims: CAPTURE is a 2-year, international, prospective, longitudinal study aiming to elevate the understanding of disease burden and treatment patterns among people living with migraine, stratified by headache frequency.

Methods: Adults with migraine diagnosed for ≥1 year, aged <50 years at onset, and taking ≥1 medication indicated for migraine with ≥4 monthly headache days (MHDs) in the prior 3 months were assigned to cohorts based on headache frequency (cohort 1: 4 to <8 MHDs; cohort 2: 8 to <15 MHDs; cohort 3: ≥15 MHDs; Figure). Descriptive data for baseline characteristics and patient-reported outcomes (PROs) (Migraine Disability Assessment [MIDAS], Migraine-Specific Quality of Life questionnaire v2.1 [MSQv2.1], Work Productivity and Activity Impairment Questionnaire [WPAI], Headache Impact Test-6, Patient Global Impression–Severity, Hospital Anxiety and Depression Scale, Migraine Interictal Burden Scale) are presented. Endpoints include durations of current/subsequent migraine treatment use and change from baseline of clinical outcomes (e.g., MHDs, medication use, PROs).

Figure. CAPTURE Study Design



P, phone call; V, visit.
Visits are clinic visits unless otherwise noted. Participants are to complete a daily headache diary for 30 days prior to visits 2–10.

CAPTURE Study Design.

Results: Among 239 participants (as of December 2023; cohort 1: $n=68$; cohort 2: $n=104$; cohort 3: $n=67$) (Table 1), baseline PROs indicated greater impairment and poorer quality of life with higher MHDs (Table 2). For cohorts 1, 2, and 3, respectively, baseline mean (SD) MIDAS total scores were 29 (40), 33 (30), and 61 (52); MSQv2.1 Role Function–Restrictive scores were 58.9 (17.5), 53.4 (20.8), and 44.8 (22.0); and WPAI migraine-related impairment was 39.4 (27.2), 40.6 (24.8), and 52.0 (22.8).

TABLE 1: Baseline demographic characteristics.

Characteristic	Cohort 1: 4 to <8 MHDs (n=68)	Cohort 2: 8 to <15 MHDs (n=104)	Cohort 3: ≥15 MHDs (n=67)

Absenteeism	14.1 (23.7)	15.2 (16.8)	25.1 (24.4)
Presenteeism	14.7 (18.3)	17.5 (16.1)	35.9 (34.1)
MSQv2.1 domain score			
Role Function-Restrictive	58.9 (17.5)	53.4 (20.8)	44.8 (22.0)
Role Function-Preventive	41.9 (11.0)	40.1 (13.0)	35.5 (14.1)
Emotional Function	30.1 (10.2)	26.7 (12.3)	22.5 (12.4)
PGI-S	1.6 (0.8)	1.8 (0.8)	2.2 (0.7)
WPAI domain score[c]			
Percent work time missed (absenteeism)	5.8 (15.0)	2.8 (5.0)	6.5 (12.4)
Percent impairment while working (presenteeism)	29.8 (25.8)	39.9 (24.1)	50.7 (22.2)
Percent overall impairment	34.0 (27.3)	41.4 (24.2)	52.8 (23.1)
Percent activity impairment due to migraine	39.4 (27.2)	40.6 (24.8)	52.0 (22.8)

HAD-S, Hospital Anxiety and Depression Scale; HIT-6, Headache Impact Test; MHD, monthly headache day; MIBS-4, Migraine Interictal Burden Scale; MIDAS, Migraine Disability Assessment; MSQ, Migraine-Specific Quality-of-Life Questionnaire v2.1; PGI-S, Patient Global Impression-Severity; WPAI, Work Productivity and Activity Impairment Questionnaire: Migraine.
[a]Numbers of participants with available data for this analysis are as follows: cohort 1, n=64; cohort 2, n=101; cohort 3, n=65.
[b]MIDAS scores were available for 100 participants in cohort 2.
[c]WPAI absenteeism, presenteeism, and percent overall impairment scores were calculated among participants reporting full-time employment: cohort 1, n=47; cohort 2, n=71; cohort 3, n=41.

Conclusion: Baseline PROs suggest greater disease burden among participants with higher MHD frequency. CAPTURE will provide critical data on migraine disease patterns and the associated burden over time.

Disclosure: This study was supported by AbbVie.

EPR-201 | Primary headache in transgender women compared with cisgender women and cisgender men: A case-control study

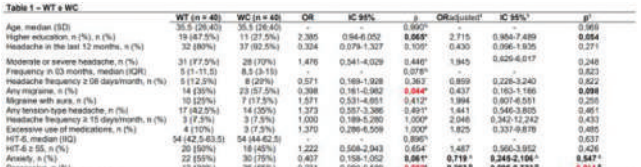
V. Arca[1]; C. Madruga[2]; J. Carreras[3]; J. Leite[2]; E. Diniz[2]; P. Rocha Filho[1]

[1]*Neurology Department – Hospital das Clínicas UFPE, Pernambuco, Brazil;* [2]*Endocrinology Department – Hospital das Clínicas UFPE, Pernambuco, Brazil;* [3]*Universidade Federal de Pernambuco UFPE*

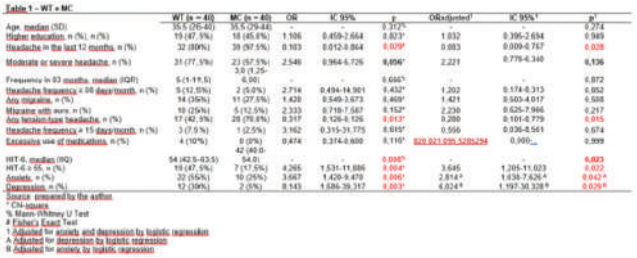
Background and Aims: The prevalence of headaches in transgender individuals using crossed hormone replacement therapy is not well established in the literature. The project aimed to evaluate the frequency, characteristics, and impact of headaches among transgender women on gender-affirming hormone therapy compared to cisgender women, and cisgender men.

Methods: We performed a case-control study carried out at a university hospital in northeast Brazil (HC-UFPE). Cases: 40 transgender women, aged 18 years or older and undergoing estrogen replacement therapy. Controls: 40 age-matched cisgender women, and 40 age-matched cisgender men. A semi-structured questionnaire, the Headache Impact Test (HIT-6), and the Hospital Anxiety and Depression Scale were performed. We performed logistic regression for the possible confounding variables. The research project was approved by the Research Ethics Committee of HC-UFPE (CAAE:58822022.2.0000.8807/number: 5.509.844).

Results: We included 120 individuals, 40 of whom were transgender women. The median age was 35.5 among the 3 groups (Mann–Whitney; $p=0.990$, and $p=0.312$). There was no statistical difference in the prevalence of migraine after logistic regression for anxiety and depression between transgender women group and cisgender women group. Cisgender women had higher rates of depression than transgender women (Mann–Whitney; $p=0.002$). We did not observe difference in the prevalence of migraine between transgender women and cisgender men group. There was a statistical difference in the prevalence of impact, anxiety, and depression in the transgender women group compared with cisgender men group (Mann–Whitney; $p=0.004/p=0.006/p=0.003$), respectively.



Sample characterization and WT × WC analysis.



Sample characterization and WT × MC analysis.

Conclusion: Transgender women had less depression than cisgender women. Transgender women had more impact of headache, anxiety, and depression rates than cisgender men.

Disclosure: We do not have conflicts of interest to declare.

Movement disorders 3

EPR-202 | Analysis of four randomized placebo-controlled trials supports pridopidine's treatment benefit in Huntington disease

M. Geva; K. Chen; R. Hand; Y. Goldberg; M. Hayden

Prilenia Therapeutics B.V., Naarden, The Netherlands

Background and Aims: In PROOF-HD, pridopidine demonstrated improvements across key measures of HD clinical progression (cUHDRS), function (TFC), cognition (SWR), motor (Q-Motor), and quality-of-life, in participants off antidopaminergic medications (ADMs).

Methods: To assess if participants off ADMs from prior pridopidine studies have consistent findings with PROOF-HD, we performed a pooled analysis from four randomized, double-blind, placebo-controlled trials assessing pridopidine in early HD (TFC 7–13) (HART, MermaiHD, PRIDE-HD and PROOF-HD).

Results: In the analysis of 435 participants ($n=227$, placebo and $n=208$, pridopidine), pridopidine showed treatment benefit versus placebo in TFC at Week 26 (Δ0.31, $p=0.03$), 39 (Δ0.43, $p=0.01$), 52 (Δ0.38, $p=0.02$), and 78 (Δ0.49, $p=0.02$), and on cUHDRS at Week 26 (Δ0.39, $p=0.006$) and 39 (Δ0.55, $p=0.003$) with a meaningful treatment benefit of Δ0.36 at Week 78 (PRIDE-HD did not measure SWR and was excluded). In the revised cUHDRS without SWR, pridopidine showed improvement above baseline up to Week 52, with benefits versus placebo at Week 26 (Δ0.30, $p=0.006$), 39 (Δ0.45, $p=0.002$), 52 (Δ 0.29, $p=0.04$), and 78 (Δ0.34, $p=0.07$). All trials contribute positively to the observed benefits. A significant benefit across all Q-motor measures was observed. For example, pridopidine shows improvement from baseline in finger tapping to Week 52 with a significant treatment benefit at Week 12 (Δ-31 msec, $p=0.046$), 26 (Δ-27 msec, $p<0.001$), 52 (Δ-25 msec, $p=0.02$), and Week 78 (Δ-25 msec, $p=0.05$). The placebo group shows an expected decline in all Q-motor measures.

Conclusion: This analysis strongly supports and validates PROOF-HD findings of a consistent, sustained, and meaningful treatment benefits of pridopidine in patients off ADMs.

Disclosure: Full disclosures will be presented.

EPR-203 | Metabolic brain correlates of visuoperceptual impairment and visual hallucinations in Parkinson's disease

M. Michelutti[1]; M. Liccari[1]; M. Catalan[1]; C. Manara[2]; A. Cucca[2]; C. Crisafulli[3]; F. Dore[3]; M. Murgia[1]; M. Ajčević[4]; A. Benussi[1]; P. Manganotti[1]

[1]*Clinical Unit of Neurology, Department of Medicine, Surgery and Health Sciences, University Hospital and Health Services of Trieste – ASUGI, University of Trieste, Trieste, Italy;* [2]*Department of Life Sciences, University of Trieste, Trieste, Italy;* [3]*Unit of Nuclear Medicine, Department of Medicine, Surgery and Health Sciences, Cattinara University Hospital ASUGI, University of Trieste, Trieste, Italy;* [4]*Department of Engineering and Architecture, University of Trieste, Trieste, Italy*

Background and Aims: This study investigated whether the same brain metabolic correlates underlie both visual hallucinations and perceptual impairment in Parkinson's disease (PD).

Methods: Eleven non-demented idiopathic PD patients experiencing visual hallucinations (PD-VH) and 9 non-demented, age-matched PD patients without a history of visual hallucinations (PD-NVH) participated in the study. They underwent positron emission tomography (PET) with [18F]fluorodeoxyglucose tracer. The University of Miami Parkinson's disease Hallucinations Questionnaire (UM-PDHQ) was administered to assess the burden of visual hallucinations. Perceptual performance was evaluated using two sets of illusory figures. A voxel-wise group comparison using 18-FDG-PET tomography was conducted, following the SPM12 software guidelines. Additionally, partial correlations between voxel-wise relative regional cerebral glucose metabolic rate, UM-PDHQ scores, and perceptual performance scores were performed.

Results: PD-VH patients showed poorer perceptual performance than PD-NVH patients ($p < 0.050$). Unlike PD-NVH patients, PD-VH patients exhibited significant relative hypermetabolism in both right and left fronto-parietal lobes ($p < 0.05$, Threshold Free Cluster Enhancement-False Discovery Rate-corrected). Additionally, in PD-VH patients, the metabolic rate of a similar set of regions positively correlated with UM-PDHQ scores ($p < 0.001$, uncorrected) and inversely correlated with perceptual performance scores ($p < 0.001$ to $p < 0.050$, uncorrected).

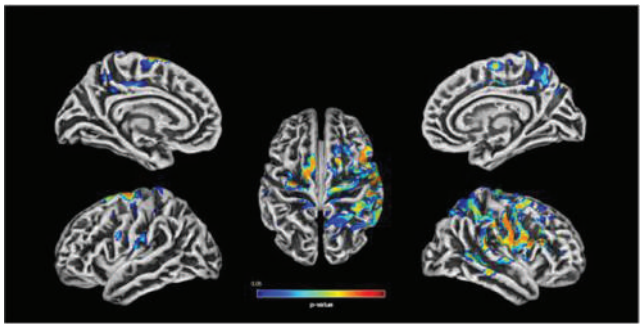


FIGURE 1: Hypermetabolic regions in Parkinson's disease patients with visual hallucinations (Threshold Free Cluster Enhancement – False Discovery Rate corrected, $p < 0.05$).

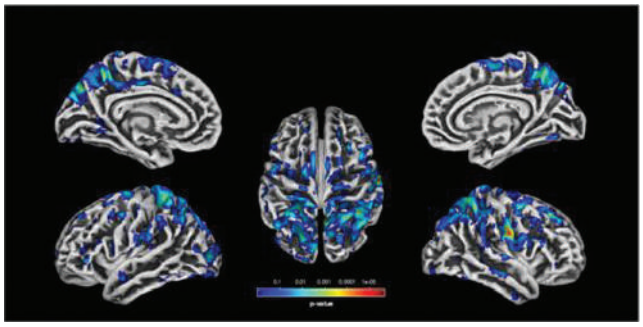

FIGURE 2: Partial positive correlation (covariates: age, sex) between University of Miami Parkinson's disease Hallucinations Questionnaire (UM-PDHQ) scores and cerebral regional relative glucose metabolic rate.

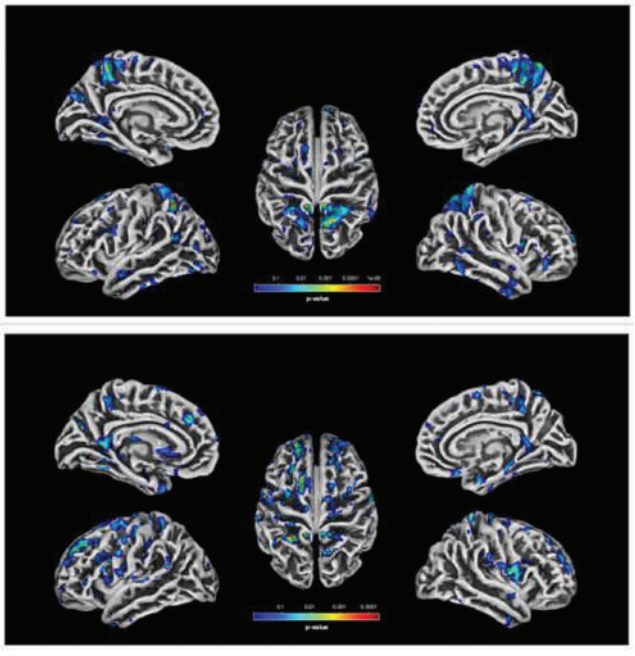

FIGURE 3a: Partial negative correlation (covariates: age and sex) between the size shrinkage of amodal completion illusion test scores and the cerebral regional relative glucose metabolic rate in the group of Parkinson's disease patients with visual hallucination.

Conclusion: Fronto-parietal hypermetabolism appears to be a common underlying factor for both visual hallucinations and perceptual impairment in Parkinson's disease. Future studies with a larger sample size could provide more precise localization of these alterations.

EPR-204 | Safety of deutetrabenazine for tardive dyskinesia in the European population: The open-label RIM-TD year 4 study

R. Hause[1]; K. Duma[2]; N. Chaijale[3]; S. Barash[3]; S. Factor[4]; J. Jimenez-Shahed[5]; N. Gross[3]; L. Marinelli[3]; M. Forrest Gordon[3]; K. Anderson[6]
[1]University of South Florida Parkinson's Disease and Movement Disorders Center, Tampa, FL, USA; [2]Teva Pharmaceuticals Europe B.V., Amsterdam, The Netherlands; [3]Teva Branded Pharmaceutical Products R&D, Inc., West Chester, PA, USA; [4]Jean and Paul Amos Parkinson's Disease and Movement Disorder Program, Emory University, Atlanta, GA, USA; [5]Icahn School of Medicine at Mount Sinai, New York, NY, USA; [6]Georgetown University, Department of Psychiatry & Department of Neurology, Washington, DC, USA

Background and Aims: Tardive dyskinesia (TD) is a hyperkinetic movement disorder that has few treatment options. Deutetrabenazine (DTBZ) is a vesicular monoamine transporter 2 inhibitor approved in 6 countries for the treatment of TD in adults. Data from the first 3 years of an open-label extension study (RIM-TD; NCT02198794) support the tolerability and efficacy of DTBZ for TD in adults, but the safety beyond this period in the European population is unknown.
Methods: Patients in the Czechia, Germany, Hungary, Poland, and Slovakia were eligible to enrol in an additional 52 weeks of DTBZ treatment (RIM-TD year 4). Safety assessed via adverse event (AE) reporting throughout year 4 is reported here.
Results: Of the 80 patients enrolled in year 4, the mean (SD) age at the start of year 4 was 61.4 (13.5) years, and 52 (65%) patients were female. Concomitant medications included antipsychotics (52 [65%]), antidepressants (31 [39%]), anxiolytics (15 [19%]), and antiepileptics (26 [33%]). At week 39 of year 4, the mean (SD) total daily dose of DTBZ was 39.1 (11.8) mg/day. AEs and treatment-related AEs were reported for 23 (28.8%) and 3 (3.8%) patients, respectively. 73 (91%) patients completed year 4; reasons for discontinuation were patient withdrawal ($n = 3$ [4%]), AEs (2 [3%]), and death (2 [3%]; due to cardiac failure and acute respiratory and circulatory failure).
Conclusion: Year 4 safety data from this European cohort of patients with TD are consistent with the 3-year RIM-TD parent study and support the safety and tolerability of DTBZ beyond 3 years.

EPR-205 | Inhaled levodopa in fluctuating Parkinson's disease: Post-commercialization experience in a movement disorders unit

P. Ros-Arlanzón[2]; N. Valverde-Mata[3]; Á. Patiño[1]; A. Alonso-Cánovas[1]; P. Pérez-Torres[1]; J. López-Sendón[1]; S. Fanjul[1]; J. Martínez-Castrillo[1]; I. Pareés[4]
*[1]Movement Disorders Unit, Neurology Department, Hospital Ramon y Cajal, Madrid, Spain; [2]Movement Disorders Unit, Neurology Department, Hospital Ramon y Cajal, Madrid, Spain; *Current Affiliation: Neurology Department, Alicante University Hospital, Alicante, Spain; [3]Movement Disorders Unit, Neurology Department, Hospital Ramon y Cajal, Madrid, Spain; *Current Affiliation: Neurology Department, Badajoz University Hospital, Badajoz, Spain; [4]Movement Disorders Unit, Neurology Department, Hospital Ramon y Cajal, Madrid, Spain and Functional Movement Disorders Unit, Movement Disorders Program, Neurology Department, Hospital Ruber Internacional, Madrid, Spain*

Background and Aims: Levodopa, the primary Parkinson's disease (PD) treatment for over 50 years, becomes less effective as the disease progresses, leading to motor fluctuations. Current treatments for these fluctuations are scarce. CVT-301, a newly available inhaled levodopa powder, has shown efficacy in clinical trials for managing OFF periods in PD without significant pulmonary side effects. It offers rapid symptom improvement and it is easy to administer, making it suitable for OFF periods uncontrolled by oral medications. However, post-commercialization data on the use of inhaled levodopa is lacking. In this study we describe the experience in our Movement Disorders Unit.
Methods: observational study at a specialized Parkinson's center in Spain. Patients treated with inhaled levodopa from April to October 2023 were included in a retrospective way. Clinical and demographic characteristics were described. All patients had been trained in treatment usage by a neurologists or specialized nurse to ensure a correct administration.
Results: Eighteen patients (55.6% females, mean age 65.17 years, mean PD duration 9 years) were included. Thirteen (77.2%) reported OFF symptom improvement (median PGI-C score 3, IQR 2–3.75). Clinical improvement was described within the first 10 min of administration. The average maximum daily usage was 1.5 (IQR: 1–3). Side effects were reported by 12 (66.7%) patients, mainly cough and dyskinesias, leading to a 11.1% discontinuation rate.
Conclusion: In our cohort, inhaled levodopa provided rapid and substantial improvement in our cohort and was overall well tolerated with a discontinuation rate of 11%.
Disclosure: IP has received honoraria as speaker in scientific meetings from Zambon, Abbvie, Exeltis Healthcare SL Sociedad Extremeña de Neurología, Sociedad Española de Neurología and travel support for scientific meetings from Esteve. Pablo Ros-Arlanzón and

EPR-206 | Post hoc subgroup analysis: Age of Friedreich ataxia onset in MOXIe trial of omaveloxolone

S. Chimalapati[1]; W. Costello[1]; A. Goldsberry[1]; S. Rich[1]; C. Ruhl[1]; D. Lynch[2]

[1]*Department of Research and Development, Biogen, Cambridge, USA;* [2]*Departments of Pediatrics and Neurology, The Children's Hospital of Philadelphia, Philadelphia, USA*

Background and Aims: Age of onset is an important predictor of clinical progression in patients with Friedreich ataxia (FA). This post hoc analysis evaluated change in modified Friedreich Ataxia Rating Scale (mFARS) scores by age of onset subgroups using data from MOXIe Part 2 (NCT02255435; EudraCT2015-002762-23) and propensity-matched data from the MOXIe open-label extension (OLE) and the FA-COMS natural history study (NCT03090789).

Methods: MOXIe Part 2 randomized patients 1:1 to placebo or omaveloxolone 150 mg once daily (primary endpoint: change from baseline in mFARS at Week 48). MOXIe OLE (ongoing study to assess long-term safety and tolerability of omaveloxolone) patients were propensity score-matched 1:1 to FA-COMS patients. Changes in mFARS scores by age of onset subgroups were analyzed using mixed models repeated measures.

Results: In MOXIe Part 2 (median age of FA onset: 15 years), patients with age of onset >15 years versus ≤15 years had lower mean baseline mFARS scores (Table 1). Placebo-treated patients with age of onset ≤15 years versus >15 years had more progression by Week 48, whereas omaveloxolone-treated patients demonstrated a similar change from baseline regardless of age of onset. In both subgroups, progression directionally favored omaveloxolone versus placebo-treated patients at Week 48 (Table 1) and versus propensity-matched FA-COMS controls after 3 years (Table 2).

TABLE 1: MOXIe Part 2: Key demographics and baseline characteristics by age of FA onset subgroups (FAS), and mFARS results by age of FA onset subgroups (FAS).

	Age of FA Onset ≤15 Years		Age of FA Onset >15 Years	
	Placebo (N=22)	Omaveloxolone (N=23)	Placebo (N=20)	Omaveloxolone (N=17)
Age (years) Mean (SD) Median [min, max]	18.3 (2.40) 17.0 [16, 24]	20.8 (4.87) 20.0 [16, 34]	29.4 (7.54) 28.0 [18, 40]	28.8 (5.58) 28.0 [20, 39]
Age of FA onset (years) Mean (SD) Median [min, max]	11.1 (3.04) 12.0 [5, 15]	12.0 (2.25) 12.0 [7, 15]	19.5 (3.58) 18.0 [16, 30]	21.1 (4.88) 21.0 [16, 36]
mFARS				
Baseline, mean (SD)	40.83 (9.086)	43.39 (10.503)	36.52 (12.683)	37.64 (9.559)
Week 48 change from baseline				
LS mean (SE)	2.03 (0.896)	−1.56 (0.960)	−0.40 (0.935)	−1.47 (1.039)
LS mean difference (SE)	—	−3.60 (1.313) p=0.0077	—	−1.07 (1.377) p=0.4411

Abbreviations: FA=Friedreich ataxia; FAS=full analysis set; LS=least squares; max=maximum; mFARS=modified Friedreich Ataxia Rating Scale; min=minimum; SD=standard deviation; SE=standard error.

TABLE 2: Propensity-matched analysis: Baseline age, age of onset, and mFARS results by age of onset subgroups (primary pooled population).

	Age of FA Onset ≤15 Years		Age of FA Onset >15 Years	
	Matched FA-COMS (N=92)	MOXIe Extension (N=75)	Matched FA-COMS (N=44)	MOXIe Extension (N=61)
Age (years) Mean (SD) Median [min, max]	20.4 (10.38) 18.0 [6, 64]	22.7 (5.64) 21.0 [16, 37]	38.3 (11.80) 36.0 [16, 61]	31.3 (6.16) 32.0 [18, 41]
Age of FA onset (years) Mean (SD) Median [min, max]	9.8 (3.42) 10.0 [2, 15]	11.7 (2.76) 12.0 [5, 15]	26.6 (11.17) 21.5 [16, 52]	20.0 (3.93) 19.0 [16, 36]
mFARS				
Baseline, mean (SD)	43.70 (15.98)	45.23 (11.55)	35.46 (15.06)	38.53 (12.94)
Year 3 change from baseline				
LS mean (SE)	6.77 (0.807)	3.45 (0.896)	5.94 (1.109)	2.47 (1.002)
LS mean difference (SE)	—	−3.33 (1.198) p=0.0057	—	−3.47 (1.478) p=0.0193

Abbreviations: FA=Friedreich ataxia; FA-COMS=Friedreich Ataxia - Clinical Outcome Measures; LS=least squares; max=maximum; mFARS=modified Friedreich Ataxia Rating Scale; min=minimum; SD=standard deviation; SE=standard error.

Conclusion: Although MOXIe Part 2 was not powered to detect efficacy by age of onset subgroups, results directionally favored omaveloxolone versus placebo regardless of age of FA onset. Similar trends were observed after 3 years in MOXIe OLE relative to propensity-matched FA-COMS patients.

Disclosure: This study was funded by Reata Pharmaceuticals. Reata was acquired by Biogen in 2023. S Chimalapati, W Costello, A Goldsberry, S Rich, and C Ruhl are employees of Biogen. D Lynch reports grants from FARA, the Muscular Dystrophy Association (MDA), the National Institutes of Health (NIH), Reata Pharmaceuticals, and Retrotope.

EPR-207 | Suvecaltamide pharmacokinetics, safety, & tolerability–Phase 1, randomized, double-blind, multiple ascending dose study

S. Markova; M. Baladi; M. Lee; C. Chen
Jazz Pharmaceuticals, Palo Alto, CA, USA

Background and Aims: Suvecaltamide (JZP385), a highly selective CaV3 channel modulator, is currently in Phase 2b development to treat essential tremor (NCT05122650) and Parkinson's disease tremor (NCT05642442). This Phase 1, double-blind, parallel design, within-participant, multiple ascending dose study evaluated the pharmacokinetics (PK), safety, and tolerability of this once-daily (QD) suvecaltamide formulation.

Methods: Healthy participants (18–75 years) were randomized to suvecaltamide or placebo (Part 1: 8 mg QD, days 1–7; Part 2: 8 mg QD, days 1–7; 16 mg QD, days 8–14; 24 mg QD, days 15–21; 36 mg QD, days 22–25). PK, time-matched electrocardiograms, treatment-emergent adverse events (TEAEs), and food-effect data were collected.

Results: Participants (suvecaltamide: $n = 20$/formulation/part; placebo: $n = 10$/part) were similar in age, sex, race, and baseline characteristics across treatment groups and study parts. Fasted, steady-state PK parameters for suvecaltamide and its major active metabolites (JZZ05000034 = M01, JZZ05000035 = M02) were approximately dose proportional (Table). A high-fat/high-calorie meal had negligible effect on suvecaltamide Cmax and AUC, but prolonged tmax. For all doses, the upper bound 90% CI of the placebo-corrected change from baseline in Fridericia's corrected QT interval at each analyte's mean Cmax was substantially below the 10-msec regulatory threshold of concern. Across study parts, the most common TEAEs were dizziness (suvecaltamide, 25%; placebo, 10%), insomnia (suvecaltamide, 20%; placebo, 20%), and headache (suvecaltamide, 18%; placebo, 30%). Most TEAEs were mild to moderate in severity, and their incidence tended to decrease with increasing dose.

Table. Suvecaltamide pharmacokinetic parameters at steady state (with fasting)

	Suvecaltamide			M01 (JZZ05000034)				M02 (JZZ05000035)			
Dose[a]	C_{max} (ng/mL)[b]	AUC_{tau} (h·ng/mL)[b]	t_{max} (h)[c]	C_{max} (ng/mL)[b]	AUC_{tau} (h·ng/mL)[b]	t_{max} (h)[c]	MR C_{max}	MR AUC_{tau}	C_{max} (ng/mL)[b]	AUC_{tau} (h·ng/mL)[b]	t_{max} (h)[c]	MR C_{max}	MR AUC_{tau}
8mg	233 (47.6)	3184 (857.6)	1.0 [0.5–6.0]	152 (33.1)	3183 (719.1)	4.3 [0.5–23.6]	0.67	1.04	90 (29.4)	1691 (356.7)	5.1 [1.1–16.0]	0.37	0.51
16mg	439 (100.0)	5859 (1932.5)	1.0 [0.5–2.0]	317 (111.1)	6806 (2334.3)	2.5 [0.5–23.6]	0.74	1.14	188 (58.1)	3612 (1101.5)	2.5 [1.0–8.0]	0.41	0.63
24mg	631 (146.6)	8213 (3003.1)	1.0 [0.5–2.5]	507 (149.5)	10,530 (3230.7)	2.3 [0.5–23.6]	0.82	1.17	261 (68.9)	5189 (1965.2)	4.0 [1.5–23.6]	0.39	0.54
36mg	962 (216.1)	12,180 (3579.6)	1.0 [0.5–6.0]	696 (184.5)	14,300 (4253.1)	2.3 [1.0–23.6]	0.79	1.20	392 (114.2)	7429 (2648.6)	2.5 [1.0–8.0]	0.41	0.58

[a]8mg data is from Day 6, 16mg data is from Day 14, 24mg data is from Day 21, 36mg data is from Day 25.
[b]PK data presented as mean (SD).
[c]t_{max} is presented as median [minimum – maximum].
AUC_{tau}, area under the curve over the dosing period, tau, at steady state tau is defined as 24 hours; C_{max}, maximum observed concentration; h, hour; MR, molar ratio (metabolite to parent); PK, pharmacokinetic; SD, standard deviation; t_{max}, time of maximum concentration.

Suvecaltamide pharmacokinetic parameters at steady state (with fasting).

Conclusion: Results from this Phase 1 study expand our understanding of suvecaltamide PK, safety, and tolerability, supporting further clinical development of the QD formulation of suvecaltamide.

EPR-208 | Diagnostic accuracy of skin biopsy in disclosing early PD

V. Donadio[1]; A. Incensi[1]; S. Bonvegna[2]; G. Rizzo[1]; A. Furia[1]; E. Olivola[3]; M. Piatti[2]; F. Ventruto[1]; V. Vacchiano[1]; E. Fileccia[1]; S. Parisini[1]; N. Modugno[3]; R. Cilia[4]; R. Liguori[1]
[1]IRCCS Istituto delle Scienze Neurologiche di Bologna, UOC Clinica Neurologica, Italy; [2]ASST Centro Specialistico Ortopedico Traumatologico Gaetano Pini – CTO, UOC Centro per la malattia di Parkinson, Milano, Italy; [3]IRCCS Istituto Neurologico Mediterraneo Neuromed, Pozzilli (IS), Italy; [4]Fondazione IRCCS Istituto Neurologico Carlo Besta, Parkinson and Movement Disorders Unit, Milano, Italy

Background and Aims: To analyse the diagnostic accuracy of phosphorylated α-synuclein (p-syn) in autonomic skin fibers in identifying early Parkinson's disease (PD).

Methods: One hundred twenty-nine participants with early parkinsonian signs (onset within the last 18 months) were included in the study. Proximal and distal skin sites were taken to analyse p-syn by immunofluorescence. Patients also underwent clinical evaluation including focused scales (UPDRS and HY, MoCA, COMPASS-31, NMSQuest) and smell analysis. Clinical evaluation was repeated over a follow-up of 18 months in all patients whereas skin biopsy was repeated in 45 patients in the follow-up. Clinical diagnosis of PD was defined according to the Movement Disorder Society (2019) criteria.

Results: Seventy-seven patients fulfilled clinical criteria for PD and 69 of them (90%) presented p-syn in autonomic fibers or plexus. By contrast, twenty-three patients meet clinical criteria of tauopathy, vascular PD or MSA. P-syn was absent in these patients except a single MSA patient showing the typical somatic p-syn. Accordingly, the overall specificity of p-syn in skin autonomic nerves was 100%. Twenty-nine patients showed an undefined clinical picture both at baseline and follow-up. PD patients showed higher smell dysfunctions, RBD incidence, UPDRS, HY and COMPASS-31 scales without any correlation with p-syn.

Conclusion: Our results showed that skin biopsy and skin p-syn in autonomic nerve fibers presented an excellent diagnostic accuracy in disclosing early PD with high sensitivity and specificity. Our study corroborates the use of skin biopsy for the diagnosis of early PD.

Disclosure: No disclosures to report.

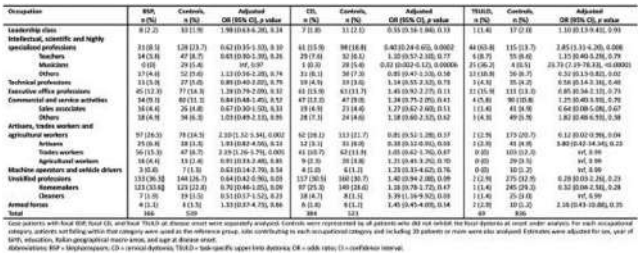
Background and Aims: Development of idiopathic adult-onset dystonia (IAOD) in different body parts is associated with specific demographic and clinical characteristics, as well as with specific risk factors. This study aimed to investigate the association between specific occupations and specific forms of idiopathic dystonia at onset, namely blepharospasm (BSP), cervical dystonia (CD), and task-specific upper limb dystonia (TSULD).

Methods: Data from 905 IAOD patients enrolled in the Italian Dystonia Registry were analyzed. Each patient was assigned to the corresponding occupational category by specialists in occupational medicine according to the Italian National Institute of Statistics classification. Logistic regression models (adjusted for sex, year of birth, age at dystonia onset, education, and Italian geographical areas) were computed to assess the association between occupation and a specific dystonia at onset, using the patients who developed focal dystonia in other body parts as controls.

ISTAT occupational category (n. patients)	Jobs (n. patients)
Leadership class (18)	Entrepreneurs (8); executives (4); restaurateurs (3); hotel managers (2); garage managers (1).
Intellectual, scientific and highly specialized professions (159)	Teachers (61); musicians (29); students (15); chartered accountants (7); healthcare professionals (7); lawyers (7); clergy members (6); engineers (5); surveyors (4); journalists (3); computer scientists (2); dancers (2); freelancers (2); research scientists (2); actors (1); biologists (1); consultants (1); home economists (1); physicists (1); project managers (1); writers (1).
Technical professions (38)	Nurses (13); real estate agents (4); commercial agents (3); insurance agents (3); programmers (2); travel agents (2); agronomists (1); oenologists (1); fitness trainers (1) interior designers (1); jewelry sales representatives (1); maritime brokers (1); opticians (1); pilots (1); radiologic technologists (1); sales representatives (1); swimming instructors (1).
Executive office professions (122)	Unclassifiable (96); secretaries (6); administrative employees (6); accountants (2); bank employees (2); municipal clerks (2); cashiers (1); customs brokers (1); postal service clerk (1); railway office workers (1); switchboard operators (1); social security administrators (1); tax consultants (1); technical officers (1).
Commercial and service activities (94)	Sales associates (42); hospitality workers (19); personal care assistants (16); hairdressers/beauticians (12); warehouse workers (2); automotive parts salespersons (1); flight attendants (1); petrol station attendants (1).
Artisans, trades workers and agricultural workers (175)	Trades workers (103); artisans (43); agricultural workers (29).
Machine operators and vehicle drivers (10)	Drivers (7); marine plants (1); train conductors (1); truck drivers (1).
Unskilled professions (277)	Homemakers (246); cleaners (26); concierges (3); nursery school attendants (2).
Armed forces (12)	Police officers (4); municipal police officers (3); unspecified (3); carabinieri (1); firefighters (1).

Distribution of specific jobs across Italian National Institute of Statistics (ISTAT) occupational categories.

Results: Compared to other professions, trades workers exhibited an increased risk for BSP at onset (OR = 2.19, 95% CI 1.26–3.79), cleaners for CD (OR = 3.39, 95% CI 1.16–9.92), and musicians for TSULD (OR = 23.73, 95% CI 7.19–78.33). The longer the duration of employment before the onset of dystonia, the greater the risk of developing the specific dystonia.



Associations between main lifetime occupation categorized according to the Italian National Institute of Statistics (ISTAT) classification and site of dystonia onset.

Site of dystonia onset	Occupation	OR (95% CI), *p* value
BSP (n = 352)	Non-trades workers	1 (reference)
	Trades workers for <22 years	1.45 (0.63-3.33), 0.38
	Trades workers for ≥22 years	2.34 (1.04-5.24), 0.04
CD (n = 383)	Non-cleaners	1 (reference)
	Cleaners for <17 years	2.43 (0.42-14.16), 0.32
	Cleaners for ≥17 years	8.93 (1.06-75.24), 0.04
TSULD (n = 53)	Non-musicians	1 (reference)
	Musicians for <14 years	Inf, 0.99
	Musicians for ≥14 years	10.09 (1.50-67.70), 0.02

Each occupational exposure was stratified according to the median duration. Estimates were adjusted by sex, year of birth, education, Italian geographical macro-areas, and age at disease onset.
Abbreviations: BSP = blepharospasm; CD = cervical dystonia; TSULD = task-specific upper limb dystonia; OR = odds ratio; CI = confidence interval.

Impact of occupational duration in trades work, cleaners, and musicians on the risk of developing blepharospasm, cervical dystonia, and task-specific upper limb dystonia, respectively.

Conclusion: We provided novel information indicating that exposure to certain occupations may trigger specific forms of IAOD, namely BSP, CD, and TSULD. The associations highlighted by this study probably reflect common pathophysiological mechanisms among different focal dystonias, relying on the frequent performance of repetitive movements in a specific body part.
Disclosure: Nothing to disclose.

EPR-210 | Validity and reliability of the Spanish version of the King's Parkinson's Pain Scale (KPPS)

Y. González Zamorano[1]; M. Moreno Verdú[2]; J. Romero Muñoz[3]; J. Fernández Carnero[1]; F. Sánchez Cuesta[3]
[1]*Department of Physical Therapy, Occupational Therapy, Rehabilitation and Physical Medicine, Universidad Rey Juan Carlos, Alcorcón, Spain;* [2]*Brain, Action and Skin Laboratory (BAS-Lab), Institute of Neuroscience (Cognition and System Division), UC Louvain;* [3]*Faculty of Experimental Sciences, Francisco de Vitoria University, Pozuelo de Alarcón, Spain*

Background and Aims: The King´s Parkinson´s Pain Scale (KPPS) has been recently translated and cross-culturally adapted to Spanish. We aim to assess its test-retest reliability, measurement error, and criterion and convergent validity in Spanish-speaking individuals experiencing Parkinson´s Disease (PD)-related pain.
Methods: Fifty-three PD patients suffering from otherwise explained pain participated. They were evaluated in one session by the KPPS, Brief Pain Inventory, two Pain Pressure Thresholds (PPT) in a painful and a non-painful location, and Conditioned Pain Modulation (CPM). A retest of the KPPS was performed via phone call by the same evaluator 7–15 days later. Internal consistency (Cronbach's alpha), test-retest reliability (Intraclass Correlation Coefficient), Standard Error of Measurement, and criterion and convergent validity (Pearson's *r*) were obtained.
Results: Internal consistency was acceptable (Cronbach's alpha = 0.77, 95% CI = 0.67–0.85). The mean test and retest Total KPPS scores were similar (test = 34.83 ± 23.50 points, retest = 35.87 ± 26.23 points), and test-retest reliability was good (ICC = 0.85, 95% CI = 0.75–0.91). Measurement error was SEM = 9.1 points. Regarding criterion validity, the Total KPPS score was not correlated to the BPI intensity subscale ($r = 0.18$, $p = 0.19$) but it was moderately and positively correlated to the interference subscale ($r = 0.43$, $p = 0.001$). Related to convergent validity, the Total KPPS was moderately and negatively correlated to both the non-painful PPT ($r = -0.4$, $p = 0.003$) and WMH ($r = -0.38$, $p = 0.005$). No statistically significant correlations were found with painfulPPT or CPM ($p > 0.05$).

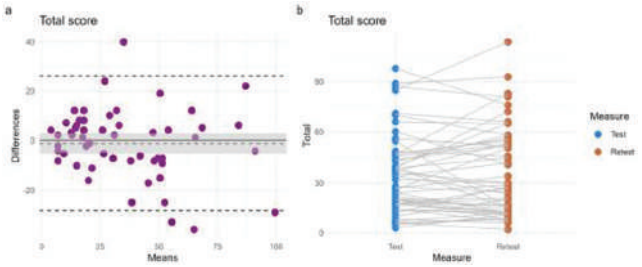


FIGURE 1: Test-retest reliability of the Spanish King's Parkinson's Disease Pain Scale (KPPS) total score.

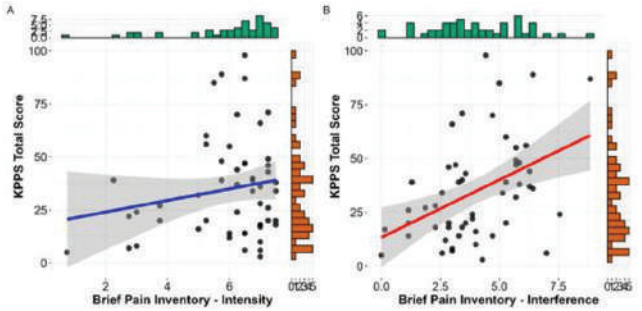

FIGURE 2: Criterion validity of the Spanish King's Parkinson's Disease Pain Scale (KPPS) total score.

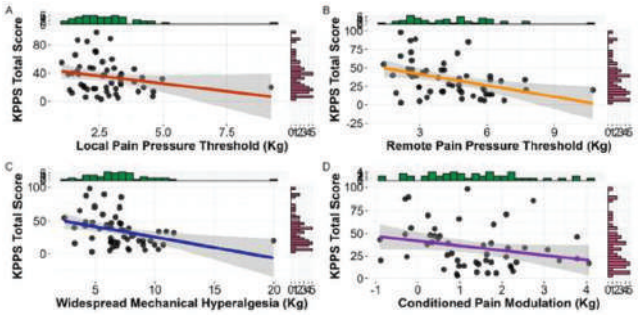

FIGURE 3: Convergent validity of the Spanish King's Parkinson's Disease Pain Scale (KPPS) total score.

Conclusion: The present study provides evidence that the Spanish version of the KPPS has good reliability, minimal measurement error, and sufficient criterion and convergent validity.
Disclosure: The availability of this scale will assist Spanish clinicians in crafting individualized treatment plans for PD patients by pinpointing characteristics such as the severity and frequency of their pain.

EPR-211 | Postganglionic autonomic dysfunction and cutaneous alpha-synuclein deposits in MSA: Role in disease progression

G. Devigili[1]; R. Telese[1]; R. Lombardi[2]; F. Cencini[1]; L. Maldera[2]; A. Elia[1]; R. Cilia[1]; V. Leta[1]; S. Mazzetti[1]; N. Golfré Andreasi[1]; F. Colucci[1]; L. Romito[1]; E. Salvi[2]; R. Eleopra[1]
[1]*Fondazione IRCCS Istituto Neurologico Carlo Besta, Department of Clinical Neurosciences, Parkinson and Movement Disorders Unit, Milan, Italy*; [2]*Fondazione IRCCS Istituto Neurologico Carlo Besta, Department of Clinical Neurosciences, Neuroalgological Disorder Unit, Milan, Italy*

Background and Aims: Multiple system atrophy (MSA) is a progressive neurodegenerative disease clinically characterized by parkinsonism (MSA-P) and/or cerebellar dysfunction (MSA-C) associated with autonomic failure. Autonomic dysfunction is generally considered to be caused by a preganglionic fibers involvement. However, growing evidence supports the presence of postganglionic autonomic involvement together with skin denervation, suggesting the concomitant peripheral nervous system involvement. The study aimed to assess peripheral autonomic involvement through sudomotor and cardiovascular tests and skin biopsy to establish their role in predicting disease progression and severity.
Methods: A cross-sectional study on patients with "clinically established" MSA diagnosis was performed. Complete clinical workup, MIBG cardiac scintigraphy, cardiovascular autonomic tests, Dynamic sweating test, skin biopsies for epidermal and dermal nerves, and p-syn quantitation at three body sites were performed.
Results: 31 patients (21 MSA-P, 10 MSA-C) were enrolled. No difference in demographic and clinical scales scoreswase found. DST was impaired in all tested patients. Cutaneous p-syn deposits were found in 81% of patients, with a topographic distribution following a distal-proximal gradient and no difference between clinical subtypes. P-syn deposits were found in both somatic and autonomic fibers, with greater prevalence in the former. The presence of widespread skin nerve p-syn deposits was associated with higher UMSARS Part II scores and with OH. Neither p-syn deposition nor sudomotor dysfunction correlated with disease duration.
Conclusion: This study highlights the presence of functional abnormalities of postganglionic sudomotor pathway in MSA and provides a preliminary support for the use of cutaneous p-syn quantitation as a prognostic biomarker in MSA in clinical practice and research studies.

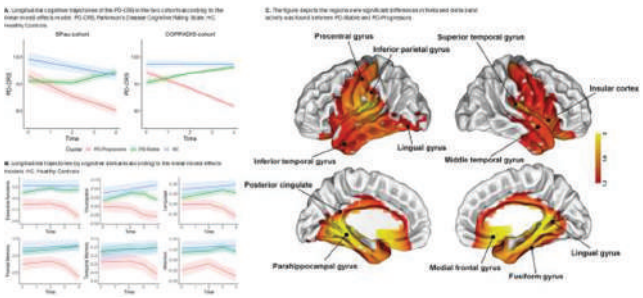
EPR-212 | Prediction of cognitive heterogeneity in Parkinson's disease: A 4-year longitudinal study

A. Puig-Davi; S. Martinez-Horta; L. Perez-Gonzalez; A. Horta-Barba; I. Aracil-Bolaños; R. Perez-Gonzalez; E. Rivas-Asensio; I. Ruiz-Barrio; F. Sampedro; A. Campolongo; J. Pagonabarraga; J. Kulisevsky
Movement Disorders Unit, Department of Neurology, Hospital Sant Pau, Barcelona, Spain

Background and Aims: Cognitive impairment in Parkinson's disease (PD) can exhibit a very heterogeneous trajectory among patients. Here we explored the mechanisms involved in the expression and prediction of different cognitive phenotypes over 4 years.
Methods: In two independent cohorts (total $n=475$), we performed a cluster analysis to identify trajectories of cognitive progression. Baseline and longitudinal Level-II neuropsychological assessments were conducted, and baseline resting EEG and NfL plasmatic quantification were done. Linear mixed-effects models were used to study longitudinal changes. Risk of mild cognitive impairment (PD-MCI) and dementia were estimated using multivariable hazard regression. Spectral power density from the EEG at baseline and source localization were computed.
Results: Two cognitive trajectories were identified. Cluster 1 presented stability (PD-Stable) over time, whereas Cluster 2 showed progressive cognitive decline (PD-Progressors). Both clusters showed equivalent clinical and sociodemographic characteristics at baseline, but the PD-Progressors group showed an increased risk for evolving to PD-MCI (Hr = 2.09; 95% CI, 1.11–3.95) and a marked risk for dementia (Hr = 4.87; 95% CI, 1.34–17.76), in turn with a pattern of worsening in posterior-cortical-dependent cognitive processes. NfL levels were equivalent between groups at baseline. Conversely, the PD-Progressors group showed a fronto-temporo-occipital and parietal slow-wave power density increase, that was in turn related to worsening at 2 and 4 years in different cognitive measures.



Cognitive trajectories and topography of slow wave activity.

Conclusion: In the absence of baseline clinical signs and markers of structural damage, further development of an aggressive cognitive decline in PD is associated with increased slow-wave power density and with a different profile of worsening in several posterior-cortical-dependent tasks.
Disclosure: Nothing to disclose.

EPR-213 | Correlates of mutant huntingtin, NfL and MRI in Huntington's disease, a multimodal analysis

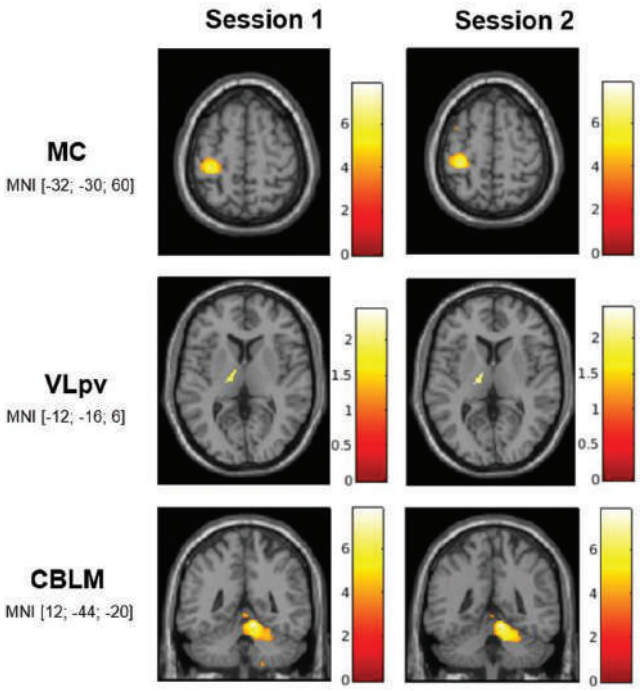
J. Pérez-Pérez; S. Martínez-Horta; G. Olmedo-Saura; A. Horta-Barba; A. Puig-Davi; A. Vazquez; E. Rivas; A. Campolongo; J. Pagonabarraga; J. Kulisevsky
Movement disorders Unit, Sant Pau Hospital, Barcelona, Spain

Background and Aims: This study aims to investigate correlations between mHtt and NfL levels and MRI findings in individuals at different stages of HD, including presymptomatic and symptomatic individuals. Understanding these correlations may provide valuable insights into disease pathogenesis and facilitate the development of effective therapeutic strategies.
Methods: Longitudinal study with cross-sectional analysis of a cohort of individuals with genetic confirmation for Huntington's disease (HD) and controls. They were grouped into presymptomatic (preHD) at the motor level (DLC <4) and symptomatic (HD) (DCL = 4). Levels of NfL in CSF (Simoa, Quanterix) and mHTT in CSF (SMC Erenna platform, Merck) were quantified. MRI 3 Tesla and gray matter analysis using VBM and cortical thickness using FreeSurfer were performed. Correlations between NfL and mHtt biomarkers and neuroimaging were established using SPM.
Results: Sixty-one participants, including 27 presymptomatic, 24 symptomatic, and 10 controls, showed age differences between groups (age covaried). Presymptomatic individuals exhibited elevated NfL and mHtt levels compared to controls, with further increases in symptomatic individuals. NfL levels correlated with caudate, putamen, and cerebellar atrophy in presymptomatics ($p < 0.005$), while mHtt levels showed weaker correlation ($p < 0.05$). In symptomatics, NfL levels correlated with thalamic, posterior cortical, and prefrontal atrophy, whereas mHtt levels correlated less with posterior cortical atrophy, suggesting NfL's higher sensitivity in detecting neurodegeneration and/or involvement of non-Huntingtin-dependent processes.
Conclusion: Levels of NfL exhibit greater sensitivity in detecting the neurodegenerative process compared to mHtt, showing a correlation with atrophy in the caudate and putamen in presymptomatic individuals that extends to cortical areas as the disease progresses.
Disclosure: Nothing to disclose.

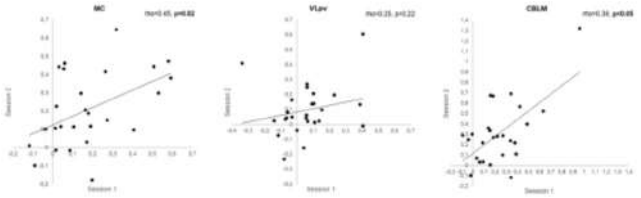
EPR-214 | Reliability of neurophysiological and cerebral tremor features in Parkinson's disease

L. Angelini[1]; K. van den Berg[2]; M. Dirkx[2]; M. Bologna[1]; R. Helmich[2]
[1]*Department of Human Neurosciences, Sapienza University of Rome, Rome, Italy*; [2]*Donders Institute for Brain, Cognition and Behaviour, Centre for Cognitive Neuroimaging, Radboud University Nijmegen, Nijmegen, The Netherlands*

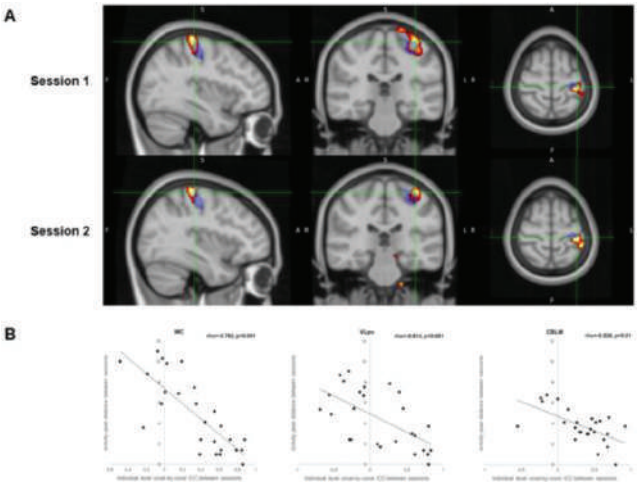
Background and Aims: The cerebello-thalamo-cortical (CTC) circuit plays a key role in pathophysiology of tremor in Parkinson's Disease (PD). Better understanding the underlying mechanisms is crucial for advancing treatment strategies. We aim to assess the test-retest reliability of clinical, neurophysiological and neuroimaging PD tremor parameters on an individualized level.
Methods: We evaluated 26 tremor-dominant PD patients OFF medication in two sessions two months apart. Evaluations included standardized clinical scales, quantitative analysis of tremor using accelerometry, and a resting state-fMRI co-registered with rest tremor accelerometric assessment. Both group and individual level analyses were conducted.
Results: At group level, clinical and accelerometric data did not change across sessions, and showed good to excellent reliability for rest and postural tremor. Significant tremor-related activity was observed in the three nodes of the CTC circuit (Figure 1). A positive correlation across sessions was also observed for the mean tremor-related activity in motor cortex (MC) and cerebellum (CBLM) (MC: $\rho = 0.45$, $p = 0.02$; CBLM: $\rho = 0.39$, $p = 0.05$) (Figure 2). At individual level, tremor-related activity evaluated voxel-by-voxel correlated significantly across sessions in 69.23%, 50%, and 76.92% of patients for MC, thalamus (VLpv) and CBLM respectively (all $p < 0.01$). Subjects with stronger correlation showed lower distance between activity peaks across sessions (Figure 3), and smaller changes in rest tremor amplitude were associated with higher reliability of tremor-related activity in MC (all $p < 0.01$).



Tremor-related activity in the three regions of the CTC circuit. For graphical representation, the cluster-forming threshold was set at $p < 0.001$ (uncorr.) for MC and CBLM; for VLpv, activity within the ROI with a threshold set at $p < 0.05$ (uncorr.) is shown.



Correlation of mean tremor-related activity in each CTC circuit region between sessions. Spearman's correlations applied. Significant *p*-values are shown in bold.



A: Tremor-related activity in MC in one patient (yellow-red) and MC ROI (blue). The ROI activity peak (green lines cross) in this case is in the same voxel in the two sessions. B: Correlation between voxel-by-voxel ICC and activity peak distance in CTC.

Conclusion: Our study demonstrates the robust reliability of neurophysiological and functional neuroimaging measures in investigating tremor mechanisms in PD. These findings support personalized treatments and targeted neuromodulation, advancing PD tremor management.

Disclosure: Supported by International Federation of Clinical Neurophysiology.

EPR-215 | Towards a clinical identification of a cholinergic subtype of Parkinson's disease

L. Batzu[1]; A. Podlewska[1]; M. Qamar[1]; A. Rizos[2]; D. Aarsland[3]; P. Svenningsson[1]; K. Chaudhuri[1,2]

[1]Department of Basic and Clinical Neuroscience, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, UK; [2]Parkinson's Foundation Centre of Excellence, King's College Hospital, London, UK; [3]Department of Old Age Psychiatry, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, UK

Background and Aims: Several non-motor subtypes of Parkinson's disease (PD) underpinned by specific neurotransmitter dysfunctions have been proposed and clinical tools to identify the noradrenergic subtype have been suggested. In this report, we describe PD cognitive profiles indicating cholinergic versus dopaminergic predominance, aiming at clinically identify a cholinergic subtype of PD, characterized by cognitive dysfunction and disability.

Methods: Data were obtained from the Non-Motor Longitudinal International Study (NILS). Potential cholinergic and dopaminergic cognitive components were identified using two simple cognitive tasks, similarly to the CamPaIGN study: intersecting pentagons copying (P) and lexical fluency (F). Patients were categorized as having impairment in both tests (PF), in one test (P, F) or no impairment (NC). Relationships between cognitive profiles and Clinical Impression of Severity Index (CISI-PD) for Cognition and Disability were investigated with multiple logistic regressions.

Results: Among 1004 patients, PF was observed in 3.9%, P and F were detected in 11.6% and 8.8% respectively, while NC was found in 75.8%. Demographic and clinical differences among groups are shown in Table 1. After including other significant predictors (age, education, disease duration, motor/non-motor burden), PF phenotype was the strongest predictor of moderate/severe cognitive problems (Or = 18.57, $p < 0.001$) and moderate/severe disability (Or = 2.81, $p = 0.023$) (Table 2).

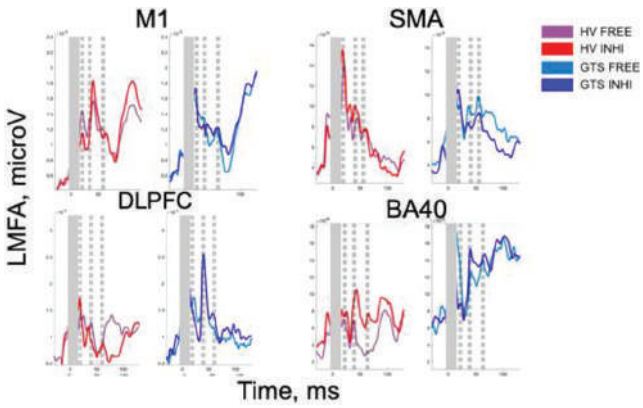
Safra Program in Parkinson's Disease, Morton and Gloria Shulman Movement Disorders Clinic, Toronto Western Hospital – UHN; Division of Neurology, University of Toronto, Toronto, Ontario, Canada; [7]Department of Neurology, Vanderbilt University Medical Center, USA; [8]Duke University Movement Disorders Center, Duke University, USA; [9]Division of Neurology, Grenoble Alpes University, CHU of Grenoble, France; [10]Center for Neurological Restoration, Cleveland Clinic Foundation, USA; [11]Oxford University Hospitals NHS Foundation Trust, UK; [12]Medtronic Neuromodulation, Medtronic, Minneapolis, MN, USA; [13]Department of Neurology and Neurological Sciences, Stanford University, USA

Background and Aims: Although deep brain stimulation (DBS) is an established advanced therapy in Parkinson's disease (PD), there are still limitations in terms of efficacy and side-effects. Recently, this has been challenged by either applying directional or adaptive stimulation. So far, both approaches have not been combined. Here we investigated this combined approach.
Methods: DBS was applied in a care as usual setting in PD patients with either omnidirectional or directional (SenSight) DBS leads and a Percept PC neurostimulator that could adapt stimulation based on the presence of local field potential (LFP) activity (ADAPT-PD Trial, NCT04547712). If adaptive DBS (aDBS) was possible (alpha-beta peak power ≥1.2 μV) and tolerated, subjects were randomized to two aDBS algorithms (single [ST] or dual threshold [DT]) each for 30 days.
Results: Eighty-five subjects were enrolled in the trial ($n = 68$ Primary Cohort, $n = 17$ Directional Stimulation Cohort; including $n = 54$ omnidirectional, $n = 31$ SenSight leads). aDBS evaluation phase included 60 subjects ($n = 53$ DT, $n = 45$ ST; $n = 26$ SenSight leads). 96.8% (30/31) of SenSight leads had adequate alpha-beta power (≥1.2 μV). Combining cohorts, similar "On" time without troublesome dyskinesia was observed versus continuous DBS in DT (94.3%); and in ST mode (93%). TEED trended lower during aDBS (median −12% DT, −12% ST). 59/60 subjects chose to continue aDBS in long-term follow-up. No serious adverse device events occurred through the evaluation phase.
Conclusion: SenSight leads detected alpha-beta peaks at a high rate. aDBS resulted in similar "On" time without troublesome dyskinesia, with a trend for reduced TEED for patients with omnidirectional and directional stimulation.
Disclosure: the study was initiated by medtronic, some authors are medtronic employees.

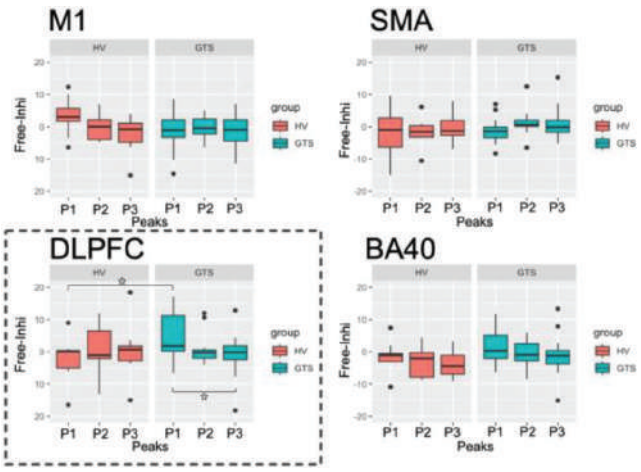
EPR-217 | Developing a neuromodulation target for GTS: A TMS-EEG study

M. Mancuso[1]; G. Leodori[2]; D. Belvisi[2]; C. Cutrona[1]; M. Costanzo[1]; A. Berardelli[2]; A. Conte[2]; G. Gallo[1]
[1]La Sapienza, University of Rome, Dept. of Human Neuroscience; [2]IRCCS NEUROMED, Pozzilli, Italy

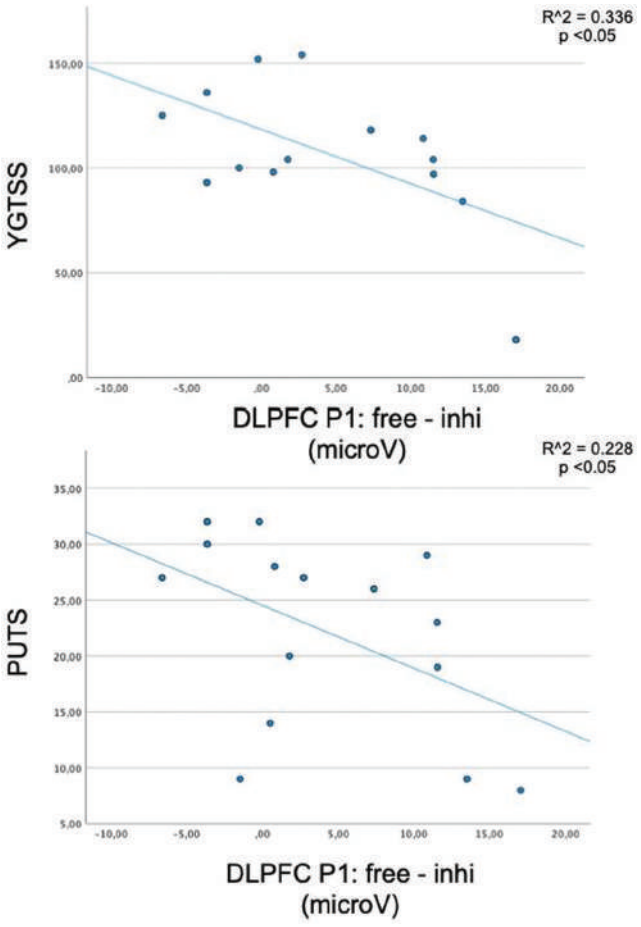
Background and Aims: Neuromodulation techniques have shown efficacy in a series of neurological disorders, but their efficacy depends on appropriate disease-specific targets. TMS-EEG can be used to probe the causal role of network hubs in neurological diseases. Gilles de la Tourette syndrome (GTS) is characterized by vocal and motor tics preceded by a premonitory urge (PU), which is considered the drive of tics. Tics can be voluntarily inhibited at the expense of increasing the PU. We used a transcranial magnetic stimulation (TMS)-EEG integrated approach to identify possible neuromodulation targets aimed at treating disease symptoms. We probed areas involved in PU and tic generation, such as M1, the dorsolateral prefrontal cortex (DLPFC), the Supplementary motor area (SMA) and the Brodmann Area 40 (BA40).
Methods: Seventeen GTS patients and ten healthy volunteers (HVs) underwent TMS-EEG. We collected TMS-evoked potentials (TEPs) from left M1, SMA, DLPFC and BA40 in two conditions: free to tic and voluntary tic suppression, a condition that worsens PU that was matched in HVs by eye blink suppression. We collected clinical scales for tics, PU, and psychiatric symptoms severity.
Results: Contrary to HVs, GTS showed suppression-related negative modulation of DLPFC local TEPs. This correlated negatively with PU Tics Scale and Yale Global Tic Severity scores.



LMFA TEPs of the four stimulated areas. Dotted lines represent the peaks from which the signal was extracted to perform further analysis. Grey bars cover the stimulation artifact.



Boxplots of free-inhi differences across the first three peaks (P1, P2 and P3) for each area. Only DLPFC showed significant peak*group interaction. Stars represent significant post-hoc comparisons.



Clinical correlations. Correlation analysis within the GTS group showed significant negative correlation of free-inhi difference at P1 with PUTS and YGTSS.

Conclusion: Negative DLPFC modulation during tics suppression and its correlation with PU and tics severity suggest a crucial role of this area in GTS pathophysiology. The DLPFC could hence be a promising target for neuromodulation to reduce symptoms in GTS.

Disclosure: Nothing to disclose.

EPR-218 | First steps in noninvasive brain stimulation of subthalamic nucleus in Parkinson's disease

M. Lamoš[1]; M. Bočková[2]; F. Missey[3]; J. Trajlínek[3]; O. Studnička[3]; C. Lubrano[3]; M. Silva[3]; J. Chrastina[4]; R. Jančálek[4]; I. Rektorová[2]; A. Williamson[3]

[1]Brain and Mind Research Program, Central European Institute of Technology, Masaryk University, Brno, Czechia; [2]First Department of Neurology, Masaryk University School of Medicine, St. Anne's Hospital, Brno, Czechia; [3]Neuromodulation Technology Research, International Clinical Research Center, St. Anne's University Hospital, Brno, Czechia; [4]Department of Neurosurgery, Masaryk University School of Medicine, St. Anne's Hospital, Brno, Czechia

Background and Aims: Temporal Interference stimulation (TIS) is a novel non-invasive brain electrical stimulation technique that has a potential to reach small size deep brain regions. The approach utilizes two high frequency signals (>1 kHz), which constructively interfere to create low frequency envelope modulating the target structure. The main goal of this pilot work was to verify the capability of TIS to focus the subthalamic nucleus (STN). Second goal was to compare the effect of TIS and conventional deep brain stimulation (DBS) on the pathological beta oscillations in Parkinson's disease.

Methods: Implanted DBS leads were temporally externalized for local field potentials (LFP) recording in 4 patients with Parkinson's disease indicated for STN-DBS therapy. TIS was performed by 2 pairs (f1 = 9.00 kHz; f2 = 9.13 kHz, 2 mA per pair max.) of scalp electrodes placed in frontoparietal regions to focus the maximum of 130 Hz interference envelope into the motor part of the STN.

Results: The maximal amplitude of 130Hz envelope was localized in the motor part of STN. The comparison of the reference LFPs and recordings after TIS and after conventional DBS 5 min sessions showed substantial suppression of beta power peak after both types of stimulation in all patients. Moreover, the power of 130 Hz envelope was significantly ($p < 0.05$) anticorrelated with pathological beta activity during TIS in three patients.

Conclusion: This pilot testing confirmed that TIS is capable to effectively focus STN. The power increase in 130Hz envelope corresponds to the decrease of the pathological beta activity in STN during TIS.

Disclosure: The work was supported by Ministry of Health of the Czechia, grant No. NU21-04-00445 and project LX22NPO5107 (MEYS) financed by European Union-Next Generation EU.

EPR-219 | The height of third ventricle discriminates the gait phenotype in patients with idiopathic normal pressure hydrocephalus

M. Todisco[1]; S. Nicolosi[2]; M. Paoletti[3]; E. Caverzasi[2]; F. Tarantino[4]; E. Ballante[5]; F. Valentino[6]; R. Zangaglia[6]; S. Figini[7]; G. Cosentino[8]; C. Pacchetti[6]; A. Pichiecchio[2]

Background and Aims: Given the high variability of phenomenology, the higher-level gait disorder (HLGD) of patients with idiopathic normal pressure hydrocephalus (iNPH) can be classified into a disequilibrium (wide-based) subtype or a locomotor (parkinsonian) subtype. First, we aimed to obtain several magnetic resonance imaging (MRI) indices used for diagnostic and research purposes in order to assess differences between the two gait phenotypes of iNPH. Second, we explored potential correlations of MRI features with clinical severity scores.

Methods: We enrolled 86 patients (53 males; age range: 69–88 years) diagnosed as probable iNPH. Based on gait evaluation, we identified 29 subjects with disequilibrium subtype and 57 patients with locomotor subtype of HLGD. All patients underwent a comprehensive clinical assessment, including neuropsychological tests, and performed a brain MRI scan for the morphometric measurement of eight linear radiological indices.

Results: Gait phenotypes differed with respect to the height of the third ventricle, which was higher in the locomotor subtype and showed a trend of correlation with the motor score of the Movement Disorder Society-Unified Parkinson's Disease Rating Scale (MDS-UPDRS III) and with the continence score of the iNPH Rating Scale.

Conclusion: A greater height of the third ventricle could be a neuroimaging marker of the locomotor phenotype of HLGD in iNPH patients. An increase of this radiological index may reflect a secondary top-down compression on the midbrain. Consequently, the reduced mesencephalic volume may increase the severity of gait disturbance, parkinsonism and urinary dysfunction in iNPH patients.

Disclosure: Nothing to disclose.

MS and related disorders 3

EPR-220 | Exploring the relationship between cognitive impairment, retinal damage, and brain atrophy in multiple sclerosis

R. Borgo; M. Altieri; A. De Rosa; R. Capuano; A. d'Ambrosio; A. Bisecco; F. Esposito; G. Tedeschi; A. Gallo

Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, Italy

Background and Aims: Cognitive impairment is a debilitating feature of Multiple Sclerosis (MS). Brain atrophy, measured by MRI, is correlated to such clinical scenario. Optical coherence tomography (OCT) may represent a rapid, low-cost, and non-invasive method evaluating neurodegeneration in MS. Our objective was to explore the relationship between cognitive performance, retinal damage, and brain atrophy in people with MS (pwMS).

Methods: 100 pwMS, consecutively enrolled at our MS Center, underwent: neurological examination; cognitive assessment through the Brief Repeatable Battery of Neuropsychological Tests and STROOP test; 3T-MRI scan for the evaluation of brain T2-lesion load and brain volumetric measures using SIENAx software; OCT for the evaluation of peripheral retinal nerve fiber layer (pRNFL) and ganglion cell–inner plexiform layer (GCIPL) thickness. Correlation and regression analyses between cognitive performance, retinal layers mean thickness and brain volumes were performed using SPSS. A p-value ≤0.05 was considered statistically significant.

Results: We found a significant correlation between pRNFL and GCIPL thinning and worse cognitive performance measured by SDMT, and STROOP tests, exploring information processing speed (IPS) and executive functions. T2 lesion volume (T2LV) and normalized white matter volume (nWMV) correlate with cognitive performance in the same cognitive domains. As expected, normalized gray matter volume (nGMV) and normalized brain volume (nBV) showed a significant correlation with cognitive performance in many cognitive domains.

Conclusion: Our results showed a relationship between retinal damage and cognitive performance in the same cognitive domains (IPS and executive functions) related with WM damage. Retinal damage (measured by OCT) may be a useful marker for cognitive decline in pwMS.

Disclosure: Nothing to disclose.

EPR-221 | First assessment of sNfL integration in everyday clinical practice – Lessons from NeofiLos

K. Akgün[1]; K. Schuh[2]; I. Schwab Sauerbeck[2]; T. Ziemssen[1]
[1]*Center of Clinical Neuroscience, Dresden, Germany*; [2]*Novartis Germany IMI, Nuernberg, Germany*

Background and Aims: Neuroaxonal damage results in release of neurofilaments such as neurofilament light chain (NfL) with elevated NfL potentially indicating RMS disease activity 1–3. Elevated levels may reveal "subclinical" disease before lesions or clinical symptoms appear4. Measuring sNfL may help elucidate subclinical disease activity potentially contributing to optimized decision making. NeofiLos enables office-based centers to access serum NfL (sNfL) testing aiming to investigate utility and practical embedding of serial measurements into everyday clinical practice in Germany.

Methods: NeofiLos is an ongoing prospective data collection at ~80 office-based neurologists assessing utility of sNfL from physician's perspective in RMS patients treated with ofatumumab or other disease-modifying therapies. sNfL will be measured at baseline followed by quarterly interval up to 5× per patient. Values embedded into scientific context using patient demographics are reported to neurologists evaluating value and assessing implementation of sNfL into clinical routine setting.

Results: These interim results will depict the assessment of integrating sNfL measurements into everyday clinical practice over time by highlighting challenges, possibilities and further needs. At baseline, physicians stated that sNfL-testing can be integrated into their daily practice routine without major restructuring (Median6.6; 7-point-Lickert-scale, SD1.1, $n = 61$). Furthermore, data will show details on accessibility and reimbursement as prerequisites for implementation in daily practice.

Conclusion: This sNfL pilot project in clinical routine setting is highlighting the importance of sNfL as additional parameter for optimal MS patient management gathering insights into translation of sNfL-testings into clinical practice. Thus, NeofiLos is a highly valuable source for defining actual gaps and optimizing future patient care.

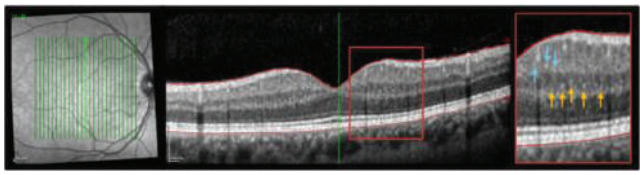
EPR-222 | Hyperreflective foci in the inner retina are not associated with optic neuritis in multiple sclerosis

N. Krajnc[1]; T. Zrzavy[1]; F. Leutmezer[1]; B. Kornek[1]; P. Rommer[1]; T. Berger[1]; B. Pemp[2]; G. Bsteh[1]
[1]*Department of Neurology, Medical University of Vienna, Vienna, Austria;* [2]*Department of Ophthalmology, Medical University of Vienna, Vienna, Austria*

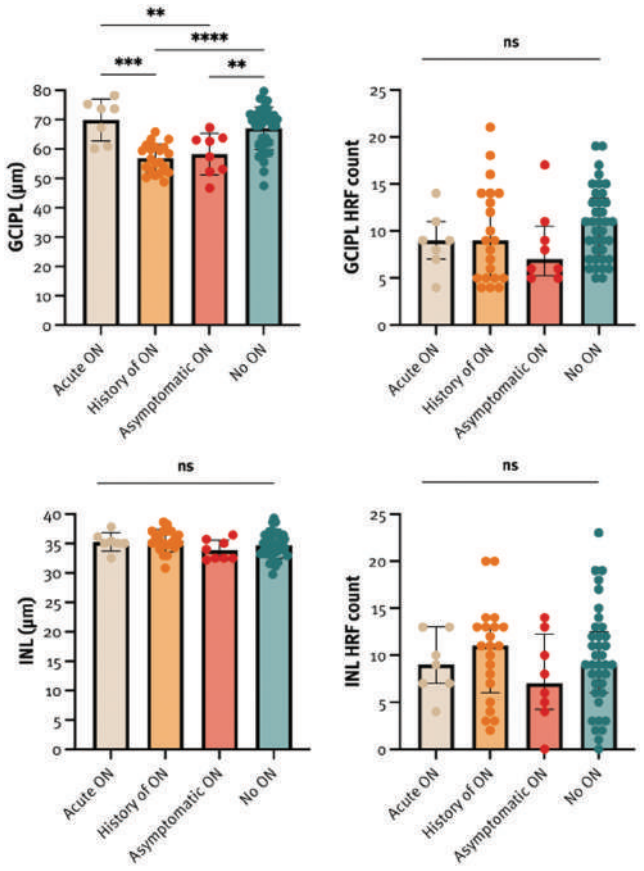
Background and Aims: Optic neuritis (ON) is a common symptom of multiple sclerosis (MS), with activated microglia being associated with neuroaxonal damage and its associated thinning of the ganglion cell-inner plexiform layer (GCIPL). Retinal microglia may be visualized as hyperreflective foci (HRF) by optical coherence tomography (OCT).

Methods: In this cross-sectional retrospective study, we included patients with MS (pwMS) who had undergone an OCT scan. HRF counting was performed separately in the GCIPL and the inner nuclear layer (INL). Eyes were grouped into four categories: (i) acute ON (≤7 days), (ii) clinical history of ON (≥6 months), (iii) asymptomatic ON (interocular asymmetry of ≥5 μm for pRNFL and/or ≥4 μm for GCIPL), and (iv) no ON.



HRF Protocol. Macular scan and HRF visualisation in a patient with MS. HRF were defined as isolated, small sized (<30 μm), punctiform elements with moderate reflectivity but without any back shadowing.

Results: In all, 71 eyes of 36 pwMS (47.2% female, median age 31.5 years (24.9–43.8), median disease duration 1.8 years (0.1–10.2), median EDSS 1.0 (0–2.5)) were included. The GCIPL thickness was significantly lower in patients with a history of ON ($n = 21$; 56.8 μm (4.8)) and/or asymptomatic ON ($n = 8$; 58.2 μm (7.0)) compared to acute ON ($n = 7$; 69.8 μm (7.2)) and eyes without ON ($n = 37$; 69.8 μm (7.2); all $p < 0.01$). We found no differences in the INL thickness, and the GCIPL HRF and INL HRF count.



The GCIPL thickness was significantly lower in eyes with a history of ON and asymptomatic ON compared to with acute ON and eyes without ON. No differences in the INL thickness, and the GCIPL HRF and INL HRF count were found.

Conclusion: HRF count does not seem to be affected by ON, implying that (i) the HRF count may not represent activated retinal microglia, and/or (ii) microglia may be activated in the stages of ON that were not included in the study. Further studies are needed to clarify the pathophysiology of MS.

Disclosure: Nothing to disclose.

EPR-223 | Circulating extracellular vesicles exhibit immune cell surface marker enrichment in multiple sclerosis patients

V. LimFalk[1]; N. Müller[2]; C. Schlup[2]; M. Evangelopoulos[3]; K. Guse[2]; D. Karathanasis[3]; A. Chan[1]; V. Pernet[1]

[1]Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [2]CSL Behring, CSL Biologics Research Center, Bern, Switzerland; [3]Department of Neurology, Eginition University Hospital, Athens, Greece

Background and Aims: Relapsing-remitting multiple sclerosis (RRMS) is a prevalent autoimmune CNS disease but pathophysiologically more heterogeneous than other demyelinating disorders such as Neuromyelitis Optica Spectrum Disorder (NMOSD) or Myelin Oligodendrocyte Glycoprotein Antibody-Associated Disease (MOGAD). In the present study, we hypothesized that the detection of immune cell surface markers in extracellular vesicles (EVs) may allow to discriminate RRMS from NMOSD and MOGAD.

Methods: EVs were isolated using a size exclusion-based-technique (SmartSEC, System Biosciences) in plasma samples from RRMS patients ($n=22$), NMOSD ($n=17$) and MOGAD ($n=10$). The concentration and the size of EVs were assessed by Nanoparticle Tracking Analysis (NTA, Malvern Panalytical). Morphological examination of EVs was carried out by cryo-electron microscopy (cryo-EM). The level of EV surface markers was assessed using MACSPlex Capture Beads (Miltenyi) allowing simultaneous detection of 37 EV markers, including a majority of immune cell-specific proteins, in individual samples, by flow cytometry.

Results: Intact EVs were visualized by cryo-EM. EVs were predominantly in the range of exosomes according to NTA measurements. With this method, a lower concentration of EVs was observed in RRMS than in NMOSD/MOGAD samples, although the mean EV size was similar. Strikingly, MACSPlex/flow cytometry measurements revealed significantly higher levels of immune cell markers such as CD19, CD29, CD40, CD44 and CD69P in RRMS than in NMOSD/MOGAD EVs. No difference was found between NMOSD and MOGAD.

Conclusion: The enrichment of specific immune cell surface markers in EV preparations may represent an immunological signature of RRMS.

Disclosure: A.C. has received speakers'/board honoraria from Actelion (Janssen/J&J), Alexion, Almirall, Bayer, Biogen, Celgene (BMS), Genzyme, Merck KGaA (Darmstadt, Germany), Novartis, Roche, and Teva, all for hospital research funds. EPR-224 | Assessment of RFC1 gene expansion in multiple sclerosis patients

G. Visentin[1]; A. Giordano[2]; S. Sciré[3]; G. Bellantuono[4]; M. Sorosina[3]; E. Mascia[3]; K. Misra[3]; P. Carrera[4]; M. Filippi[5]; F. Esposito[2]
[1]*Vita-Salute San Raffaele University, Milan, Italy; Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; Laboratory of Human Genetics of Neurological Disorders, IRCCS San Raffaele Scientific Institute, INSPE, Milan, Italy;* [2]*Laboratory of Human Genetics of Neurological Disorders, IRCCS San Raffaele Scientific Institute, INSPE, Milan, Italy; Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [3]*Laboratory of Human Genetics of Neurological Disorders, IRCCS San Raffaele Scientific Institute, INSPE, Milan, Italy;* [4]*Unit of Genomics for Human Disease Diagnosis, Division of Genetics and Cell Biology, IRCCS Hospital San Raffaele, Milan, Italy;* [5]*Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, Neurophysiology Service IRCCS San Raffaele Scientific Institute, Milan, Italy; Vita-Salute San Raffaele University, Milan, Italy*

Background and Aims: Biallelic expansion of the AAGGG sequence in the Replication Factor C Subunit 1 (RFC1) gene is implicated in the pathogenesis of Cerebellar Ataxia with Neuropathy and Vestibular Areflexia syndrome (CANVAS). The spectrum of RFC1-related neurological disorders is growing; some case reports have shown the association between the AAGGG expansion and central nervous system inflammatory lesions, but this relationship remains unclear. We explored the prevalence of RFC1 expansion in multiple sclerosis (MS) patients.

Methods: A cohort of 2788 MS patients and 415 healthy controls (HC), with already available whole-genome genetic data obtained with different Illumina genotyping platforms, were eligible to the study. The presence of the homozygous haplotype linked to AAGGG expansion was evaluated by assessing four single-nucleotide polymorphisms (SNPs; rs2066790, rs11096992, rs17584703, and rs6844176) previously observed to be shared by CANVAS patients.

Results: Within our cohort, 58 individuals were carriers of the homozygous haplotype, 54 MS and 4 HC. A twofold increase in the haplotype frequency was observed in MS patients compared to HC (1.94% vs. 0.96%). Among the 54 MS patients, 72% were women, the average age at symptom onset was 32 years and 20.3% had a diagnosis of primary progressive MS.

Conclusion: Our study revealed the presence of the investigated haplotype in a small proportion of MS patients. Polymerase Chain Reaction analyses are ongoing to validate this finding, providing comprehensive insight into the observed association. If confirmed, our data suggest the importance of excluding RFC1-associated spectrum disorders when performing a diagnosis of MS.

EPR-225 | Ocrelizumab-induced colitis in patients with multiple sclerosis: An emerging safety issue

V. Viti[1]; Z. Chiara[2]; R. Capra[3]; M. Rocca[4]; M. Filippi[5]
[1]*Vita-Salute San Raffaele University, Milan, Italy; Neurology Unit, Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [2]*Neurology Unit, Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [3]*Centro Regionale per la Sclerosi Multipla, ASST Spedali Civili di Brescia, Montichiari, Brescia, Italy;* [4]*Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; Vita-Salute San Raffaele University, Milan, Italy; Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [5]*Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, Neurophysiology Service IRCCS San Raffaele Scientific Institute, Milan, Italy; Vita-Salute San Raffaele University, Milan, Italy*

Background and Aims: Drug-induced colitis is being increasingly diagnosed in people on biological therapy, including patients with Multiple Sclerosis (pwMS) under ocrelizumab. The exact pathophysiology is unknown, but immunological dysregulation through B-cell depletion has been proposed as a possible mechanism. We present a case of ocrelizumab-associated colitis (OAC) and review available literature on the topic.

Methods: We report the case of a pwMS with suspected OAC, who presented to our Center in December 2023. A retrospective literature search on OAC was also conducted from March 2020 to January 2024.

Results: A 38-year-old female with relapsing-remitting MS started ocrelizumab on April 2022 after having failed fingolimod. Several weeks after treatment initiation, she developed watery diarrhea, vomiting and lower abdominal pain, exacerbated by ocrelizumab re-treatment in December 2022, requiring hospitalization. History of infection, fever, travelling, ill contact or bowel disease was denied. Flexible sigmoidoscopy was normal and biopsies of various part of duodenum and left colon showed non-specific chronic inflammation. Patient was treated with oral prednisone with improvement and a diagnosis of suspected OAC was made. Table 1 summarizes published reports of OAC among pwMS. Furthermore, an analysis of the Food and Drug (FDA) Adverse Event Reporting System pharmacovigilance database revealed 43 OAC cases, out of 15.701 adverse events reported for ocrelizumab.

TABLE 1: Summary of ocrelizumab-associated colitis ($n = 12$) among patients with multiple sclerosis.

MS= multiple sclerosis, yr: years; OCRE= ocrelizumab; GI= gastrointestinal; IBD= inflammatory bowel disease; PPMS= primary progressive multiple sclerosis; SPMS= secondary progressive multiple sclerosis; RRMS= relapsing remitting multiple sclerosis; M= male subjects; F= female subjects; UC= ulcerative colitis; ASA= acetylsalicylic acid; IV= intravenous; ER= endoscopic; CMV= cytomegalovirus; NA= data not available.

Conclusion: FDA recently issued a warning regarding OAC, which could be potentially severe. We highlight the importance for clinicians of being aware of this safety risk and of a prompt intervention with multidisciplinary approach, including endoscopic evaluation and timely treatment.

Filippi is Editor-in-Chief of the Journal of Neurology, Associate Editor of Human Brain Mapping, Neurological Sciences, and Radiology; received compensation for consulting services, direction of educational events, participation on Advisory Boards and/or speaking activities from Alexion, Almiral, Bayer, Biogen, Bristol-Myers Squibb, Celgene, Chiesi Italia SpA, Eli Lilly, Genzyme, Janssen, Merck-Serono, Neopharmed Gentili, Novartis, Novo Nordisk, Roche, Sanofi, Sanofi-Aventis, Sanofi-Genzyme, Takeda, and TEVA; he receives research support from Biogen Idec, Merck-Serono, Novartis, Roche, the Italian Ministry of Health and Research, and Fondazione Italiana Sclerosi Multipla.

EPR-226 | Cladribine tablets in highly-active relapsing MS real-world effectiveness in UK clinical practice (CAMELOT-MS)

W. Brownlee[1]; D. Rog[2]; N. Macdougall[3]; M. Mattoscio[4]; N. Evangelou[5]; T. Arun[6]; E. The[7]; P. Gallagher[8]; H. Evans[9]
[1]Queen Square MS Centre, UCL Institute of Neurology, London, UK; [2]Manchester Centre for Clinical Neurosciences, Northern Care Alliance NHS Trust , Manchester, UK; [3]Neurology Department, University Hospital Hairmyres, East Kilbride and the Institute of Neurological Sciences, Glasgow, UK; [4]Queen's Hospital MS Centre, Division of Neuroscience, Barking Havering and Redbridge Hospital NHS Trust, Romford, UK; [5]Mental Health and Clinical Neurosciences Academic Unit, University of Nottingham, Nottingham, UK; [6]University Hospitals of Coventry and Warwickshire, Neuroscience , Coventry, UK; [7]University Hospitals of Leicester NHS Trust, Leicester, UK; [8]Institute of Neurological Sciences, Glasgow, UK; [9]Merck Serono Ltd, Feltham, UK an affiliate of Merck KGaA

Background and Aims: Real-world evidence increasingly informs treatment choice in multiple sclerosis (MS). Cladribine tablets (CladT) received EU marketing authorisation in August 2017 in high-disease activity relapsing-remitting MS (HDA-RRMS). The aim of the study was to understand effectiveness and safety of CladT in UK real-world setting up to 5 years after CladT initiation.

Methods: Phase 4 observational multi-centre study for patients who initiated CladT monotherapy for HDA-RRMS.

Results: 116 patients were enrolled, 40 (34.5%) were disease-modifying therapies (DMT) naïve. 112 patients (96.6%) completed both treatment courses and 4 (3.4%) discontinued treatment. Annualized relapse rate (ARR) during pre-treatment (-1-0 years) was 0.595 (95% CI: 0.470; 0.753). A declining ARR trend was observed after CladT initiation with an ARR of 0.101 (95% CI: 0.052; 0.194) during 0–1 years, 0.052 (95% CI: 0.023; 0.115) for 1–2 years and 0.063 (95% CI: 0.024; 0.169) for 4–5 years. Relapse-free rate after CladT initiation was 0.75 (95% CI: 0.58; 0.86) at 5 years. Only TEAEs of special interest were reported. Serious TEAE was reported in 1 (0.9%) patient; no TEAEs led to death. CladT-related TEAEs were lymphopenia (33/116, 28.4%), herpes zoster (4/116, 3.4%), onychomycosis and oral herpes (1/116, 0.9% each).

Conclusion: Overall ARR showed a declining trend over 5 years after CladT initiation in both DMT naïve and platform therapy groups. There was no significant difference in relapse-free rates. This study showed a tolerable safety profile with CladT.

EPR-227 | Misdiagnosis and underdiagnosis of multiple sclerosis: A systematic review and meta-analysis

W. Zürrer[1]; A. Cannon[1]; D. Ilchenko[1]; M. Gaitán[2]; T. Granberg[3]; F. Piehl[3]; A. Solomon[4]; B. Ineichen[1]

[1]*Center for Reproducible Science, University of Zurich, Zurich, Switzerland;* [2]*Translational Neuroradiology Section National Institute of Neurological Disorders and Stroke, National Institute of Health, Bethesda, USA;* [3]*Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden;* [4]*Department of Neurological Sciences, Larner College of Medicine at The University of Vermont, Burlington VT, USA*

Background and Aims: Misdiagnosis and underdiagnosis of multiple sclerosis (MS) pose significant risks to patients and healthcare systems. Yet, there is a lack of high-level evidence on the frequency of such errors. We here conducted a systematic review and meta-analysis of the prevalence of MS misdiagnosis and underdiagnosis, time delay to correct diagnosis, and the impact of sex.

Methods: An Ovid Medline and Embase database search until September 16, 2023, yielded 3910 studies. Based on pre-defined criteria (original studies on MS diagnostic errors with ≥10 individuals, excluding conference abstracts and reviews) 62 were included for qualitative synthesis and 24 for random-effects meta-analyses, assessing bias with the Newcastle-Ottawa scale. Main outcomes included the proportion of misdiagnosis, underdiagnosis, and diagnostic delay.

Results: Frequency of MS misdiagnosis (incorrect assignment of MS diagnosis) ranged from 5% to 41%, with a pooled proportion of 15% [95%-CI: 9%–26%, 1621 cases] (Figure 1A). Delay to rectify MS misdiagnosis ranged from 0.3 to 15.9 years. MS underdiagnosis (unrecognized diagnosis of MS) ranged from 3% to 58%, with a pooled proportion of 36% [95%-CI: 20%–55%, 728 cases] (Figure 1B). Diagnostic delay for underdiagnosed cases was 1.5 years [95%-CI: 1.1–1.9] (Figure 2). A sub-analysis of 8 studies indicated that women were 2.1 times more likely to be misdiagnosed with MS compared to men [95% CI: 1.53–2.86] (Figure 3).

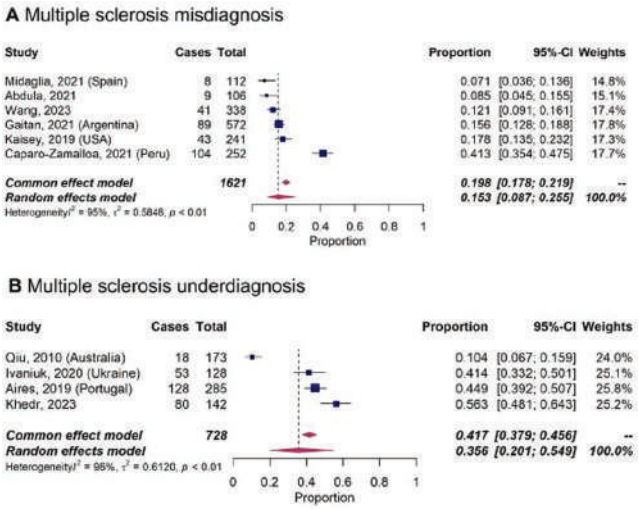

FIGURE 1: Meta-analysis on misdiagnosis and underdiagnosis proportions in multiple sclerosis (MS).

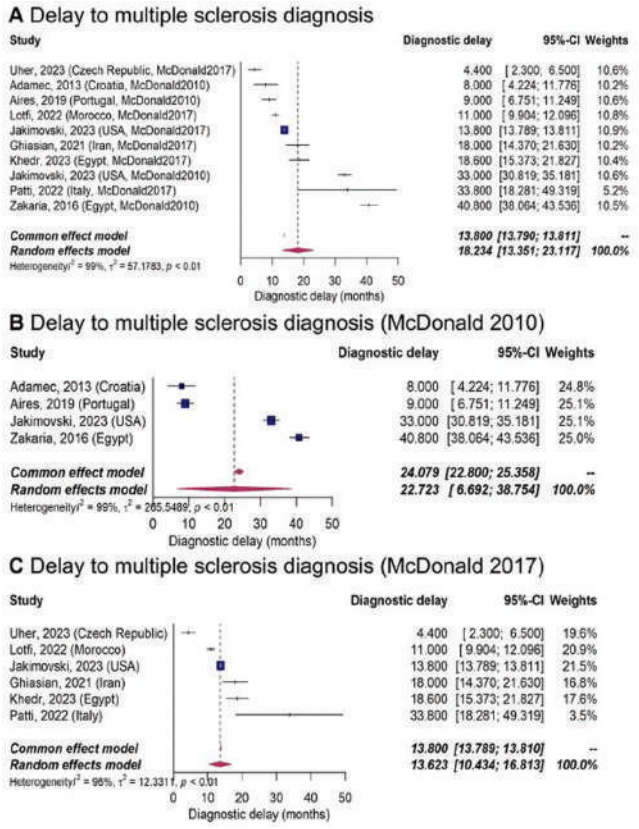

FIGURE 2: Meta-analysis on diagnostic delay in cases with MS underdiagnosis.

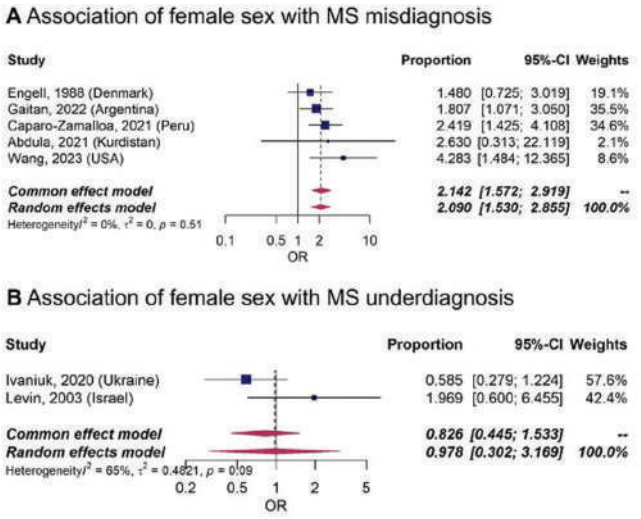

FIGURE 3: Meta-analysis on association of female sex with multiple sclerosis misdiagnosis and underdiagnosis.

Conclusion: This study provides high-level evidence for the high prevalence of MS misdiagnosis and underdiagnosis. Future studies should explore the causes of diagnostic challenges, the influence of sex, and interventions to improve diagnostic accuracy.

Background and Aims: Increase in liver enzymes among patients with multiple sclerosis (pwMS) is frequent, but often underreported and insufficiently investigated. Incidence and predictive factors are unknown. We describe liver injury (LI) in pwMS, documenting histological liver disease pattern, diagnosis and consequences for therapy.

Methods: PwMS who underwent liver biopsies because of increased liver enzymes during/after DMTs were included. Indices of hepatocellular damage, autoimmune antibodies and viral serology were evaluated, along with liver biopsies.

Results: Nine patients were included: baseline characteristics are reported in Table 1. Table 2 summarizes LI course and characteristics in each patient. Five pwMS developed LI under treatment with DMTs, 3 with fingolimod and 2 with natalizumab, while 1 subject was untreated. Four subjects were under intravenous methylprednisolone. In 6/9 patients anti-nucleus autoantibodies were found and autoimmune hepatitis was suspected. No patients had viral infection. There was no evidence of metabolic or storage liver disease. On liver biopsies, no patient had histology consistent with autoimmune hepatitis. PwMS under methylprednisolone and natalizumab developed severe acute hepatitis, with confluent necrosis. Moderate inflammation in the portal tracts was found in one case of methylprednisolone and in another treated with natalizumab. Patients treated with fingolimod exhibited vascular alterations, suspicious for porto-sinusoidal vascular disease, with minimal lobular inflammation. One subject, undergoing methylprednisolone during fingolimod treatment, had overlapping features with pwMS under methylprednisolone. Figure 1 displays slides of histological findings.

TABLE 1: Demographic and clinical characteristics of study population.

	ALL PATIENTS
Total N (Female n, %)	9 (7, 77.8)
Age at liver enzyme elevation (y), mean (SD)	37.0 (10.7)
MS Duration at liver enzyme elevation (y), median (IQR)	7.7 (3.3-12.7)
EDSS at liver enzyme elevation, median (IQR)	1.5 (1.0-2.0)
Relapsing Remitting Phenotype, N (%)	9 (100)
Treatment characteristics Ongoing treatment at liver enzyme elevation, N (%) •Fingolimod •Natalizumab •Methylprednisolone •Untreated	 3 (33.3) 2 (22.2) 4 (44.4) 1 (11.1)
Time between treatment start and liver enzyme elevation (m), mean (SD) •Fingolimod •Natalizumab •Methylprednisolone	 38.7 (60.1) 8.0 (1.4) 0.3 (1.0)
Time between treatment start and liver enzyme elevation in each treated patient (m) •Case 1, fingolimod •Case 2, fingolimod •Case 3, natalizumab •Case 4, fingolimod and methylprednisolone •Case 6, methylprednisolone •Case 7, methylprednisolone •Case 8, methylprednisolone •Case 9, natalizumab	 3.0 5.0 8.0 108.0 and 3.0 1.0 1.0 2.0 2.0

N= number of subjects; Y= years; M= months; SD= standard deviation; IQR= interquartile range; MS= Multiple Sclerosis; EDSS= Expanded Disability Status Scale.

TABLE 2: Livery injury course and characteristics in each patient.

M= male subjects; F= female subjects; DMT= Disease Modifying Treatment; NTP= methylprednisolone; AST= aspartate aminotransferase; ALT= alanine aminotransferase; GGT= gamma-glutamyl transferase; U/L= unit per liter; d= days; ANA= antinuclear antibody; ASMA= anti-smooth muscle antibody; NASH= non-alcoholic steatohepatitis; PSVD= porto-sinusoidal vascular disorder; DMF= dimethyl fumarate; OCRE= ocrelizumab; OFA= ofatumumab; NA= data not available.

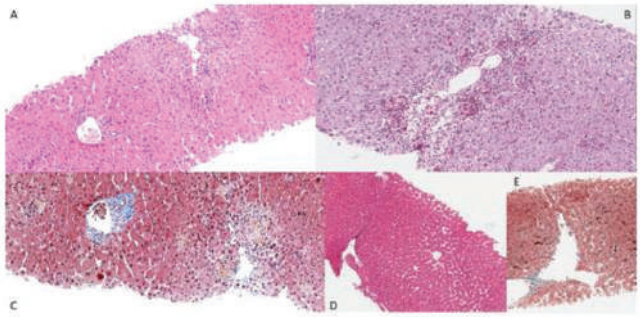

FIGURE 1: Slides of histological findings. A, B, C: methylprednisolone and natalizumab induced liver injury; D, E: fingolimod.

Conclusion: LI in pwMS is a concern. Vigilant monitoring and a multidisciplinary approach are fundamental. Liver biopsy can contribute in differential diagnosis and informing therapeutic decisions.

EPR-230 | **Frexalimab reduces plasma neurofilament light chain in relapsing multiple sclerosis: Week 48 data from a phase 2 trial**

J. Kuhle[1]; P. Vermersch[2]; B. Djukic[3]; S. Geertsen[3]; A. Shafer[3]; P. Truffinet[4]; G. Giovannoni[5]

[1]University Hospital Basel, Basel, Switzerland; [2]Univ. Lille, Inserm U1172 LilNCog, CHU Lille, FHU Precise, Lille, France; [3]Sanofi, USA; [4]Sanofi, France; [5]Queen Mary University of London, London, UK

Background and Aims: Frexalimab, a second-generation anti-CD40L monoclonal antibody, demonstrated safety and efficacy in participants with relapsing multiple sclerosis (pwRMS) in the 12-week (W) double-blind period of a phase 2 trial (NCT04879628), with an 89% reduction in new gadolinium-enhancing lesions in the high-dose group versus placebo. This was accompanied by a 24% reduction in plasma neurofilament light (pNfL), a biomarker of neuroaxonal damage. Here, we describe changes in pNfL levels with frexalimab treatment until W48.

Methods: 129 pwRMS were randomized 4:4:1:1 to frexalimab-high, frexalimab-low, placebo-high, or placebo-low groups; participants receiving placebo switched to respective frexalimab groups at W12. Plasma samples were collected at baseline, W12, W24 and W48, and pNfL levels were measured using the Simoa® NF-LIGHT™ assay. Here, geometric means are reported at baseline and W48. A one-way ANOVA was used to examine differences in pNfL levels across treatment groups at baseline. Differences from baseline were calculated using percent change.

Results: 125/129 (97%) participants completed the double-blind period and entered the open-label extension. At baseline ($n=123$), pNfL levels (geometric mean [SD]) were similar across groups ($F=0.09$, $p=0.97$): 11.9 [2.0] in frexalimab-high, 12.7 [1.8] in frexalimab-low, 12.5 [1.9] in placebo-high/frexalimab-high, and 12.2 [1.8] pg/mL in placebo-low/frexalimab-low. At W48 ($n=108$), pNfL levels were reduced to 6.7 [2.0] in frexalimab-high, 8.1 [1.7] in frexalimab-low, 9.6 [1.7] in placebo-high/frexalimab-high, and 7.8 [2.1] pg/mL in placebo-low/frexalimab-low corresponding to a 41%, 35%, 24%, and 33% reduction from baseline, respectively.

Conclusion: The observed reduction in pNfL through W48 provides evidence that frexalimab markedly reduces neuroaxonal damage in pwRMS.

Disclosure: Jens Kuhle: speaker fees, research support, travel support, and/or served on advisory boards of the Swiss MS Society, Swiss National Research Foundation (320030_189140/1), University of Basel, Progressive MS Alliance, Bayer, Biogen, Celgene, Merck, Novartis, Octave Bioscience, Roche, and Sanofi. Patrick Vermersch: Received honoraria and/or consulting fees (Janssen, Biogen, Sanofi, Novartis, Teva, Merck, Roche, Imcyse, AB Science, and BMS-Celgene) and research support (Novartis, Sanofi, and Roche). EPR-231 | Pregnancy outcomes after glucocorticosteroid and apheresis in pregnancy in women with multiple sclerosis

K. Dost-Kovalsky; S. Haben; N. Bast; N. Friedmann; L. Witt; R. Gold; S. Thiel; K. Hellwig
Department of Neurology, St. Josef-Hospital/Ruhr-University, Bochum, Germany

Background and Aims: Information on pregnancy outcomes after high-dose intravenous glucocorticosteroid (ivGC) and apheresis exposure in women with Multiple Sclerosis (MS) is scarce. TOur objective is to assess pregnancy outcomes after ivGC and apheresis treatment in women with MS.

Methods: Pregnancies with ivGC and/or apheresis exposure, documented in the German Multiple Sclerosis and Pregnancy Registry are presented. Information on pregnancy outcomes was collected with a standardized questionnaire in regular telephone interviews during pregnancy and postpartum. For analysis, this cohort was stratified into the following groups: (i) ivGC only (ii) Apheresis with or without ivGC iii) DMT matched unexposed control group.

Results: 313 pregnancies were exposed to ivGC, 30 to apheresis (25 in combination with ivGC, 5 to apheresis only) and 938 matched controls. IvGC versus controls showed a significant difference in small for gestational age (SGA) (26.2% vs. 18.6%, $p=0.005$), and lower birthweight (3134 g ±600 g vs. 3259 g ±587 g, $p=0.001$) whereas major congenital malformations (4.47% vs. 4.16%, $p=0.94$) did not. Preterm birth (PTB) (12.7% vs. 8.74%, $p=0.057$) showed a positive trend towards significance. In the apheresis group, birthweight (2731 g ±783 g vs. 3134 g ±600 g, $p=0.010$) was significantly lower compared to ivGC, whereas PTB (23.3% vs. 12.7%, $p=0.156$) and SGA (36.7% vs. 26.2%, $p=0.310$) showed no significant differences. Further adjusted analysis will be presented at the time of the conference.

Conclusion: IvGC exposure showed statistically significant impact on SGA and decreased mean birth weight significantly. Compared to ivGC alone, pregnancies exposed to apheresis have a higher risk of PTB and SGA, but differences did not reach statistical significance. Our data adds useful information on pregnancies with generally healthy newborns after treatment with ivGC and apheresis in pregnancy but is limited by the small sample of apheresis pregnancies.

Disclosure: KDK has nothing to disclose. SH has nothing to disclose. NB received payment for manuscript writing from Thieme. NF received speakers' honoraria and a sponsorship for congress participation from Biogen GmbH. LW received travel grants from Novartis. RG has received speaker honoraria and research support from Bayer-Schering Healthcare, Biogen-Idec Germany, Chugai, Eisai, Merck Serono, Nikkiso Pharma, Novartis, Roche, Sanofi-Genzyme and TEVA, has received consulting honoraria from CSL Behring, Baxter, Janssen and Talecris and has stock options in Bayer, Merck and Roche. KH has received speaker honoraria and research support from Bayer, Biogen, Merck, Novartis, Sanofi-Genzyme, Roche and Teva, has received support for congress participation from Bayer, Biogen, Merck, Roche, Sanofi Genzyme and Teva, and has served on scientific advisory boards for Bayer, Biogen, Sanofi, Teva, Roche, Novartis and Merck. S.T. received speakers' honoraria from Bayer Healthcare and Biogen GmbH, payment for manuscript writing from HEXAL AG as well as sponsorship for congress participation from Biogen GmbH.

EPR-232 | Remibrutinib, a BTKi, has no impact on serum immunoglobulin levels: Insights from chronic spontaneous urticaria

Background and Aims: Remibrutinib is a highly selective, potent, covalent, oral Bruton's tyrosine kinase inhibitor (BTKi) that downregulates B cell as well as myeloid cell activation without cellular depletion. Here, we report on serum immunoglobulin (Ig) levels over time in a Phase 2b core (NCT03926611) and extension (NCT04109313) study of remibrutinib in patients with chronic spontaneous urticaria (CSU), receiving various doses for up to 52 weeks including 100 mg b.i.d.,

the dosing regimen being evaluated in the Phase 3 REMODEL trials (NCT05147220, NCT05156281) in relapsing multiple sclerosis (MS).

Methods: Patients were randomized to receive various doses of remibrutinib (10–100 mg q.d./b.i.d.) or placebo for up to 12 weeks (core study). Eligible patients entered a 52-week open-label extension study with remibrutinib 100 mg b.i.d. Total serum levels of different immunoglobulins were assessed at baseline, Week 12 (end of core) and Week 52 (end of extension).

Results: Of the 309 patients included in the analysis, 194 rolled-over to the 52-week extension. No relevant changes in the total serum immunoglobulin levels up to Week 12 and Week 52 were observed. In the 194 patients receiving remibrutinib 100 mg b.i.d. in the extension study (mean age: 45.5 years; % female: 71.6), mean baseline and Week 52 IgG levels (μg/mL) were 11.0 ±2.41 and 10.5 ±2.47, respectively, and the corresponding mean IgM levels were 1.0 ±0.80 and 0.9 ±0.73.

Conclusion: Remibrutinib treatment did not affect total immunoglobulin levels in CSU patients of phase 2 studies, including with long-term treatment up to 52 weeks with 100 mg b.i.d., the dose used in MS clinical trials.

Disclosure: The study was supported by Novartis Pharma AG, Switzerland. The detailed author disclosures will be presented in the subsequent presentation.

EPR-233 | TYSABRI® observational program: Intravenous to subcutaneous natalizumab efficacy and safety switch analysis

M. Trojano[1]; L. Kappos[2]; H. Butzkueven[3]; H. Wiendl[4]; T. Spelman[5]; Z. Sun[6]; A. Drenth[7]

[1]Department of Translational Biomedicines and Neurosciences, University of Bari Aldo Moro, Bari, Italy; [2]Research Center for Clinical Neuroimmunology and Neuroscience Basel (RC2NB), Depts. of Clinical Research, Biomedicine and Biomedical Engineering, Univ Hospital and University of Basel, Dept. of Neurology, Univ Hospital Zurich, Basel and Zurich, Switzerland; [3]Department of Neuroscience, Central Clinical School, Alfred Campus, Monash University, Melbourne, Victoria, Australia, and Department of Neurology, Box Hill Hospital, Monash University, Box Hill, Victoria, Australia; [4]University of Münster, Münster, Germany; [5]Department of Medicine and Melbourne Brain Centre at the Royal Melbourne Hospital, University of Melbourne, Melbourne, Victoria, Australia; [6]Biogen, Cambridge, MA, USA; [7]Biogen, Baar, Switzerland

Background and Aims: The Tysabri® Observational Program (TOP) is the largest real-world observational study to inform on long-term safety and effectiveness of natalizumab (Biogen, NTZ-B) in relapsing remitting multiple sclerosis in clinical practice. This analysis compares efficacy and safety outcomes in patients switching from intravenous (IV) to subcutaneous (SC) NTZ-B.

Methods: Annualized relapse rates (ARR) were compared in the 6-month periods before and after switch. Mean annual increase in Expanded Disability Status Scale (EDSS) scores was compared between the periods of 4 clinical visits pre-switch and 2 visits post-switch. Serious adverse events (SAEs) were assessed in the period 6 months post-switch. Sub-analysis was also performed for patients treated with SC NTZ-B with an extended 6-week dosing interval (Q6W).

Results: As of May 2023, TOP included 6321 patients. 448 patients switched from IV to SC NTZ-B and had ≥6 months follow-up on SC NTZ-B. ARR was 0.080 (95% confidence interval [CI]: 0.051, 0.126) pre-SC NTZ-B and 0.076 (95% CI: 0.047, 0.121) post-SC NTZ-B switch ($p=0.847$). Mean annual EDSS increase was 0.026 pre-SC NTZ-B and 0.077 ($p=0.085$) post-SC NTZ-B switch. A total of 11 SAEs were reported in 10 patients (2.2%), none related to NTZ-B treatment or MS relapse. In the Q6W sub-analysis ARR was 0.042 (95% CI: 0.016, 0.112) prior to SC switch, compared to 0.085 (95% CI: 0.043, 0.167) post-SC switch ($p=0.258$). There was no significant difference in EDSS score change.

Conclusion: Efficacy and safety appear to be maintained in patients switching from IV to SC NTZ-B formulation, also with Q6W dosing interval.

Disclosure: Study supported by Biogen. Background and Aims: To compare disability trajectories over time and the risk of reaching the first progression independent of relapse activity (PIRA) event in pediatric onset (POMS; ≤18 years), adult onset (AOMS; 19–49 years) and late onset (LOMS; >49 years) relapsing-remitting multiple sclerosis (RRMS).

Methods: MS patients with a first visit within 1 year from onset, ≥5-year follow-up and ≥1 visit every 6 months were selected from the Italian MS Registry. Disability trajectories over time and risk of PIRA event were assessed by longitudinal models for repeated measures (adjusted for sex, proportion of follow-up time spent on active treatment and relapses) and multivariable Cox models, respectively. The adjusted disability evolution over time was assessed by calculating the mean annual estimated EDSS changes compared to baseline estimated values (delta-EDSS).

Results: 3777 RRMS patients (268 POMS, 3282 AOMS and 227 LOMS) were included. The slope of disability trajectories over 5 years was significantly lower in POMS than in AOMS and LOMS ($p < 0.004$). The POMS and LOMS curves diverged from the beginning of the follow-up and reached a difference of the estimated EDSS score of 0.62 (0.40; 0.84, $p < 0.0001$) at year 5. A first PIRA event occurred in 844 (22.3%) patients. The risk of PIRA was 54% higher in LOMS than in POMS. Age significantly predicted the risk of PIRA ($p = 0.02$).

Conclusion: These findings indicate that age remains highly relevant in determining onset and rate of disability progression in MS. POMS show a less steep increase in EDSS scores over time than older patients.

Disclosure: The authors report no conflicts of interest with respect to the contents of the current study, but note that the patients in the study were treated with a number of disease-modifying drugs and that authors have received advisory board, membership, speakers honoraria, travel support, research grants, consulting fees or clinical trial support from the manufacturers of those drugs, including Actelion, Allergan, Almirall, Bayer Schering, Biogen, Celgene, Excemed, Genzyme, Forward Pharma, Ipsen, Medday, Merck, Merz, Mylan, Novartis, Sanofi, Roche, Teva and their local affiliates.

EPR-235 | Exploring the therapeutic landscape of NMOSD: Patterns of use over time, efficacy and factors influencing attack risk

O. Aktas[1]; J. Stellmann[2]; C. Trebst[3]; V. Häußler[4]; N. NEMOS[5]

[1]Department of Neurology, Medical Faculty, Heinrich Heine University Düsseldorf, Düsseldorf, Germany; [2]APHM, Hopital de la Timone, CEMEREM, Marseille, France; [3]Department of Neurology, Hannover Medical School, Hannover, Germany; [4]Department of Neurology and Institute of Neuroimmunology and MS (INIMS), University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [5]Förderverein NEMOS e.V., Düsseldorf

Background and Aims: In neuromyelitis optica spectrum disorder (NMOSD), attack prevention is crucial to avoid disability accumulation. Considering a changing therapeutic landscape with recent drug approvals, we explored use and effectiveness of long-term immunosuppressive therapies.

Methods: Longitudinal cohort study on NMOSD (2015 IPND criteria) from the Neuromyelitis Optica Study Group (NEMOS; database closure October 2022). Calculating treatment episodes, we compared established & new immunotherapies for annualized attack rates (AAR), survival analysis (time until next attack) and multivariate Cox proportional hazard regression (attack risk factors).

Results: We included 364 patients: 320 with AQP4-IgG+ and 44 with seronegative NMOSD (also MOG-IgG-seronegative). Median follow-up was 8.6 and 10.0 years, respectively. Rituximab (980 patient years) was most commonly used, with comparable attack rates in both subgroups. The therapeutic landscape changed over time,

with an increase of rituximab (52.9% in AQP4-IgG+, 73.1% in seronegative) up to 2018, while new therapies increased post 2019, with approval of eculizumab for AQP4-IgG+ NMOSD. All treatments, except specific MS medications, reduced AAR for AQP4-IgG+ (untreated 0.80 (CI 0.69–0.96), treated 0.48 (CI 0.41–0.56)) and seronegative NMOSD (untreated 0.42 (CI 0.30–0.59), treated 0.33, (CI 0.21–0.53)). Survival analysis supported these findings. Attack risk factors were younger age, prior attack under same therapy and female sex. Significant attack risk reduction were only observed for rituximab (HR 0.68, CI 0.51–0.89, $p = 0.006$) and eculizumab (<0.001, CI NA, $p < 0.001$) for AQP4-IgG+ NMOSD.

Conclusion: Our data indicate a dynamic pattern, with emerging monoclonal antibody therapies delivering increasingly efficacious attack prevention in NMOSD.

Disclosure: Project support by Alexion AstraZeneca Rare Disease and NEMOS e.V.

EPR-236 | Race and ethnicity in multiple sclerosis phase 3 clinical trials, a systematic review

M. Ponzano[1]; A. Carbone[1]; A. Bellavia[2]; A. Signori[1]; M. Sormani[1]
[1]Department of Health Sciences, Section of Biostatistics, University of Genova, Genoa, Italy; [2]Department of Environmental Health, Harvard T.H. Chan School of Public Health

Background and Aims: Distinctive differences in multiple sclerosis (MS) have been observed by race and ethnicity, probably driven by social determinants of health (SDoH). In this context, it is imperative that research can be generalized to the overall population, including minorities. We aim to (1) assess how often race or ethnicity was reported in ClinicalTrials.gov, (2) evaluate whether the population was diverse enough, (3) make comparisons with the corresponding published material.

Methods: This systematic review included all the MS phase 3 clinical trials registered on ClinicalTrials.gov between September 2007 and December 2023. When race/ethnicity was reported, we searched for the corresponding published results using PubMed as well as a machine learning-based web tool.

Results: Out of the 99 included studies, 56% reported race or ethnicity, of which only 26% of those registered before 2017, when reporting race/ethnicity in ClinicalTrials.gov, if collected, became mandatory. Studies reporting race or ethnicity contributed to a total of 33,891 participants, mainly enrolled in Eastern Europe (60%). Most were white (93%) and the median percentage of White participants in the studies was 93% (IQR 86%–98%), compared to 3% for Black (IQR 1%–12%) and 0.2% for Asian (IQR 0%–1%). Eight trials completely omitted race/ethnicity in the main official publication and even when information was reported, some differences in terminology were identified and categories with fewer participants were often collapsed.

Conclusion: More efforts should be done to improve transparency and representativeness of data, in publications as well as at a design phase, by addressing SDoH that historically limit the enrollment of underrepresented population.

Disclosure: Nothing to disclose.

Ltd., Hyderabad, India; [12]Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA; [13]Novartis Pharma AG, Basel, Switzerland; [14]Department of Neurology, Medical Faculty, Heinrich-Heine University Düsseldorf, Düsseldorf, Germany; [15]Department of Neurology, Section of Neuroimmunology, Washington University School of Medicine, Saint Louis, Missouri, USA; [16]Department of Paediatrics and Adolescent Medicine, Division of Paediatric Neurology, University Medical Centre Göttingen, Georg August University Göttingen, Göttingen, Germany; [17]Research Center for Clinical Neuroimmunology & Neuroscience Basel (RC2NB) & MS Center, Departments of Head, Organs, Spine and Neuromedicine, Clinical Research, Biomedicine & Biomedical Engineering, University Hospital and University of Basel, Switzerland

Background and Aims: Ofatumumab demonstrated superior efficacy and similar safety versus teriflunomide in the Phase 3 ASCLEPIOS I/II overall relapsing multiple sclerosis (RMS) population and in recently diagnosed treatment-naive (RDTN) participants (diagnosed ≤3 years). Data from ALITHIOS (open-label extension study) previously demonstrated sustained efficacy for up to 5 and 4 years in the overall and RDTN subgroups, respectively. Here, of atumumab's efficacy in RDTN participants up to 5 years is reported, with 6-year data to be presented at Congress.

Methods: These analyses (data cut-off: 25-Sep-2022 [up to 5 years]/25-Sep-2023 [up to 6 years]) include cumulative data from RDTN participants originally randomized to ofatumumab (continuous group) and those originally randomized to teriflunomide and switched to ofatumumab in ALITHIOS (switch group).

Results: The RDTN subgroup comprised 314/301 in the continuous/switch groups (mean age at baseline: 36.8/35.7 years; 69.1%/65.8% female; mean EDSS: 2.30/2.28). In the 5-year analyses, the continuous group sustained a low annualized relapse rate (ARR) over Years 1–5 (0.1–0.01). Marked reductions in ARR in the switch group from Year 2–3 (0.1–0.053) were sustained through Years 3–5 (0.053–0.037). T2 lesion activity was suppressed in the continuous group up to Year 5, and from Year 3–5 in the switch group. The odds of achieving no evidence of disease activity (NEDA-3) in the continuous/switch groups increased from 89%/36% at Year 2 to ≥90% in both groups at Year 5 (Figure 1).

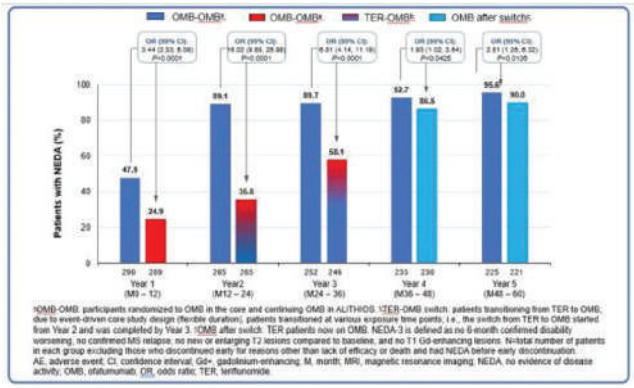

FIGURE 1: NEDA-3 status up to 5 years of ofatumumab treatment.

Conclusion: Ofatumumab demonstrates sustained long-term efficacy in people with RDTN RMS, supporting its use early in the disease course.

Disclosure: The study was supported by Novartis Pharma AG, Switzerland. The detailed author disclosures will be presented in the subsequent presentation.

EPR-238 | **Abstract withdrawn**

Muscle and neuromuscular junction disorder 2

EPR-239 | **Interleukin-6 inhibition in myasthenia gravis: A case series using tocilizumab**

A. Eriksson Dufva; M. Hietala; S. Brauner; F. Piehl
Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden

Background and Aims: Inhibition of interleukin-6 (IL6) with satralizumab is currently in clinical trials for myasthenia gravis (MG). Existing evidence supporting IL6 blockade is however limited to rare case reports with tocilizumab. Our objective was to examine a possible clinical utility in MG.

Methods: Single center retrospective observational cohort study. Patients exposed to ≥1 dose of subcutaneous/intravenous tocilizumab were included. Clinical effectiveness was assessed by Quantitative Myasthenia Gravis (QMG) score, prednisolone dose, rescue treatment and/or additional immunosuppressive drugs.

Results: We identified 19 MG patients. Clinical characteristics at baseline were: Mean age 45.8 years (standard deviation, SD 17.6), 42% Females, 58% Acetylcholine receptor antibody-positive, 53% Early onset MG, 16% Thymoma-associated MG and, 95% generalized MG. Disease duration was 9.1 years (SD 10.5), QMG score 9 (SD 6), prednisolone dose 13 mg (SD 15), 85% were previously exposed to rituximab. Treatment indication was refractory disease (79%), increased susceptibility to infections (16%) and/or severe new onset disease (21%). Mean follow-up time was 2.0 years (SD 2.0), with 37% with still ongoing treatment (reasons to discontinue; time-limited rescue treatment 25%, stable disease 8%, lack of effect 25%, adverse events 17%, mortality 17%, or other 17%). Effectiveness outcomes will be included in the final presentation.

Conclusion: IL6 inhibition represents a novel approach to treat MG and benefits from robust safety data obtained from rheumatic conditions. While firm conclusions about clinical effectiveness in MG awaits ongoing trials, our data provide an initial indication of clinical utility in certain clinical scenarios.

Disclosure: SB has received in non-restricted research grants from UCB Pharma and Janssen, not related to this study. FP has received research grants from Janssen, Merck KGaA and UCB, and fees for serving on DMC in clinical trials with Chugai, Lundbeck and Roche, and preparation of expert witness statement for Novartis.

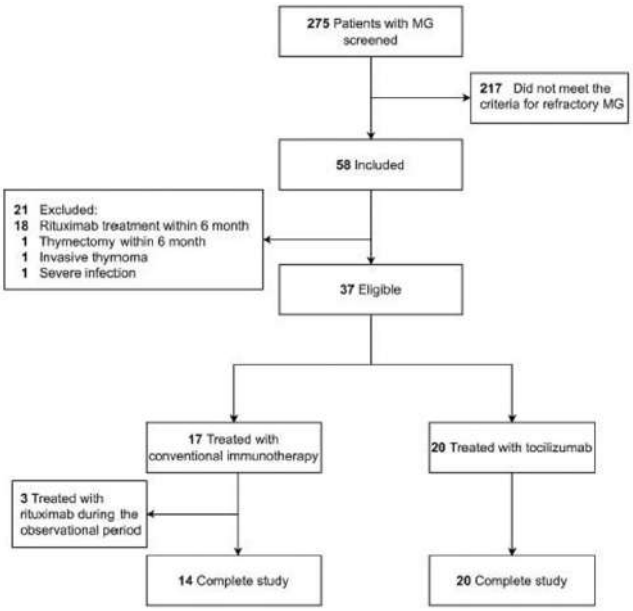
EPR-240 | **Efficacy and safety of tocilizumab in patients with refractory generalized myasthenia gravis**

T. Chang; Z. Ruan; Z. Li; Y. Tang; T. Gao
Department of Neurology, Tangdu Hospital, The Fourth Military Medical University, Xi'an, China

Background and Aims: We aimed to compare the efficacy of tocilizumab with conventional immunotherapy in refractory patients with acetylcholine receptor antibody-positive (AChR-Ab+) generalized myasthenia gravis (gMG).

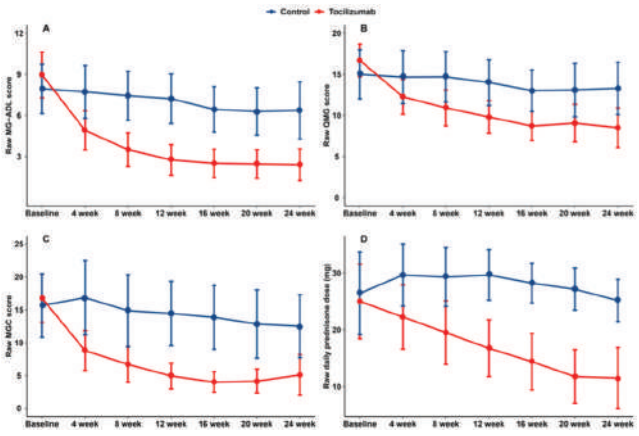
Methods: This single-center prospective cohort study was based on patients from an MG registry study in China and conducted from February 10, 2021 to March 31, 2022. Adult refractory patients with AChR-Ab+ gMG were assigned to tocilizumab or conventional immunotherapy groups. The primary efficacy outcome was the mean difference of MG activities of daily living (MG-ADL) change at weeks 4, 8, 12, 16, 20, 24 corresponding to that at baseline between the two groups. A generalized estimating equation (GEE) model was used for the primary outcome analysis. Safety was assessed based on adverse events (AEs).

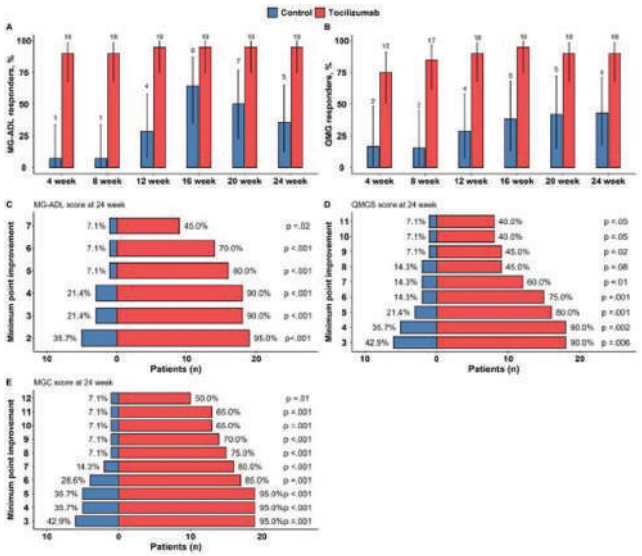
Results: Of 34 eligible patients, 20 (mean [standard deviation] age, 53.8 [21.9] years; 12 [60.0%] female) received tocilizumab and 14 received conventional immunotherapy (45.8 [18.0] years; 8 [57.1%] female). The tocilizumab group had greater reduction in MG-ADL score at week 4 (adjusted mean difference, −3.4; 95% CI, −4.7 to −2.0; $p < .001$) than the conventional immunotherapy group. At week 24, the proportion of patients achieving higher levels of MG-ADL (up to 7-point reduction) and QMG (up to 11-point reduction) scores improvement was significantly greater with tocilizumab. Tocilizumab had acceptable safety profiles without severe or unexpected safety issues.



Study flowchart showing the selection process for patients with MG.

Mean changes in MG-ADL (A), QMG (B), MGC (C) scores, and the daily prednisone dose (D) from baseline to 24 weeks in the tocilizumab and control groups.





Sensitivity analyses

Conclusion: Tocilizumab is safe and effective in improving the MG-ADL score and reducing prednisone dose in refractory AChR-Ab+ gMG, suggesting tocilizumab has the potential to be a valuable therapeutic option for such patients.

Disclosure: Nothing to disclose.

EPR-241 | Response over time with zilucoplan in generalized myasthenia gravis: Post hoc analysis of RAISE-XT 60-week follow-up

C. Hewamadduma[1]; S. Bresch[2]; M. Freimer[3]; M. Leite[4]; A. Maniaol[5]; K. Utsugisawa[6]; R. Beau Lejdstrom[7]; B. Boroojerdi[8]; F. Grimson[9]; N. Savic[7]; J. Howard Jr.[10]

[1]Academic Neuroscience Unit, Sheffield Teaching Hospitals Foundation Trust, Sheffield, UK; Sheffield Institute for Translational Neurosciences (SITRAN), University of Sheffield, Sheffield, UK; [2]Service de Neurologie, Hospital Pasteur, Centre Hospitalier Universitaire de Nice, Nice, France; [3]Department of Neurology, The Ohio State University Wexner Medical Center, Columbus, OH, USA; [4]Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, UK; [5]Department of Neurology, Oslo University Hospital, Oslo, Norway; [6]Department of Neurology, Hanamaki General Hospital, Hanamaki, Japan; [7]UCB Pharma, Bulle, Switzerland; [8]UCB Pharma, Monheim, Germany; [9]UCB Pharma, Slough, UK; [10]Department of Neurology, The University of North Carolina at Chapel Hill, Chapel Hill, NC, USA

Background and Aims: In an interim analysis of RAISE-XT (NCT04225871), an ongoing open-label extension (OLE) study, zilucoplan, a macrocyclic peptide complement component 5 inhibitor, showed clinically meaningful and significant improvements in myasthenia gravis-specific outcomes in patients with acetylcholine receptor autoantibody-positive generalized myasthenia gravis (gMG). In this post hoc analysis, we assessed the long-term outcomes of Myasthenia Gravis Activities of Daily Living (MG ADL)

and Quantitative Myasthenia Gravis (QMG) responders or non-responders at Week 12 of a qualifying, double-blind study (Phase 2, NCT03315130 or Phase 3, NCT04115293).

Methods: Eligible adults with gMG self-administered daily subcutaneous injections of zilucoplan 0.3 mg/kg in RAISE-XT. MG-ADL and QMG responder rates (≥3-point and ≥5-point reductions from double-blind baseline without rescue therapy, respectively) were exploratory endpoints.

Results: Of 93 patients randomized to zilucoplan 0.3 mg/kg in the double-blind studies, 74.2% ($n=69/93$) were MG-ADL and 59.8% ($n=55/92$) were QMG responders at Week 12. Among Week 12 responders, responder rates were >88% for MG-ADL (Figure 1) and >90% for QMG throughout the OLE up to Week 60. Among Week 12 non-responders, 50.0% (12/24) were MG-ADL responders and 47.2% (17/36) were QMG responders at Week 14; 42.9% (6/14) and 47.8% (11/23) were Week 60 responders, respectively (Figure 2).

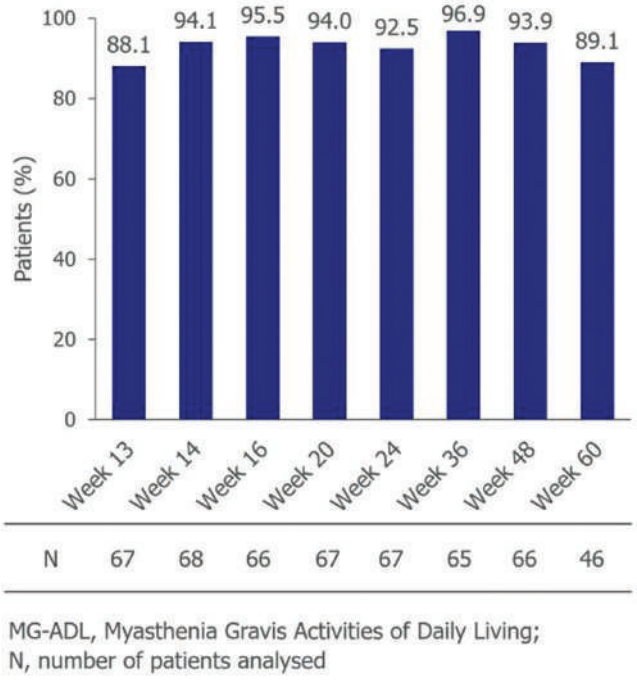


FIGURE 1: Proportion of MG-ADL responders at Week 12 who responded during RAISE-XT visits up to Week 60.

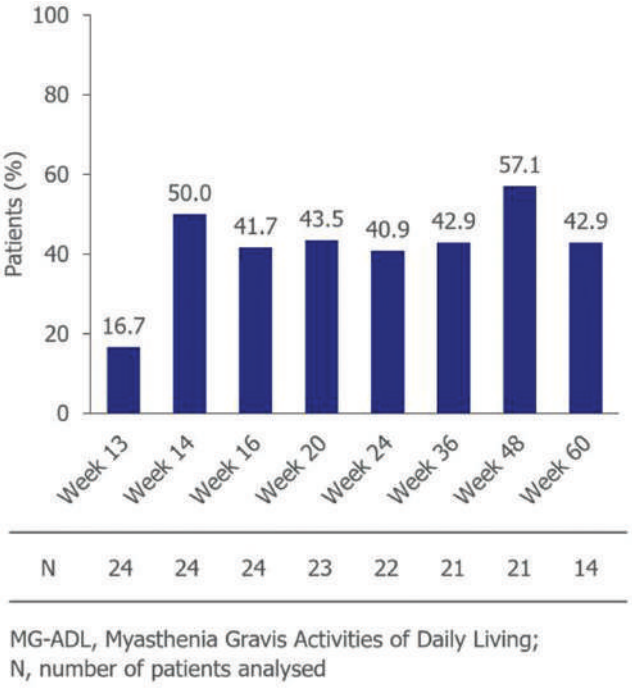

FIGURE 2: Proportion of MG-ADL non-responders at Week 12 who responded during RAISE-XT visits up to Week 60.

Conclusion: Most patients on zilucoplan were responders at Week 12 of the double-blind studies and, among them, responder rates remained high (>88%) throughout the OLE up to Week 60. Of patients who were non-responders at Week 12, approximately half became responders during the OLE, suggesting the benefit of continuing zilucoplan treatment beyond Week 12.

Disclosure: This study was funded by UCB Pharma. Raphaelle Beau Lejdstrom, Babak Boroojerdi, Fiona Grimson and Natasa Savic are employees and shareholders of UCB Pharma. Full disclosure of all industry relationships will be made during congress presentation if accepted.

EPR-242 | Ravulizumab and efgartigimod in myasthenia gravis: A real-world study

F. Stascheit[1]; C. Sousa[2]; A. Aigner[3]; M. Behrens[2]; C. Keller[2]; L. Klotz[2]; S. Lehnerer[1]; M. Stein[1]; M. Herdick[1]; P. Doksani[1]; L. Gerischer[1]; K. Lazaridis[4]; J. Tzartos[5]; H. Wiendl[2]; A. Meisel[1]; J. Lünemann[2]

[1]*Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt Universität zu Berlin, Department of Neurology with Experimental Neurology, Berlin, Germany;* [2]*Department of Neurology with Institute of Translational Neurology, University Hospital Münster, Münster, Germany;* [3]*Institute of Biometry and Clinical Epidemiology, Charité—Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin, Germany;* [4]*Department of Immunology, Hellenic Pasteur Institute, Athens, Greece;* [5]*2nd Neurology Department, School of Medicine, "Attikon" University Hospital, National and Kapodistrian University of Athens, Athens, Greece*

Background and Aims: Myasthenia gravis (MG) is an autoimmune disease leading to localized or general muscle weakness. The complement inhibitor ravulizumab and neonatal Fc-receptor antagonist efgartigimod have recently been approved for the treatment of acetylcholine receptors (AChR) antibody-positive MG. Both therapies led to sustained meaningful improvement in the MG-specific Activities of Daily Living scale (MG-ADL), the primary endpoint in pivotal placebo-controlled phase III clinical trials, but comparative studies are lacking.

Methods: In this prospective, exploratory study we aimed to estimate the clinical efficacy of ravulizumab and efgartifgimod and profiled their biological effects on Auto-Ab features in a real-world cohort of patients with AChR-Ab+ generalized MG.

Results: A total of 42 patients starting with ravulizumab and 21 patients starting with efgartigimod were prospectively included between January 2023 and December 2023. Baseline MG-ADL and quantitative myasthenia gravis (QMG) scores were clinically similar in both groups. MG-ADL-based response rates in our real-world cohorts were considerably lower and clinical efficacy assessed by the QMG scale did not reach statistical significance in either treatment group after 4, 8, and 10 weeks compared to the pivotal randomized controlled phase III trials that led to approval of ravulizumab and efgartigimod. Ravulizumab reduced terminal complement activation, but neither treatment showed significant effects on complement pathways proximal to C5 or functional capacities of AChR-Abs.

Conclusion: Our data suggest that durable disease control in MG requires continuous administration of both fast-acting agents. Combination with more deeply intervening immunotherapies might restrain pathogenicity of AChR-Abs, improving long-term therapeutic efficacies.

Disclosure: F.S. received travel/accommodation/meeting expenses from Alexion Pharmaceuticals and argnx and received speaking

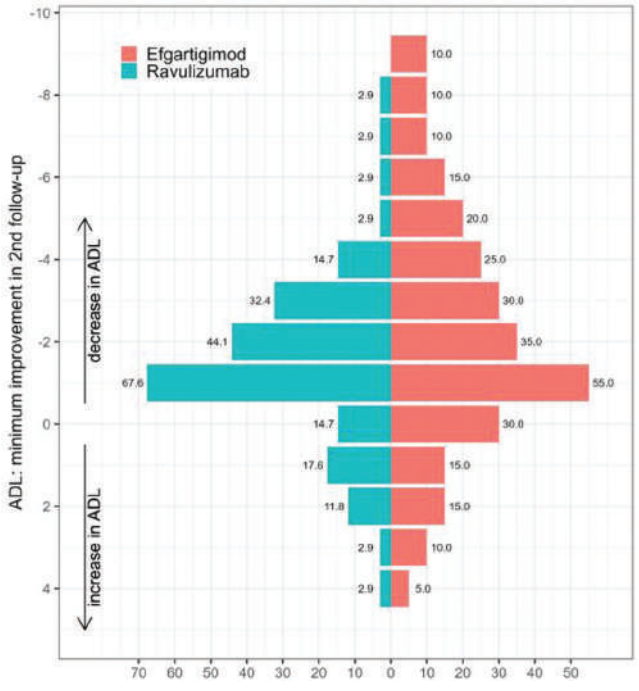

FIGURE 1A: Clinical response to ravulizumab and efgartigimod in patients with AChR-Ab-positive gMG. Bar chart for the distribution of clinically meaningful improvement in MG-ADL score from baseline to second follow-up (week 8 or week 10).

EPR-243 | DNTH103: Preventing nerve damage in a NHP CIDP model via sustained complement inhibition

H. Katzberg[1]; T. Dysgaard[2]; C. Briggs[3]; R. Arvan[3]; J. Stavenhagen[3]; S. Gokhale[3]

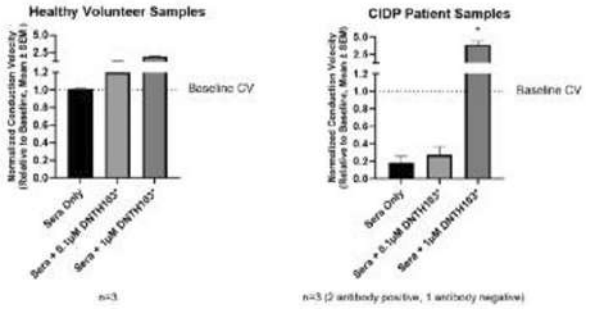
[1]*Division of Neurology, Department of Medicine, University of Toronto, Toronto, Ontario;* [2]*Copenhagen Neuromuscular Center, Dept. of Neurology, Rigshospitalet, University of Copenhagen, Denmark;* [3]*Dianthus Therapeutics, New York City, USA*

Background and Aims: Chronic inflammatory demyelinating polyneuropathy (CIDP) is an autoimmune disease with complement pathway involvement.1 DNTH103 is a fully human, potent, monoclonal antibody with a long half-life that selectively blocks the classical complement pathway.

Methods: The aim of these studies was to demonstrate the selectivity, potency, and efficacy of DNTH103 in a CIDP model and sustained pharmacokinetic/pharmacodynamic activity in nonhuman primates (NHPs). Study 1: Real-time binding of DNTH103 to C1s and proC1s by surface plasmon resonance (Biacore). Study 2: Characterisation of DNTH103 pharmacokinetic/pharmacodynamic by ligand-binding assay and CH50 haemolysis (Haemoscan) in NHPs. Study 3: DNTH103 functional activity was characterized with Human-on-a-Chip Motoneuron Axon Model using healthy iPSC-derived motoneurons, Schwann cells, and sera from 3 healthy and 3 CIDP patients (2 anti-NF155+). Conduction velocity was assessed in serum conditions with and without DNTH103.

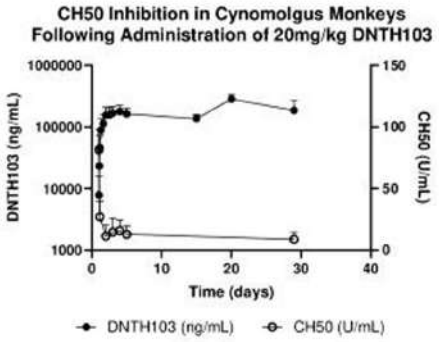
Results: DNTH103 bound selectively to active C1s with high affinity (KD: 7.1 pM) with minimal binding to proC1s (KD: ~500 nM). After a single subcutaneous administration of 20 mg/kg DNTH103 in NHPs, drug levels reached a Cmax of 191 μg/mL between 60 and 72 h; the circulating level of drug resulted in a sustainable >90% reduction in CH50 levels for the duration of the study period. DNTH103 prevented nerve conduction velocity slowing in antibody-positive CIDP patient sera.

Figure 1: DNTH103 Prevents Conduction Velocity Slowing in CIDP Sera Samples



Note: Fisher's LSD one-way ANOVA multi-comparison statistical analysis performed. *$p = 0.320$ CIDP, chronic inflammatory demyelinating polyneuropathy; CV, conduction velocity; SEM, standard error of the mean.

Figure 2: PK/PD of DNTH103 in NHP Following a 20 mg/kg Single Acute Dose by Subcutaneous Administration



NHP, nonhuman primate; PD, pharmacodynamics; PK, pharmacokinetics.

Conclusion: DNTH103 selectively binds to active C1s and effectively blocks complement-mediated inhibition of conduction detected in sera from CIDP patients. DNTH103 is an attractive research candidate for CIDP due to its potent activity, selectivity for active C1s, and extended circulating half-life.

Disclosure: This study was funded by Dianthus Therapeutics. The authors declare no conflicts of interest.

EPR-244 | Efgartigimod in generalized myasthenia gravis: A Chinese multicenter cohort study

S. Luo[1]; Q. Jiang[2]; W. Zeng[3]; Q. Wang[4]; Z. Zou[5]; D. Hong[6]; Y. Yu[6]; S. Tan[7]; Q. Zeng[7]; Y. Zhang[8]; Z. Zhang[8]; X. Guo[9]; Z. Zhao[10]; S. Huang[10]; J. Shi[11]; Y. Chen[12]; L. Du[13]; C. Zhao[1]

Background and Aims: Efgartigimod is a neonatal Fc receptor antagonist that facilitates antibody degradation including pathogenic IgGs. Recently, the ADAPT study showed that efgartigimod was well tolerated and efficacious in generalized myasthenia gravis (gMG). However, there is very limited evidence from China, and it remains inconclusive about which kind of patients are selected to preferentially receive efgartigimod in real-world settings.

Methods: This multicenter study included gMG patients from 14 neuromuscular reference centers in China. The Myasthenia Gravis Activities of Daily Living (MG-ADL) score, immunosuppressants, and safety profile were prospectively collected. Clinically meaningful improvement (CMI) was defined as the change in ADL of ≥2. Minimal symptom expression (MSE) was defined as MG-ADL total score of 0–1.

Results: Of 1640 gMG patients admitted between September to December 2023, 60 (3.6%) patients (M:F = 3:7) received efgartigimod for at least one treatment cycle and completed the 12-week follow-ups. Among them, 55 patients (91%) were AChR antibody-positive, 4 were MuSK antibody-positive and 1 was seronegative. Thymoma-associated Myasthenia gravis accounts for the majority (45%, 27/60), while the principal cause for efgartigimod initiation was MG acute exacerbation (MGAE) (48%, 29/60) or myasthenic crisis (MC) (15%, 9/60). CMI was rapidly achieved in 97% (58/60) of patients with a mean time of 1.3 weeks. By Week 4, the maximum reduction in MG-ADL was 7.9 and 45% (27/60) achieved MSE. Overall, all but 1 patient did not require additional rescue therapies after efgartigimod initiation.

Conclusion: This multicenter clinical cohort study demonstrated that efgartigimod provides rapid disease control for gMG in real-world clinical practice.

Disclosure: Nothing to disclose.

EPR-245 | Long-term zilucoplan in generalized myasthenia gravis: 96-week follow-up interim analysis of RAISE-XT

M. Leite[1]; S. Bresch[2]; C. Hewamadduma[3]; R. Juntas-Morales[4]; A. Maniaol[5]; R. Mantegazza[6]; M. Smilowski[7]; K. Utsugisawa[8]; T. Vu[9]; B. Boroojerdi[10]; G. de la Borderie[11]; P. Duda[12]; M. Vanderkelen[13]; J. Howard Jr[14]

Background and Aims: Long-term data from RAISE-XT (NCT04225871), an ongoing, Phase 3, open-label extension study, will enhance understanding of the safety and efficacy of the macrocyclic peptide complement component 5 inhibitor, zilucoplan, in patients with acetylcholine receptor autoantibody-positive generalized myasthenia gravis (gMG). We assessed responder rates for Myasthenia Gravis Activities of Daily Living (MG-ADL), Quantitative Myasthenia Gravis (QMG) and minimal symptom expression (MSE) up to 96 weeks.

Methods: RAISE-XT enrolled adults with gMG who completed a qualifying, double-blind study (NCT03315130/NCT04115293). Patients self-administered daily subcutaneous injections of zilucoplan 0.3 mg/kg. Primary outcome: incidence of treatment-emergent adverse events (TEAEs). Exploratory outcomes included responder rates for MG-ADL, QMG and MSE (reduction of ≥3 points, ≥5 points, or an MG-ADL score 0 or 1, respectively, without rescue therapy).

Results: Overall, 200 patients had enrolled at data cut-off (11 May 2023); median (range) exposure was 1.8 (0.11—5.1) years. Of 183 who received zilucoplan 0.3 mg/kg or placebo in the qualifying study, 93 continued zilucoplan 0.3 mg/kg; 90 switched from placebo

to zilucoplan 0.3 mg/kg. At RAISE-XT baseline (double-blind study Week 12), MG-ADL, QMG and MSE responder rates were 74.2%, 59.8% and 19.4% for zilucoplan ($n=93$) and 52.2%, 37.1% and 7.8% for placebo ($n=90$), respectively. At Week 96, pooled zilucoplan ($n=183$) MG-ADL, QMG and MSE responder rates had improved to 88.2% (Figure 1), 80.3% and 48.2%. TEAEs occurred in 191/200 (95.5%) patients; 71/200 (35.5%) patients experienced a serious TEAE (Table 1).

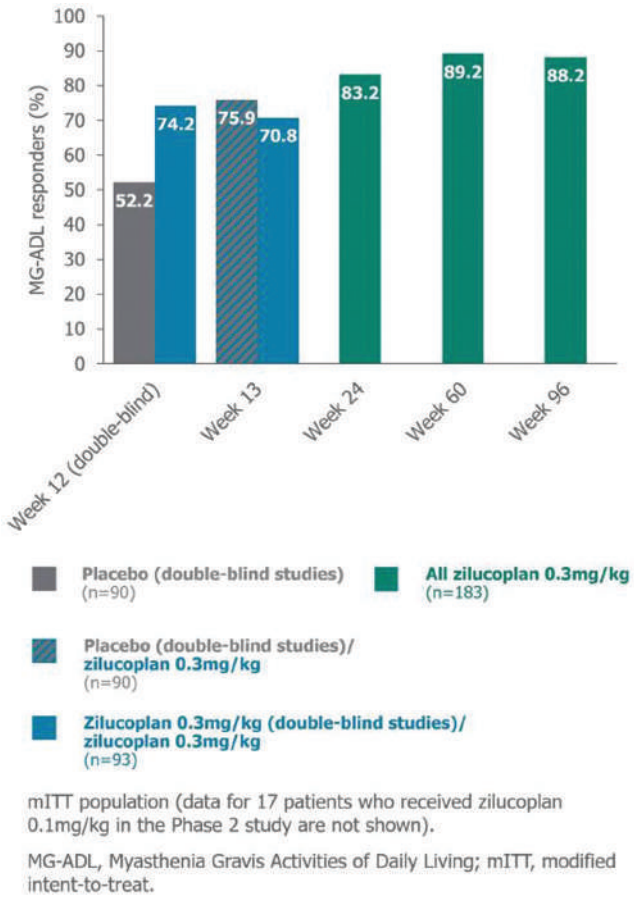

FIGURE 1: MG-ADL responder rates through to Week 96.

TABLE 1: Overview of TEAEs.

	All zilucoplan (N=200)
Any TEAE, n (%)	191 (95.5)
Serious TEAE, n (%)	71 (35.5)
TEAE resulting in permanent withdrawal from IMP,* n (%)	19 (9.5)
Treatment-related TEAE, n (%)	70 (35.0)
Severe TEAE, n (%)	64 (32.0)
TEAE leading to death, n (%)	4 (2.0)

Safety set, includes all patients who entered RAISE-XT.

*Includes the four deaths, which were: two cardiac arrests in patients with major cardiovascular risk factors, and one head injury. For one participant, the cause of death was unknown: a non-serious and severe TEAE of pneumonia reported two days prior to death, but it is not known whether the cause of death was related to pneumonia. None of the deaths were considered treatment-related (as determined by the investigator).

IMP, investigational medicinal product; TEAE, treatment-emergent adverse event.

Conclusion: In this interim analysis, zilucoplan demonstrated a favourable safety profile and improved MG-ADL, QMG and MSE responder rates, sustained up to 96 weeks of treatment.

Disclosure: This study was funded by UCB Pharma. Babak Boroojerdi, Guillemette de la Borderie, Petra W. Duda and Mark Vanderkelen are employees and shareholders of UCB Pharma. Full disclosure of all industry relationships will be made during congress presentation if accepted.

EPR-246 | Phenotypic description of 40 patients with p.Ser55Phe variant in the MYOT gene: The MYOT-MUR study

M. Aledo-Serrano; M. Lorenzo Diéguez; A. Mena Bravo; A. García Leal; E. Pérez García; R. Martínez Marín
Neurology Department, La Paz University Hospital, Madrid, Spain

Background and Aims: The Spanish myotilinopathy cohort is the most extensive to date (Olive et al., 2011). While most patients, especially those carrying the p.Ser55Phe variant, may have originated from a founding population in Murcia, South-Eastern Spain, there is a lack of published data regarding the phenotypic spectrum of this original population.

Methods: A clinical assessment of patients with the p.Ser55Phe variant in the MYOT gene was conducted, involving the collection

of genealogical diagrams, neuromuscular history, and a neurological exam.

Results: Forty patients from 12 families in Murcia were included. All patients had familial antecedents. The mean age of symptom onset was 48 years for men and 56 years for women, with two female patients older than 60 years remaining asymptomatic. The most common initial symptom was unilateral foot drop (90.4%), progressing to upper limbs after 6–8 years for male patients and within the first year for female patients. Two patients presented with a limb-girdle muscular dystrophy phenotype.

Conclusion: The Spanish region of Murcia might host the largest cluster of myopathy linked to MYOT variants. In our study, we described a phenotype for female patients not previously documented, characterized by early involvement of the upper limbs and a more favorable course, with a later onset and the existence of asymptomatic carriers. This broadening of the phenotype underscores the need to enhance knowledge of the natural history of myotilinopathies, particularly in areas of high prevalence.

Disclosure: Nothing to disclose.

Neuropathies

EPR-247 | Clinical findings in a couple of Italian siblings of Romani ancestry with CMT4D and review of the current literature

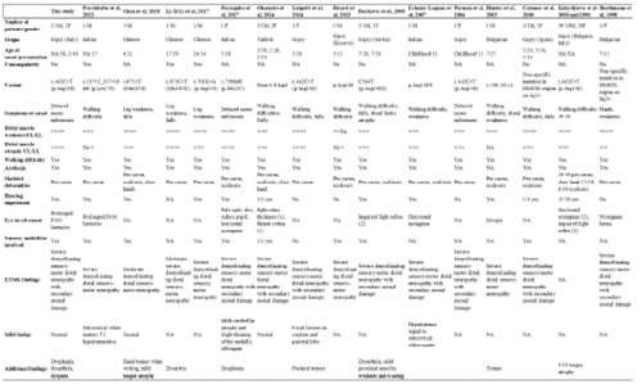
C. Ferrari Aggradi; E. Abati; S. Mambriani; G. Furciniti; G. Baso; D. Velardo; S. Corti; G. Comi

Department of Neurology, Policlinico Ospedale Maggiore di Milano, University of Milan, Milan, Italy

Background and Aims: Charcot-Marie-tooth disease type 4D (CMT4D) is an early onset form of CMT characterized by severe demyelinating motor-sensory neuropathy, muscle weakness and atrophy and hearing impairment. It is caused by mutations in the N-myc downstream-regulated gene 1 (NDRG1). Eight different mutations in NDRG1 have been identified so far. We report the case of two siblings of Romani ancestry, a 38-year-old man and a 40-year-old woman, with a NDRG1 mutation, p.R148, and provide a review of the literature.

Methods: Disease staging was assessed through a battery of clinical and instrumental examinations: CMT neuropathy score, electromyography, fiberoptic endoscopic evaluation of swallowing, pulmonary function tests and visual evoked potentials. The review included all articles focusing on CMT4D available online, published from 1998 to 2022.

Results: Both patients showed severe muscle weakness and atrophy, mild dysphagia, mild pulmonary restrictive syndrome and sensorineural deafness. Neurophysiological parameters showed a severe motor-sensory polyneuropathy. Fifteen articles were included in the review. The age at onset, in the first decade of life, and the clinical features were in line with the literature. The variant p.R148 accounts for the majority of CMT4D cases, almost all of Romani ancestry. Because of the lack of data regarding other pathogenic variants, it is difficult to provide a comparison between potential differences in clinical phenotypes. Nevertheless, it is interesting to notice that all the patients who had an onset with delayed motor milestones were p.R148 variant carriers.



Demographic, genetic, clinical, neuropsychological and radiological characteristics of patients carrying NDRG1 mutations.

Conclusion: Additional research into NDRG1 variants and phenotypic characteristics may provide further information about potential genotype-phenotype correlations and prognosis.

Disclosure: Nothing to disclose.

EPR-248 | Phase 3 trial designs evaluating riliprubart, a C1s-complement inhibitor, in CIDP

R. A. Lewis[1]; J. A. Allen[2]; I. S.J. Merkies[3]; P. A. Van Doorn[4]; C. Sommer[5]; E. Wallstroem[6]; X. Luo[7]; M. Alonso-Alonso[6]; N. Atassi[6]; L. Querol[8]

[1]Cedars Sinai Medical Center, Los Angeles, California, USA; [2]Department of Neurology, Division of Neuromuscular Medicine, University of Minnesota, Minneapolis, Minnesota, USA; [3]Department of Neurology, Maastricht University Medical Center, The Netherlands; Curaçao Medical Center, Willemstad, Curaçao; [4]Erasmus MC, University Medical Center, Rotterdam, The Netherlands; [5]Neurologische Klinik und Poliklinik, Universitätsklinikum Würzburg, Germany; [6]Sanofi R&D, Neurology Development, Cambridge, Massachusetts, USA; [7]Sanofi R&D, Biostatistics and Programming, Bridgewater, New Jersey, USA; [8]Neuromuscular Diseases Unit, Department of Neurology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; Centro para la Investigación Biomédica en Red en Enfermedades Raras (CIBERER), Madrid, Spain

Background and Aims: Standard-of-care (SOC) therapies (immunoglobulins/corticosteroids) for chronic inflammatory demyelinating polyneuropathy (CIDP) have variable efficacy and side-effects. Riliprubart, a first-in-class, humanized, IgG4-monoclonal antibody, selectively inhibits activated-C1s and has low-volume subcutaneous route of administration. Phase 2 trial (NCT04658472) results

indicated promising clinical benefits with a favourable benefit-risk profile. We present two Phase 3 trial designs which will evaluate riliprubart in two different CIDP populations with high unmet needs: patients refractory to SOC therapies and responders to intravenous immunoglobulins (IVIg) with residual disability.

Methods: Two global, multicentre, randomized, Phase 3 trials are planned: MOBILIZE, a placebo-controlled trial targeting SOC-refractory patients; VITALIZE, a double-dummy trial targeting IVIg-treated patients with residual disability. Each trial consists of a 24-week double-blinded period (Part-A), then a 24-week open-label period (Part-B). In Part-A, participants will be randomized (1:1) to receive riliprubart or placebo (MOBILIZE; $N \leq 140$), and riliprubart plus IVIg-placebo or IVIg plus riliprubart-placebo (VITALIZE; $N \leq 160$). Sample sizes will be re-estimated based on a pre-defined interim analysis during Part-A. Eligible adults with CIDP diagnosed based on 2021 EAN/PNS guidelines with Inflammatory Neuropathy Cause and Treatment (INCAT) score 2–9 (score 2 exclusively from legs) can be included. Primary endpoint is percentage of participants responding, defined as ≥1 point decrease from baseline in adjusted INCAT score at Week-24 (Part-A). Key secondary endpoints include change from baseline in additional disability/impairment measures (Part-A) and long-term efficacy (Part-B).

Results: Both trials are expected to begin enrolment in 2024.

Conclusion: These Phase 3 trials aim to demonstrate riliprubart efficacy for CIDP, including people with refractory disease or residual disability.

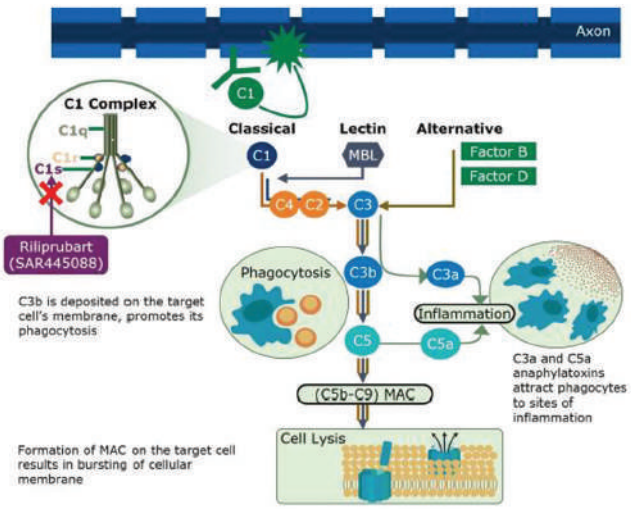
EPR-249 | Phase 2 efficacy and safety of riliprubart, a C1s-complement inhibitor, in CIDP

L. Querol[1]; R. A. Lewis[2]; H. -P. Hartung[3]; P. A. van Doorn[4]; E. Wallstroem[5]; K. Auwarter[6]; X. Luo[7]; M. Alonso-Alonso[5]; N. Atassi[5]; R. A. C. Hughes[8]

[1]Neuromuscular Diseases Unit, Department of Neurology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; Centro para la Investigación Biomédica en Red en Enfermedades Raras (CIBERER), Madrid, Spain; [2]Cedars Sinai Medical Center, Los Angeles, CA, USA; [3]Heinrich-Heine-University, Düsseldorf, Germany; Brain and Mind Center, University of Sydney, Sydney, NSW, Australia; Medical University of Vienna, Vienna, Austria; Palacky University Olomouc, Olomouc, Czechia; [4]Erasmus MC, University Medical Center, Rotterdam, The Netherlands; [5]Sanofi R&D, Neurology Development, Cambridge, MA, USA; [6]Sanofi, USA; [7]Sanofi R&D, Biostatistics and Programming, Bridgewater, NJ, USA; [8]UCL Queen Square Institute of Neurology, University College London, London, UK

Background and Aims: Riliprubart, a first-in-class humanized IgG4-monoclonal antibody, selectively inhibits activated-C1s within the classical-complement pathway (Figure). We report efficacy and safety of riliprubart in chronic inflammatory demyelinating polyneuropathy (CIDP).



Riliprubart targeting C1s and the classical complement pathway.

Methods: Global, multicentre, Phase-2, open-label trial (NCT04658472) evaluating riliprubart across three subgroups: Standard-of-care (SOC)-Treated, SOC-Refractory, and SOC-Naïve. Participants undergo 24-week treatment (Part-A), followed by optional treatment-extension (Part-B: 52-weeks, Part-C: until end-of-study). In Part-A, primary endpoint is %-participants with relapse (SOC-Treated) or response (SOC-Refractory/Naïve), defined as ≥1-point change in adjusted Inflammatory Neuropathy Cause and Treatment (INCAT) disability score from baseline up to 24-weeks. Part-B evaluates efficacy durability based on % relapse-free

participants (SOC-Treated) or those with sustained-response (SOC-Refractory/Naïve), defined as no-increase in adjusted INCAT score ≥2-points relative to 24-weeks. Exploratory endpoints include additional efficacy measures (INCAT, I-RODS, MRC-SS, grip-strength), change in total-complement, and plasma neurofilament-light chain (NfL). Safety is also evaluated.

Results: As of May-2023, Part-A results from pre-specified interim-analysis show 88% (*N* = 22/25) SOC-Treated participants improved/remained stable (44%; *N* = 11/25 improved), and 12% relapsed (*N* = 3/25). 50% (*N* = 9/18) SOC-Refractory participants responded to riliprubart. Clinically meaningful improvements were observed across secondary efficacy measures. Sustained inhibition of complement-activity and reduction in NfL-levels were also observed in these subgroups. Treatment-emergent adverse events occurred in 60% (*N* = 15/25) of SOC-Treated and 72% (*N* = 13/18) of SOC-Refractory participants. Two deaths were reported in participants with significant medical comorbidities aside from CIDP. Available Part-A and Part-B data for three subgroups will be presented at the meeting.

Conclusion: These preliminary results support proof-of-concept for riliprubart in CIDP, with a favourable benefit-risk profile, supporting further investigation in Phase-3.

Disclosure: LQ: Received research grants from Instituto de Salud Carlos III – Ministry of Economy and Innovation (Spain), CIBERER, Fundació La Marató, GBS-CIDP Foundation International, UCB and Grifols. EPR-250 | Empasiprubart (ARGX-117) in multifocal motor neuropathy: Initial safety and efficacy data of the phase 2 ARDA study

L. Querol[1]; W. Ludo van der Pol[2]; S. Peric[3]; Y. Hussain[4]; S. Cadour[5]; I. Van de Walle[5]; E. Persson[5]; I. Van Hoomissen[5]; O. Mashchenko[5]; M. Vujcic[5]; O. Van de Steen[5]; J. A. Allen[6]

[1]Hospital de la Santa Creu i Sant Pau, Neuromuscular Disorders Unit, Barcelona, Spain; [2]Department of Neurology and Neurosurgery, University Medical Center Utrecht, The Netherlands; [3]University of Belgrade, Faculty of Medicine, Neurology Clinic, University Clinical Center of Serbia; [4]Austin Neuromuscular Center, Austin, TX, USA; [5]Argenx, Ghent, Belgium; [6]University of Minnesota, Department of Neurology, Minneapolis, MN, USA

Background and Aims: Multifocal motor neuropathy (MMN) is a rare immune-mediated neuropathy resulting from motor nerve conduction block leading to axonal degeneration and progressive asymmetric limb weakness with absence of sensory loss. Currently, IVIg is the only proven efficacious therapy. Empasiprubart blocks the activation of classical and lectin complement pathways via C2 binding. ARDA (NCT05225675) is a phase 2, multicentre, randomized, placebo-controlled, double-blinded, parallel-group study that will assess the safety, efficacy, and tolerability of empasiprubart in adults with MMN.

Methods: ARDA enrolled 52 participants with probable or definite MMN (2010 EFNS/PNS guidelines). All had proven IVIg dependency and were on stable IVIg regimen leading to randomisation. MMN diagnosis and IVIg dependency were confirmed by committee. Enrolled participants were assigned to one of two dosing cohorts; each randomized 2:1 to empasiprubart or placebo. Key efficacy endpoints include IVIg retreatment, change in muscle strength, and disability scores.

Results: Cohort 1 randomized 27 participants. During double-blind treatment period, empasiprubart demonstrated a 91% reduction (HR [95% CI]: 0.09 [0.02, 0.44]) in the risk for IVIg retreatment compared with placebo (Figure 1). Since starting therapy, 94% of empasiprubart-treated patients rated their condition improved, with 55% being much/very much improved (Figure 2) (Patient Global Impression of Change scale). 89% of placebo patients had no change/worsened. Empasiprubart was well tolerated overall. Most adverse events were mild or moderate. Additional results presented at the congress.

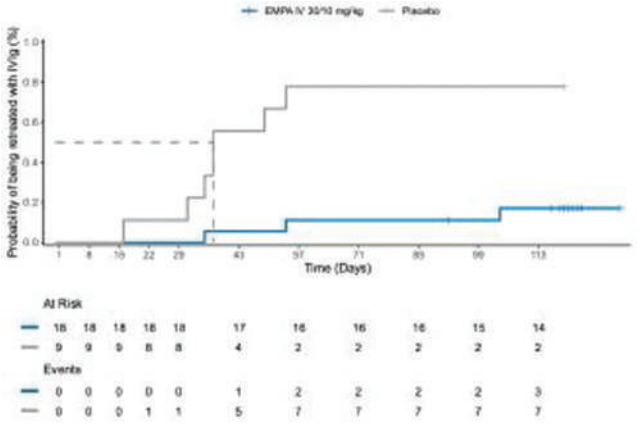

Figure 1 Time to first retreatment with IVIg during treatment period. During double-blind treatment period, empasiprubart demonstrated a 91% reduction (HR [95% CI]: 0.09 [0.02, 0.44]) in the risk for IVIg retreatment compared with placebo. Time to first retreatment with IVIg is defined as the time from last IVIg administration before randomisation (including unscheduled visits) up to the first IVIg retreatment during double-blind trial period.

FIGURE 1

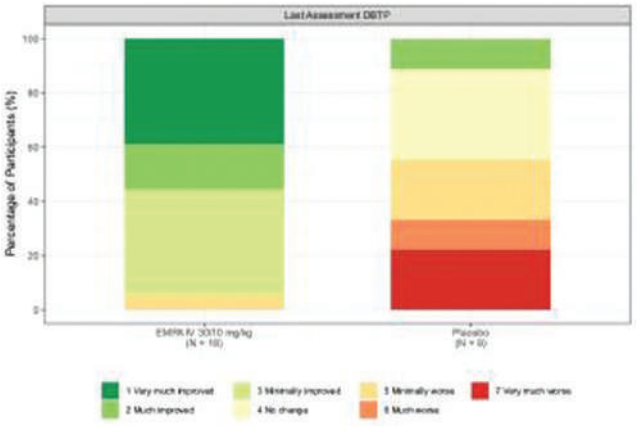

Figure 2 PGIC: Actual values at last assessment during treatment period. Since starting therapy, 94% (31/18) of treated patients rated their condition improved, with 55% being much/very much improved (Patient Global Impression of Change scale). Conversely, 89% (8/9) of placebo patients had no change/worsened.

FIGURE 2

Conclusion: Early efficacy and safety signals in cohort 1 from the ongoing ARDA study support proof of concept of empasiprubart in MMN.

Disclosure: LQ received research grants from Instituto de Salud Carlos III – Ministry of Economy and Innovation (Spain), CIBERER, Fundació La Marató, GBS-CIDP Foundation International, UCB and Grifols; speaker or expert testimony honoraria from CSL Behring, Novartis, Sanofi-Genzyme, Merck, Annexon, Alnylam, Biogen, Janssen, Lundbeck, ArgenX, UCB, LFB, Avilar Therapeutics, Octapharma and Roche; serves at Clinical Trial Steering Committee for Sanofi Genzyme; and was Principal Investigator for UCB's CIDP01 trial. WLvdP employer received fees for ad hoc consultancy from Argenx, Takeda, Biogen, Roche and Novartis gene therapies. SP received lecture honoraria from argenx, Viatris, Pfizer, Teva Actavis, Berlin Chemie Menarini, Mylan, Worwag, Adoc, Remedica and Salveo; research grants from argenx, Kedrion Biopharma and Octapharma; consultant fees from argenx, Dianthus Therapeutics and Mylan; and travel grants from Octapharma, Kedrion, Teva Actavis, Sanofi Genzyme, Pfizer, Roche, ADOC, Wörwag, Medis, and Berlin–Chemie Menarini; and reports no other conflicts of interest outside or related to this work. YH Nothing to disclose. IVW, IVH, EP are employees of argenx. OVS works as a consultant for argenx. MV, OM, SC work as consultants for argenx and PPD. JA has received consulting honoraria from argenx, Alexion, Akcea, CSL Behring, Johnson & Johnson, Grifols, Takeda, and Sanofi.

EPR-251 | Photobiomodulation for managing chemotherapy-induced peripheral neuropathy: Follow-up of a randomized, controlled trial

M. Claes[1]; J. Lodewijckx[1]; S. Hermans[2]; P. Peeters[3]; J. Mebis[4]; J. Robijns[1]

[1]*Faculty of Medicine and Life Sciences, Hasselt University, Hasselt, Belgium;* [2]*Department of Neurology, Jessa Hospital, Hasselt, Belgium;* [3]*Department of Gastroenterology, Jessa Hospital, Hasselt, Belgium;* [4]*Department of Medical Oncology, Jessa Hospital, Hasselt, Belgium*

Background and Aims: Chemotherapy-induced peripheral neuropathy (CIPN) is one of the most common side effects of chemotherapy (CTx) and severely impacts the patients' quality of life. Managing CIPN is often based on CTx dose reduction or a premature stop of treatment. Photobiomodulation (PBM) therapy stimulates cell repair by using (near)-infrared light and previous research shows its efficiency in preventing CIPN. This trial evaluated the effectiveness of PBM in treating CIPN while optimizing the PBM dosage.

Methods: A randomized, controlled trial was conducted at the Jessa Hospital (Hasselt, Belgium) including 60 cancer patients diagnosed with CIPN. Patients were randomly allocated to the PBM-1 (6 J/cm^2, $n=28$) or PBM-2 group (8 J/cm^2, $n=32$). PBM was applied twice a week for three weeks. The severity of CIPN was assessed using the modified Total Neuropathy Score (mTNS), while the Numeric Rating Scale (NRS) was used to evaluate the patient's pain. Outcome measures were collected at baseline, the end of PBM, and three weeks post-PBM. The NRS was also assessed at six months and a year post-PBM.

Results: The NRS score decreased significantly over time in the PBM-1 ($p=0.02$) and PBM-2 group ($p=0.017$). Post-hoc analysis showed a significant difference between baseline and one-year follow-up in the PBM-1 group ($p=0.007$). The mTNS also decreased significantly over time in both groups ($p=0.007$, and $p=0.029$, respectively).

[*]The percentages may not add up to 100% due to combinations of chemotherapy [a]unpaired t-test (two-tailed) [b]Chi-square tests (two-tailed), or Fisher's exact tests, as appropriate. Body Mass Index (BMI); photobiomodulation (PBM); standard deviation (SD)

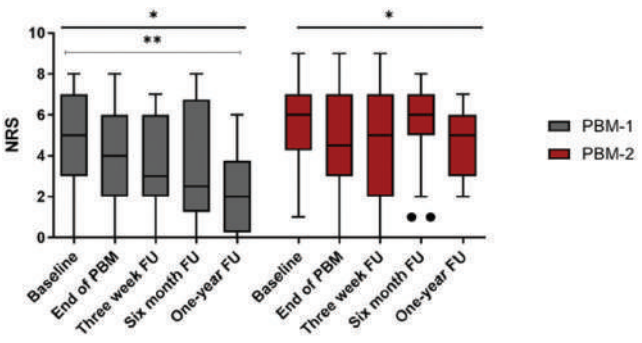

FIGURE 1: Pain scored on the Numeric Rating Scale (NRS). A higher score indicates a higher level of pain. Outliers are displayed as dots. Significance is shown as $^{*}p < 0.05$, $^{**}p < 0.01$. PBM, Photobiomodulation.

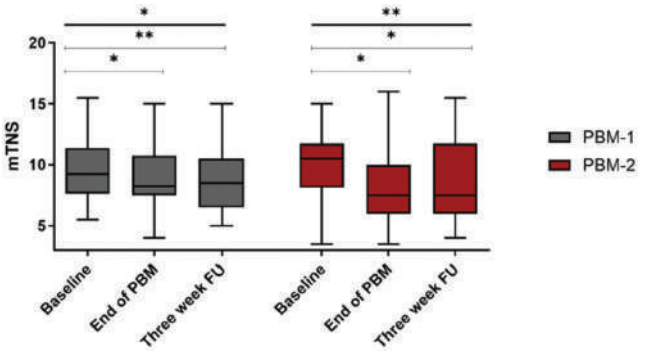

FIGURE 2: Modified Total Neuropathy Score (mTNS). A higher score indicates a more severe grade of peripheral neuropathy. Significance is shown as $^{*}p < 0.05$, $^{**}p < 0.01$. PBM, Photobiomodulation.

Conclusion: This trial shows that PBM can reduce the symptoms and pain associated with CIPN. A larger trial with a more extensive follow-up is necessary to support these findings.

Disclosure: This research is funded by Limburg Clinical Research Center, Kom op tegen Kanker (Stand up to Cancer), the Flemish cancer society, and the Limburgs Kankerfonds.

EPR-252 | Intraepidermal nerve fibre density in Val30Met aTTRv amyloidosis: Correlation with disease and amyloid deposition

J. Moura[1]; I. Reis[2]; A. Sousa[3]; C. Alves[3]; D. Pereira[3]; M. Cardoso[3]; T. Coelho[3]; R. Taipa[2]; M. Pinto[2]

[1]*Neurology Department, Unidade Local de Saúde Santo António, Porto, Portugal;* [2]*Portuguese Brain Bank, Neuropathology Department, Unidade Local de Saúde Santo António, Porto, Portugal;* [3]*Corino de Andrade Unit, Unidade Local de Saúde Santo António, Porto, Portugal*

Background and Aims: Hereditary transthyretin amyloidosis (aTTRv amyloidosis) is characterized by a length-dependent polyneuropathy. Besides classical amyloid deposition, skin biopsies (SB) show changes in the intraepidermal nerve fibre density (IENFD). We aimed to study the value of IENFD in identifying aTTRv patients.

Methods: Retrospective collection of data from patients with the Val30Met mutation who underwent SB between 2019 and 2023. Clinical and neurophysiological data and the disease conversion status were retrieved.

Results: In total, 70 cases were identified (52.9% female), with a mean age at SB of 48.54 ±16.76 years. At the time of the SB, 22 were symptomatic (31.4%), 38 had doubtful symptoms (54.3%) and 10 were asymptomatic (14.3%). Thirteen cases (27.1%) with doubtful or no symptoms were considered affected by the disease during 4-year follow-up. Overall, patients (50.0%) had significantly lower distal IEFND compared to carriers (4.08 ±3.52 vs. 7.91 ±4.28) after adjusting for age and sex ($p = 0.002$). There was no association between IEFND and starting disease during follow-up in the group with doubtful or no symptoms. In asymptomatics, the distal/proximal IEFND ratio was significantly lower in patients that started the

disease (0.203 ±0.153 vs. 0.739 ±0.242, $p=0.018$). Amyloid deposits were present in 33 (47.1%) SB and associated with significantly lower IEFND both distally (3.88 ±3.65 vs. 7.78 ±4.08, $p<0.001$) and proximally (10.16 ±5.92 vs. 13.09 ±4.64, $p=0.041$). In the subset with doubtful symptoms and absent amyloid deposits, the two cases that became diseased had lower proximal IEFND (7.18 ±0.74 vs. 13.37 ±4.62, $p=0.038$).

Conclusion: Analysis of IEFND was not able to assert patients without explicit aTTR symptoms, while a clear association between amyloid deposition and IEFND reduction was seen.

Disclosure: The authors have nothing to disclose.

EPR-253 | Safety profile of subcutaneous efgartigimod PH20 from clinical trials in immunoglobulin G-mediated autoimmune diseases

P. van Doorn[1]; J. De Bleecker[2]; J. Howard Jr[3]; T. Vu[4]; J. Allen[5]; S. Agha[6]; P. Ulrichts[6]; J. Guptill[7]; J. Podhorna[6]; L. Liu[6]; R. Lewis[8]

[1]Department of Neurology, Erasmus MC, University Medical Center, Rotterdam, The Netherlands; [2]Department of Neurology, Ghent University, Ghent, Belgium; [3]Department of Neurology, The University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, USA; [4]Department of Neurology, University of South Florida Morsani College of Medicine, Tampa, Florida, USA; [5]Department of Neurology, Section of Neuromuscular Medicine, University of Minnesota, Minneapolis, Minnesota, USA; [6]Argenx, Ghent, Belgium; [7]Argenx, Ghent, Belgium; School of Medicine, Duke University, Durham, North Carolina, USA; [8]Department of Neurology, Cedars-Sinai Medical Center, Los Angeles, California, USA

Background and Aims: Efgartigimod (EFG), a human immunoglobulin G (IgG) 1 Fc fragment, blocks the neonatal Fc receptor, selectively decreasing IgG levels. The safety profile of subcutaneous (SC) EFG PH20 (co-formulated with recombinant human hyaluronidase PH20) was assessed across generalized myasthenia gravis (gMG) and chronic inflammatory demyelinating polyneuropathy (CIDP).

Methods: EFG PH20 SC was assessed using cyclical dosing (4 once-weekly injections) in gMG (ADAPT-SC noninferiority study and ongoing open-label extension ADAPT-SC+ trial [data cut-off: 19 June 2023]) and weekly continuous dosing in CIDP (ADHERE [stage A: open-label; stage B: placebo-controlled] and ongoing open-label extension ADHERE+ trials [data cut-off: 15 June 2023]).

Results: EFG PH20 SC was well-tolerated and demonstrated a consistent safety profile, with similar rates of treatment-emergent adverse events (TEAEs) to placebo in ADHERE, across indications, and across routes of administration; a higher rate of injection site reactions (ISRs) was observed with EFG PH20 SC versus placebo in ADHERE (Table 1). Most TEAEs were mild to moderate in severity across studies. Discontinuation rates due to TEAEs were consistently low, ranging from 0% to 6.8% across studies. There was no increase in TEAE rates, including infections with repeated treatment. ISRs were mild to moderate in severity, and only 1 participant (in CIDP studies) discontinued EFG PH20 SC because of an ISR (Preferred term: Injection site rash). EFG PH20 SC did not reduce albumin or increase cholesterol levels.

TABLE 1:

Table 1 Incidence and event rates of adverse events for subcutaneous efgartigimod in ADAPT-SC, ADAPT-SC+, ADHERE and ADHERE+ trials, and intravenous efgartigimod in ADAPT-SC

Indication	Generalised myasthenia gravis			Chronic inflammatory demyelinating polyneuropathy

AE, adverse event; EFG, efgartigimod; IV, intravenous; PH20, recombinant human hyaluronidase PH20; PYFU, patient-year(s) of follow-up; SAE, serious adverse event; SC, subcutaneous; TEAE, treatment-emergent adverse event.

[a]TEAEs grouped under Preferred Terms leading to EFG PH20 SC discontinuation were 'COVID-19' (n=1) and 'Myasthenia gravis' (n=1) in ADAPT-SC (EFG PH20 SC; 'Cardiac arrest' (n=1), 'COVID-19' (n=1), 'Renal cancer metastatic' (n=1), 'Myasthenia gravis crisis' (n=1) and 'Respiratory failure' (n=1) in ADAPT-SC+; 'Cardiac arrest' (n=1), 'Injection site rash' (n=1), 'COVID-19' (n=1), 'COVID-19 pneumonia' (n=1), 'Muscular weakness' (n=1), 'Chronic inflammatory demyelinating polyradiculoneuropathy' (n=15), 'Quadriparesis' (n=1) and 'Pruritus' (n=1) in ADHERE stage A; 'COVID-19 pneumonia' (n=1), 'Prostate cancer' (n=1) and 'Transitional cell carcinoma' (n=1) in ADHERE stage B EFG PH20 SC; 'Pneumonia' (n=1) in ADHERE stage B PBO SC; 'Lymphadenitis' (n=1), 'Eye movement disorder' (n=1), 'Asthenia' (n=1), 'Hepatic function abnormal' (n=1), 'COVID-19' (n=1), 'Chronic inflammatory demyelinating polyradiculoneuropathy' (n=4) and 'Cranial nerve disorder' (n=1) in ADHERE+.

[b]Infections and infestations are grouped under System Organ Class (Medical Dictionary for Regulatory Activities v. 24.1 for ADAPT-SC and ADAPT-SC+ and v. 25.1 for ADHERE and ADHERE+).

[c]Injection site reactions are defined as AEs in the Medical Dictionary for Regulatory Activities high-level term injection site reactions regardless of the time of AE onset relative to an injection.

Event rates were calculated as the number of events divided by the PYFU.

ADAPT-SC+ data cut-off: 19 June 2023; ADHERE+ data cut-off: 15 June 2023.

Conclusion: EFG PH20 SC was well-tolerated across indications and dosing regimens. Most TEAEs were mild to moderate in severity and did not increase in frequency with recurrent dosing.

Background and Aims: Hereditary amyloid transthyretin amyloidosis with polyneuropathy (ATTRv-PN) is a multisystemic is a rare, inherited, progressive adult-onset disease, affecting the sensorimotor nerves and other organs. It is caused by mutations in the TTR gene, leading to misfolded monomers which aggregate generating amyloid fibrils. Patisiran is a small, double-stranded interfering RNA encapsulated in a lipid nanoparticle, able to penetrate into hepatocytes, where it selectively targets TTR mRNA, reducing TTR production. We report and discuss a multi-center real-life experience of patisiran in ATTRv-PN.

Methods: We enrolled patients with genetically confirmed diagnosis of ATTRv-PN, from 29 specialized centers from Italy. All subjects underwent neurologic evaluation, each obtaining a Polyneuropathy Disability (FAP) score, Neuropathy Impairment Score (NIS), quality-of-life assessment with the Norfolk Quality of Life–Diabetic Neuropathy (Norfolk QOL-DN) questionnaire and Compound Autonomic Dysfunction Test (CADT).

Results: One hundred seventy-five ATTRv patients (70% males) have been recruited. Most patients presented multisystemic involvement and only 15% presented isolated polyneuropathy. In 70% of patients, patisiran was the first treatment while in 30% it was switched from tafamidis or inotersen. Mean NIS values were stable during follow-up suggesting no progression of neuropathy. Patisiran was safe without any side effects in 90% patients. A significant positive correlation was demonstrated between the age at the start of patisiran and the severity of neuropathy assessed by NIS (R^2 =0.043) and quality of life assessed with Norfolk QOL-DN (R^2 =0.006).

Table 1. Demographics of ATTRv-PN patients

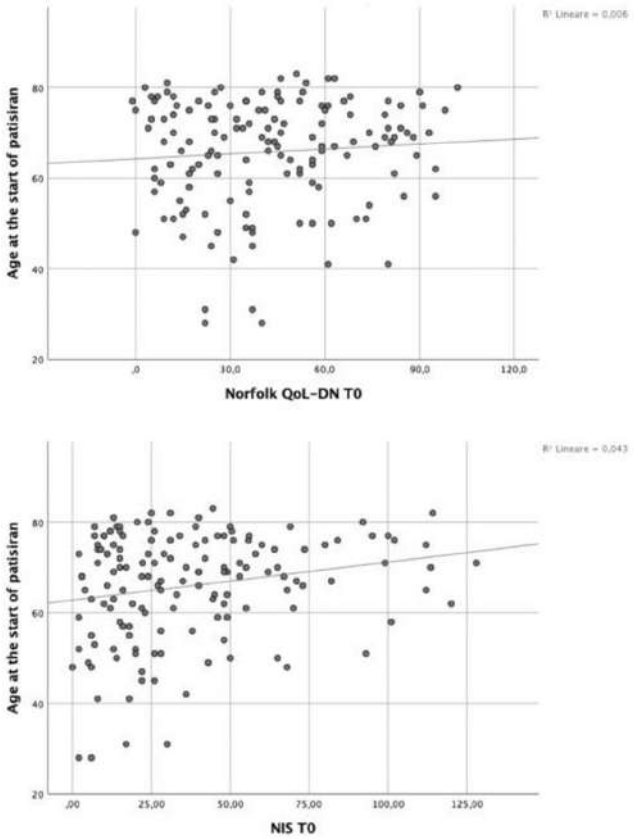
	ATTRv patients (n=175)
Age (years)	
Age at onset neuropathy (years)	62.9±13.1
Age at the start of patisiran (years)	65.9±11.9
Males	121 (70%)
FAP	FAP 1: 128 (74%)
	FAP 2: 47 (26%)
Follow-up	
<9 months	21 (12%)
9-18 months	82 (47%)
18-24 months	60 (34%)
>36 months	12 (7%)
Neuropathy Impairment Score (NIS)	
Baseline (T0)	38.6±30.3
9 months (T1)	39.2±32.5
18 months (T2)	39.2±31.1
Norfolk Quality of Life–Diabetic Neuropathy (Norfolk QOL-DN) questionnaire	
Baseline (T0)	43.8±26.5
9 months (T1)	44.3±27.2
18 months (T2)	41.8±25.9
Compound Autonomic Dysfunction Test (CADT)	
Baseline (T0)	16.9±8.3
9 months (T1)	16.7±9.4
18 months (T2)	18.7±8.7

Demographics of ATTRv-PN patients.

Table 2. Adverse event (AE) reported in 175 ATTRv-PN patients treated with patisiran

Adverse event (AE)	Frequency
AE (any type)	17 (9%)
Back pain	6 (3%)
Renal impairment	3 (2%)
Headache	2 (1%)
Rush	2 (1%)
Infusion site reaction	2 (1%)
Itching	1 (0.5%)
Intolerance to premedication	1 (0.5%)
Fatigue	1 (0.5%)
Abdominal pain	1 (0.5%)
AE leading to treatment discontinuation	0
AE leading to treatment interruption	0
Serious AE	0

Adverse event (AE) reported in 175 ATTRv-PN patients treated with patisiran.



A positive correlation was demonstrated between the age at the start of patisiran and the severity of neuropathy assessed by NIS and quality of life assessed with Norfolk QOL-DN.

Conclusion: Our data show that patisiran is effective and safe and that this drug stabilizes neurological symptoms, and QoL, of ATTRv amyloidosis patients.

Disclosure: Vincenzo Di Stefano received compensation for speaking from Alexion and Alnylam; he is SI in clinical trials for Alexion, Alnylam, Argenx, and Sanofi.

Motor neurone diseases

EPR-255 | Prediction of survival outcomes for patients with amyotrophic lateral sclerosis utilizing machine learning

I. Xu[1]; G. Ling[2]; Z. Simmons[3]; S. Ramasamy[2]; C. Yeo[4]
[1]*Duke-NUS Medical School;* [2]*Institute for Infocomm Research, A*STAR;* [3]*Penn State Hershey Med Center;* [4]*National Neuroscience Institute Singapore*

Background and Aims: ALS is a heterogeneous disorder for which survival prediction has been challenging. The European Network to Cure ALS (ENCALS) utilized the Royston–Parmar (RP) model to predict survival from symptom onset, using data from the diagnosis day. However, data from diagnosis days may not always be available. Hence, a model which predicts survival outcome from any clinical visit may be helpful to physicians and patients for individualized therapy.

Methods: We utilized demographic, clinical, and laboratory parameters from 11024 patient samples in the Pooled Resource Open-Access ALS Clinical Trials (PRO-ACT) database to develop and validate both an ML Extreme Gradient Boosting (XGBoost) and RP model to predict 12-month survival from any clinical visit. Top predictive features for survival were identified using XGBoost. Refined XGBoost and RP models were trained utilizing the top 5 features.

Results: XGBoost demonstrated superior performance with an AUROC of 0.819 ±0.011 for 12-month forecasts, exceeding the RP's AUROC of 0.798 ±0.021. Top survival predictors identified by XGBoost included albumin level, onset location, ALSFRS-R slope, bicarbonate level, and basophil count. A refined XGBoost model using the top 5 features still performed robustly, with an AUROC of 0.762 ±0.012, compared to the refined RP model's 0.731 ±0.009.

Conclusion: We have developed a simple machine learning model that can accurately predict 12-month survival outcome from any clinical visit. Future studies would involve validating the model in more clinic patient cohorts. Key predictors identified by our ML model provide targets for further ALS research.

Disclosure: This abstract has been submitted to the annual meeting of the American Academy of Neurology.

EPR-256 | An observational cohort study on safety and efficacy in adult 5q SMA patients receiving risdiplam treatment

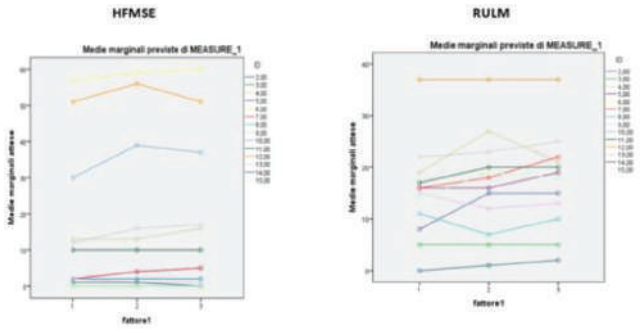
A. Nanni[1]; G. Milella[1]; G. Piccirilli[1]; S. Idrissi[1]; A. Introna[1]; A. Fraddosio[1]; I. Ladisa[2]; M. Megna[2]; V. Scacco[2]; M. Ucci[1]; D. Paolicelli[1]; I. Simone[1]
[1]*Neurology Unit, Department of Translational Biomedicine and Neurosciences (DiBraiN), University of Bari – Italy;* [2]*Department of Basic Medical Sciences, Neurosciences and Sense Organs, Aldo Moro University of Bari, Bari, Italy*

Background and Aims: Risdiplam is an orally administered molecule recently approved for the treatment of Spinal Muscular Atrophy (SMA). It increases functional SMN (survival motor neuron) protein by modifying pre- mRNA splicing of the gene SMN2. Aim of the study was to investigate safety, and efficacy of risdiplam in our adult cohort of SMA patients.

Methods: Inclusion criteria were clinical and molecular diagnosis of SMA2/SMA3; starting Risdiplam in adulthood; availability of clinical data and specific motor scale [Hammersmith Functional Motor Scale Expanded (HFMSE); Revised Upper Limb Module (RULM), six minute walking test (6MWT)] at treatment baseline (T0) and after 6 months (T6).

Results: We included 18 patients (9 SMA 2 and 9 SMA3), with a median age of 41 years at the first administration (IQR 37.7–48.6).

HFMSE significantly increased from T0 to T6 ($p=0.027$) and from T0 to T12 (p: 0.033). Moreover RULM showed a significant improvement at T12 ($p=0.016$). No changes in the 6MWT were detected in walking patients. Ten patients (55.6%) were classified as responders at T6, and 8 out of the 14 patients (71, 43.1%) were also classified as responders at T12. Among all demographic and clinical variables, the number of SMN2 copies was independently associated with clinical improvement at T6 ($p=0.023$) and T12 ($p=0.045$). No severe adverse events were reported.



Spaghetti plot show improvement from T0 to T6 and T12 on the HMFSE and RULM scales.

		N. of patients (%)	MEDIAN	IQR
AGE (YEARS)			42,7	37,7-48,6
AGE AT ONSET (MONTHS)			8,2	13,5-42
DISEASE DURATION (YEARS)			40,3	33,6-47,1
SEX	FEMALE	8 (44,4%)		
	MALE	10 (55,5%)		
SMA TYPE	SITTERS	14 (77,8%)		
	WALKERS	4 (22,22%)		
SMA COPIES	2	4 (11%)		
	3	14 (77,8%)		
	4	2 (11,1%)		
HMFSE 0	18		2	0,25-12,75
HMFSE 1	18		3	0,25-15,25
HMFSE 2	14		5	1,25-16,75
RULM 0	18		6,50	15,50-21,25
RULM 1	18		7,5	17,00-26,00
RULM 2	14		13,50	19,50-24,25

TABLE

Conclusion: our data highlight that the efficacy of Risdiplam is evident even in the first months of treatment, regardless of age/gender/functional clinical status at baseline and SMA type. Number of SMN2 copies influence positively clinical improvement.
Disclosure: Nothing to disclose.

EPR-257 | Impairment of brain "neurovascular coupling" in ALS: Correlations with cognitive abilities and prognosis

G. D'Alvano[1]; A. Canna[1]; M. Sharbafshaaer[1]; F. Canale[1]; C. Passaniti[1]; F. D'Ammora[1]; M. Siciliano[1]; G. Tedeschi[1]; F. Esposito[1]; F. Trojsi[1]
[1]*Department of Advanced Medical and Surgical Sciences, MRI Research Center, Università degli Studi della Campania Luigi Vanvitelli, Naples, Italy*

Background and Aims: Alterations of brain-blood barrier, part of neurovascular unit (NVU), have been evidenced in Amyotrophic Lateral Sclerosis (ALS). We aim at exploring the potential NVC alterations across different resting state networks via the spatial combination of "cerebral blood flow" (CBF) and amplitude of low frequency fluctuations (ALFF) maps, respectively derived from arterial spin labeling (ASL) and blood oxygen level dependent (BOLD) RS-fMRI measurements, in a sample of ALS patients compared to healthy controls (HC). Additionally, we compared the NVC data at baseline in subsets of patients with different disease progression.
Methods: 51 ALS patients were screened by clinical and neuropsychological scales, and were classified a posteriori as very fast, fast, and slow progressors (VFPs, FPs, and SPs), according to change in the disability score over 12 months. 25 HCs were enrolled.
Results: No patient was affected by dementia, while 17 patients had cognitive impairment according to Strong Criteria. A statistically significant reduction of NVC (ALFF-CBF) was found in the default mode network (DMN) in ALS patients compared to HC. We found significant correlations between the NVC in the DMN and the executive function, memory, visuospatial ability and ALS-non-specific ECAS subscores. We identified significant differences in NVC at baseline in the DMN between VFPs and SPs groups.
Conclusion: Our findings suggest that significant changes in NVC occur outside the motor areas in ALS patients; NVC measures might represent a valuable tool to explore early signature of cognitive/extra-motor impairment in ALS. Moreover, NVC alterations in DMN could represent a predicter of faster clinical progression.
Disclosure: I have no disclosure.

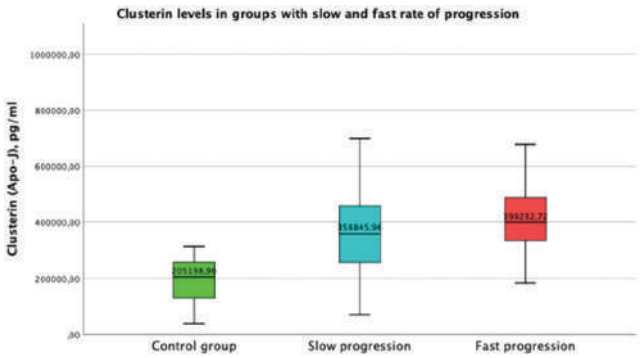
EPR-258 | Characteristics of proteostasis changes in amyotrophic lateral sclerosis

D. Shevchuk[1]; A. Tukhvatulin[2]; A. Dzharullaeva[2]; M. Zakharova[1]
[1]*6th neurological department, Research Center of Neurology, Moscow, Russian Federation;* [2]*The Gamaleya National Research Center for Epidemiology and Microbiology, Moscow, Russian Federation*

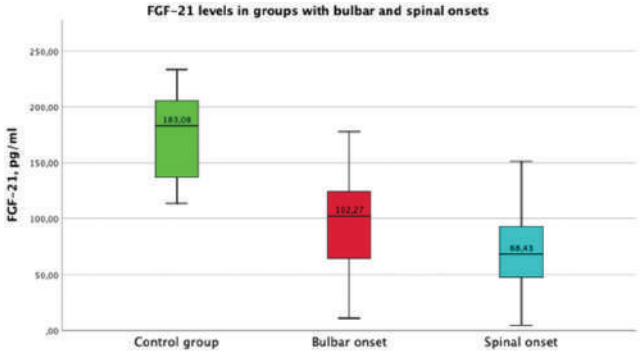
Background and Aims: Amyotrophic lateral sclerosis (ALS) is a fatal, rapidly progressive neurodegenerative disease. Increasing evidence suggests that disturbances in proteostasis play a significant role in the pathogenesis of ALS.

Methods: The study enrolled 100 patients diagnosed with ALS, while the control group consisted of 20 healthy volunteers. We performed clinical assessment with neurological examination and ALSFRS-R functional status evaluation. The concentrations of amyloid beta 1-40 and 1-42, FGF-21, Kallikrein-6, Neurogranin, Tau (total), Tau (pT181), Apolipoprotein E4, Clusterin and complement component C3 in cerebrospinal fluid were measured using the multiplex ELISA kit.

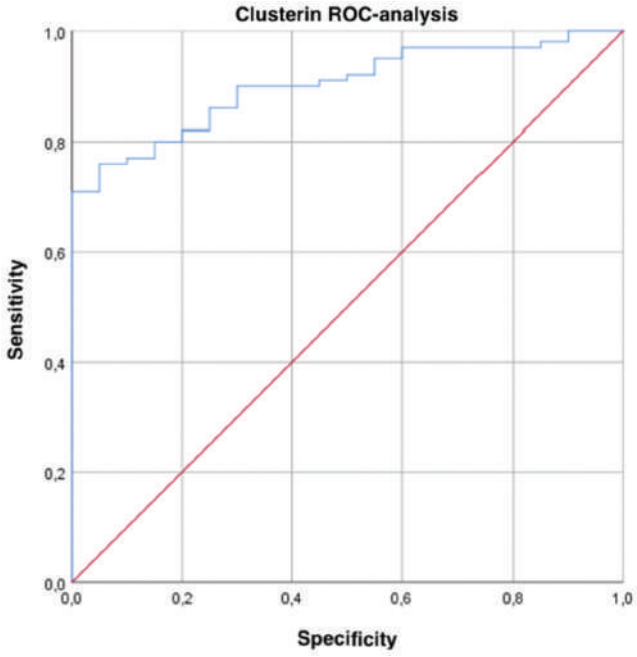
Results: Significant differences between the main and control groups ($p < 0.05$) were observed in the concentrations of Amyloid beta 1-40 and 1-42, FGF-21, Tau (total), Tau (pT181), Clusterin, S100B and complement C3. Multiple comparisons revealed significant difference in the levels of clusterin and apolipoprotein E4 between patients with slow and rapid rates of progression, with increased concentration in the group with rapid progression. It is known that clusterin involved in the elimination process of pathologically aggregated TDP-43 and SOD1. As a promising supplementary diagnostic biomarker clusterin demonstrated 76% and 95% of sensitivity and specificity relatively. FGF-21 levels significantly differ between patients with bulbar and spinal onsets and its concentration decreased in the case of spinal onset. In animal models it was shown that activation of the FGF21 pathway induces an effective anti-inflammatory response.



Clusterin levels in the groups with slow and fast rate of progression.



FGF-21 levels in the groups with bulbar and spinal onsets.



Clusterin ROC-analysis.

Conclusion: Investigating various aspects of proteostasis disruption in amyotrophic lateral sclerosis may provide future promising therapeutic opportunities and a potential diagnostic algorithm for assessing the progression of the neurodegenerative process.

Disclosure: Nothing to disclose.

EPR-259 | Parenteral nutrition in amyotrophic lateral sclerosis: An exploratory population-based study

G. Pellegrino; F. Palumbo; A. Canosa; U. Manera; R. Vasta; M. Grassano; E. Matteoni; S. Cabras; F. Di Pede; F. De Mattei; B. Iazzolino; C. Moglia; A. Chiò; A. Calvo
ALS Centre, "Rita Levi Montalcini" Department of Neuroscience, University of Turin (Torino)

Background and Aims: Nutritional support is a crucial aspect in the management of amyotrophic lateral sclerosis (ALS). However, the realm of home parenteral nutrition (HPN) remains relatively unexplored in ALS research, and a thorough comparison with enteral nutrition (EN) regarding main health outcomes is lacking. This study aims to evaluate HPN within an ALS cohort.

Methods: We included 55 patients from the Turin ALS Centre diagnosed with probable, probable laboratory-supported or definite ALS between 2015 and 2022. Site of onset (bulbar – BO/spinal – SO), cognitive status (normal – CN/impaired – CI) and ventilatory support (none/not invasive – NIV/invasive – IV) were assessed.

Results: BO (50.9%), CI (58.2%) and ventilated (65.5%) patients were predominant. The mean interval between diagnosis and the initiation of HPN was 697 days, shorter in BO (614 days) and in CI (518 days). The mean survival (or time to IV) from the start of HPN was 120 days, shorter in BO (106 days) and in CI (104 days). The overall rate of

HPN-related complications was 43.6%, mainly consisting of local adverse events (66.7%).

Conclusion: The shorter survival in CI may primarily stem from suboptimal treatment compliance (e.g. NIV), yet the association with cognitive impairment may explain similar data in BO. Given the prevailing compromised status in our representative cohort, the mean overall survival observed with HPN, consistent with prior studies and comparable to that reported with EN plus respiratory insufficiency, may justify its utilization in advanced stages characterized by cognitive and respiratory impairment.

Disclosure: Nothing to disclose.

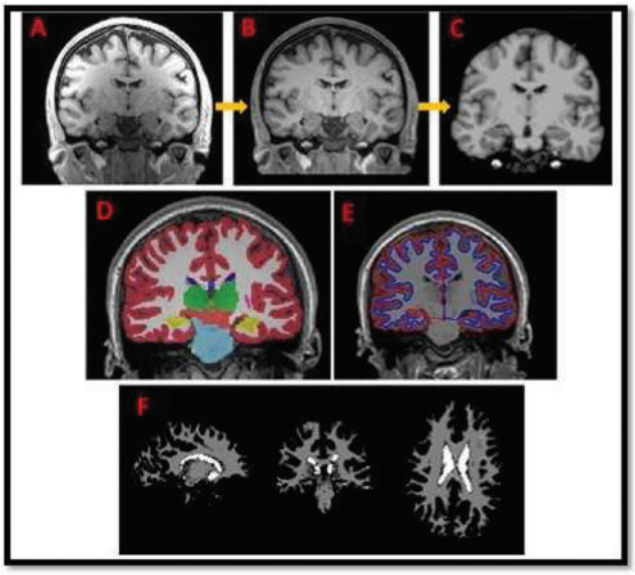
EPR-260 | Specific subcortical degeneration pattern is associated with bulbar-onset phenotype and social cognition deficits in ALS

G. Fiamingo[1]; L. Mazzocchi[3]; M. Collesi[2]; E. Ballante[4]; M. Paoletti[3]; S. Cappa[5]; A. Pichiecchio[3]; V. Bettoni[1]; L. Diamanti[6]

[1]Department of Brain and Behavioural Sciences, University of Pavia, Pavia, Italy; [2]IRCCS Mondino Foundation, Pavia, Italy; [3]Advanced Imaging and Radiomics Center, IRCCS Mondino Foundation, Pavia, Italy; [4]Department of Mathematics, University of Pavia, Pavia, Italy; [5]University School for Advance Studies IUSS, Pavia, Italy; [6]Neuro-oncology unit, IRCCS Mondino Foundation

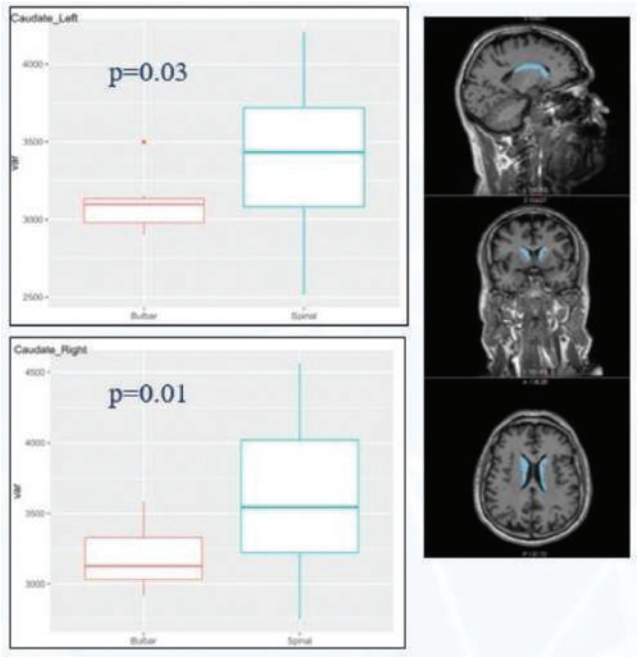
Background and Aims: Cognitive impairment is reported in up to 50% of ALS patients. Recent investigations suggest the presence of social cognition deficits, possibly unrelated to executive dysfunction. Only a few neuroimaging studies have attempted to correlate brain structural alterations to social cognition performance in ALS.

Methods: We enrolled 45 ALS patients. 20% had bulbar-onset. Disease severity was staged according to the King's Staging System (KSS, stage 0 = 1, stage 1 = 34%, stage 2 = 31%, stage 3 = 33%). All patients were tested with ECAS, Ekman and SET scale, and performed 3D T1-weighted sequences on 3T MRI. Imaging reconstruction and segmentation were performed with FreeSurfer. Clinical, neuropsychological and structural changes and their correlation with scores on social cognition tests were explored.



Representation of FreeSurfer pipeline steps for brain imaging parcellation and segmentation. (A) Raw T1-3D MRI; (B) intensity corrected; (C) removal of all non-brain areas; (D) automatic volume labelling; (E) White matter labelling; (F) segmentation.

Results: Group comparison analysis showed worse results for Ekman ($p = 0.0375$) and SET-IA ($p = 0.0047$) in bulbar-onset and KSS-3 patients, and lack of correlation with executive dysfunction. The bulbar-onset group showed lower bilateral caudate volumes compared to spinal-onset patients (L: $p = 0.03$, R: $p = 0.01$). KSS-3 patients had reduced left caudate volume ($p = 0.01$) and left inferotemporal cortical thickness ($p = 0.04$). In the bulbar-onset subgroup, SET-IA score and right caudate volume were positively correlated, without reaching significance level possibly because of reduced sample size ($n = 8$, $r = 0.60$, $p = 0.54$).



Box plots of the bilateral caudate volumes according to disease type of onset (bulbar vs. spinal).

Bulbar (n=8) r coefficient	SAND			SET	Ekman				Imaging

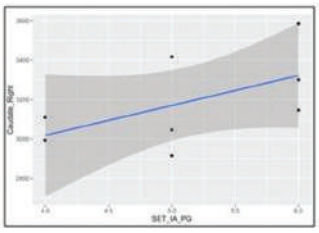
SET_IA	-
Ekman_GS_PG	0.8462
Ekman_ surprise	0.5868
Ekman_fear	0.0238
Ekman_ sadness	0.6079
Caudate_Left	0.5472
Caudate_Right	0.1122



Pearson correlation coefficients for all the areas and volumes considered (upper) and SET-IA corresponding p-values (lower) and graphic representation of the linear correlation between SET-IA raw score and the right caudate volume in bulbar subjects.

Conclusion: Social cognition and emotion recognition deficits are worse in bulbar-onset phenotype, in advanced disease stages, and are at least partly unrelated to executive dysfunctions. The possible correlation between the caudate volume and SET-IA score in bulbar patients provides preliminary evidence of a phenotype-specific subcortical degeneration pattern associated with social cognition deficits.

Disclosure: Nothing to disclose.

EPR-261 | Genetics screening in an Italian cohort of patients with ALS: The importance of early testing and its implication

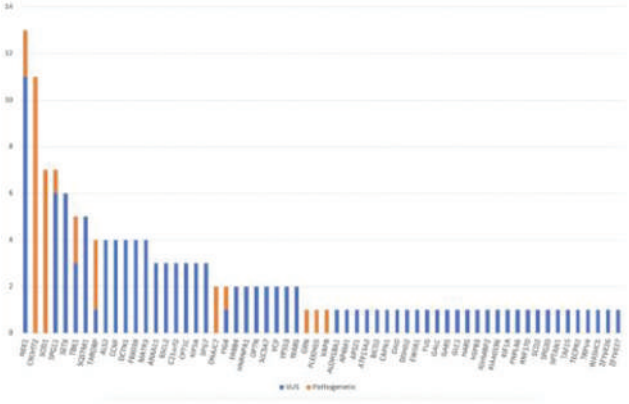
L. Libonati; C. Cambieri; M. Ceccanti; E. D'Andrea; F. Moret; M. Inghilleri

Rare Neuromuscular Diseases Centre, Department of Human Neurosciences, Sapienza

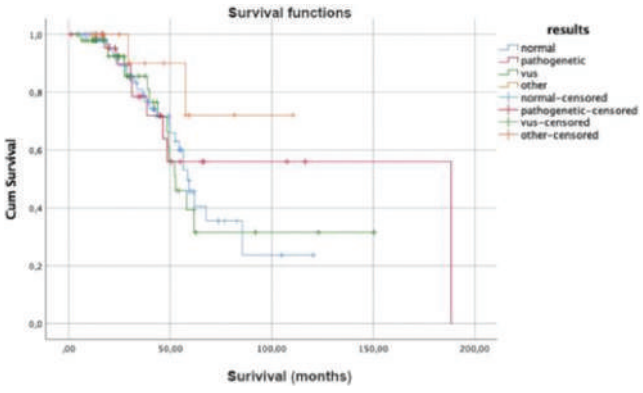
Background and Aims: Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disease with an elusive etiology. The genetic connection is increasingly evident, even in patients with sporadic ALS. We allowed access to the genetic test to all patients attending our clinic to identify the prevalence and the role of genetic variations in the development of the disease and to identify patients with potentially treatable forms of the disease.

Methods: 194 patients with probable or definite ALS, were enrolled. A comprehensive genetic testing was performed, including sequencing all exons of the SOD1 gene and testing for repeat expansions in the C9orf72 gene. Whole Exome NGS Sequencing (WES) was performed, followed by an in silico multigene panel targeting neuromuscular diseases.

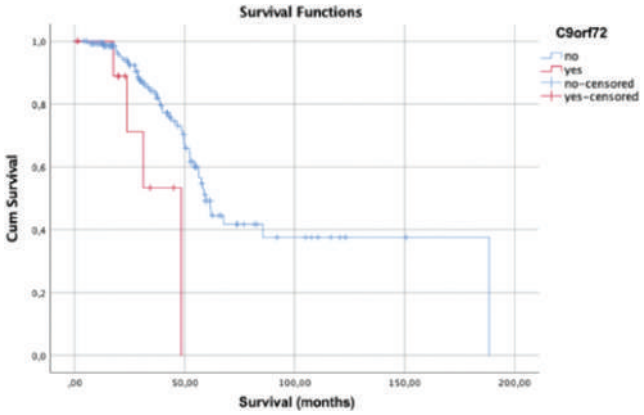
Results: Clinically significant pathogenetic variants were detected in 14.43% of cases. The highest prevalence of pathogenetic variants was observed in fALS patients, but a substantial proportion of sALS patients also displayed at least one mutation. The most observed pathogenetic mutation was the expansion of the C9orf72 gene, which was associated with a shorter survival. SOD1 mutations were found in 1.6% of fALS and 2.5% of sALS patients.



Distribution of mutated genes across our cohort, including pathogenic and variants of uncertain significance (VUS). Pathogenic and likely pathogenic variants are considered together.



No significant difference in survival among patients with and without genetic mutations (Log-rank p value = 0.448).



Patients with C9orf72 had a significative lower survival than patients without the mutation (log-rank *p* value of 0.013).

Conclusion: This study emphasizes the diverse genetic basis of ALS and advocates for integrating comprehensive genetic testing into diagnostic protocols. The evolving landscape of genetic therapies requires identifying all eligible patients transcending traditional familial boundaries. The presence of VUS highlights the multifaceted nature of ALS genetics, prompting further exploration of complex interactions among genetic variations, environmental factors, and disease development.

Disclosure: Nothing to disclose.

EPR-262 | Quantitative MRI study of paraspinal muscles in patients with ALS and correlation with neurophysiological data

L. Scanu[1]; L. Diamanti[2]; G. Cosentino[3]; G. Tammam[3]; M. Todisco[4]; P. Prunetti[4]; M. Paoletti[5]; C. Asteggiano[5]; C. Bonizzoni[5]; L. Barzaghi[6]; A. Pichiecchio[7]

[1]*Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; Unit of Neuro-oncology and Neuroinflammation, IRCCS Mondino Foundation, Pavia, Italy;* [2]*Unit of Neuro-oncology and Neuroinflammation, IRCCS Mondino Foundation, Pavia, Italy;* [3]*Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; Unit of Elettrophysiologhy, IRCCS Mondino Foundation, Pavia, Italy;* [4]*Unit of Elettrophysiologhy, IRCCS Mondino Foundation, Pavia, Italy;* [5]*Advanced Imaging and Artificial Intelligence Center, Neuroradiology Department, IRCCS Mondino Foundation, Pavia, Italy;* [6]*Advanced Imaging and Artificial Intelligence Center, Neuroradiology Department, IRCCS Mondino Foundation, Pavia, Italy; Department of Mathematics F. Casorati, University of Pavia, Pavia, Italy;* [7]*Advanced Imaging and Artificial Intelligence Center, Neuroradiology Department, IRCCS Mondino Foundation, Pavia, Italy; Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy*

Background and Aims: Examining paraspinal muscles is crucial for diagnosing and staging Amyotrophic Lateral Sclerosis (ALS), typically accomplished through electromyography. This study aims to assess quantitative MRI of paraspinal muscles in ALS cohort and find the correlations between radiological and neurophysiological data.

Methods: Seventy-three subjects were enrolled at the IRCCS Mondino in Pavia. They were tested with quantitative muscular MRI, utilizing waterT2 (wT2) and Fat Fraction (FF) sequences, coupled with standard electromyography focusing on the paraspinal muscles. These examinations were conducted for specific muscles: Multifidus muscles, Longissimus thoracis muscles, Iliocostalis muscles and Iliopsoas muscles.

Results: The analysis of 55 muscle MRI did not show statistically significant difference in wT2 and FF values between right and left sides of the dorsal and lumbar portions of the paraspinal muscles; no statistically significant difference emerged after the stratification of patients based on the type of onset. Comparison between quantitative muscle MRI data and electrophysiological values did not reveal strong positive correlations.

Conclusion: This is the first study in which paraspinal muscles were evaluated in patients with ALS using quantitative muscle MRI techniques. Our results highlight a widespread and symmetric involvement of the paraspinal muscles, regardless of the onset site. Furthermore, quantitative muscular MRI have shown a greater sensitivity of electromyography in detecting muscular alterations present in the early stages of disease. Longitudinal data were not included as they are still being acquired.

Disclosure: None.

Peripheral nerve disorders

EPR-263 | Clinical evaluation of presymptomatic carriers of TTR mutations

D. Arslan; B. Koksal; E. Yılmaz; Z. Ergul-Ulger; F. Yildiz; C. Bekircan-Kurt; S. Erdem-Ozdamar; E. Tan

Hacettepe University, School of Medicine, Neurology Department

Background and Aims: The identification and monitoring of asymptomatic carriers is gaining importance after the therapeutic advances in hereditary transthyretin amyloidosis with polyneuropathy (ATTRv-PN). However, there is not any consensus regarding genetic screening of family members of ATTR-PN and the diagnostic tools to monitor presymptomatic carriers of TTR mutations.

Methods: Presymptomatic p.Val50Met mutation carriers were included to the study. Individuals were evaluated by nerve conduction studies, DN4 neuropathic pain score, single fiber neuropathy questionnaire (SFN-SIQ), warm and cold sensation thresholds assessed by quantitative sensory testing (QST), and intraepidermal nerve fiber density (IENFD) annually until symptom onset.

Results: Thirteen members of five different families with a history of ATTRv-PN were included. The mean age was 40.6 (±11.9) years and three of them were male. The neurological examinations remained normal during follow-up in all carriers as well as the nerve conduction studies. Baseline DN4 score, SFN-SIQ, warm and cold sensation thresholds were normal in all individuals. Four carriers developed symptoms of small fiber neuropathy during a median follow-up of 2 (1–3) years. At symptom onset, warm and cold sensation

thresholds were increased and IENFD decreased to below normative values. In addition, IENFD decreased below normal values in four asymptomatic carriers despite normal clinical and other laboratory findings.

Conclusion: In our cohort, symptom onset of ATTRv-PN was concomitant with QST and IENFD abnormality. However, IENFD was below before symptom onset in four carriers. Our results underline the use of multiple diagnostic tools for the follow-up of presymptomatic ATTRv-PN carriers.

Disclosure: Nothing to disclose.

EPR-264 | Mobile health technologies in monitoring treatment response to immunoglobulins in CIDP: A pilot longitudinal study

E. Olivieri[1]; A. Pilotto[1]; A. Rizzardi[3]; C. Zatti[1]; C. Hansen[4]; R. Romijnders[4]; B. Labella[1]; B. Risi[5]; F. Caria[5]; S. Damioli[5]; L. Ferullo[1]; L. Poli[2]; S. Cotti Piccinelli[5]; W. Maetzler[4]; A. Padovani[1]; M. Filosto[1]

[1]Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy; [2]Unit of Neurology, ASST Spedali Civili, Brescia, Italy; [3]Laboratory of Digital Neurology and Biosensors, University of Brescia, Italy; [4]Department of Neurology, Christian-Albrechts-University of Kiel, Kiel, Germany; [5]NeMO-Brescia Clinical Center for Neuromuscular Diseases, Brescia, Italy

Background and Aims: Response to treatment in chronic inflammatory demyelinating polyneuropathy (CIDP) is defined by using disability and impairment scales, despite their limited accuracy in detecting minimal but significant changes in clinical settings. The aim of our study was to explore the potential role of mobile health technologies (MHT) in assessing treatment response in CIDP patients treated with I.V. immunoglobulins (Ig).

Methods: Seven patients with a diagnosis of CIDP according to EAN/PNS criteria treated with Ig and sixteen age- and sex-matched healthy controls (HC) were enrolled. Patients performed digital mobility assessments using MHT at drug administration and after 21 and 45 days. Differences between groups in postural transition, balance, turning, and gait MHT parameters were assessed using non-parametric tests. The comparison of the three time points was evaluated through repeated measures ANOVA.

Results: Compared to HC, CIDP patients showed greater jerks, longer step time and duration of turns, and lower peak angular velocity (all p values <0.02). At follow-up, an improvement in MHT parameters for time to rise from a chair ($p = 0.01$), duration of turns during the TUG test ($p = 0.04$), and jerks while standing on a widened base with eyes open ($p = 0.03$) was observed compared to baseline.

Conclusion: Mobile health technology was able to detect mobility alterations in CIDP and track the beneficial effects of Ig treatment. Therefore, MHT may be a useful tool to monitor patients with CIDP and their response to different management strategies.

Disclosure: Nothing to disclose.

EPR-265 | Diagnostic delay and burden of disease in chronic inflammatory demyelinating polyneuropathy: A real-world survey

G. Boggia[1]; A. Borsi[1]; C. Gary[1]; W. Noel[1]; W. Karmous[1]; J. DeCourcy[2]; J. Wright[2]; Y. Taylor[2]; H. Iqbal[2]; G. Meyer zu Hörste[3]

[1]Johnson & Johnson Innovative Medicine EMEA; [2]Adelphi Real World, Bollington, UK; [3]University Hospital Münster, Münster, Germany

Background and Aims: Chronic inflammatory demyelinating polyneuropathy (CIDP) is a rare condition of the peripheral nervous system characterized by progressive muscle weakness and impaired sensory function. The aim of this study was to describe the diagnostic pathway and disease burden experienced by CIDP patients in Europe.

Methods: Data were drawn from the Adelphi CIDP Disease Specific Programme™, a cross-sectional survey of neurologists in France, Germany, Italy, Spain, UK (September 2022–April 2023), treating at least two CIDP patients per typical month. Patients completed patient-reported outcome measures including the EuroQol-5 Dimension (EQ-5D-5L) and Functional Assessment of Chronic Illness Therapy – Fatigue Scale (FACIT-Fatigue). This real-world data is limited by participating physicians' confirmation of the included patient's CIDP diagnosis.

Results: 83 physicians provided data for 542 patients with CIDP. Mean (SD) patient age was 54.0 (12.4) years; 62.2% were male. Median (IQR) time from symptom onset to CIDP diagnosis was 7.0 (3.8, 13.1) months; 36.7% of patients were initially misdiagnosed/suspected to have a different condition, most frequently Guillain-Barré syndrome. Maintenance treatment was prescribed to 85.4% of patients. Physicians were only partially satisfied with 57.9% of patients' treatment. 12.8% of patients had been hospitalized within the last 12 months, most frequently to treat a complication of CIDP. Patients reported a mean (SD) EQ-5D-5L health utility of 0.63 (0.24) (UK value sets) and FACIT-Fatigue of 34.8 (9.9).

Conclusion: These results highlight the challenges experienced by CIDP patients in Europe, pre-/post-diagnosis. Increased disease knowledge and awareness among physicians may improve diagnostic timelines and outcomes for CIDP patients.

Disclosure: Data collection was undertaken by Adelphi Real World as part of an independent survey, entitled the Adelphi Real World CIDP Disease Specific Programme. Janssen were one of multiple subscribers to the dataset. The study described here was funded by Janssen.

EPR-266 | Conceptualizing innovative approaches in the treatment of peripheral neuropathies

M. Trad[1]; F. Rombouts[2]; J. vanEyll[2]; C. Szyndralewiez[2]; S. Celanire[2]; R. Prior[3]

[1]Neuraltra, Paris, France; [2]Augustine Therapeutics, Leuven, Belgium; [3]Priority Ventures, Kessel-lo, Belgium

Background and Aims: Effective therapies in hereditary and acquired peripheral neuropathies remain limited and focused on

disease symptom management. We describe an orally bioavailable, selective Histone deacetylase 6 inhibitor (HDAC6i) with potential to revert pathological hallmarks of Charcot-Marie-Tooth (CMT) disease and Chemotherapy-induced peripheral neuropathy (CIPN) through axonal regeneration and nerve function restoration.

Methods: HDAC6i AGT-100216 was profiled in a CMT1A C3 mice model, and in a curative mouse model of CIPN.

Results: In a CMT1A C3 mice model AGT-100216 exhibited high potency and selectivity on the HDAC6 enzyme resulting in a dose-dependent improvement of grip strength, compound muscle action potential (CMAP) and nerve conduction velocity. Increased acetylated alpha-tubulin, reduction of neurofilament light chain (NFL), improved axonal diameters and myelin g-ratios were also observed. In a curative CIPN model, AGT-100216 dose-dependently rescued sensory and motor function deficits, matching biomarker changes.

Conclusion: The discovery of a highly selective HDAC6 inhibitor AGT-216 with a potential of reverting axonal degeneration and restoring peripheral nerve function allows for further exploration of new paradigms in the treatment of PNS disorders. Confirming this inherent capacity of AGT-216 in future research in humans will allow for an innovative approach in the treatment of peripheral neuropathies.

Disclosure: Trad M. receives fees as a consulting part time Chief Medical Officer at Augustine Therapeutics; Prior R. receives consultancy fees from Augustine Therapeutics; Rombouts F., van Eyll J., Szyndralewiez C., Celanire S. EPR-267 | Whole genome sequencing in patients with clinically diagnosed Charcot-Marie-Tooth disease

S. Nam[1]; Y. Kim[2]; H. Kwon[1]; J. Park[2]; C. Ha[2]; S. Shin[2]; W. Heo[2]; H. Kim[1]; K. Chung[3]; J. Jang[2]; J. Kim[2]; S. Kim[4]; W. Kim[5]; B. Choi[1]

[1]Department of Neurology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; [2]Department of Laboratory Medicine and Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; [3]Department of Biological Sciences, Kongju National University, Gongju, Republic of Korea; [4]Department of Neurology, Kyung Hee University Hospital at Gangdong, Kyung Hee University School of Medicine, Seoul, Korea; [5]Department of Neurology, Kangdong Sacred Heart Hospital, Hallym University

Background and Aims: Charcot-Marie-Tooth disease (CMT) is a genetically and clinically heterogeneous disorder characterized by progressive muscle weakness and sensory disturbances. Advances in genetic diagnosis have led to the identification of many genetic causes of CMT, but many patients clinically diagnosed with CMT do not have a genetic diagnosis. Whole-genome sequencing (WGS) is the most comprehensive next-generation sequencing assay because it can assess the entire extent of the human genome, including non-coding regions. In this study, we aimed to evaluate the diagnostic yield of WGS in CMT compared to whole-exome sequencing (WES).

Methods: WGS was conducted in 72 families with clinically diagnosed CMT where no genetic diagnosis was obtained from WES and 17p12 duplication screening. WGS was performed using the NovaSeq6000 platform, in accordance with the manufacturer's instructions.

Results: Among these families, 14 were diagnosed through WGS, resulting in a yield of 19.4%. The genotype-based analysis used in this study identified the cause of four cases and contributed the most to the diagnostic yield. The other cases included those due to better coverage of whole genome sequencing (two cases) and those due to structural or non-coding variants (one case each).

Conclusion: This study was the first to evaluate the additional diagnostic yield of WGS after performing WES in patients with clinically diagnosed CMT. A wider range of genes should be targeted in WGS using genotype-driven analysis. In addition to the well-known advantages of WGS compared with WES, such as structural variants and non-coding variants, better coverage even in the coding regions could be another important advantage of WGS.

Disclosure: Nothing to disclose.

EPR-268 | Clinical diversities of INF2 mutations in patients with Charcot-Marie-Tooth disease

S. Nam[1]; J. Park[2]; H. Kwon[1]; D. Nam[2]; H. Kim[1]; S. Kim[3]; K. Chung[2]; B. Choi[1]

[1]Department of Neurology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; [2]Department of Biological Sciences, Kongju National University, Gongju, Korea; [3]Department of Neurology, Kyung Hee University Hospital at Gangdong, Kyung Hee University School of Medicine, Seoul, Korea

Background and Aims: Charcot-Marie-Tooth disease (CMT) is the most common inherited peripheral neuropathy. Patients with CMT occasionally exhibit complex clinical symptoms depending on genetic causes. As an example of the complex phenotypes, patients with mutations in the inverted formin-2 (INF2) gene have shown autosomal dominant Intermediate CMT type E (CMTDIE) with nephropathy of focal segmental glomerulosclerosis (FSGS). In this study, we aimed to identify INF2 mutations in patients with CMT and FSGS, and to define the clinical characteristics in affected patients.

Methods: The families with CMT or FSGS were examined for INF2 mutations. Clinical information was obtained using the standard methods. Nerve conduction study was used to assess the function of peripheral nervous system as an electrophysioological tool. Lower limb axial MRI scans of the bilateral thigh and calf muscles were reviewed.

Results: Four dominant missense INF2 mutations were identified as the underlying causes of CMT and/or FSGS. Four families with INF2 mutations showed different clinical symptoms. Two families had

symptoms of CMT and FSGS, while the others had symptoms of either CMT or FSGS. Moreover, different CMT types including CMT1 and CMTDIE were observed in families with INF2 mutations. The affected individuals with the two CMT types showed clearly different features in terms of onset age, muscle atrophy, nerve conduction, and functional disability.

Conclusion: We suggest that genotype-phenotype correlations may be more complex than we thought. This study expands the clinical spectrum of patients with INF2 mutations and will be helpful in the molecular diagnosis of CMT and FSGS.

Background and Aims: Efgartigimod, a human immunoglobulin G (IgG)1 antibody Fc fragment, blocks the neonatal Fc receptor, decreasing IgG recycling and reducing pathogenic IgG autoantibody levels. Multi-stage, double-blinded, placebo-controlled ADHERE, and ongoing open-label extension ADHERE+, assessed the efficacy and safety of efgartigimod PH20 subcutaneous (SC; coformulated with recombinant human hyaluronidase PH20) in chronic inflammatory demyelinating polyneuropathy (CIDP).

Methods: Enrolled participants with CIDP (treatment-naïve or on standard treatments withdrawn during run-in period) had active disease and received efgartigimod PH20 SC weekly (stage A). Responders were randomized (1:1) to weekly efgartigimod PH20 SC or placebo (stage B). Participants with clinical deterioration in stage B or those who completed ADHERE could enter ADHERE+ (efgartigimod once weekly). Primary outcomes were clinical improvement (stage A), efficacy (stage B) and safety (ADHERE+) (Figure 1).

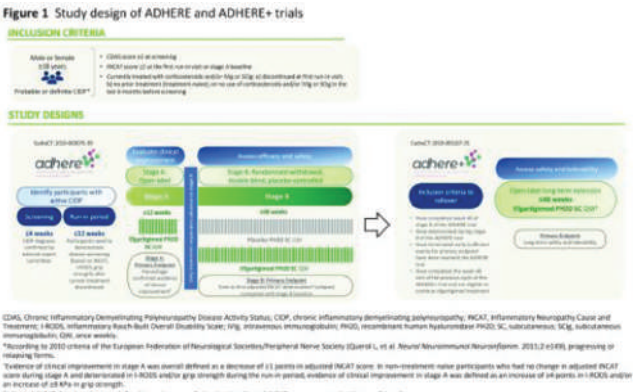

FIGURE 1

Results: In stage A, 214/322 (66.5%) participants demonstrated evidence of clinical improvement. In stage B, efgartigimod significantly reduced relapse risk (HR: 0.394; 95% CI: 0.253–0.614) versus placebo ($p = 0.00004$). Reduced risk of clinical deterioration was shown in participants regardless of prior CIDP therapy. Selected secondary outcomes are shown in Table 1. 99% of eligible participants entered ADHERE+. The safety profile of efgartigimod-treated participants was consistent over 137.42 total patient-years of follow-up for ADHERE+. Most treatment-emergent adverse events were mild/moderate; their incidence/severity did not increase in ADHERE+ (Table 2).

TABLE 1

Table 1 Key secondary efficacy endpoints in the ADHERE trial

	ADHERE		
	Stage A Efgartigimod PH20 SC (N=322)	Stage B Efgartigimod PH20 SC (N=111)	Stage B Placebo PH20 SC (N=110)
Mean (SD) change from baseline to last assessment*			
Adjusted INCAT score	−0.9 (1.71)	0.1 (1.08)	0.9 (1.98)
I-RODS score	7.7 (15.48)	0.8 (12.33)	−7.0 (19.10)
Mean grip strength (dominant hand), kPa	12.3 (18.68)	2.1 (13.29)	−8.2 (20.69)
Mean grip strength (non-dominant hand), kPa	11.2 (21.12)	2.0 (17.33)	−6.9 (21.30)
I-RODS deterioration of ≥4 points, n (%)		40 (36.0)	57 (51.8)
Hazard ratio (95% CI)		0.537 (0.354–0.814)	
Nominal *P* value		0.0034	
I-RODS improvement of ≥4 points, n (%)		50 (45.0)	40 (36.4)
Odds ratio (95% CI)		1.441 (0.814–2.567)	
Nominal *P* value		0.2294	

CI, confidence interval; INCAT, Inflammatory Neuropathy Cause and Treatment; I-RODS, Inflammatory Rasch-built Overall Disability Scale; PH20, recombinant human hyaluronidase PH20 SC, subcutaneous; SD, standard deviation.
*For stage A, this was the change from stage A baseline to stage A last assessment, and for stage B, this was the change from stage B baseline to stage B last assessment.

TABLE 2

Table 2 Incidence and event rates of adverse events in ADHERE and ADHERE+ trials

	ADHERE			ADHERE+
Incidence, n (%) [event rate]	Stage A Efgartigimod PH20 SC (N=322; PYFU= 46.9)	Stage B Efgartigimod PH20 SC (N=111; PYFU= 56.7)	Stage B Placebo PH20 SC (N=110; PYFU= 42.1)	Efgartigimod PH20 SC (N=228; PYFU= 137.4)
≥1 TEAE	204 (63.4) [13.4]	71 (64.0) [3.5]	62 (56.4) [5.1]	131 (57.5) [3.5]
≥1 treatment-related TEAE*	101 (31.4) [5.5]	27 (24.3) [1.1]	22 (20.0) [1.5]	54 (23.7) [0.9]
≥1 SAE	21 (6.5) [0.5]	6 (5.4) [0.1]	6 (5.5) [0.2]	21 (9.2) [0.3]
≥1 treatment-related SAE*	4 (1.2) [0.09]	0	4 (3.6) [0.2]	3 (1.3) [0.03]
≥1 AE of Infections†	44 (13.7) [1.2]	35 (31.5) [0.8]	37 (33.6) [1.3]	73 (32.0) [0.7]
Discontinued due to TEAEs	22 (6.8) [0.5]	3 (2.7) [0.05]	1 (0.9) [0.02]	9 (3.9) [0.1]
Deaths‡	2 (0.6) [0.04]	0	1 (0.9) [0.02]	1 (0.4) [0.007]

AE, adverse event; PH20, recombinant human hyaluronidase PH20; PYFU, patient-year(s) of follow-up; SAE, serious adverse event; SC, subcutaneous; TEAE, treatment-emergent adverse event.
*Deemed treatment-related by the investigator.
†Infections and infestations are grouped under System Organ Class (Medical Dictionary for Regulatory Activities v. 25.1).
‡Deemed to be not related to efgartigimod PH20 SC by the investigator.
Event rates were calculated as the number of events divided by the PYFU.
ADHERE+ data cut-off: 15 June 2023.

Conclusion: ADHERE+ demonstrated long-term effectiveness of efgartigimod PH20 SC for the prevention of relapse. The safety profile of efgartigimod PH20 SC was similar between ADHERE and ADHERE+ and was consistent with the previously demonstrated safety profile of efgartigimod.

EPR-270 | Transthyretin amyloid deposition in ligamentum flavum in an Italian cohort of patients with lumbar spinal stenosis

F. Vitali[1]; A. Romano[2]; V. Guglielmino[2]; M. Sciarrone[1]; D. Arciuolo[3]; M. Gessi[3]; N. Montano[4]; F. Polli[4]; A. Rapisarda[4]; A. Izzo[4]; M. Luigetti[2]

[1]Università Cattolica del Sacro Cuore, Department of Neurosciences, Rome, Italy; [2]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Neurology Unit, Rome, Italy; [3]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Institute of Pathologic Anatomy, Rome, Italy; [4]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Department of Neurosurgery, Rome, Italy

Background and Aims: Transthyretin amyloidosis (aTTR) is a disorder characterized by extracellular accumulation of misfolded transthyretin (TTR). As TTR deposition potentially occurs in every tissue, it also can lead to lumbar spinal stenosis (LSS), a clinical syndrome determined by hypertrophy of ligamentum flavum (LF) and narrowing of the lumbar spinal canal. Several studies report a strong association between LSS and TTR amyloid deposits in the LF. In this study, we prospectively investigated the frequency of TTR amyloid deposits in material obtained at LSS surgery performed at our Center.

Methods: LF specimens were provided from patients who underwent surgery for LSS in the Neurosurgery Department of Policlinico Gemelli, Rome, from June 2023. Demographic, clinical and radiological data were collected. Extensive pathological analysis to detect possible amyloid deposits was performed in all specimens.

Results: The study included 30 patients. Males/females ratio was 18/12. The mean age at the time of surgery was 64 ± 12.75 years. We detected amyloid deposits in 1/30 cases, which also resulted positive at immunohistochemistry with anti-TTR antibodies. Genetic investigations yielded a negative result for hereditary aTTR.

Conclusion: Lumbar canal stenosis is a common spinal condition in elderly patients. Although previous studies have shown a relevant frequence of amyloid deposits in LF hypertrophy, suggesting a possible role in LSS pathogenesis, in our cohort this occurrence was extremely rare. This result should be confirmed in different populations of the same non-endemic country in order to better define a possible geographic contribute to occurrence of amyloid deposits in LSS.

Disclosure: Nothing to disclose.

EPR-271 | **Clinical outcome measures and biomarkers in chronic inflammatory demyelinating neuropathy (CIDP): A literature review**

Y. Rajabally[1]; G. Boggia[2]; C. Gary[2]; W. Noel[2]; D. Riley[3]; S. Riley[3]; E. Nobile-Orazio[4]

[1]*Aston University, Birmingham, UK;* [2]*Johnson & Johnson Innovative Medicine EMEA;* [3]*Adelphi Values PROVE™, Bollington, Cheshire, UK;* [4]*IRCCS Humanitas Clinical and Research Hospital; University of Milan, Italy*

Background and Aims: CIDP displays various clinical subtypes, and variability exists when assessing therapy and disease progression using clinical outcome assessments (COA). Biomarkers may be a novel way of establishing outcome and tracking progression in CIDP. This literature review aimed to identify COAs and biomarkers used, proposed, or studied to date in CIDP, and to attempt to inform future management.

Methods: A structured literature review was conducted to explore COAs and biomarkers in CIDP, covering publications from 2010-September 2023 and conference proceedings from 2020-September 2023, with older relevant publications also considered. COAs and biomarkers were mapped into groupings, based on type of assessment, which was then reviewed and validated by clinical experts for prioritization.

Results: Out of 1,863 publications screened, 778 were prioritized for mapping (Figure 1, Figure 2). Key COAs included the INCAT (Inflammatory Neuropathy Cause and Treatment) scale, RODS (Inflammatory Rasch Built Overall Disability Scale), MRC (Medical Research Council) sum scores, and grip strength. Disease-specific health-related quality of life measures were limited in number and lacked widespread use, while more generic COAs focused on specific, non-neuropathic, disease aspects. CIDP biomarker research is growing, with some demonstrating possible correlations with disease activity and therapeutic effects.

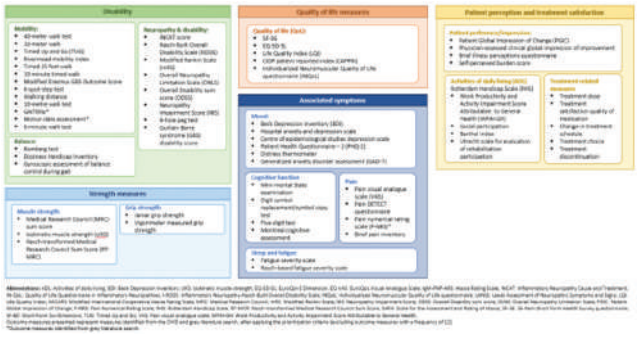

FIGURE 1: Clinical outcome assessments (COAs) mapping.

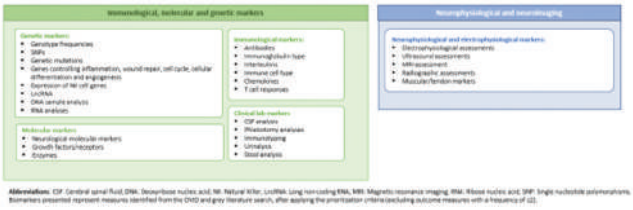

FIGURE 2: Biomarker mapping.

Conclusion: Commonly used COAs in CIDP are mostly specific to inflammatory neuropathy, rather than specifically to CIDP. All have documented limitations. Combining biomarkers with COAs may help to detect clinically meaningful changes in CIDP and aid therapeutic management. Further research is needed to determine the optimal integration of COAs and biomarkers for improved assessment and management of CIDP.

Disclosure: The study was funded by Janssen Pharmaceutical and provided Adelphi Values PROVE with funding for the review; Janssen employees GMB, CG, and WN, may possibly hold stock or stock options. YAR has received speaker/consultancy honoraria from LFB, Polyneuron, Argenx, Takeda, Janssen, Sanofi, Dianthus, has received educational sponsorships from LFB and CSL Behring and has obtained research grants from LFB. EN-O has received speaker/consultancy honoraria from Argenx, Takeda, CSL Behring, Dianthus, Janssen, Kedrion, LFB, Roche and has received a research grant from Takeda. Expert opinions were provided by two independent consultant neurologists.

Infectious diseases

EPR-272 | **The key role of neurological complications in infectious endocarditis: Frequency, diagnostic clue, and consequences**

B. Martínez[1]; J. Chico[1]; D. Pérez[1]; P. Garay[1]; A. Llanes[1]; E. Navas[2]; P. Martín[2]; C. Quereda[2]; J. Masjuan[1]; I. Corral[1]

[1]*Neurology Department, Ramón y Cajal Hospital, Madrid, Spain;* [2]*Infectious Diseases Department, Ramón y Cajal Hospital, Madrid, Spain*

Background and Aims: Neurological complications (NC) are the most frequently observed in infectious endocarditis (IE). We aim to describe the spectrum of NC presented by inpatients with IE in our centre.

Methods: Retrospective observational study including all the cases of IE who displayed symptomatic NCs, attended at our institution between 2003 and 2023. We analysed for epidemiological, clinical, paraclinical, treatment and outcome differences among the different groups of NCs.

Results: Among 661 patients diagnosed of IE, 118 (17.8%) suffered any symptomatic NC (30.5% women, median age: 68 years old, IQR: 57–77). The most frequent diagnosis was ischaemic stroke (69.5%), followed by cerebral haemorrhage (28.9%), seizures (16.9%),

spondylodiscitis (11%) and meningitis (5.9%). *S. aureus* (30%) was the main causative microorganism, and *S. pneumoniae* was associated with meningitis ($p=0.01$). IE affected a prosthetic valve in 33.9% of cases, and surgical treatment was required in 44.1% of patients. In 47 cases (40.5%) the NC was the cause of patients' hospitalization, allowing the diagnosis of IE in 45 patients (38.1%). Median time between symptoms onset to antibiotic treatment was 4 days (IQR: 1.25–5), decreasing to 1 day in ischaemic stroke (IQR: 1–2). Cerebral haemorrhages presented an Or=4 for death (1.34–11.96, $p=0.01$) and an Or=4.89 (1.3–18.2, $p=0.01$) for unfavourable 90-day modified Rankin Scale score.

Conclusion: Cerebrovascular disorders were the most frequent NC in patients with IE. Clinical outcome seems to depend on the type of event, with a significant association of cerebral hemorrhages with higher rates of mortality.

Disclosure: None.

EPR-273 | Disseminated nocardiosis with cerebral lesions in immunocompetent patient

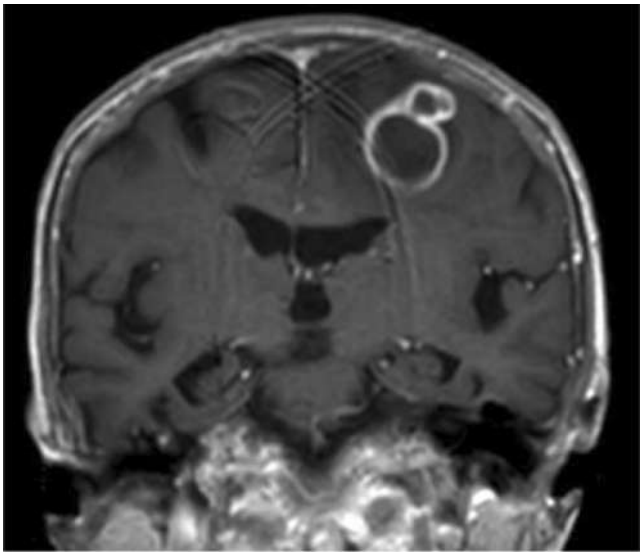
G. Regonesi[1]; A. Formenti[2]; A. Tetto[2]; M. Vaccaro[2]; E. Tagliabue[2]; M. Di Stefano[2]; P. Melzi[2]; L. Airoldi[2]; L. Lorusso[2]; S. Piconi[3]

[1]*Department of Neurology, Fondazione IRCCS San Gerardo dei Tintori, School of Medicine and Surgery, Milan Center for Neuroscience, University of Milano-Bicocca, Monza, Italy;* [2]*Department of Neurology, San Leopoldo Mandic Hospital, ASST Lecco, Merate, Italy;* [3]*Department of Infectious Diseases, Alessandro Manzoni Hospital, ASST Lecco, Lecco, Italy*

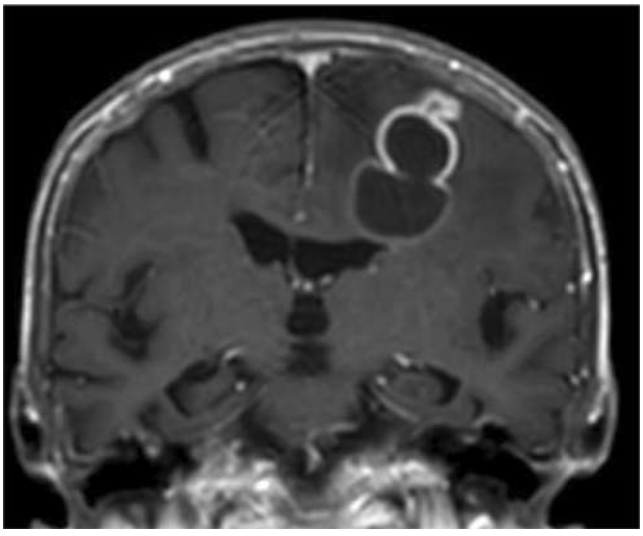
Background and Aims: Nocardiosis is an uncommon, life-threatening and opportunistic infection caused by an aerobic actinomycete in the genus Nocardia, an unusual gram-positive. The most common disease sites are the lungs, central nervous system (CNS) and skin. Parenchymal abscesses are typical hallmarks of CNS nocardiosis, which affects up to 40% of patients with systemic disease.

Methods: We report the case of an 86-year-old immunocompetent woman with a few months-history of progressive motor disorder with gait impairment and subsequent onset of altered mental status, difficulty in verbal expression, mild right hemiparesis and bilateral tonic-clonic seizures.

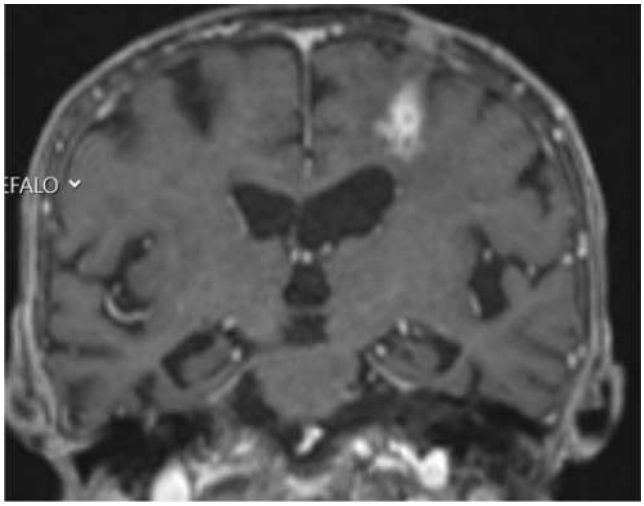
Results: Brain CT scan showed two left hemispheric lesions of suspected metastatic significance and whole-body CT scan revealed involvement of the lungs, left kidney and spleen. Brain MRI scan allowed the suspicion of abscesses, but the lumbar puncture pointed out just elevated CSF protein concentration and the blood infectious screening was negative. Because of worsening clinical conditions and difficulty in making a diagnosis, the patient underwent neurosurgical evacuation surgery: drained material was positive for Nocardia Cyriacigeorgica. Since the introduction of appropriate antibiotic therapy (imipenem and trimethoprim-sulfamethoxazole first, linezolid then plus a two-week course of amikacin), progressive improvement in radiological investigations and neurological status was observed until complete recovery.



Contrast-enhanced brain MRI T1-weighted sequence showing two ring enhancing lesions in the left frontal lobe (the smaller one consisting of at least three small confluent cysts).



First follow-up contrast-enhanced brain MRI showing in the T1-weighted sequence the appearance of a new colliquative lesion with incomplete capsule and slight enhancement after gadolinium.



Second follow-up contrast-enhanced brain MRI, performed after antibiotic therapy, showing in the T1-weighted sequence substantial reduction in volume of the left frontal lobe contrast enhancing lesions.

Conclusion: Nocardia has special tropism for CNS where it can present with symptoms suggesting a mass lesion without typical infectious signs, thus mimicking primary or metastatic brain neoplasm. Diagnosis usually requires an invasive procedure which, although questionable, allows to set up specific antibiotic therapy and to obtain restitutio ad integrum.

Disclosure: The authors declare that they have no conflict of interest.

EPR-274 | Newer insights into clinical features and neuroradiology in rabies encephalitis: A prospective study from north India

M. Mohata[1]; M. Mohata[4]; P. Singh[2]; R. Ratho[3]; G. Mohi[3]; R. Soni[1]; B. Singh[3]; N. Thakur[3]; R. Mohindra[1]; V. Suri[1]

[1]Department of Internal Medicine, Post Graduate Institute of Medical Education and Research, Chandigarh; [2]Department of Radiodiagnosis, Post Graduate Institute of Medical Education and Research, Chandigarh; [3]Department of Virology, Post Graduate Institute of Medical Education and Research, Chandigarh; [4]Department of Infectious Diseases, All India Institute of Medical Sciences, New Delhi

Background and Aims: Rabies is the most lethal infectious disease, with ~100% case fatality. It is highly neglected disease thus there is limited literature available, mostly via retrospective studies.This prospective study aims to narrow the gap.

Methods: 31 patients were enrolled in this prospective observational study over a period of 22-months.Detailed clinical history was obtained and patients were managed with Milwaukee protocol. Contrast-enhanced MRI brain was done for 21 patients. CSF, saliva, nape of neck skin biopsy samples were obtained for diagnosis.

Results: Only 61% took adequate wound care. 48% initiated PEP, but only 26% received RIG; despite availability of adequate infrastructure. Adherence to vaccination schedule was poor, with only 13.3% completing full course. Median incubation period was 29 days, with variations depending upon the type of rabies, site of the bite, and the application of irritant red chili on the wound. The study revealed a spectrum of findings related to autonomic dysfunction-variability in heart rate (90%), blood pressure (90%), and temperature (81%); hypersalivation (61%), hyperhidrosis, spontaneous ejaculations (29%), neurogenic pulmonary edema (19%), etc. MRI revealed dorsal brainstem (90%), peri-aqueductal-grey (72.7%), basal ganglia (63.6%) and cervical spinal-cord (72.2%) being most commonly affected regions. Antemortem diagnosis revealed the following positivity rate–nape of neck skin biopsy IHC (40%), saliva-PCR (23.8%), skin biopsy PCR (20%), and CSF-PCR (4.3%). Postmortem brain-biopsy-PCR had 100% positivity.

Clinical features at presentation	ENCEPHALITIC (n = 27)	PARALYTIC (n = 4)	TOTAL (n = 31)
Pharyngeal muscle hyperactivity	**27 (100%)**	**1 (25%)**	**28 (90%)**
Hydrophobia	27 (100%)	1 (25%)	28 (90%)
Inability to swallow liquids	25 (93%)	1 (25%)	26 (84%)
Inability to swallow solids	24 (89%)	1 (25%)	25 (80%)
Aerophobia	23 (85%)	0	23 (80%)
Inspiratory spasms	22 (81%)	0	22 (80%)
Autonomic dysfunction			
Hypersalivation	18 (67%)	1 (25%)	19 (61%)
Spontaneous ejaculation	9 (33%)	0	9 (29%)
Increased Sweating	8 (30%)	0	8 (26%)
Increased oro-nasal secretions	8 (30%)	1 (25%)	9 (29%)

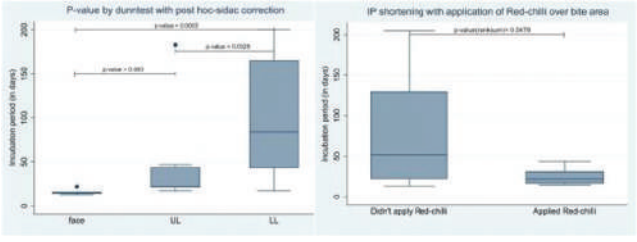
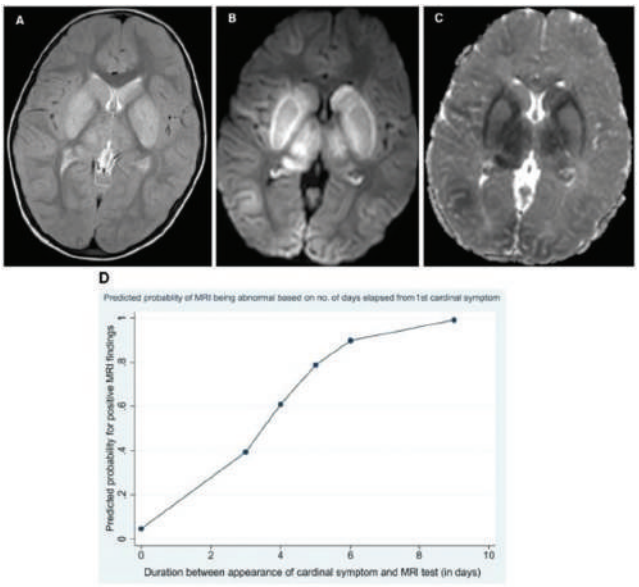
Clinical features of rabies encephalitis at the time of presentation.



Incubation period based on (A) the site of bite and (B) application of the irritant, red chilli.



MRI images of a patient (A) T2 TSE showing hyperintensities in bilateral basal ganglia & thalamus; & corresponding (B) DWI & (C) ADC Images; (D) Univariable logistic regression to estimate predicted probability of appearance of MRI abnormality after 1st symptom.

Conclusion: The study highlights autonomic dysfunction as major clinical syndrome of rabies encephalitis, the most striking features include repeated unprovoked spontaneous ejaculations, neurogenic-pulmonary-edema and rapid variability in heartrate and bloodpressure. Neuroradiology highlighted specific pattern of involvement which can aid in ante-mortem diagnosis. Moreover, it also reveals that MRI may be absolutely normal during the early stages of disease even when the patient is E1VTM1, which highlights the important fact that the MRI changes take time to develop.

Disclosure: Nothing to disclose.

EPR-275 | Concurrent longitudinal extensive transverse myelitis and leptomeningitis in West Nile virus

I. Joseph; D. Vadlamuri; I. Riveral Agosto; M. Ghasemi
Department of Neurology, Lahey Hospital and Medical Center, Burlington, MA, USA

Background and Aims: Here we report a rare case with concurrent longitudinal extensive transverse myelitis (LETM) and leptomeningitis due to West Nile virus (WNV) infection.

Methods: Case Report.

Results: A 47-year-old man initially presented with a 6-day progressive, intermittent low-grade fever, headache, diplopia, malaise, myalgia, lower back pain, and difficulty walking that developed to progressive asymmetric paralysis. Initial lab work was notable for mild lactic acidosis and hyperCKemia. Brain MRI with contrast demonstrated small foci of leptomeningeal enhancement in the cerebellum, pons, medulla and right CN VI at the cisternal segment. MRI of the spine was remarkable for edema in the spinal cord extending from T10 to L1 with diffuse enlargement of the cord contour at T11 to L1 and subtle enhancement of nerve roots within the thecal sac and cauda equina regions. The patient responded favorably to 5-day intravenous immunoglobulin therapy (total dose, 2 g/kg).

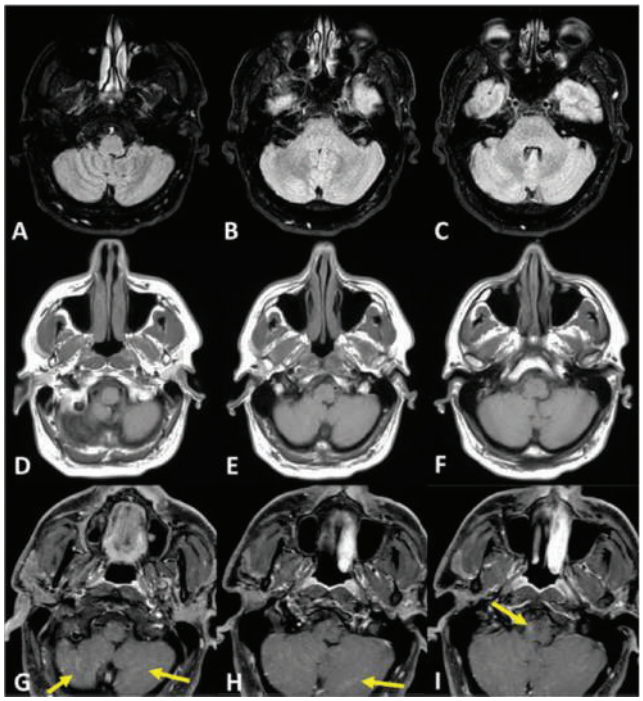


FIGURE 1: Axial FLAIR (A–C), axial T1 pre- (D–F) and post-contrast (G–I) brain magnetic resonance imaging (MRI) from day 2 of hospitalization.

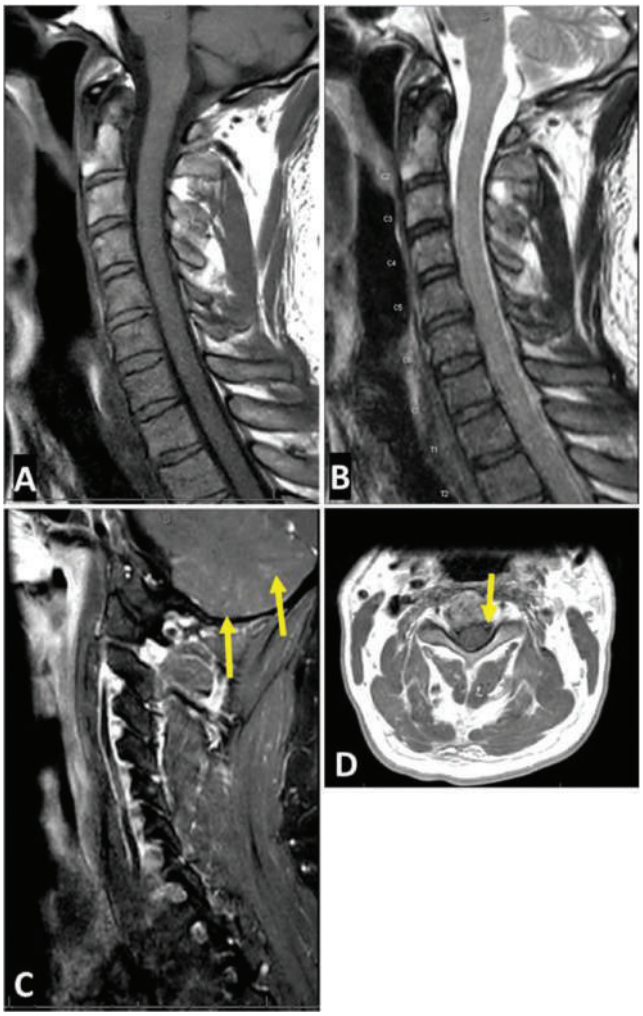

FIGURE 2: Sagittal T2 (A), T1 pre- (B) and post-contrast (C), as well as axial T1 post-contrast (D) MRI cervical spine from day 2 of hospitalization.

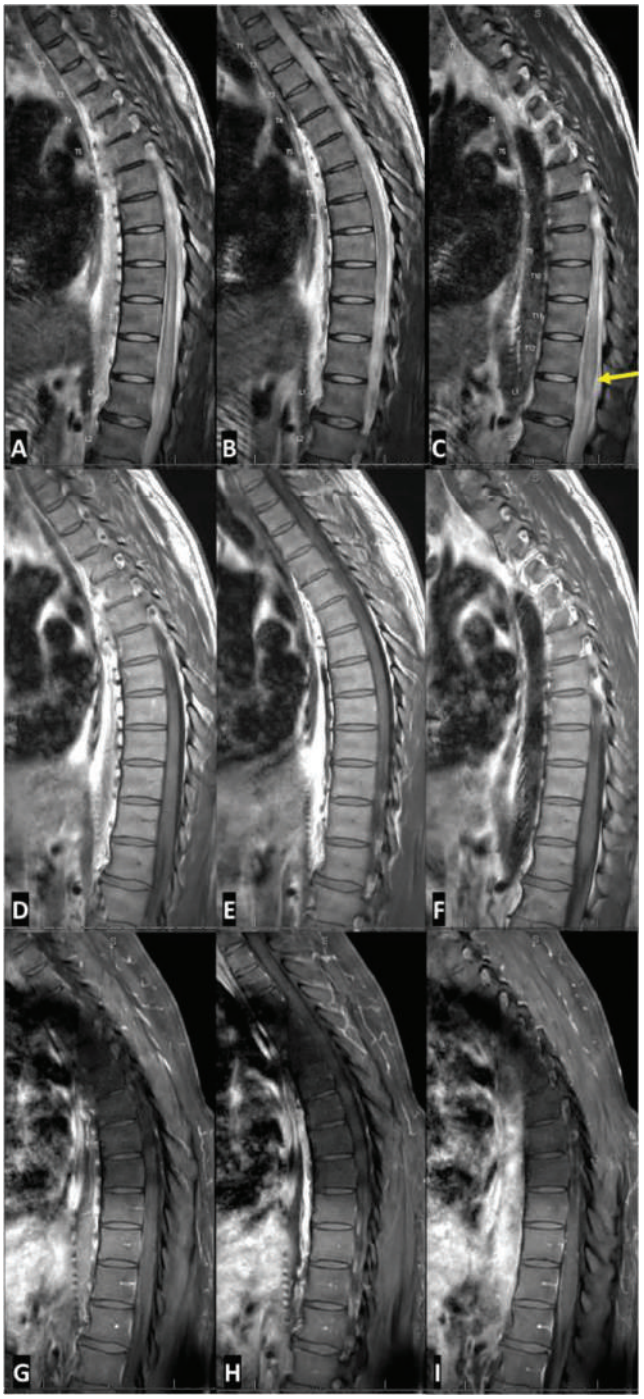

FIGURE 3: Sagittal T2 (A–C), T1 pre- (D–F) and post-contrast (G–I) MRI thoracic spine from day 2 of hospitalization.

Conclusion: Clinically, this case highlights the ill-defined and non-specific nature of the presentation of West Nile neuroinvasive disease. It can pose a diagnostic challenge for clinicians and, if unrecognized, is associated with significant morbidity and mortality in older and compromised individuals.

Disclosure: Nothing to disclose.

EPR-276 | Characteristics and prognostic factors of bacterial meningitis in the intensive care unit: A prospective cohort study

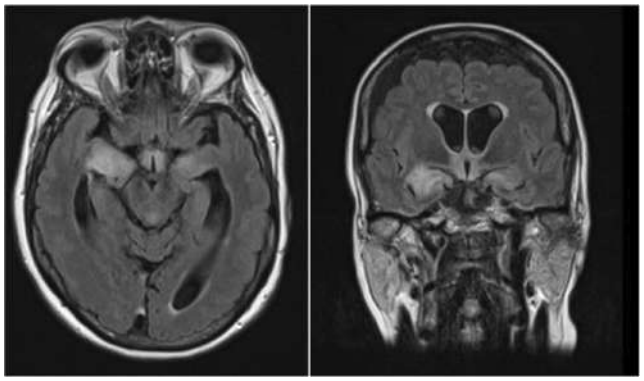
N. Chekrouni; M. Kroon; E. Drost; T. van Soest; M. Bijlsma; M. Brouwer; D. van de Beek
Amsterdam UMC, Location AMC, Department of Neurology

Background and Aims: Patients with bacterial meningitis can be severely ill necessitating intensive care unit (ICU) treatment.
Methods: We prospectively assessed clinical features and outcome of adults (age >16 years) with community-acquired bacterial meningitis included in the MeninGene study, that were initially admitted to the ICU. We identified independent predictors for initial ICU admission and for unfavourable outcome by multivariable logistic regression.
Results: A total of 2709 episodes of bacterial meningitis were included, of which 1369 (51%) were initially admitted to the ICU. We observed a decrease in proportion of patients being admitted to the ICU during the Covid-19 pandemic in 2020 (decreased to 39%, $p=0.004$). Median age of the 1369 patients initially admitted to the ICU was 61 years (IQR 49–69), and the rates of unfavourable outcome (47%) and mortality (22%) were high. During the Covid-19 pandemic, we observed a trend towards an increase in unfavourable outcome. Prognostic factors predictive for initial ICU admission were younger age, immunocompromised state, male sex, factors associated with pneumococcal meningitis, and those indicative of systemic compromise. Independent predictors for unfavourable outcome in the initial ICU cohort were advanced age, admittance to an academic hospital, cranial nerve palsies or seizures on admission, low leukocyte count in blood, high C-reactive protein in blood, low CSF:blood glucose ratio, listerial meningitis, need for mechanical ventilation, circulatory shock and persistent fever.
Conclusion: The majority of patients with community-acquired bacterial meningitis is admitted to the ICU, and the unfavourable outcome and mortality rates of these patients remains high.

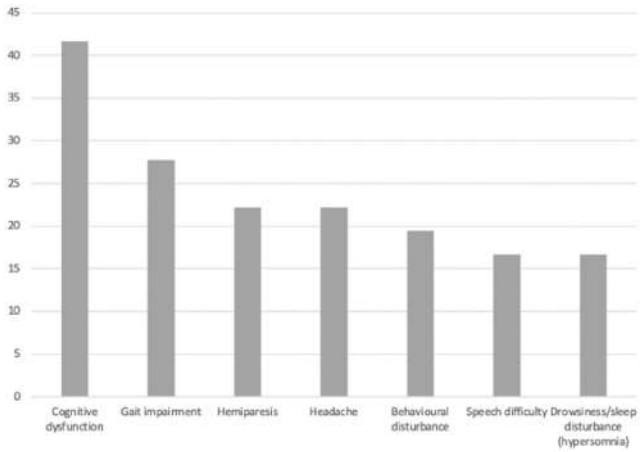
EPR-277 | Primary CNS Whipple disease: Clinical case, systematic review and diagnostic recommendations of a fatal condition

R. Ronco[1]; G. Marucci[2]; V. Levi[3]; A. Erbetta[4]; L. Caputi[5]; A. Bersano[6]; G. Tringali[3]; A. Vulcano[7]; M. Paglia[7]; E. Parati[8]; A. Priori[9]; E. Scelzo[1]
[1]*Neurology Unit, Department of Neuroscience, ASST Santi Paolo e Carlo, Milan, Italy;* [2]*Division of Neurology and Neuropathology, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy;* [3]*Functional Neurosurgery Unit, Department of Neurosurgery, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy;* [4]*Neuroradiology Unit, Fondazion IRCCS Istituto Neurologico Carlo Besta, Milan, Italy;* [5]*Neurology Unit, Ospedale Maggiore di Crema, Crema, Italy;* [6]*Cerebrovascular Disease Unit, IRCCS Istituto Neurologico Carlo Besta, Milan, Italy;* [7]*National Institute for Infectious Diseases Lazzaro Spallanzani IRCCS, Rome, Italy;* [8]*IRCCS Maugeri, Milan, Italy;* [9]*"Aldo Ravelli" Center for Neurotechnology and Experimental Brain Therapeutics, Milan, Italy*

Background and Aims: Whipple disease is a rare multi-systemic disease involving the nervous system in 15%–43% of cases. Few cases of pCNS WD have been reported and no diagnostic recommendations for this potentially fatal, yet treatable condition are available. We conducted a systematic review on pCNS WD in order to guide clinicians through its diagnosis.
Methods: We report a representative case report and systematic literature review via PubMed was performed. Cases with previous arthritis, diarrhea or abdominal pain were excluded.
Results: A 64 year old woman presented with left arm numbness followed by hypersomnia and slowly progressive cognitive impairment. MRI showed bilateral temporal lobe enhancement. CSF results were normal, with negative T. whipplei PCR. Brain biopsy revealed typical PAS+ histiocytes and positive T. whipplei PCR. The patient was treated with ceftriaxone and co-trimoxazole with full recovery. In our review 35 cases of pCNS WD were included. The most common clinical presentation at onset was cognitive impairment (42%), followed by ataxia (28%), headache (22%), hemi-or paraparesis (22%), behavioral alterations (19%), and sleep disturbances (17%). In 17% of cases the clinical presentation is acute. CSF WBC elevation was reported in 29% of cases, protein elevation in 43% of cases. Although specific, T. whipplei PCR has a relatively low sensibility (71%).



Bitemporal and hippocampal FLAIR hyperintensities.



Initial clinical presentation of pCNS WD.

Conclusion: This is the largest dataset of pCNS WD so far. This disease has an extremely variable presentation. Importantly, CSF analysis might result negative. Because of low sensibility of T. whipplei PCR, in cases of high clinical suspicion brain biopsy is indicated early in the disease course.

Disclosure: No disclosure.

EPR-278 | Target enriched metagenomics in cerebrospinal fluid of patients with a central nervous system infection

S. Olie[1]; A. da Cruz Campos[1]; D. van de Beek[1]; M. Brouwer[1]
[1]*Department of Neurology, Amsterdam UMC location AMC, Amsterdam, The Netherlands*

Background and Aims: Metagenomic next-generation sequencing (mNGS) is a promising diagnostic tool for recognizing a broad spectrum of pathogens in clinical samples. Adding a target enrichment step might increase sensitivity of pathogen detection in samples with a low pathogen load, as is often the case in cerebrospinal fluid (CSF). We conducted a study on the performance of mNGS with targeted enrichment for pathogen detection in CSF.

Methods: Patients with a microbiologically confirmed CNS infection were included from two prospective cohort studies from The Netherlands. The index test, targeted mNGS using the Respiratory Pathogen ID/AMR Enrichment Panel Kit (RPIP), was performed using the isolated DNA from the CSF and resulting data was analyzed with the RPIP Data Analysis Solution in BaseSpace Sequence Hub (Illumina). Results from the regular diagnostics were considered the reference standard.

Results: We performed targeted metagenomics on 43 CSF samples: 15 of patients with bacterial, 20 with viral and 6 with fungal CNS infections. Positive agreement was achieved in 28 of 41 (68%) microbiologically confirmed samples. In 7 (17%) samples an incorrect pathogen was detected and in 6 (15%) cases no reads or pathogen was detected. The yield of targeted mNGS differed per pathogen, ranging from 89% for Varicella Zoster virus and 29% for Epstein–Barr virus.

Conclusion: Targeted mNGS was in concordance with regular diagnostics in 68% of CNS infections, but yield differed greatly between pathogens. Further fine-tuning of the methods is needed to improve test characteristics prior to implementation in clinical practice.

Disclosure: Nothing to disclose.

EPR-279 | Cerebrospinal fluid metabolome in adults suspected of a central nervous system infection: A study of diagnostic accuracy

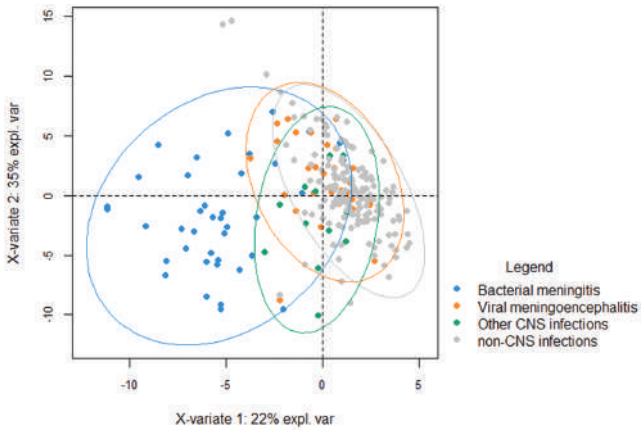
S. Staal; S. Olie; L. ter Horst; I. van Zeggeren; D. van de Beek; M. Brouwer
Amsterdam UMC, University of Amsterdam, Department of Neurology – Amsterdam (The Netherlands)

Background and Aims: To assess the diagnostic accuracy of metabolites in the cerebrospinal fluid (CSF) for the diagnosis of central nervous system (CNS) infections.

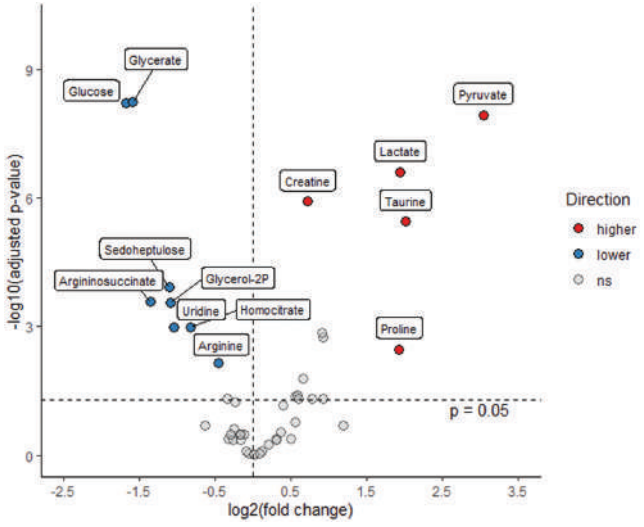
Methods: CSF samples were derived from two prospective cohort studies in The Netherlands that included patients ≥16 years suspected of a CNS infection whom underwent a diagnostic lumbar puncture. Semi-targeted high-performance liquid chromatography with tandem mass spectrometry was used to detect metabolites in 235 randomly selected patients. Metabolite quantification was the index test; final clinical diagnosis was the reference standard.

Results: Of the 235 patients, 82 (35%) had a CNS infection. A total of 39 of 235 (17%) were diagnosed with bacterial meningitis, 31 (13%) with viral meningoencephalitis and 12 (5%) with other CNS infections. Patients without a CNS infection were diagnosed with CNS inflammatory diseases in 17 of 153 (7%) cases, other neurologic diseases in 74 (31%) or systemic infections in 62 (26%). A distinct metabolite profile was observed in patients with bacterial meningitis which was driven by 17 (26%) of 66 metabolites detected in CSF (Figure 1 and 2). Pyruvate, lactate and glycerate showed high diagnostic accuracy for the diagnosis of bacterial meningitis, especially when compared to viral meningoencephalitis, with an area under the

curve of respectively 0.94 (95% confidence interval [CI] 0.88–0.94), 0.93 (95% CI 0.86–0.93) and 0.92 (95% CI 0.86–0.92).



Partial least squares-discriminant analysis of the CSF metabolome in patients suspected of a central nervous system infection. Colors indicate the clinical diagnosis.



Volcano plot of individual metabolites in CSF for bacterial meningitis versus viral meningoencephalitis. Significant metabolites with a VIP (variable importance in the projection) score >1 are labelled, ns = not significant.

Conclusion: CSF metabolites have a high diagnostic accuracy for the diagnosis of bacterial meningitis in patients suspected of a CNS infection. This finding highlights the potential of CSF metabolite testing in clinical practice.

Disclosure: Nothing to disclose.

EPR-280 | Boutonneuse fever associated with CNS vasculitis: A case report

A. Acsente Acsente[1]; E. Sánchez Villanueva[1]; G. Mena Gómez[1]; F. Domingo Monge[1]

[1]*Department of Neurology, Hospital General Universitario, Valencia, Spain*

Background and Aims: Boutonneuse fever is a disease caused by Rickettsia Conorii, endemic of the Mediterranean area. It usually presents with a rash, fever and a characteristic necrotic eschar. Focal neurological manifestations are unusual. We describe such a case, presenting with acute oculomotor symptoms secondary to CNS vasculitis.

Methods: 43-year-old male with acute bifrontal oppressive headache, nausea, vertigo, binocular diplopia and oscillopsia, in the context of fever of 38.7°C and a skin lesion on the right forearm. Physical examination: horizontal-rotatory nystagmus on dextroversion of the right eye and upbeat vertical nystagmus with restricted adduction and exotropia of the left eye, generalized maculopapular exanthema and a necrotic eschar.

Results: Elevated blood inflammatory markers. Negative blood cultures. Serology of Rickettsia Conorii IgG+ (titers 1/64) and IgM+. Normal total-body CAT scan. CSF analysis: normal cytobiochemistry; negative PCR and serology. Skin biopsy and exudate: positive PCR for Rickettsia. Normal transthoracic echocardiography. Brain MRI with contrast and vascular study: Five hyperintense lesions in T2 and FLAIR sequences with diffusion restriction and hypointensity in ADC map, located in corpus callosum, periventricular and subcortical white matter and left medial midbrain, without enhancement. Vascular study showed no large vessel occlusion. CNS vasculitis secondary to Rickettsiosis was diagnosed. After starting Doxycycline 100 mg/12 h IV, fever and exanthema resolved in 24 h. At discharge the patient presented only left internuclear ophthalmoplegia.

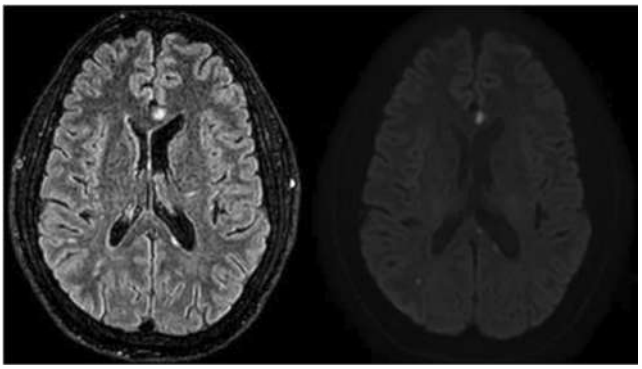


IMAGE 1: Brain MRI in FLAIR T2-Weigted sequence (left) and DWI (right) showing ischemic lesions in splenium, periventricular and subcortical white matter.

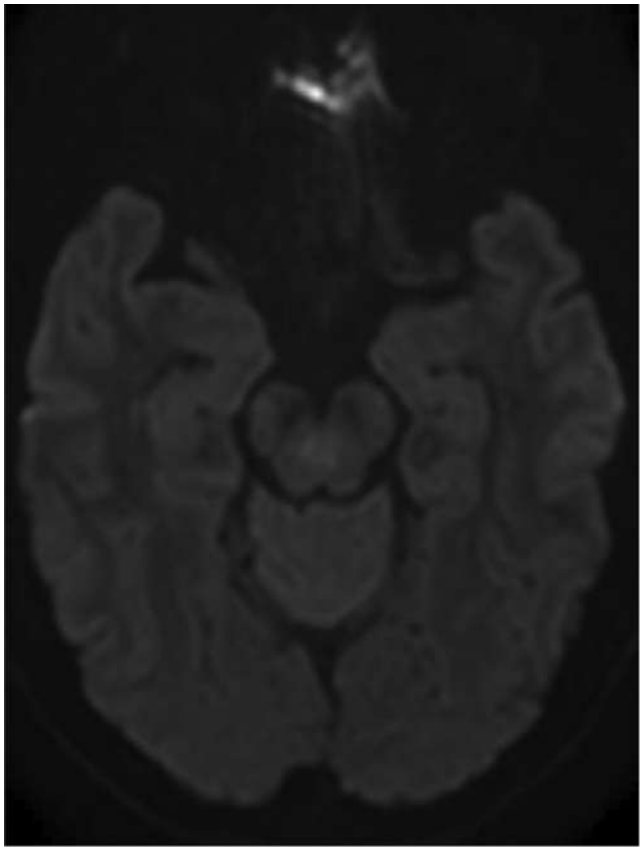

IMAGE 2: Brain MRI in DWI showing restricted diffusion in midbrain region.

IMAGE 3: Internuclear Ophthalmoplegia evidenced by restricted adduction of left eye and rotational nistagmus of right eye during right side gaze; with conserved convergence.

Conclusion: In cases of neurological symptoms, fever and exanthema CNS vasculitis secondary to Rickettsiosis should be considered, especially in endemic areas such as the mediterranean basin, and treat it early with Doxycycline.

Disclosure: Nothing to disclose.

Background and Aims: Given the variable risk of relapse and generally good response to acute treatment, watchful-waiting may be a potential long-term management approach for some patients with myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD).

Methods: This is an international, case series. We identified MOGAD patients who (1) fulfilled the 2023 International MOGAD criteria; (2) presented to the participating institutions with the first clinical attack; and (3) had >3 years of follow-up. We compared chronic steroid-sparing immunotherapy versus watchful-waiting after the onset attack and determine the proportion of relapsing disease and worsening disability.

Results: Among 81 incident cases of MOGAD, the median age of onset was 31 years, and 57% were female. After the onset attack, 65 (80%) underwent watchful-waiting. Forty-one (63%) watchful-waiting patients had relapsing disease with a median number of 3 (IQR 2–5) relapses. At the last visit, 7/64 (11%) watchful-waiting patients had poor disability outcomes from the onset attack and 4/64 (6%) from relapses. Acute treatment delay was longer for the onset attack than for relapses ($p=0.001$). Twenty-five (38%) patients later received chronic immunotherapy: 12/41 (29%) after a second attack, 11/24 (46%) after a third attack, and two after at least 4 attacks. Annualized relapse rate (ARR) was lower among relapsing patients who underwent watchful-waiting throughout their disease (0.2) compared to those who later received chronic immunotherapy (0.3, $p=0.039$).

Conclusion: Watchful-waiting is a potential long-term management option for MOGAD patients with good recovery and lower ARR given timely access to acute treatment. Future prospective studies are warranted.

Disclosure: Nothing to disclose.

EPR-282 | A retrospective multicenter study in MuSK myasthenia gravis patients with and without general immunosuppression

A. De Rosa[1]; I. Koneczny[2]; M. Mané-damas[2]; S. Zong[2]; S. De Haas[2]; S. Huda[3]; M. Maestri[1]; M. Guida[1]; P. Van Damme[4]; J. Damoiseaux[5]; P. Molenaar[2]; A. Fichtenbaum[6]; T. Perkmann[6]; M. De Baets[2]; K. Lazaridis[7]; V. Zouvelou[8]; S. Tzartos[7]; R. Ricciardi[1]; M. Losen[2]; P. Martinez-Martinez[2]

[1]Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa, Pisa, Italy; [2]Research group neuroinflammation and autoimmunity, Department of Psychiatry and Neuropsychology, School for Mental Health and Neuroscience, Maastricht University, Maastricht, The Netherlands; [3]Neurosciences Group, Nuffield Department of Clinical Neurosciences, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, UK; [4]Neurology Department, University Hospital, Leuven, Belgium; [5]Central Diagnostic Laboratory, Maastricht University Medical Center, Maastricht, The Netherlands; [6]Division of Neuropathology and Neurochemistry, Department of Neurology, Medical University of Vienna, Vienna, Austria; [7]Department of Immunology, Hellenic Pasteur Institute, Athens, Greece; [8]1st Neurology Department, National and Kapodistrian University of Athens, Greece

Background and Aims: Muscle-specific kinase (MuSK)- myasthenia gravis (MG) is caused by pathogenic autoantibodies against MuSK that correlate with disease severity and are predominantly of the IgG4 subclass. Immunosuppressants are the first-line treatment but their effect on IgG4 and MuSK IgG4 levels has not been fully investigated.

Methods: We analysed the clinical data and sera from 52 MuSK-MG patients from Italy, The Netherlands, Greece and Belgium, and 43 AChR-MG patients from Italy, that were receiving prednisone, azathioprine, cyclosporine, intravenous immunoglobulin, combinations thereof or no immunosuppression, and sera from 45 age- and sex-matched non-disease controls from The Netherlands. We analysed the disease severity, and measured concentrations of MuSK IgG4, MuSK IgG, total IgG4 and total IgG in the sera by ELISA, RIA and nephelometry.

Results: We observed that MuSK-MG patients showed a robust clinical improvement and reduction of MuSK IgG after therapy, and that MuSK IgG4 concentrations, but not total IgG4 concentrations, correlated with clinical severity. MuSK IgG levels and MuSK IgG4 concentrations were reduced after immunosuppression in 4/5 individuals with before-after data, but data from non-linked patients showed no significant difference. MuSK-MG patients improved within the first four years after disease onset, but longer disease duration (>4 years) did not lead to further clinical improvement or MuSK IgG4 reduction.

Conclusion: Based on our observations, we conclude that MuSK-MG patients improve clinically with general immunosuppression but may require further treatment to reach remission. Inter-assay variability may hide individual changes of MuSK IgG4 levels; therefore longitudinal testing of individual patients may be clinically more useful than single measurements.

Disclosure: Nothing to disclose.

EPR-283 | Anti-MuSK antibody resurgence precedes exacerbation

C. Elmas Tunc[1]; R. Weng[2]; F. Zimprich[2]; R. Höftberger[1]; I. Koneczny[1]

[1]Division of Neuropathology and Neurochemistry, Department of Neurology, Medical University of Vienna, Vienna, Austria; [2]Department of Neurology, Medical University of Vienna, Vienna, Austria

Background and Aims: Myasthenia Gravis (MG) is an autoimmune disease of the neuromuscular junction, where a subset of patients exhibit predominantly IgG4 antibodies against muscle-specific kinase (MuSK). Considered immunologically inert and anti-inflammatory, pathogenicity of IgG4 is unusual. As a typical IgG4 autoimmune disease, MuSK-MG has distinct clinical features and differs in treatment response. This study aims to investigate IgG subclass profile changes in MuSK-MG patients across disease states and treatments to assess their prognostic potential.

Methods: Sixteen MuSK-MG patients (10 female, 6 male) contributed 55 serum samples to KINbiobank. The disease severity was assessed using the Myasthenia Gravis Foundation of America (MGFA)

classification at sample collection. Anti-MuSK seropositivity was established with cell-based assays, employing semiquantitative scoring (0–4 points). The IgG subclass profiles were analyzed with flow cytometry, defining high (>75th%) and low (<25th%) levels.

Results: IgG subclass analysis showed a predominance of IgG4 (mean 89%), followed by IgG1 (mean 5%). IgG4 levels correlated with CBA and MGFA scores. IgG4 levels during exacerbation were significantly higher than during remission ($p=0.0001$). Lower IgG4 levels were associated with favourable clinical outcomes (minimal residual symptoms or remission), while high levels preceeded exacerbations. Post-rituximab treatment, IgG4 levels decreased in the first month, remaining low for 6–10 months before a resurgence (>20%).

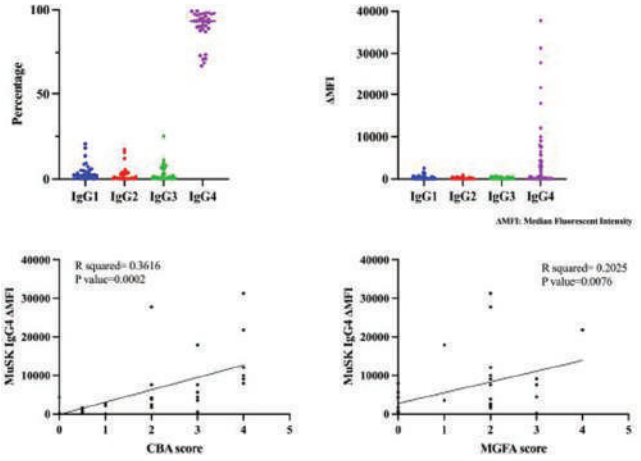

FIGURE 1: IgG subclass profiles showed IgG4 predominance, IgG4 correlated with CBA and MGFA scores (MFI: median fluorescence intensity).

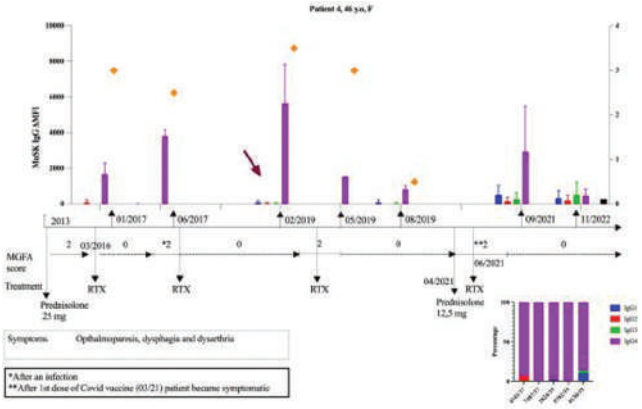

FIGURE 2: IgG subclass profile of a 42 y.o. female patient, arrow showing high IgG4 levels during remission period, followed by exacerbation (RTX: rituximab).

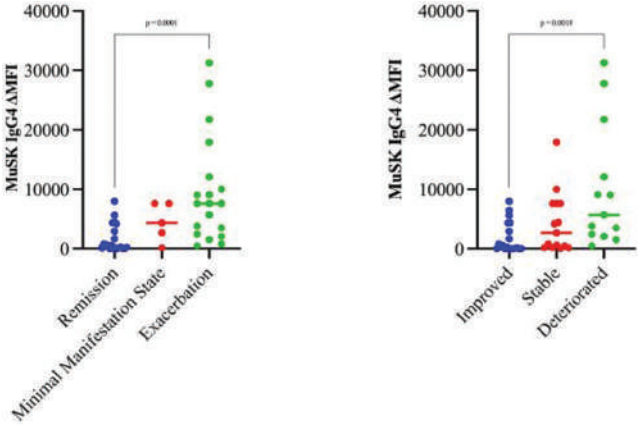

FIGURE 3: IgG4 levels were significantly higher during clinical deterioration and exacerbation.

Conclusion: IgG subclass profiles showed IgG4 predominance which correlated with the clinical severity. IgG4 levels decreased after treatment, while sustained high levels and resurgence may indicate exacerbation and worse clinical outcome. Our results suggest possible prognostic value of MuSK-IgG4 levels.

Disclosure: Author C.E.T. received EAN Research Training Grant in 2023.

EPR-284 | Performance of the 2023 MOGAD diagnostic criteria in children and adults

E. Fonseca[1]; G. Olive-Cirera[1]; E. Martínez-Hernández[1]; J. Cabrera-Maqueda[1]; M. Guasp[1]; L. Naranjo[2]; R. Ruiz-García[2]; E. Caballero[1]; S. Llufriu[1]; Y. Blanco[1]; A. Saiz[1]; J. Dalmau[1]; M. Sepulveda[1]; T. Armangué[3]

[1]*Neuroimmunology Program, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clínic de Barcelona, University of Barcelona, Barcelona, Spain;* [2]*Immunology Service, Hospital Clinic, University of Barcelona, Barcelona, Spain;* [3]*Pediatric Neuroimmunology Unit, Neurology Department, Sant Joan de Déu Children's Hospital, University of Barcelona, Barcelona, Spain;*

Background and Aims: The recently reported MOGAD criteria perform well in adults but have not been assessed in children. We determined their performance in two large cohorts of adults and children, considering the acute and remission phases of the disease.

Methods: This prospective observational study includes patients of all ages whose serum or CSF harbored MOG-IgG determined with a live cell-based assay. We assessed core syndromes, MOG-IgG titers, and supportive features. Patients tested within 3 months of symptom onset (acute phase) or afterward (remission) were considered separately.

Results: 257 patients (133 children) were included (median age 15 years [IQR 6–38], 54% female). Among 202 assessed during an acute attack; 158 (78%) had high MOG-IgG titers, 36 (18%) low titers, and 8 (4%) antibodies only in CSF. No differences were identified

between patients with high and low titers, but those with low titers were more likely to have an alternative diagnosis at last follow-up (2/36 [6%] vs. 0/158, $p=0.012$). Supportive features were present in 230/257 (89%) patients, without differences regarding age, MOG-IgG titers, and core syndromes except for optic neuritis in adults which assessment was limited by the lack of systematic orbital MRI. Overall, the criteria performed better during the acute phase than during remission (190 [94%] vs. 49 [89%] well-classified patients, $p=0.038$) and in patients harboring MOG-IgG in serum versus those with MOG-IgG only in CSF (187 [96%] vs. 3 [38%], $p<0.00001$).

Conclusion: MOGAD criteria performed similarly well in children and adults. The best performance was obtained when applied during the acute phase of the disease.

Disclosure: Nothing.

EPR-285 | Predictive serological biomarkers of disease outcome in myasthenia gravis

F. Beretta[1]; E. Schiavo[1]; G. Spagni[2,3]; S. Falso[2]; S. Cornacchini[1]; M. Verza[1]; L. Palazzo[1]; L. Massacesi[1]; A. Evoli[2]; V. Damato[1]

[1]*Department of Neurosciences, Psychology, Drug Research and Child Health, University of Florence, Florence, Italy;* [2]*Department of Neuroscienze, Università Cattolica del Sacro Cuore, Rome, Italy;* [3]*German Center for Neurodegenerative Diseases (DZNE) Berlin, Berlin, Germany*

Background and Aims: Myasthenia gravis (MG) is an autoimmune disorder caused by antibodies targeting the neuromuscular junction. Most patients have autoantibodies against the acetylcholine receptor (AChR) which can bind specifically to either the adult or the fetal AChR isoform. To date, there are no reliable predictive biomarkers of MG clinical outcome. We investigated whether antibody reactivity for the adult-AChR or the fetal-AChR isoform correlated with MG clinical outcome.

Methods: We conducted a cross-sectional study on 174 patients with a confirmed MG diagnosis and positive radioimmunoassay for AChR-antibodies. Antibody reactivity against the adult-AChR versus the fetal-AChR isoforms was assessed by live cell based assay on flow cytometry. Clinical outcome was assessed through the "patient acceptable symptom state" (PASS-question) and the post-intervention status (PIS).

Results: We found a significantly lower adult/fetal AChR immunoreactivity ratio in patients who answered "yes" to the PASS-question compared to those whose answer was "no" ($p=0.039$, Mann–Whitney test) showing that patients with good clinical outcome (PASS = yes) have antibodies mostly binding to fetal-AChR. This finding was confirmed by testing the adult/fetal ratio in patients in minimal manifestation or better ("MM or better") versus those who were still symptomatic ($p=0.001$, Mann–Whitney test). The adult/fetal AChR immunoreactivity ratio was significantly lower in patients in complete stable remission versus those in MM status ($p=0.04$, Mann–Whitney test). No significant differences in the A/F ratio were found when comparing ocular and generalized MG.

Conclusion: The adult/fetal AChR immunoreactivity ratio may constitute a biological marker predictive of AChR-MG outcome and should be investigated in larger prospective studies.

EPR-286 | Defining molecular and cellular pathways of paraneoplastic antigen expression

D. Gianniou[1]; L. Kampani[1]; V. Palaiologou[1]; S. Mavromati[2]; A. Papacheimona[1]; M. Pechlivanidou[3]; G. Tsivgoulis[4]; I. Trougakos[1]; I. Tzartos[4]; H. Alexopoulos[1]

[1]*Department of Cell Biology and Biophysics, Faculty of Biology, National and Kapodistrian University of Athens, Athens, Greece;* [2]*Department of Neurology, General and Oncological Hospital of Athens, Kifisia, Athens;* [3]*Tzartos NeuroDiagnostics, Athens, Greece;* [4]*2nd Department of Neurology, Attiko University Hospital, Faculty of Medicine, National and Kapodistrian University of Athens*

Background and Aims: Classical paraneoplastic antigens are intracellular proteins with diverse functions typically expressed in both tumors and neuronal cells. Tumor immunosurveillance leads to cross-reactive T-cells and autoantibodies that cause damage to neuronal cells expressing the tumor antigen. It is unclear why from numerous tumor antigens only a few trigger aberrant immune responses leading to autoimmunity. To address this question, we used carcinogenesis cellular models to explore the mechanism driving paraneoplastic antigen.

Methods: We employed a genetically induced cellular model (Hahn, 1999, Nature. 400, 464) which comprises the following: a. BJ, normal human fibroblasts or epithelial cells b. BJ-E, cells genetically modified to lack telomerase c. BJ-LE, cells expressing SV-40 antigens and inactivated p53 and d. BJ-LER, cells with activated hRAS oncogene. Cell lines represent progressive stages of carcinogenesis of either a fibroblast or epithelial lineage.

Results: We performed Western Blot using cell-line derived proteins and sera from patients harboring anti-Hu, Yo, Ri, Ma2, SOX-1, Tr/DNER and amphiphysin antibodies. In the fibroblast-derived model, we detected binding of anti-Ri and anti-amphiphysin antibodies (from 3/15 patients tested) according to the stage of carcinogenesis.

In the epithelial-derived model, we detected binding of anti-Hu and anti-Yo antibodies, again on a stage-dependent pattern. Results were validated using qPCR. We are currently testing our cell lines with immunofluorescence to determine sub-cellular localization of binding.

The carcinogensis model (A) and representative Ri antigen expression data (B).

Conclusion: Our preliminary results support that our cellular models are fitting to study the mechanisms that drive expression of paraneoplastic antigens. Pending experiments aim to unveil post-translational modifications that affect antigen-antibody binding avidity and transcriptional activators or suppressors.

Disclosure: Nothing to disclose.

EPR-287 | Phenotypic adaptation of surveilling T cells at the borders of the human central nervous system

C. Hsiao[1]; J. Engelenburg[1]; I. Huitinga[2]; J. Hamann[3]; J. Smolders[4]
[1]*Neuroimmunology Research Group, Netherlands Institute for Neuroscience, Amsterdam, The Netherlands;* [2]*Neuroimmunology Research Group, Netherlands Institute for Neuroscience, Amsterdam, The Netherlands; Center for Neuroscience, Swammerdam Institute for Life Sciences, University of Amsterdam, Amsterdam, The Netherlands;* [3]*Neuroimmunology Research Group, Netherlands Institute for Neuroscience, Amsterdam, The Netherlands; Department of Experimental Immunology, Amsterdam Institute for Infection and Immunity, Amsterdam University Medical Center, Amsterdam, The Netherlands;* [4]*Neuroimmunology Research Group, Netherlands Institute for Neuroscience, Amsterdam, The Netherlands; MS Center ErasMS, Departments of Neurology and Immunology, Erasmus Medical Center, Rotterdam, The Netherlands*

Background and Aims: Immune surveillance by T cells is indispensable for maintenance of a healthy central nervous system (CNS), yet infiltrating T cells can also contribute to inflammatory diseases. It is unknown how and where human perivascular white matter (WM) T cells acquire their characteristic brain tissue-resident memory (TRM) phenotype. We investigated the phenotypic profiles and transcriptional programs of human CD4+ and CD8+ T cells in several CNS compartments.

Methods: Of consecutive Netherlands Brainbank fresh autopsies, CD4+ and CD8+ T cells were isolated from paired peripheral blood (PB), border organs (choroid plexus and leptomeninges), cerebrospinal fluid (CSF), and WM. Cells were analyzed with flow cytometry. FACS-sorted T cells from PB, CSF, and WM T cells were analyzed with RNA-bulk sequencing.

Results: Compared to PB, CD4+ and CD8+ T cells in border organs were enriched for CD45RAloCD45R0hi memory T cells. In border organs, T cells were characterized by a high expression of brain TRM-associated integrins (CD49a, CD103), chemokine receptors (CCR2, CCR5, CXCR3), and surface markers (CD20) yet preserve their tissue egress-associated CD69lo phenotype. CSF T cells displayed an enrichment of TRM-associated markers and transcripts including high CD69 expression and lack of tissue egress mediators (S1PR1). Compared to CSF, WM T cells expressed less surface markers and transcripts associated with recent activation (HLA-DR, CD25) and co-stimulation (CD28).

Conclusion: CNS-surveilling T cells show enrichment for brain TRM-associated phenotypic characteristics at the border organs and further display a TRM-phenotype within the CSF. These data provide insights to modulate CNS immune-surveillance for the benefit of patients with neurological diseases.

EPR-288 | Patient-derived monoclonal antibodies as a tool to study CASPR2-autoantibody encephalitis

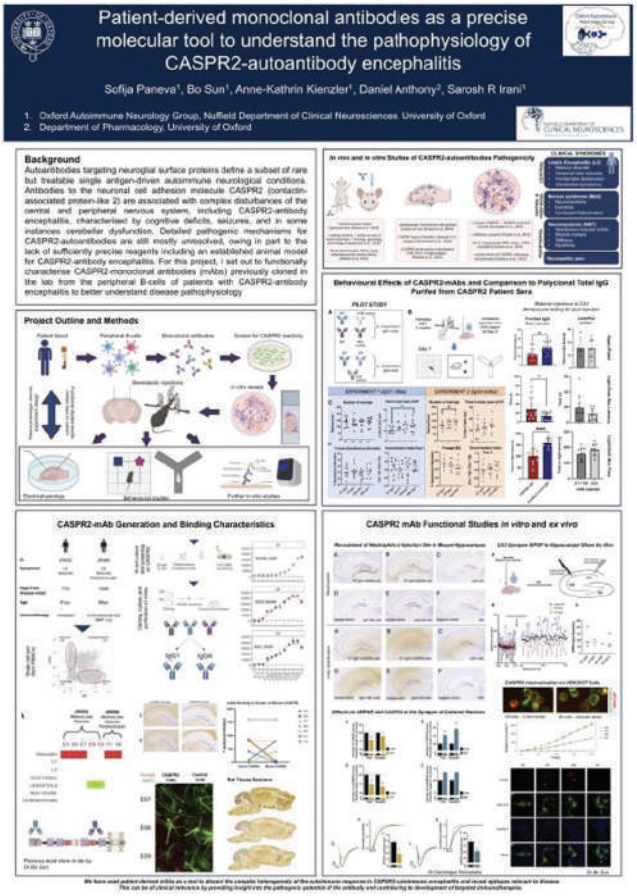
S. Paneva
Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, UK

Background and Aims: Antibodies to the neuronal cell adhesion molecule CASPR2 are associated with complex disturbances of the central and peripheral nervous system, but. detailed pathogenic mechanisms for CASPR2-autoantibodies are still mostly unresolved.

Methods: We functionally characterize CASPR2-monoclonal antibodies (mAbs) cloned from peripheral B-cells of patients with CASPR2-autoantibody encephalitis. Cloning was done using a bulk B-cell culture method, followed by screening for human and moue CASPR2 reactivity, target affinity and internalisation assays, and staining on neurons and rodent tissue, Antibody effects were assessed via electrophysiology on cultured neurons and stereotaxic injection into mouse hippocampi.

Results: mAbs targeting the discoidin and the L3/EGF2/L4 domains of CASPR2 were generated. Three out of seven (3/7) mAbs bound to hippocampal neurons in culture and to rat and mouse tissue sections. Two were found to be high-affinity binders while one was a low-affinity binder. The mAbs induced CASPR2 internalisation on HEK293T cells, reduced AMPAR and CASPR2 levels at the synapse of cultured neurons, and recruited neutrophils upon injection in

mouse hippocampus. A low affinity discoidin-mAb reduced rearing in the open field, whereas a high-affinity L3/EGF2/L4-mAb produced an anxiety-like phenotype in mice. Co-injection of multiple mAbs failed to produce behavioural deficits, in contrast to injection of IgG from CASPR2-reactive sera.



Poster showing results.

Conclusion: We demonstrate for the first time the effects of patient-derived CASPR2-mAbs across multiple experimental paradigms, offering an unprecedented view into diesase pathophysiology.

Disclosure: None.

Sleep-wake disorders

EPR-289 | Sex affects REM sleep behavior disorder identification: Clinical data, screening questionnaires and REM without atonia

A. Ibrahim[1]; M. Serradell[2]; M. Cesari[1]; C. Gaig[2]; E. Holzknecht[1]; P. Marrero[2]; E. Brandauer[1]; L. Pérez-Carbonell[2]; M. Bergmann[1]; A. Fernández-Arcos[2]; N. Matos[2]; J. Santamaria[2]; B. Högl[1]; A. Iranzo[2]; A. Stefani[1]

[1]*Medical University of Innsbruck, Department of Neurology;* [2]*Hospital Clinic de Barcelona, IDIBAPS, CIBERNED, Neurology Service, Barcelona, Spain*

Background and Aims: Accurate REM sleep behavior disorder (RBD) diagnosis is essential due to the risk of injuries, and as isolated-RBD is an early alpha-synucleinopathy. Although RBD is more frequently reported in men, epidemiological studies reported similar prevalence in both sexes, suggesting underdiagnosis in women. We investigated sex differences in RBD identification.

Methods: In this bicentric prospective study, 300 subjects (159 men, 141 women) referred to sleep center for the first time, completed three RBD screening questionnaires: RBD-screening- questionnaire (RBDSQ), RBD-single-question (RBD1Q), and Innsbruck-RBD-Inventory (RBD-I) before sleep-expert interview, and underwent 8-h-video-polysomnography (V-PSG) to confirm/exclude RBD. Clinical history, questionnaires, and RWA were compared between men and women.

Results: Among RBD patients ($N=30$ (10.0%): women = 12 (8.5%), men = 18 (11.3%)), women were less likely to have bed partners ($p=0.002$) and to report abnormal sleep behaviors ($p=0.006$). Only for men, being above the published cut-off for all three RBD questionnaires was associated with RBD diagnosis (RBD1Q: Log odds ratio (LOR) 95% CI 2.837 (1.716–4.347), $p<0.001$; RBDSQ: LOR 3.076 (1.671–5.362), $p=0.003$; RBD-I: LOR 3.076 (1.671–5.362), $p=0.003$). For women, only being above the RBD-I was associated with RBD diagnosis, $p=0.023$. Women had a higher RWA-SINBAR-index ($p=0.035$) and lower flexor digitorum superficialis activity ($p=0.003$). RWA scores had higher RBD identification performance for women compared to the questionnaires (AUC >0.82 for all variables).

Conclusion: This study demonstrated sex-related variability in RBD screening questionnaires, probably related to sex-specific differences in RBD awareness, likely affecting referral to V-PSG. These findings emphasize the need for sex-specific approaches for RBD screening and diagnosis.

Disclosure: Nothing to disclose. Acknowledgements: We are thankful to Mr. Heinz Hackner for accurate V-PSG scoring and technical support.

EPR-290 | Effects of acute exposure to altitude on restless legs syndrome

A. Ibrahim[1]; E. Holzknecht[1]; M. Faulhaber[2]; H. Gatterer[3]; T. Wild[1]; N. Seelose[1]; P. Sorschag[1]; B. Resch[1]; S. Sevborn[4]; H. Hackner[1]; J. Ulfberg[5]; M. Burtscher[2]; B. Högl[1]; A. Stefani[1]
[1]*Medical University of Innsbruck, Department of Neurology, Innsbruck, Austria;* [2]*University of Innsbruck, Department of Sport Science, Innsbruck, Austria;* [3]*Eurac Research, Institute of Mountain Emergency Medicine, Bolzano, Italy;* [4]*Swedish RLS Association, Sweden;* [5]*Uppsala University, Uppsala, Sweden*

Background and Aims: Restless Legs Syndrome (RLS) pathogenesis involves several factors. Some studies suggested a role of hypoxia, supported by an upregulation of the vascular endothelial growth factor in leg muscles of RLS patients and higher RLS prevalence in high altitude (HA) regions. We aimed to investigate the effect of acute HA exposure in RLS versus healthy subjects.
Methods: Fifty-six individuals, 28 with RLS and 28 matched healthy-controls were included. For two nights, 1-h Suggested-Immobilization-Test (SIT) was followed by 8-h polysomnography in an altitude chamber. In randomized, double-blinded order, one night was spent in normobaric hypoxia corresponding to 3000 m above sea-level, while the other night was spent at Innsbruck altitude (574 m). During SIT, PLM during wakefulness (PLMW) and subjective symptoms were recorded every 15 min, utilizing a visual analog scale. Sleep stages and associated events were scored according to AASM criteria.
Results: Fifty-six participants aged 45.1 ± 10.8 years were included, 51.8% female. At both altitudes, RLS patients had more discomfort and urge to move during SIT at any time point, versus controls ($p < 0.01$). Only in RLS patients, the urge to move during SIT was higher after 30 and 45 min at 3000 m versus 574 m ($p = 0.048$, $p = 0.031$). PLMW during SIT and PLM during sleep (PLMS) did not change with HA exposure. Only men had an increased PLMS index at 3000 m, $p = 0.032$.
Conclusion: In RLS patients, the urge to move the legs during SIT is stronger at HA. In men with RLS the PLMS index increases at high-altitude. These data support a role of hypoxia in the pathogenesis of RLS.
Disclosure: Nothing to disclose. We are thankful to the Swedish RLS Foundation for supporting this study, and to Nikolaus Prinz, Katrina Lehner, and Timon Schwarz-Wissel for helping to conduct the polysomnographies.

EPR-291 | Frailty in isolated REM sleep behavior disorder (iRBD): Prevalence and clinical characterization

E. Capriglia[1]; G. Malomo[1]; M. Solbiati[1]; L. Spelta[2]; A. Rubino[2]; C. Totaro[2]; M. Terzaghi[1]
[1]*Department of Brain and Behavioral Sciences, University of Pavia, Unit of Sleep Medicine and Epilepsy, IRCCS Mondino FoundationPavia, Italy;* [2]*Unit of Sleep Medicine and Epilepsy, IRCCS Mondino Foundation, Pavia, Italy*

Background and Aims: This study aims to investigate prevalence and associated features of frailty in iRBD. Frailty significantly affects the well-being of the elderly population. The interaction between frailty and Parkinson's disease (PD) is complex and bidirectional, since PD is a potential contributor to frailty in the elderly. In turn, iRBD, representing a prodromal stage of PD, potentially amplifies the risk and severity of frailty.
Methods: 35 iRBD patients (33 males, 2 females, age 70.77 ± 9.6 years) underwent a comprehensive clinical and instrumental phenotyping. In particular, each patient underwent assessment of frailty through the SHARE-FI scale, and clinical scales: MMSE, UPDRS part III, UPSIT-40, SCOPA-AUT, RBD-HK, PSQI, ESS, HADS-A, HADS-D, BDI, EQ-5D; Schellong Test and neuroimaging studies (DATSCAN, FDG-PET).
Results: 8 patients (22.9%) resulted to be fragile. Statistically significant correlations were found between frailty and MMSE corrected score ($p = 0.046$), UPDRS part III ($p = 0.05$), UPSIT-40 ($p = 0.012$) and BDI score ($p = 0.002$). HADS-A was pathologic in 57.1% fragile patients versus 14.8% non-fragile patients ($p = 0.019$); BDI in 62.5% versus 22.2% ($p = 0.031$), alteration in dopaminergic reuptake (DAT-scan) in 87.5% versus 39.1% ($p = 0.018$) and brain glucose metabolism (FDG-PET) in 62.5% versus 21.7% ($p = 0.034$).
Conclusion: Frailty is frequent in prodromal PD (1/5 of the patients) and it is associated with worse cognitive and motor performances, with depression, anxiety and functional imaging of the brain. Clinicians should be aware of frailty in iRBD, although further studies should clarify its effective clinical consequences.
Disclosure: Nothing to disclose.

EPR-292 | COVID-19 associated sleep disorders and the role of inflammation in the pathogenesis

F. Uslu[1]; İ. Uzun[2]; G. Okay[3]; E. Güler[4]; F. Durmaz[4]
[1]*Bezmialem Vakıf University, Faculty of Medicine, Department of Neurology;* [2]*Bezmialem Vakıf University, Faculty of Medicine Student;* [3]*Bezmialem Vakıf University, Faculty of Medicine, Department of Infectious Diseases and Clinical Microbiology;* [4]*University of Health Sciences Turkey, Hamidiye Medicine Faculty, Department of Clinical Biochemistry*

Background and Aims: Insomnia is a common sleep disorder in Covid-19 patients. Previous research has demonstrated that

extreme elevations in IL-1β-NF-α can impair sleep. Based on these findings, we hypothesized that COVID-19 and insomnia cooperation developing on an inflammatory background.

Methods: Patients diagnosed with insomnia were included in the study; those who still had insomnia 3 months after being diagnosed with covid-19 acute infection and who were diagnosed with insomnia as a result of insomnia diagnostic criteria. Three groups were formed for the study: (1) COVID-19 patient with insomnia (CWI), (2) COVID-19 patient without insomnia (CWoI), (3) Healthy control (HC) were designed. Epworth Sleepiness Scale (ESS), Pittsburgh Sleep Quality Index (PSQI), Beck Anxiety Inventory (BAI), Insomnia Severity Index (ISI) were applied. BDNF, IL-6, TNF-α, IL-1β, IL-10, MMP-9 levels were measured in the volunteers' blood.

Results: A total of 96 participants were recruited. Group 1:33 patients, group 2:31 patients, group 3:32 volunteers. BDNF ($p < 0.001$), IL-6 ($p < 0.001$), TNF-α ($p < 0.001$) ($p < 0.036$), IL-1β ($p < 0.001$), IL-10 ($p < 0.001$) values were shown a significant difference in insomnia patients compared to CWoI and HC. Insomnia patients were increased cytokine levels than the other groups. Therewithal CWoI were increased cytokine levels than the HC. MMP-9 levels were shown a significant difference between control group and covid patients ($p < 0.001$). ESS, PSQI, BAI, ISI scores were shown a significant difference in CWI compared to CWoI and HC ($p < 0.001$).

Conclusion: Patients who developed insomnia after covid 19 had increased inflammatory cytokines and PUKI, BAI, ESS, ISI scores compared to CWoI and HC. Based on the data obtained, it was demonstrated that the basis of insomnia is inflammatory pathogenesis.

Disclosure: Nothing to disclose.

EPR-293 | Variability of REM sleep without atonia in consecutive polysomnographies of patients with hypersomnia

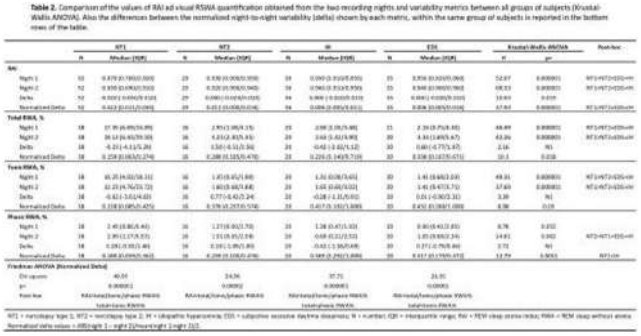
F. Buracchi Torresi[1]; F. Biscarini[1]; R. Ferri[1]; S. Vandi[1]; G. Plazzi[2]; F. Pizza[1]

[1]*Department of Biomedical and Neuromotor Sciences (DIBINEM), University of Bologna, Bologna, Italy;* [2]*Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio-Emilia, Modena, Italy*

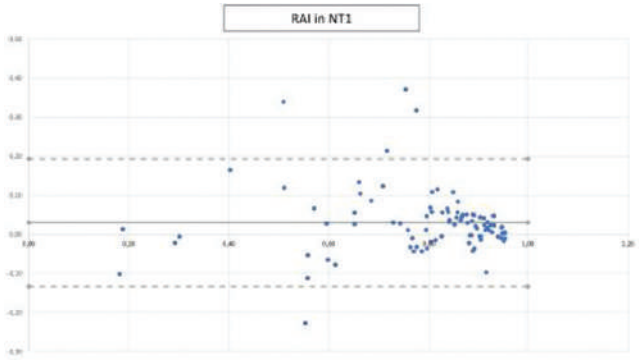
Background and Aims: To explore inter-night variability of motor dyscontrol during REM sleep in patients with central disorder of hypersomnolence (CDH).

Methods: Two consecutive overnight polysomnographies (PSG) of 250 adults with suspected CDH (92 NT1; 29 narcolepsy type 2; 36 idiopathic hypersomnia; 93 other diagnoses) were analyzed. Chin REM atonia was quantified with the automatic REM atonia index (RAI), and visually, in a subgroup of 111 patients, with percentage of REM sleep without atonia (RSWA%) according to American Academy of Sleep Medicine manual. The variability of RAI and RSWA between the two nocturnal PSG was assessed stratified by diagnosis, and the normalized inter-night variabilities of the different measures were compared.

Results: In patients with NT1 RAI resulted more frequently altered (63% with RAI <0.9 on night 1) than in other groups (<27% with RAI <0.9 on night 1), $p < 0.001$, and the rates of patients with altered values remained stable across the two nights in all groups. RAI significantly decreased from night 1 to night 2 in NT1 only (from 0.87 (IQR 0.76–0.92) to 0.83 (IQR 0.69–0.91), $p < 0.001$), whereas it did not vary in other groups. Normalized inter-night variability was lower for RAI than for visual RSWA in all groups ($p < 0.001$).



Comparison of the values of RAI ad visual RSWA quantification obtained from the two recording nights and variability metrics between all groups of subjects (Kruskal–Wallis ANOVA). Also the differences between the normalized night-to-night variability (delta)



Bland-Altman plot: agreement between night1/night2 in NT1.

Conclusion: Motor dyscontrol during REM sleep is a distinctive feature of NT1, and it is stable across different nights. RSWA could provide a potential utility in the diagnosis and characterization of NT1, especially if computed with automatic algorithms that appeared less variable than the visual scoring method in all disorders of hypersomnolence.

Disclosure: Nothing to disclose.

EPR-294 | Unattended home-video-PSG monitoring in 325 patients with sleep disorders: Hazards and values of diagnosis

G. Rimmaudo[1]; C. Cilona[1]; G. Di Liberto[1]; V. Di Stefano[2]; A. Torrente[2]; F. Brighina[2]; M. Bonsignore[3]; A. Gagliardo[1]

[1]*Sleep Lab, "Clinical Course"Neurology and Neurophysiology Unit, Palermo, Italy*; [2]*Department of Biomedicine, Neuroscience and advanced Diagnostic (BIND), University of Palermo, Palermo, Italy*; [3]*PROMISE Department, University of Palermo, and Institute of Translational Pharmacology (IFT), National Research Council (CNR), Palermo, Italy*

Background and Aims: Polysomnography (PSG) recorded in a sleep lab is the International gold standard for the diagnosis of sleep disorders. The cardio-respiratory home monitoring is scientifically validated for in the suspicion of OSAS. However, this approach does not detect all sleep disorders or coexistent multiple sleep disorders. The objective of the study is to evaluate the feasibility of the unattended Home-Video-PSG monitoring for all sleep disorders.

Methods: All the adult collaborating outpatients with a Sleep Disorder afferent to the Sleep Lab of the "Clinical Course" Neurophysiology Unit of Palermo between the years 2018–2019 were consecutively enrolled. Placement of all electrodes and sensors always took place in the lab and the recording was carried out at the patients' home without supervision.

Results: We recruited 325 patients (201 males, mean age 54.6, range 13–88). The final diagnoses were isolated sleep-disordered breathing (SDB) (35.1%), isolated neurological sleep disorders (14.8%), combined neurological-SDB (47.7%) and negative (2.5%). The video recording was confirmatory in 69.4% of cases, integrative or diagnostic in 18.2% and negative in 12.4%. In 4.1% of the videotaped cases the patient was out of the frame, in 31.1% the patient was partially recorded. Unsuccessful recordings were 7.3%; 8.6% had artifacts on the neurological channels; 4.6% presented cardio-respiratory pitfalls.

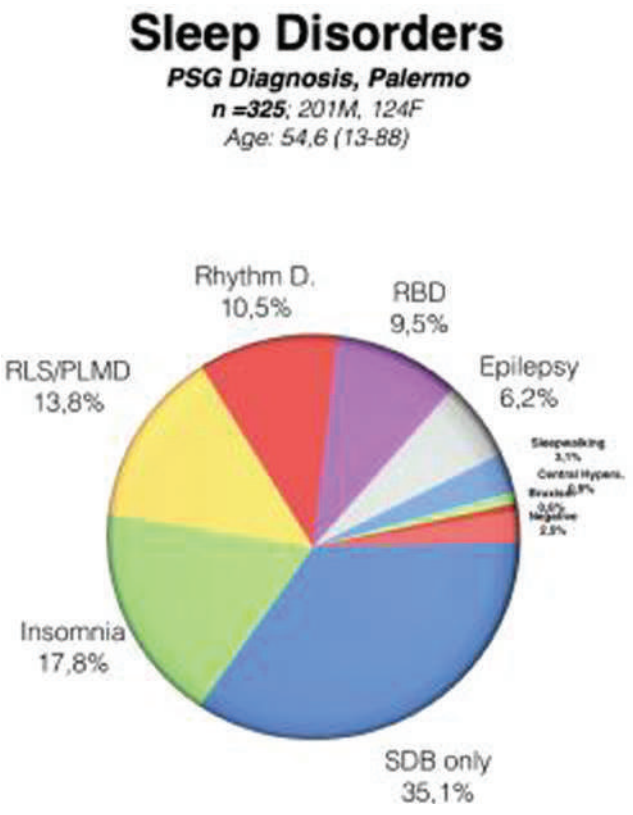
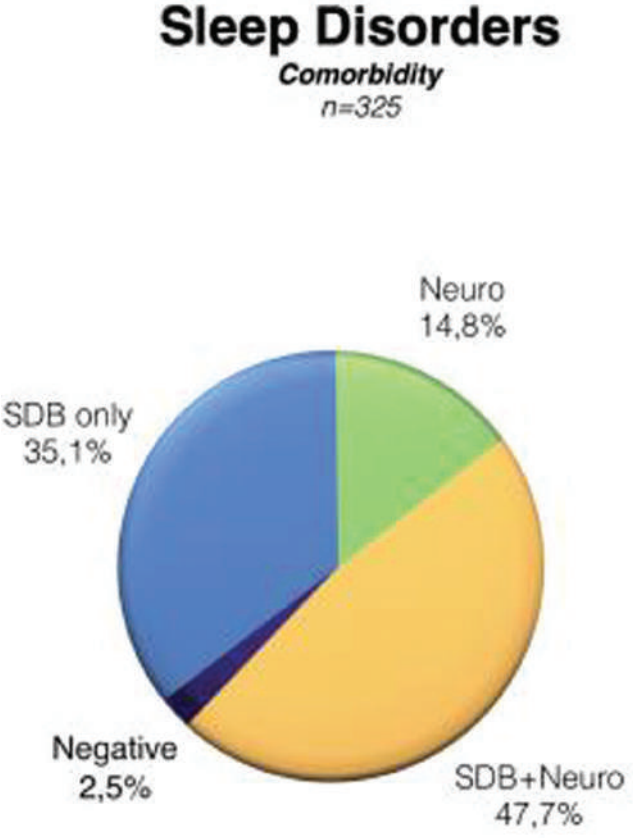
Demographics and sleep parameters of the studied population expressed as mean and standard deviation; ANOVA for group comparisons, $p < 0.05$ as significant in bold. Post- hoc LSD sign. diff.: # SDB versus Neuro;° Neuro versus SDB+Neuro; § SDB versus SDB+Neuro.

Sleep disorders: PSG diagnosis, Palermo (Italy) *n* =325; 201M, 124F Age: 54.6 (13–88).





Sleep disorders: Comorbidity $n = 325$.

Conclusion: Despite the technical difficulties and possible artifacts, video-PSG offers the opportunity for the evaluation of complex pathologies, being diagnostic in nocturnal seizures, behavioral/agitation disorders during sleep and parasomnias; in movement disorders it helps in diagnostic confirmation; it also provides additional information on respiratory disorders associated with neurological disorders.

Disclosure: We declare no conflict of interests.

EPR-295 | The clinical and socioeconomic consequences of insomnia: An umbrella systematic review

L. Vignatelli[1]; S. Seidel[2]; U. Kallweit[3]; E. Beghi[4]; M. Lolich[5]; M. Konti[5]; E. Pupillo[4]; M. Leone[4]; C. Bassetti[6]

[1]IRCCS Institute of Neurological Sciences of Bologna (ISNB), Bologna, Italy; [2]Medical University of Vienna, Department of Neurology, Vienna, Austria; [3]University Witten/Herdecke, Center for Biomedical Education and Research (ZBAF), Witten, Germany; [4]Department of Neuroscience, Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan, Italy; [5]European Academy of Neurology, Vienna, Austria; [6]Department of Neurology, University of Bern, Inselspital, Bern, Switzerland

Background and Aims: Insomnia – defined by disturbed sleep initiation and -maintenance and impairment of daytime functioning despite adequate opportunity and circumstances for sleep – is the most common sleep disorder among adults. Good quality sleep is one of the determinants to preserve brain health. The aim of this umbrella systematic review is to assess the role of insomnia as risk factor for many health and socio-economic consequences in the general population.

Methods: Cohort studies and systematic reviews of these studies were eligible for inclusion if including general population, considering insomnia as possible risk factor and death, cognitive impairment, stroke, mental disorders, social and economic consequences as outcomes. This systematic review was registered with PROSPERO database (CRD42021285454).

Results: Preliminary data are available for death, cognitive impairment, and work injuries. Three systematic reviews did not find insomnia as risk factor for death. One systematic review found two components of insomnia associated with death (difficulty falling asleep – DFA – HR 1.13, 95% CI 1.03–1.23; non-restorative sleep HR 1.23, 1.07–1.42). Two systemic reviews with meta-analysis found insomnia as risk factor for dementia (any cause OR 1.53, 1.07–2.18; RR 1.27, 1.16–1.39). One systemic review found two components of insomnia as risk factors for work injuries (DFA OR 1.29, 1.07–1.55; non-restorative sleep OR 1.40, 1.05–1.86).

Conclusion: Insomnia seems to be a risk factor for dementia and work injuries in general population. Less clear data are available on mortality. When completed, this systematic review will show the current knowledge on insomnia as risk factor for clinical and socioeconomic consequences.

Disclosure: Nothing to disclose.

EPR-296 | Exploring REM sleep behavior disorder across pathologies: A cinematic and emotional journey through clinical phenotypes

S. Bouden[1]; R. Debs[2]; A. Mazel[2]; P. Calvat[2]; C. Boucly[2]; M. Rafiq[2]; E. Barbeau[1]; J. Curot[2]

[1]Brain Research and Cognition Center (CerCo), CNRS, UMR5549, France; [2]Department of Neurology, Toulouse University Hospital, France

Background and Aims: Loss of muscle atonia during REM sleep behavior disorder (RBD) results in movements mimicking dream content. RDB manifests early in 60%–100% of patients with synucleinopathy. Additionally, it affects 10%–15% of patients with narcolepsy, and often presents as idiopathic (RBDi) with a substantial proportion later diagnosed as synucleinopathy. These pathologies have their own semiological frameworks. However, scarce data exist to differentiate specific RBDs between these diseases. Our hypothesis posits distinctive patterns of RBD (movement types, kinetics, emotional valence…) across narcolepsy, synucleinopathies, RBDi and other disorders (e.g., autoimmune encephalitis).

Methods: We applied a new classification on RBDs to visually compare their movements (elementary, violent, scenic…), their topography (legs, hands, face…), and their emotional valence (negative, positive, neutral) in patients belonging to each group, who underwent a polysomnography (2014–2024) in Toulouse University Hospital. We added objective markers detected by a semi-automating tracking of RBD movements using a deep learning algorithm.

Results: Sixty patients, including 16 patients with synucleinopathy, 26 RBDi, 10 narcoleptics, and 8 with other disorders have been included. According to first results, in a subgroup of 38 patients, RBD is more violent in RBDi and narcolepsy, more scenic in synucleinopathies. Narcolepsy-associated RBD tended to exhibit a positive emotional valence, while it is negative in RBDi and synucleinopathies. A deep learning algorithm is currently being trained on RDB videos to confirm these distinctive profiles.

Conclusion: Our results highlight identifying pathology-specific patterns holds significant clinical importance, positioning RBD as a potential diagnostic marker. This is especially relevant for identifying the conversion from RBDi to synucleinopathy.

Disclosure: Nothing to disclose.

EPR-297 | Disorders of arousal motor patterns in isolated RBD patients: A video-polysomnography analysis of 48 patients

T. Jesus[1]; G. Mainieri[2]; L. Baldelli[2]; G. Loddo[4]; A. Montini[2]; F. Mignani[3]; C. Pazzaglia[3]; M. Sala[3]; F. Provini[2]
[1]*Serviço de Neurologia, Unidade Local de Saúde do Estuário do Tejo, Vila Franca de Xira, Portugal;* [2]*Department of Biomedical and NeuroMotor Sciences, University of Bologna, Bologna, Italy;* [3]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy;* [4]*Department of Primary Care, Azienda AUSL di Bologna, Bologna, Italy*

Background and Aims: Disorders of Arousal (DoA) and REM sleep behaviour disorder (RBD) are sleep parasomnias arousing from NREM and REM sleep, respectively. DoA episodes can be classified from simple to complex patterns (Loddo et al., Sleep Medicine, 2017). RBD consists of dream-enactment episodes, however, during video-polysomnography, these patients mostly show simple jerks, very distinct from DoA patterns, which include mainly truncal/axial movements. Our aim was to search for these patterns on our cohort of iRBD patients.

Methods: We reviewed all video-polysomnographies from our cohort of 48 iRBD patients, consecutively recorded at the Bologna Sleep Centre between 2011 and 2023. All recordings were examined by one observer, blinded to clinical history, in search for DoA patterns, according to Loddo et al. Each episode was characterized by sleep stage, sleep cycle, triggers, onset, DoA pattern (type of movement, duration, progression).

Results: Our sample comprised 37 (77%) males, median age of 71.8 years-old. We identified 32 DoA patterns in 18 patients (38%). The most observed pattern was simple arousal movements – head flexion/extension with/without limb movement or partial trunk flexion/extension – accounting for 29 (91%) events. Rising arousal movements – trunk flexion followed by sitting – were observed in three events. 22 events (69%) arose from REM sleep and 10 from NREM sleep.

Conclusion: DoA patterns can be found in some patients with iRBD and may expand the current description of sleep-related motor patterns in iRBD patients, inciting more studies. A further correlation with clinical data could explain the significance of these patterns and their prognostic implications.

Disclosure: Nothing to disclose.

Neuroimaging 1

EPR-298 | Neuronal remodeling in migraine patients correlates with disease activity

M. Li[1]; L. Eskandarian[2]; K. Gaudet[2]; S. Huang[2]; K. Eikermann-Haerter[3]
[1]*Department of Neurology, NYU Grossmann School of Medicine, New York, NY, USA;* [2]*Martinos Center for Biomedical Imaging, Harvard Medical School, Boston, USA;* [3]*Department of Radiology, Division of Neuroradiology, NYU Grossmann School of Medicine, New York, NY, USA*

Background and Aims: Migraine represents one of the most prevalent neurological conditions worldwide. There is evidence for reduced gray matter (GM) and white matter (WM) volume with an increased incidence of white matter lesions (WML) in migraine patients, particularly in those with aura. Advanced MRI techniques allow us to evaluate the underlying microstructural substrate and glymphatic system function.

Methods: Using a Connectome scanner, we utilized the diffusion weighted imaging (DWI) models TractCaliber and Soma and Neurite Density Imaging (SANDI) to characterize the microstructure of GM and WM in 17 patients with migraine with aura and 17 matched healthy controls (HC). All patients completed a clinical questionnaire on disease activity. We assessed glymphatic system activity with diffusion-tensor image analysis along the perivascular space (DTI-ALPS).

Results: The GM of migraine patients exhibits reduced neuronal density with an increase in soma radius of the remaining cells, in both cortex and deep GM structures. WM shows evidence of axonal loss with increased axonal diameter, also in WM that appears normal on conventional MRI. WM TractCaliber CSF volume fraction correlates with disease duration in years ($r = 0.5$ and $p = 0.04$). There is no difference in glymphatic activity between migraine patients and HC.

Conclusion: High-gradient diffusion MRI shows occult changes in the microstructural integrity of GM and WM in migraine patients, which correlates with migraine duration. Our findings suggest that migraine is associated with neuronal remodeling, which may contribute to increased cerebral vulnerability in patients.

Disclosure: Melanie Li, Laleh Eskandarian, Kyla Gaudet have nothing to disclose. Susie Huang has NIH grants R01NS118187 and P41EB030006. Katharina Eikermann-Haerter has Ralph Schlaeger Award (MGH).

EPR-299 | Diagnostic accuracy of computed tomography in detection of carotid plaque characteristics: A systematic review

D. Pakizer[1]; J. Kozel[1]; J. Elmers[2]; J. Feber[1]; P. Michel[3]; D. Školoudík[1]; G. Sirimarco[3]

[1]Center for Health Research, Faculty of Medicine, University of Ostrava, Ostrava, Czechia; [2]Medical Library, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland; [3]Stroke Center, Service of Neurology, Department of Clinical Neurosciences, Lausanne University Hospital, Lausanne, Switzerland

Background and Aims: Beyond the stenosis degree, the carotid plaque morphology assessed by noninvasive imaging may improve the stroke risk stratification. This study aimed to assess the accuracy of computed tomography (CT) to detect the carotid plaque characteristics compared to histology in patients with symptomatic and asymptomatic carotid plaques, conducting a systematic review.

Methods: We registered the protocol in PROSPERO (ID CRD4202232969) and searched Medline Ovid, Embase.com, Cochrane Library, and Web of Science for diagnostic accuracy of CT in specific carotid plaque characteristic imaging compared to histology, without any search limitation.

Results: Of 8,168 studies, 20 studies that evaluated seven specific plaque characteristics were included in our systematic review. The best diagnostic accuracy was found for the detection of ulceration (sensitivity 39.4%–100%, specificity 74%–100%), followed by calcification (sensitivity 72.7%–100%, specificity 35.7%–100%), lipid-rich necrotic core (sensitivity 63.2%–95.6%, specificity 60%–100%), and intraplaque hemorrhage (sensitivity 61.5%–100%, specificity 20%–99.5%). Only a few studies evaluated specifically vulnerable, mixed, and fibrous plaque. Novel CT techniques promise more accuracy and patient safety in carotid plaque features imaging.

Conclusion: CT allows for highly accurate detection of carotid plaque features, in particular ulceration and calcification, followed by the lipid-rich necrotic core and intraplaque hemorrhage. These results underline the role of routine CT examinations not only to assess the stenosis degree but also plaque morphology and individual patient stroke risk to better guide management.

Disclosure: Nothing to disclose.

EPR-300 | Abstract withdrawn

EPR-301 | Exploring the relation among choroid plexus enlargement, glymphatic dysfunction and brain damage in multiple sclerosis

P. Preziosa[1]; E. Pagani[2]; M. Rubin[1]; M. Margoni[3]; G. Corazzolla[1]; M. Filippi[4]; M. Rocca[1]

[1]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy; [2]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; [3]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: Choroid plexus (CP) regulates immunological functions and cerebrospinal fluid (CSF) production within the CNS. In multiple sclerosis (MS), CP enlargement is associated with higher inflammatory activity and more severe brain damage. We investigated whether the associations of CP enlargement with white matter (WM) lesions and brain volumes is mediated by glymphatic system dysfunction.

Methods: Brain 3T MRI scans were obtained from 146 MS patients and 72 age- and sex-matched healthy controls (HC). We quantified the diffusion along the perivascular space (DTI-ALPS) index as a proxy of glymphatic function, and normalized (n) CP volume using a fully automatic method on brain three-dimensional T1-weighted and FLAIR MRI sequences.

Results: Compared to HC, MS patients showed significantly higher WM lesion and nCP volumes ($p < 0.001$), together with significantly lower DTI-ALPS index, normalized brain, thalamic, and cortical volumes ($p \leq 0.048$). In MS patients, higher nCP volume correlated with lower DTI-ALPS index (standardized-$\beta = -0.332$, $p < 0.001$). Both measures were significantly associated with higher brain, periventricular and juxtacortical WM lesion volumes (nCP volume: standardized-β range = 0.291; 0.332, $p < 0.001$; DTI-ALPS index: standardized-β range = −0.229; −0.315, $p \leq 0.005$), as well as with lower normalized brain, thalamic and cortical volumes (nCP volume: standardized-β range = −0.238; −0.364, $p \leq 0.003$; DTI-ALPS index: standardized-β range = 0.233; 0.351, $p \leq 0.001$). DTI-ALPS index partially mediated the associations of normalized CP with WM lesion volumes (standardized-β range = 0.073; 0.115) and brain volumetric measures (standardized-β range = −0.075; −0.125).

Conclusion: In MS, enlarged nCP may contribute to structural brain damage accumulation, particularly in regions close to the CSF, possibly through the promotion of a chronic pro-inflammatory state and the occurrence of glymphatic system dysfunction.

Background and Aims: CogEx (ClinicalTrials.gov, NCT03679468) was a trial determining effectiveness of cognitive rehabilitation (CR) and aerobic exercise (EX) in progressive multiple sclerosis (PMS). We present resting-state (RS) functional connectivity (FC) findings.

Methods: Participants were randomized (1:1:1:1) to "CR-plus-EX", "CR-plus-sham-EX (EX-S)", "EX-plus-sham-CR (CR-S)", and "CR-S-plus-EX-S" and attended 12-week intervention. Physical/cognitive assessments were performed at baseline, immediately after intervention (week-12) and 6 months post-intervention (month-9). MRI sub-study participants underwent RS-fMRI to estimate RS FC in the main cognitive networks.

Results: 104 PMS participated in the MRI sub-study ("CR-plus-EX": $n=25$; "CR-plus-EX-S": $n=28$; "CR-S-plus-EX": $n=25$; "CR-S-plus-EX-S": $n=26$); 87 (83%) completed baseline and week-12 RS-fMRI. At week-12 and month-9, no differences were found among interventions for symbol-digit modalities test (SDMT) correct responses, nor SDMT, California verbal learning test (CVLT) and brief visuospatial memory test *Z*-scores (p = range 0.12–0.94). Time-by-treatment interactions of voxel-wise RS FC changes at week-12 versus baseline indicated increased RS FC in most analyzed networks ($p<0.001$, uncorrected) in "CR-plus-EX" and "CR-plus-EX-S" patients, and decreased RS FC over time in "CR-S-plus-EX" and "CR-S-plus-EX-S" patients ($p<0.05$, corrected). Whole-network RS FC of salience (SN, $p=0.07$) and default-mode network (DMN, $p=0.08$) exhibited similar trends, becoming significant (SN: $p=0.01$; DMN: $p=0.02$) when comparing all patients performing CR versus CR-S. In CR patients, increased DMN RS FC at week-12 versus baseline showed trend correlation with increased CVLT Z-score ($r=0.27$, $p=0.06$).

Conclusion: CR modulated RS FC in cognitive networks of PMS. Funding. Funded by the MS Society of Canada (grant #EGID3185). Ancillary funding from CMSC, Danish MS Society, and National MS Society.

Disclosure: Nothing to disclose.

EPR-303 | Unveiling the power of nerve ultrasonography in Guillain–Barre syndrome diagnosis

T. Salem[1]; A. Moustafa Aboutaleb[2]; A. Ebrahim[3]; M. Moustafa Elweshahi[3]; O. Y. ElBasatiny[3]; H. Mousa[3]; M. Hefnawy[4]; K. Ashraf Mohamed[3]; R. Abdelnaby[5]

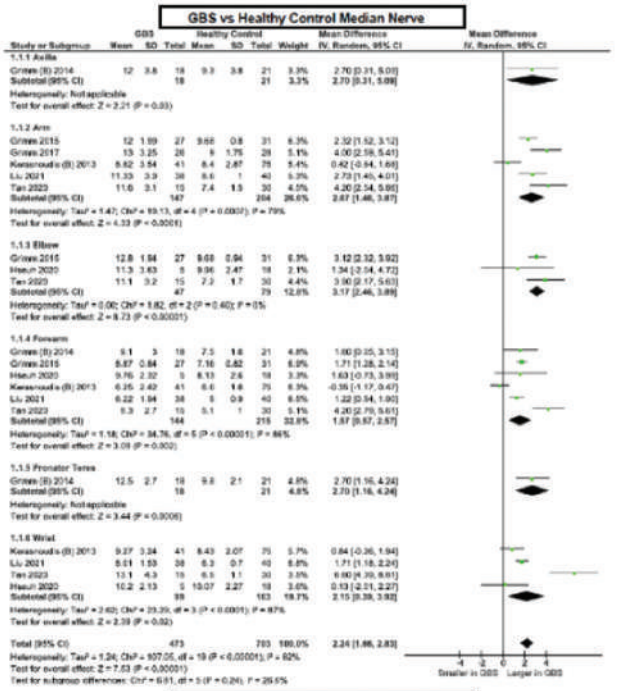
[1]Faculty of Medicine, Masaryk University, Brno, Czechia; [2]Faculty of Medicine, Zagazig University, Zagazig, Egypt; [3]Faculty of Medicine, Cairo University, Cairo, Egypt; [4]Neurology Department, Ruhr University Bochum, Bochum, Germany; [5]Department of Neurology, RWTH Aachen University Hospital, Aachen, Germany

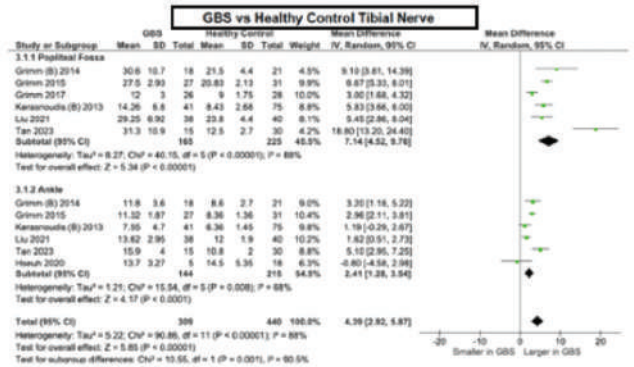
Background and Aims: Guillain–Barré syndrome (GBS) is an inflammatory disorder of the peripheral nervous system. Distinguishing

GBS from chronic inflammatory demyelinating polyneuropathy (CIDP) can be challenging. Nerve ultrasonography emerged as a non-invasive diagnostic tool that provides quantitative information about nerve morphology. This study aims to compare the cross-sectional areas (CSAs) of upper and lower limb nerves in GBS patients with healthy individuals, CIDP patients, and axonal neuropathy patients.

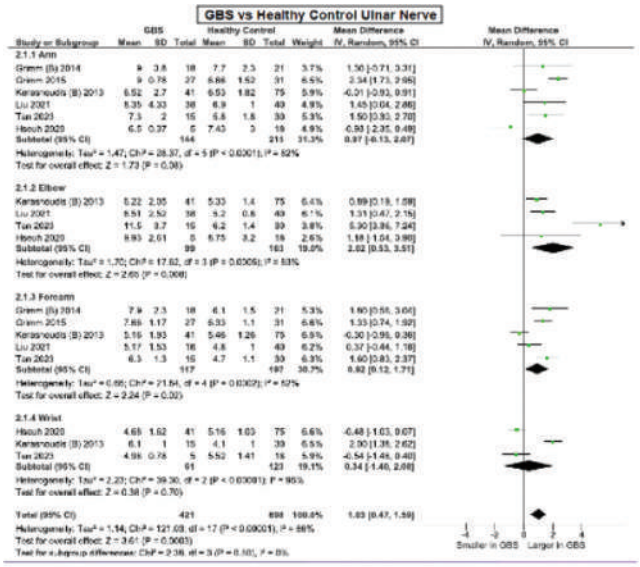
Methods: We performed a systematic search of Medline (PubMed), Scopus, Embase, and Web of Science up to May 24, 2023. After article selection and screening, we performed a quality assessment. Furthermore, a statistical analysis and subgroup analysis were performed.

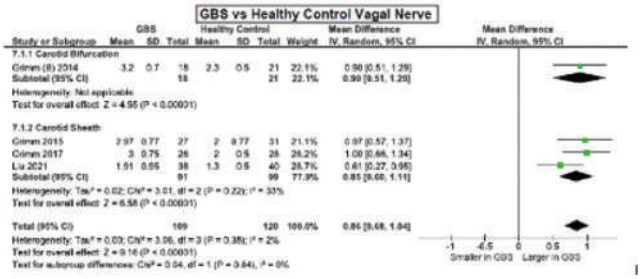
Results: 12 studies included 624 participants, yielding 6284 nerve CSA measurements. The median, radial, ulnar, tibial, sural, fibular, and vagus nerves were found to be significantly larger in GBS patients than in healthy controls. Whereas the median, ulnar, sural, and fibular nerves were found to be significantly smaller in GBS patients than in CIDP patients. Additionally, reference values for peripheral nerve CSAs at different anatomical sites were reported for GBS patients.



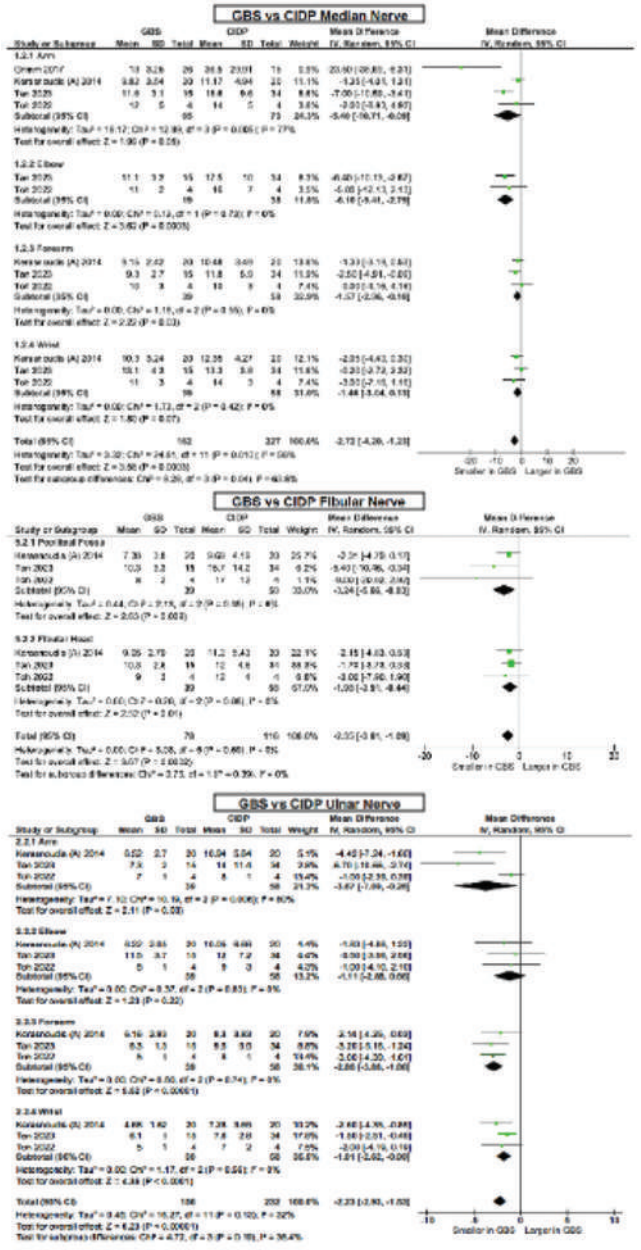


Mean difference in median and tibial nerves CSAs between GBS patients and healthy controls.





Mean difference in the ulnar and vagal nerves CSAs between GBS patients and controls.



Mean difference in median, ulnar & fibular nerves CSAs between GBS patients and CIDP patients.

Conclusion: Measuring the CSA of the tibial nerve at the level of the popliteal fossa, the median and ulnar nerves at the elbow level and the cervical nerve roots can aid in the diagnosis of GBS. However, measuring the CSA of the median at proximal sites, ulnar at distal sites and fibular nerve can help in distinguishing GBS from CIPD.

Disclosure: Nothing to disclose.

EPR-304 | The "swallow tail sign" in the diagnosis of dementia with Lewy bodies: A systematic review and meta-analysis

V. Tseriotis[1]; T. Mavridis[2]; K. Eleftheriadou[1]; G. Konstantis[3]; D. Chlorogiannis[4]; P. Pavlidis[3]; C. Pourzitaki[3]; M. Arnaoutoglou[5]; S. Konitsiotis[6]

[1]Department of Neurology, Agios Pavlos General Hospital of Thessaloniki, Thessaloniki, Greece; [2]Department of Neurology, Tallaght University Hospital (TUH)/The Adelaide and Meath Hospital, Dublin, incorporating the National Children's Hospital (AMNCH), Dublin, Ireland; [3]Laboratory of Clinical Pharmacology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece; [4]Department of Radiology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; [5]First Neurology Department of AHEPA University General Hospital of Thessaloniki, Thessaloniki, Greece; [6]Department of Neurology, General Hospital of Ioannina, Ioannina, Greece

Background and Aims: Loss of dorsolateral nigral hyperintensity (DNH) on susceptibility-weighted imaging (SWI) has proven useful in Parkinson's disease. We aim to quantitatively synthesize evidence regarding diagnostic accuracy of DNH loss on SWI for the differential diagnosis of dementia with Lewy bodies (DLB), an a-synuclein-related pathology, from other dementias, investigating the role of MRI, a first-line imaging modality, in early disease detection.

Methods: We searched MEDLINE, Scopus, Web of Science and Cochrane Library using the terms "lewy body dementia", "swallow tail sign", "dorsolateral nigral hyperintensity", "nigrosome-1, "SWI". We included English-written peer-reviewed diagnostic accuracy studies that compared SWI to a reference standard. QUADAS-2 was used for quality assessment.

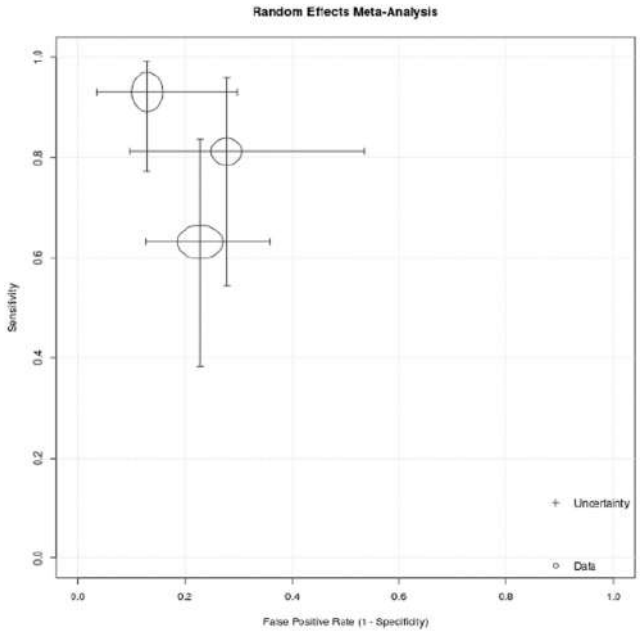
Results: Among 363 search results, three studies were eligible. The overall quality of the included studies was considered adequately high. In total 227 patients were included, 63 with DLB, 164 with other pathologies (Alzheimer disease, frontotemporal dementia, mild cognitive impairment). Meta-analysis of mixed 1.5 and 3T data with a univariate random-effects logistic regression model resulted in pooled sensitivity, specificity and DOR of 0.82 [0.62; 0.92], 0.79 [0.70; 0.86] and 16.26 ([3.3276; 79.4702], $p=0.0006$), respectively. Subgroup analysis of 3T scans showed pooled sensitivity, specificity and DOR of 0.82 [0.61; 0.93], 0.82 [0.72; 0.89] and 18.36 ([4.24; 79.46], $p<0.0001$), respectively.

Table 1: Study characteristics

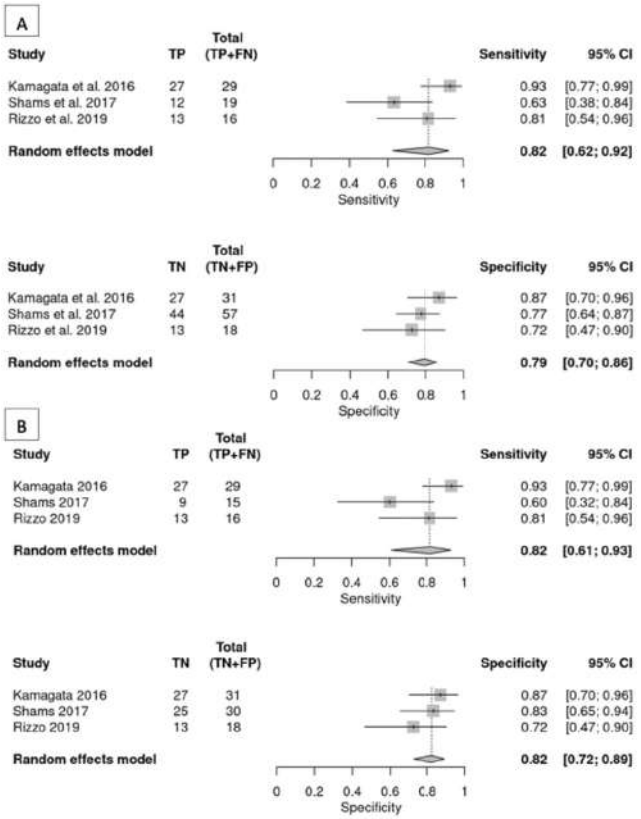
	MRI scan characteristics				Reliability			Second index test	Reference standard
	Field strength	Sequence	Section thickness	Duration (seconds)	Intra-rater	Inter-rater (k)	Rater's experience in years, mean (SD)		
Kamagata 2016	3T	SWI	2mm	108s	NR	0.84	5.5 (0.7)	DaT-SPECT	Clinical diagnosis (Consensus DLB criteria 2005)
Shams 2017	1.5T (n = 31) 3T (n = 45)	SWI	1.5-1.6mm (n = 36) 2mm (n = 40)	NR	NR	0.4	12.5 (4.9)	No	Clinical diagnosis (Consensus DLB criteria 2005)
Rizzo 2019	3T	SWI	1.6mm	180s	NR	0.71	NR	No	Clinical diagnosis (Consensus DLB criteria 2005)

MRI: magnetic resonance imaging; SWI susceptibility weighted imaging; DaT-SPECT: Dopamine transporter single-photon emission computed tomography' DLB: Dementia with lewy bodies

Study characteristics.



Summary receiver operating characteristic (SROC) curve of primary studies using both 1.5 and 3T. Confidence intervals for each study are presented.



Forest plot of pooled sensitivity and specificity of mixed 1.5T and 3T field strength (A) and using only 3T data from each study (B).

Conclusion: Our results suggest the possible use of STS loss on SWI as a biomarker for DLB detection. Further evaluation of standardized protocols is needed, with direct comparison to other indicative and supportive DBL biomarkers.

Disclosure: Nothing to disclose.

EPR-305 | Brain and spinal cord lesion distribution criteria for differentiation of MS, NMOSD and MOGAD

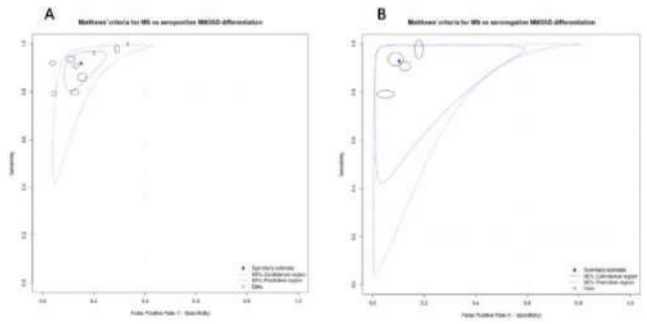
V. Tseriotis[1]; D. Chlorogiannis[2]; E. Ioannidou[3]
[1]*Department of Neurology, Agios Pavlos General Hospital of Thessaloniki, Thessaloniki, Greece;* [2]*Department of Radiology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA;* [3]*Department of Ophthalmology, Hippokration General Hospital, Athens, Greece*

Background and Aims: Multiple sclerosis (MS), Neuromyelitis optica spectrum disorder (NMOSD) and Myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) can present with similar clinical attacks and radiological characteristics on Magnetic Resonance Imaging (MRI), causing diagnostic confusion and delay of appropriate treatment initiation, especially in cases of uninformative or unavailable serologic tests. We conducted a systematic review and diagnostic accuracy meta-analysis on the MRI lesion distribution criteria, that have been proposed for disease differentiation.

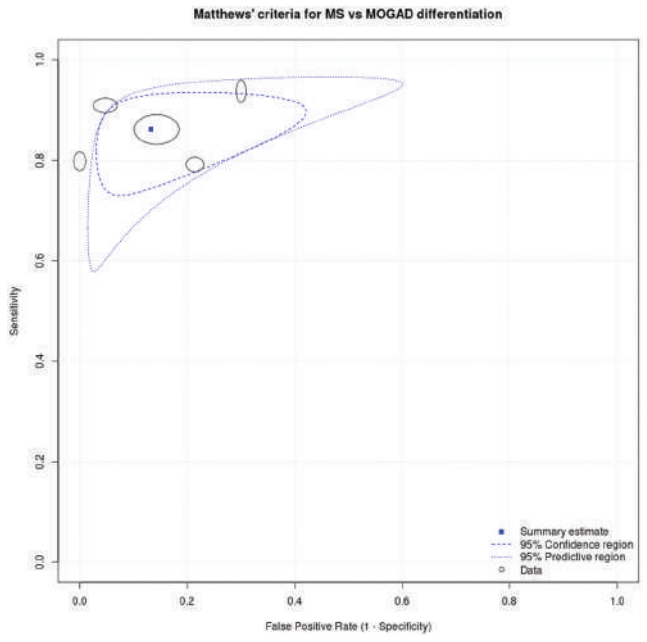
Methods: Our review complies with the PRISMA statement. We searched MEDLINE, SCOPUS, Web of Science, ProQuest and Google Scholar and included English-written peer-reviewed diagnostic accuracy studies. We used QUADAS-2 for quality assessment. We quantitatively synthesized evidence using hierarchical logistic regression models.

Results: Among 313 search results, eleven studies of adequate to high quality (2041 patients; MS, 1037; NMOSD, 862; MOGAD; 142) were eligible. Matthews' brain MRI criteria demonstrated pooled sensitivity and specificity of 0.92 [0.86; 0.96] and 0.85 [0.79; 0.90] for MS versus AQP4-positive-NMOSD, 0.93 [0.84; 0.97] and 0.90 [0.80; 0.95] for MS versus AQP4-negative-NMOSD, 0.86 [0.81; 0.90] and 0.87 [0.76; 0.93] for MS versus MOGAD. The addition of spinal cord MRI raised both sensitivity and specificity (up to 1.00 and 0.87) in one study. Cacciaguerra's brain-spinal cord criteria for NMOSD versus MS differentiation showed pooled sensitivity and specificity of 0.96 [0.76; 0.99] and 0.84 [0.73; 0.92], respectively.

Forest plots of sensitivity and specificity of the Matthews criteria diagnostic accuracy meta-analysis for MS versus seropositive NMOSD.



Graphical representation (summary receiver-operating characteristic model curve) of the Matthews criteria diagnostic accuracy meta-analysis for MS versus seropositive NMOSD (A) and seronegative NMOSD (B) differentiation.



Graphical representation (summary receiver-operating characteristic model curve) of the Matthews criteria diagnostic accuracy meta-analysis for MS versus MOGAD differentiation.

Conclusion: Atypical NMOSD and MOGAD often satisfy MS diagnostic criteria leading to misdiagnosis. Brain and spinal cord distribution criteria are easily applicable and can accurately help distinguish between the three entities.

Disclosure: Nothing to disclose.

EPR-306 | In vivo γ-aminobutyric acid alterations as a biomarker of the therapeutic effect of MRI-negative temporal lobe epilepsy

S. Wu[1]; G. Yan[2]; R. Wu[1]

[1]*Department of Radiology, Second Affiliated Hospital of Shantou University Medical College, Shantou, China;* [2]*Department of Radiology, Second Affiliated Hospital of Xiamen Medical Hospital, Xiamen, China*

Background and Aims: The effectiveness of magnetic resonance imaging (MRI)-negative temporal lobe epilepsy (TLE) treatment depends on accurate localization of the epileptogenic brain region and timely adjustment of the therapeutic schedule. Imaging biomarkers are particularly important because they are noninvasive and real-time. Therefore, we used proton magnetic resonance spectroscopy (1H-MRS) to investigate the associations between γ-Aminobutyric acid (GABA) alteration in the epileptogenic regions indicated by interictal video electroencephalography (EEG) and therapeutic effects in MRI-negative TLE to search for significant biomarkers.

Methods: Overall, 40 patients (17 women) were enrolled in this study. Routine 1H-MRS and MEshcher–GArwood Point RESolved Spectroscopy sequences were acquired. Moreover, we followed up with the patients to obtain reexamination data from seven patients (three women) with an interval of at least 3 months and analyzed the correlation between the increasing index of tonic–clonic seizure frequency and the increasing index of GABA in the region of interest.

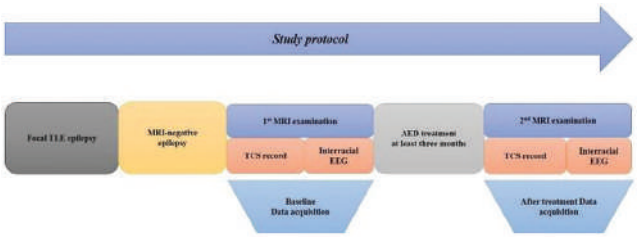


Diagram of the study protocol. The study protocol according to the procedure is presented schematically.

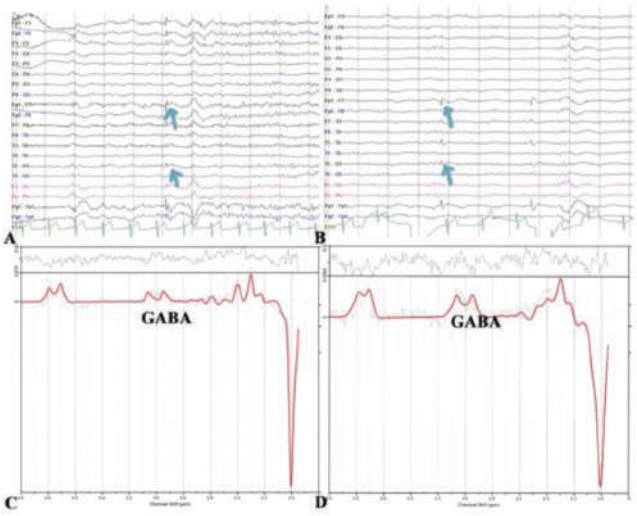
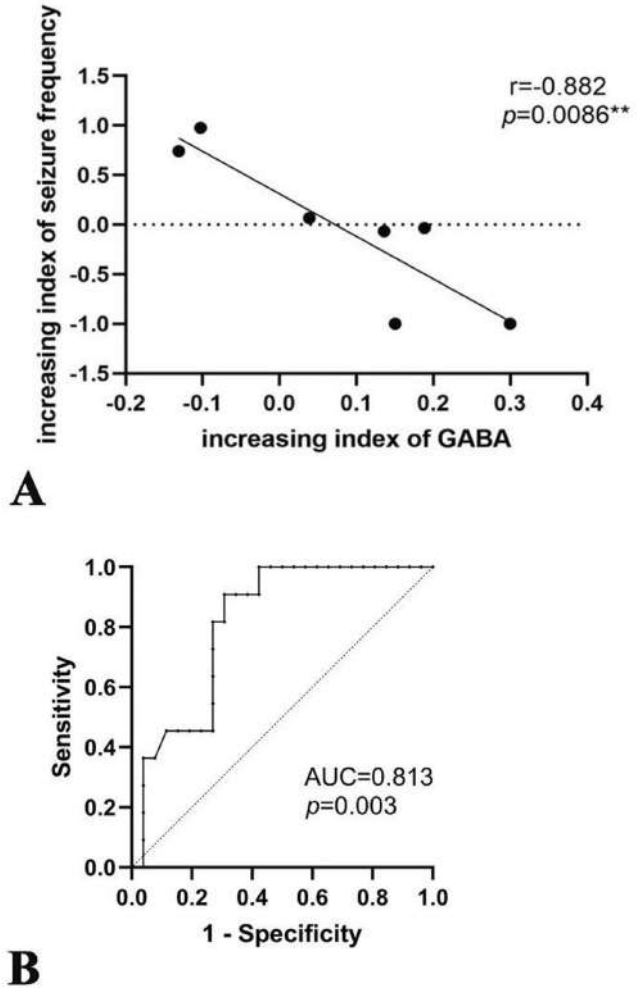
Results: We found that GABA levels is significantly lower on the epileptic side (2.355 ±0.883) than on the contralateral side (2.693 ±0.723, $p=0.033$*) on the mesial temporal lobe cortex (MTLC) of the patients. In the prospective drug effect monitoring analysis, a significant negative correlation was found between the increasing index of GABA values and the increasing index of seizure frequency in epileptogenic MTLC ($r=-0.882$, $p=0.008$**).



(a) and (b) show the initial and after treatment EEG respectively, and seizure waves frequency decreased; (c) shows the GABA peaks in the initial examination, and (d) shows the increased GABA peaks in the same voxel after treatment.



(a) Correlation between the increasing index of GABA and increasing index of seizure frequency in epileptic MTLC. (b) Receiver operating characteristic (ROC) curve was used to evaluate the diagnostic efficacy of epileptic MTLC GABA levels in patients.

Conclusion: GABA level in the MTLC will be a specific and effective biomarker for therapeutic effect monitoring in MRI-negative TLE.

Disclosure: The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Epilepsy 3

EPR-307 | "An Artificial intelligence (AI)-driven retrospective study to predict depression in patients with epilepsy"

A. Ruggieri[1]; M. Pili[2]; A. Comandini[1]; J. Gallinaro[2]; J. Leach[1]; E. Alvarez[1]; D. von Bredow[2]; P. Farhadi Ghalati[2]; P. Costa[2]; A. Raslan Sattar[2]; A. O'Loughlin[2]; B. Vamosi[2]; A. Cattaneo[1]
[1]*Global Medical Department, Angelini Pharma S.p.A., Rome, Italy;*
[2]*IQVIA, Real World and Commercial Services, EMEA*

Background and Aims: Literature suggests a bi-directional relationship between epilepsy and the development of depressive symptoms. However, little is known about the exact mechanisms underlying this relationship, which could involve a combination of many factors. Machine learning (ML) can identify complex patterns within systems of many variables, allowing detection of unexpected associations, generation of new testable hypotheses, as well as support clinical decision making through its predictive power. This study aims to leverage ML to identify predictors of depression onset in patients with epilepsy.

Methods: A tree-based risk prediction model was trained on data from 50,000 epilepsy patients recorded between 2010 and 2023 in German Electronic Medical Records. Recorded diagnoses, prescriptions, and other outcomes (visits, hospitalisations, referrals) were used as input features. Explainable AI identified important features for prediction.

Results: The model correctly identified 62% of patients with epilepsy developing depression, with a precision 70% better than random screening. Age, gender, usage patterns of medical care and use of anti-depressants were found to be potentially associated with onset of depression.

Conclusion: Model results were aligned with the literature, confirming applicability of the approach, with interesting findings for further exploration. This analysis is part of a multi-country AI-driven database study that will address how comorbid epilepsy and depression affect patient management, treatment choices and clinical outcomes. Knowledge on features relevant for onset of depression in patients with epilepsy could be helpful for early diagnoses and improved treatment choices.

Disclosure: Angelini is the sponsor and funded IQVIA to conduct the study.

EPR-308 | Epicranial stimulation for drug-resistant epilepsy at Ghent University Hospital, Belgium

A. Mertens[1]; F. Dewaele[2]; I. Garrez[1]; E. Carrette[1]; A. Meurs[1]; P. Boon[1]; K. Vonck[1]

[1]*Brain, Neurology, Ghent University Hospital, Ghent, Belgium;* [2]*Neurosurgery, Ghent University Hospital, Ghent, Belgium*

Background and Aims: Epicranial stimulation is a novel minimally invasive treatment option for drug-resistant epilepsy. The EASEE ® System (Epicranial Application of Stimulation Electrodes for Epilepsy) was implanted in the first Belgian patient in February 2020.
Methods: After a 1- month baseline period, the EASEE® System was implanted epicranially above the seizure onset zone. Focal cortical stimulation was delivered using both high-frequency and direct current components performed via electrode arrays. We evaluated the safety and efficacy of the EASEE ® System up to 3 years follow-up.
Results: The monthly seizure frequency decreased from 75 seizures at baseline to 70, 56, 33 and 27 seizures after 4 months, 8 months, 2 years and 3 years follow-up respectively. The beck depression inventory decreased from 19 at baseline to 13, 12 and 10 after 8 months, 2 years and 3 years follow-up. The Epitrack cognitive screening score increased from 20 at baseline to 30, 32 and 28 after 8 months, 2 years and 3 years follow-up. Adverse events were pain at the incision site and paresthesia behind the left ear, both mild and transient.
Conclusion: Treatment with the EASEE® System was well tolerated and associated with an effective reduction in seizure frequency. Additionally, positive effects on mood and cognition were reported. Similar to other neurostimulation therapies, there seems to be an increased effect over time. The EASEE® System may offer a promising treatment option for patients with a predominant epileptic focus who are not suitable candidates for epilepsy surgery.
Disclosure: This patient was included in the EASEE II trial by Precisis.

EPR-309 | The efficacy of vagus nerve stimulation in adults with drug-resistant epilepsy beyond seizure count

A. Scarabello[1]; L. Zanuttini[1]; L. Ferri[2]; L. Muccioli[1]; L. Volpi[2]; F. Bisulli[1]; R. Michelucci[2]; P. Tinuper[3]; M. Zucchelli[2]; M. Martinoni[2]; B. Mostacci[2]

[1]*DIBINEM Deparment of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy;* [2]*IRCCS Istituto delle Scienze Neurologiche di Bologna, AUSL Bologna, Bologna, Italy;* [3]*University of Bologna, Bologna, Italy*

Background and Aims: Vagus nerve stimulation (VNS) represents a therapeutic option for people with drug-resistant epilepsy who are not eligible to curative surgery, resulting in a >50% seizure reduction in 45%–65% of cases. This study aims to assess the impact of VNS on seizure burden, as indicated both by frequency and severity, across different seizure types.
Methods: Seizure frequency and severity were evaluated at 1-year post-implantation (T1) and at the last follow-up (FU) (T2). Seizure occurrence was categorized into frequency groups (multidaily-daily-weekly-monthly-annually), and severity was assessed based on patients' reports.
Results: At our center, 91 individuals (53-males, 38-females) with epilepsy of different etiology (structural-47%; genetic-14%), of whom 45% with an encephalopathy, underwent VNS treatment. We observed an overall reduction in seizure frequency in 46% of cases at T1 and in 63% at T2 (mean FU = 95 months). 66% of patients reported a reduction in seizure intensity at both T1 and T2. Generalized/focal-to-bilateral Tonic-Clonic seizures (TCS) disappeared in 37% of patients at T2 and decreased in an additional 46% (T1)–51% (T2). Clusters and seizures-associated falls decreased in 71% (T1)–69% (T2), and 54% (T1)–42% (T2) of patients, respectively. Although adverse effects were common (45%), they were mostly transient and mild (hoarseness/cough).
Conclusion: In our population, VNS proves to be a safe procedure improving seizure control, especially for the most threatening ones: TCS, falls, and seizure-clusters. Developing outcome measures that include seizure type and severity might offer a more comprehensive quantification of VNS efficacy than counting seizures, which, as a single measure, poorly represents the quality of life in people with refractory epilepsy.
Disclosure: Dr Mostacci and Professor Tinuper report research funding to their Institution from LIVANOVA.

EPR-310 | Intraoperative seizures: Does everything end in the operating room?

A. Nilo[1]; C. Lettieri[1]; L. Verriello[2]; F. Toraldo[3]; M. Valente[3]; T. Ius[4]; G. Pauletto[2]

[1]*Clinical Neurology Unit, Head-Neck and Neurosciences Department, Santa Maria della Misericordia University Hospital, Udine, Italy;* [2]*Neurology Unit, Head-Neck and Neurosciences Department, Santa Maria della Misericordia University Hospital, Udine, Italy;* [3]*Department of Medicine, University of Udine, Udine, Italy;* [4]*Neurosurgery Unit, Head-Neck and Neurosciences Department, Santa Maria della Misericordia University Hospital, Udine, Italy*

Background and Aims: Intraoperative seizures (IOSs) occur in about 2.9%–54.3% of glioma surgery, often considered as provoked events without a clear clinical impact. Notwithstanding, less is known about the effect of IOSs on seizure and clinical outcome. Our aim is to assess the possible role of IOSs on short- and long-term epileptological and clinical outcome in patients with tumor-related epilepsy (TRE).
Methods: This is a retrospective, monocentric study of 155 patients affected by glioma and TRE who underwent surgery. Seizure and clinical outcome were evaluated considering Engel class, Karnofsky Performance Status scale and modified Rankin Scale, at 12 and 24 months of follow-up.

Results: Thirty-nine subjects (25.16%) presented with IOSs. Focal cognitive seizures were the prevalent seizures type (20.9%). In the 89.74% of cases, seizures occurred during awake surgery without changing in the anesthesiologic protocol. Comparing patients with versus without IOSs, any significant difference was found in term of development risk of early post-operative seizures (POSs) ($p=0.453$). IOSs occurrence did not influence both epileptological and clinical outcome at 12 ($p=0.595$; $p=0.348$; $p=0.559$) and 24 months ($p=0.544$; $p=0.750$; $p=0.410$). Otherwise, the development of early POSs was associated with a worse epileptological and clinical outcome at 1 ($p=0.020$; $p=0.05$) and 2 years ($p=0.023$; $p=0.05$; $p=0.04$).

Conclusion: IOSs seem to be possibly harmful during surgery, not influencing short- and long-term seizure control and clinical outcome, unlike early POSs that present a higher impact.

Disclosure: Nothing to disclose. This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

EPR-311 | Barriers in access to care for persons living with epilepsy in rural Rwanda

A. Ndayisenga[1]; S. Mutungirehe[2]; J. Umwiringirwa[3]; F. Sebera[2]; G. Umuhoza[3]; P. Dedeken[4]; P. Boon[5]; D. Teuwen[5]

[1]Department of Neurology, King Faisal Hospital Rwanda, Kigali (Rwanda); [2]Department of Neurology, Ndera Neuropsychiatric Teaching Hospital, Kigali (Rwanda); [3]Division of Education, Training and Research, King Faisal Hospital Rwanda, Kigali (Rwanda); [4]Department of Neurology, Heilig Hart Ziekenhuis, Lier (Rwanda); [5]Department of Neurology, University Hospital, Ghent (Belgium)

Background and Aims: Epilepsy is a common neurological condition with nearly 80% of 70 million persons with epilepsy (PwE) worldwide living in low- and middle-income countries. In Rwanda the prevalence varies between 29 and 73/1000 population and the treatment gap is >75%.

Methods: The Rwandan Organisation Against Epilepsy (ROAE) screened for epilepsy in 48 villages in the Rulindo District, north of Kigali in October 2021. PwE completed the Limoges questionnaire, socio-demographic data, reasons for treatment non-adherence and QOLIE10.

Results: Epilepsy screening was performed by community health workers. Epilepsy diagnosis was confirmed by neurologists in 146 PwE. Eighty-three were newly diagnosed. Mean age of seizure onset was 16.1 years. The male:female ratio was 1.00:1.24. More than 67% of PwE aged ≥20 years were single. Farming was the most frequent reported profession (37.7%). Half of the PwE expressed seizure recurrence worry, more frequently reported by women compared to men. A reduced or absent mood was reported by 83% (downheartedness). Nearly 60% reported poor QoL. Important barriers to access to care were misunderstanding of the disease (27.4%), ignorance (21.0%), lack of household finances (10.5%) and stigma, despair and hopelessness resulting in demotivation (13.7%).

Conclusion: This field study highlights an urgent need for increased education and awareness among caregivers and families in rural communities as only a limited number of PwE were identified in a routine screening programme. Significant educational efforts are needed to improve epilepsy care, knowledge, and attitudes.

Disclosure: None.

EPR-312 | Clinical characteristics and treatment approach of established new-onset status epilepticus (eNOSE)

F. Dono[1]; G. Evangelista[1]; D. Rodrigo[2]; E. Rollo[2]; M. Romozzi[2]; C. Corniello[1]; D. Liviello[1]; M. Dasara[1]; S. Servidei[2]; G. Della Marca[2]; P. Calabresi[2]; S. Sensi[1]; C. Vollono[2]

[1]Department of Neuroscience, Imaging and Clinical Science, "G. d'Annunzio" University of Chieti-Pescara, Chieti, Italy; [2]Department of Neuroscience, "Sacred Heart" University of Cattolica, Roma

Background and Aims: Status epilepticus (SE) can occur in patients without a previous epilepsy diagnosis, a condition identified as "new-onset status epilepticus" (NOSE). Treatment with benzodiazepine may fail in NOSE termination, requiring anti-seizure medication (ASM) employment. In this context, the term "established NOSE" (eNOSE) is generally employed. This study aims to describe the main clinical characteristics of a large sample of patients suffering from eNOSE comparing the ASM efficacy and exploring the risk factors associated with ASM treatment unresponsiveness and E-NOSE associated mortality.

Methods: Adult patients with eNOSE were retrospectively selected between January 2016 and December 2022. Demographics and clinical data as well as diagnostic work-up and treatment were reviewed. We considered effective the last ASM introduced or increased in dose before the eNOSE termination.

Results: 123 patients were included (age: 67.9 ± 17.3). eNOSE acute etiology was mostly reported. In the overall cohort, phenytoin showed the highest response rate. In the pairwise comparisons, valproate was superior to levetiracetam ($p=0.02$), but not to lacosamide ($p=0.65$). Phenytoin had a significantly higher resolution rate compared to levetiracetam ($p=0.0005$) but not to lacosamide ($p=0.16$). Thirty patients were refractory to ASM treatment. No predictors of refractoriness were identified. Thirty-nine patients died. Age and GCS were identified as eNOSE-related mortality risk factors.

Conclusion: eNOSE frequently shows an acute etiology with several associated semiologies. Phenytoin shows the higher effectiveness in eNOSE management, even if lacosamide, valproate and levetiracetam can represent further therapeutic options. Age and GCS represent the main risk factor of eNOSE-associated mortality.

Disclosure: Nothing to disclose.

EPR-313 | Status epilepticus in elderly: An Italian multicenter, retrospective, real-world study

M. Dasara[1]; F. Dono[2]; G. Evangelista[1]; P. Quintieri[2]; S. Cipollone[2]; C. Corniello[2]; M. Romozzi[3]; E. Rollo[3]; F. Anzellotti[2]; S. Servidei[3]; P. Calabresi[3]; C. Vollono[3]; V. Tomassini[1]; S. Sensi[1]
[1]*Department of Neuroscience, Imaging and Clinical Sciences, "G. d'Annunzio" University of Chieti-Pescara;* [2]*Epilepsy Center, Neurology Institute, "SS Annunziata" University Hospital, Chieti, "G. d'Annunzio" University of Chieti-Pescara;* [3]*Epilepsy Center, IRCCS "A. Gemelli", Rome*

Background and Aims: Status Epilepticus (SE) is a neurological emergency with a mortality risk around 20%. SE onset can be observed in all ages, including elderly. Clinical hallmarks as well as the therapeutic approaches of SE in elderly have not been exhaustively explored in the current literature
Methods: in this retrospective, multi-center, real-world study, patients aged >75 have been selected from two third-level epilepsy centers between 2011 and 2023. Demographics, clinical as well as SE four axis characteristics (i.e., age, semiology, etiology and EEG correlates) and therapeutic intervention were collected. GCS, STESS, EMSE and CARING scales were evaluated as outcome predictors
Results: 87 patients (age: 83 ±6, 28 male) were included. Non-convulsive SE with acute etiology was mainly described. Patients were treated with 2.7 ±1.5 drugs. First-line treatment consisted of diazepam (mean dose: 10.4 ±3.3 mg) in most of patients followed by levetiracetam (mean dose: 1815.8 ±931.1 mg). Among the ASM, levetiracetam, valproic acid, phenytoin and lacosamide were mostly administered. Thirty-three patients developed a refractory SE and 32 patients died for SE. Compared to survivors, patients who died for SE showed an increased prevalence of cardiological comorbidities ($p=0.03$). Refractoriness was not a predictor of mortality ($r=0.21$). STESS ($p=0.002$), EMSE ($p=0.01$) and CARING ($p=0.01$) scales resulted as good outcome predictors tools
Conclusion: SE is associated with a great mortality in elderly. Treatment strategies generally consist of benzodiazepine and ASM. Anesthetics are less employed. Commonly used prognostic scales have a good reliability. CARING scale may be employed in elderly patients as outcome predictor tool.
Disclosure: Nothing to disclose.

EPR-314 | Markers of oxidative stress in patients with drug-resistant and drug-sensitive focal epilepsy

F. Iannaccone; A. Calvani; C. Milano; L. Chico; A. Lo Gerfo; L. Petrozzi; G. Siciliano; E. Bonanni; C. Pizzanelli
Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

Background and Aims: Epilepsy affects over 70 million individuals globally, thus representing a prevalent neurological disorder. Current anti-seizure medications, while symptomatically effective, lack preventive efficacy against epileptogenesis. Approximately 30% of patients develop pharmacoresistance, wherein poorly understood mechanisms thwart therapy. Recent research highlights neuroinflammation and oxidative stress as pivotal in epileptogenesis and pharmacoresistance. This study explores the role of oxidative stress in epilepsy, aiming to unravel its mechanisms, assess drug resistance, and consider therapeutic implications.
Methods: A cohort of 100 focal epilepsy patients was analyzed, stratified by therapy response and epileptogenic focus. Plasma levels of oxidative stress biomarkers (AOPP, FRAP, thiols) were quantified and compared with 100 age- and gender-matched healthy controls.
Results: Patients displayed significantly elevated AOPP ($p<0.001$) and reduced thiols ($p<0.001$) compared to controls, while differences in FRAP were nonsignificant ($p>0.05$). Multivariate analysis confirmed group significance for AOPP and thiols, irrespective of age and gender. Additionally, drug-resistant patients exhibited lower thiols levels than drug-sensitive subjects ($p=0.039$) after adjusting for confounding variables. Thiols also showed lower levels in temporal epilepsy compared to extratemporal epilepsy, regardless of age or gender ($p=0.005$). Lastly, therapy sensitivity and focal epilepsy type, simultaneously considered and normalized by age and gender, showed a significant and independent impact on thiols levels ($p=0.026$ and $p=0.029$, respectively).
Conclusion: Our findings highlight the pivotal role of oxidative stress in epileptogenesis and drug resistance. The observed antioxidant capacity decrease, especially in resistant cases and temporal lobe epilepsy, suggests potential therapeutic avenues. Ongoing research may refine early detection and personalized interventions for improved patient outcomes.
Disclosure: Nothing to disclose.

EPR-315 | Descriptive analysis of prehospital seizure management protocols – We need standardized guidelines

I. Hustad; E. Taubøll; M. Horn; M. Hov
Dept. of Neurology, Oslo University Hospital, Oslo, Norway

Background and Aims: No common European clinical practice guidelines on prehospital seizure management exists. Today most patients are transported to hospital for seizure treatment with great variation in which prehospital treatment is provided. Only 33% of all SE patients receive the recommended benzodiazepine as first anti-seizure medication (ASM). The specialist healthcare in Norway is organized into four Regional Health Authorities, comprising 18 local Emergency Medical Services (EMS). Patients with seizures constitutes a significant group in acute neurology. Norway lacks national guidelines for the prehospital management of seizures. The aim of this study is to assess the current prehospital seizure control protocols in the EMSs in Norway, and comparisons to recent evidence for acute management.

Methods: A descriptive analysis of protocols used by EMSs in Norway and compare the findings to recent evidence on prehospital treatment. Analysis will be done on drug of choice, dosages used, route of medication administered, number of additional rescue doses permitted, requirements for glucose testing prior to medication and requirement for registration of type of seizures and seizure duration.
Results: We identified 18 local protocols for seizure management in the Norwegian ambulance service. The protocols vary in terms of medication of choice, administration method, dosage, recommendation regarding first- and second-line therapy choices.
Conclusion: There are disparities in the prehospital seizure management protocols within the Norwegian healthcare system, a system comparable to other European countries. To shorten time to seizure control we should agree on standardized guidelines for prehospital treatment.
Disclosure: Nothing to disclose.

Pain

EPR-316 | Brain imaging predictors of pain catastrophizing in chronic pain

O. Alenikova; M. Dymkovskaya; L. Parhach; N. Alenikov
Republican Research and Clinical Center of Neurology and Neurosurgery

Background and Aims: The chronic pain development is associated with maladaptive cognitive and emotional disorders, the basis of which can be the pain catastrophizing. We hypothesize that in addition to lifestyle, comorbidities and others, there are structural changes in the brain that contribute to pain catastrophizing. Objective: to study cognitive and emotional components of pain catastrophizing and its predisposing MRI morphometric features in patients with chronic pain
Methods: 28 patients with chronic primary and secondary musculoskeletal pain were tested using the Four-Dimensional Symptom Questionnaire (4DSQ), MoCAtest, the Visual Analogue Scale (VAS) and the Pain Catastrophizing Scale (PCS). Additionally to standardized MRI morphometry, we manually segmented the periaqueductal grey (PAG) with an assessment of its signal intensity.
Results: 15 patients with total PCS score above 35 were included in the first group, and 13 patients with a score below 25 comprised the second group. Group 1 had a more pronounced pain intensity and a higher score on the 4DSQ, both total and on all subscales, compared to Group 2. Despite the lack of differences in the MoCA total, attention and recall were more impaired in the 1st group. MRI morphometry identified an increase in volume of the fronto-limbic circuit structures as well as PAG density in the first group (Table 1).

TABLE 1: Comparative assessment of patients of the first and second groups.

Parameters	1st Group n = 15	2nd Group n = 13
	Median (IQR)	
Age, years	49 (44 – 56)	50 (44 – 54)
Men / Women	9/6	7/6
Disease duration (months)	19 (10 – 28)	22 (12 – 26)
Visual Analogue Scale	7 (6 – 8)	4 (4 – 6) *
MoCA total	27 (26 – 29)	28 (27 -30)*
Attention	4 (3 – 5)	6 (5 – 6) *
Recall	3 (3 – 4)	5 (4 – 5) *
4DSQ total	75 (66 – 88)	40 (33 – 51) *
Distress	27 (20 – 34)	20 (16 – 26) *
Depression	8 (6 – 11)	4 (3 – 7) *
Anxiety	11 (6 – 13)	6 (5 – 9) *
Somatization	28 (24 – 30)	13 (10 – 18) *
Pain Catastrophizing Scale total	41 (37 - 48)	20 (17 – 23) *
MRI morphometry		
Medial orbitofrontal cortex	5768 (5567 – 5985)	5415 (5230 – 5453) *
Anterior cingulate cortex	980 (845 – 1047)	893 (754 – 997) *
Amygdala	1424 (1363 – 1579)	1254 (1184 – 1368) *
PAG density	73,3 (67,3 – 78,8)	62,5 (58,9 - 74,6) *

MoCA - Montreal Cognitive Assessment
* - p ≤ 0,05 - Significant differences between the 1st and 2nd group (Mann-Whitney test)

Conclusion: The Identified changes in the structures of the cortico-limbic loops with PAG density reorganization contribute to the enhance of nociceptive inputs. These changes can be considered as a preexisting pain catastrophizing marker in people with chronic pain, and should be taken into account in psychotherapeutic procedures.
Disclosure: Nothing to disclose.

EPR-317 | Contribution of the cannabinoid receptors to the antinociceptive actions of mesenchymal stem cells in neuropathic pain

H. Yerafeyeva; S. Rjabceva; A. Molchanova
Institute of Physiology of the National Academy of Sciences, Minsk, Belarus

Background and Aims: Mesenchymal stem cells (MSCs) have the ability to alleviate neuropathic pain (NP) and this may be linked to cannabinoid receptors. Our objective was to investigate the impact of cannabinoid receptors on the MSC-induced antinociception in experimental peripheral NP.
Methods: We induced NP in Wistar rats through sciatic nerve injury. On the 7th day post-surgery, animals received a consistent dose of adipose tissue-derived MSCs. To explore the influence of cannabinoid receptors, we utilized selective agonists and antagonists (anandamide and AM251 for the CB1 receptor, AM1241, and AM630 for the CB2 receptor). These ligands were either added to the MSC culture or locally injected around the nerve injury area before MSCs. Additionally, we tested combinations of these ligands. The analgesic effect of MSCs was evaluated over a 90-day period.
Results: Anandamide, when added to the culture of cells, enhances their ability to alleviate pain. Stimulation of CB2 receptors on MSC has a weaker impact on pain relief. Blockade of CB1 receptors

weakens the analgesic effect. Surprisingly, it completely disables the alleviation of thermal hyperalgesia when anandamide is injected before MSCs. This fact underscores the critical role of CB1 receptors in this process. A similar trend was observed when a combination of locally injected AM1241 and MSCs preincubated with AM630 was used. When a CB1 or CB2 receptor antagonist was injected locally, and then MSCs preincubated with agonists were transplanted, the analgesic effect gradually declined.

Conclusion: Obtained data suggests that the therapeutic impact of MSCs on pain relief is contingent upon cannabinoid receptor activity.

Disclosure: Nothing to disclose.

EPR-318 | The multimodal rehabilitation of complex regional pain syndrome – A nonrandomized controlled trial

J. Wiśniowska; B. Tarnacka; D. Robak; N. Salata; A. Zalewski
Department of Rehabilitation, Eleonora Reicher National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw

Background and Aims: To investigate whether Multimodal Rehabilitation Program (MRP) affects the change in visual-spatial abilities, especially attention, information processing speed and visual-spatial learning, severity of depression, and coping with pain strategies.

Methods: The study was conducted, with a 4-week rehabilitation program that included: individual physiotherapy, manual and physical therapy, and psychological intervention such as psychoeducation, relaxation, and Graded Motor Imagery therapy. The study was a 2-arm parallel: twenty CRPS participants with MRP intervention and twenty healthy control group matched to the CRPS group according to demographic variables. Before and after, the MRP participants in the CRPS group had visual-spatial, attention abilities, severity of depression, and pain-coping strategy assessment. The healthy control group had the same assessment without intervention before two measurements.

Results: In the post-test compared to the pre-test, the participants with CRPS obtained a significantly high score in visual-spatial learning ($p < 0.01$) and visual information processing speed ($p = 0.01$). They made significantly fewer omission types of mistakes in visual working memory ($p = 0.01$). After MRP compared to the pre-test, the CRPS participants declared a decrease in the severity of depression ($p = 0.04$) and more often used task-oriented coping with pain strategy than before the rehabilitation program ($p = 0.02$).

Conclusion: After a 4-week MRP, the following outcomes were obtained: an increase in visual-spatial learning, visual information processing speed, a decrease in severity of depression and a change in the pain-coping strategies – which became more adaptive.

Disclosure: Nothing to disclose.

EPR-319 | Sensory phenotyping in trigeminal neuralgia

D. Litewczuk; G. De Stefano; C. Leone; E. Galosi; G. Di Pietro; P. Falco; G. Di Stefano; A. Truini
La Sapienza, University of Rome

Background and Aims: Trigeminal neuralgia (TN) is characterized by recurrent paroxysmal episodes of unilateral facial pain in the distribution of one or more branches of the fifth cranial nerve. Beside paroxysmal pain, about 50% of patients experience a concomitant continuous pain, which may be underlied by distinct pathogenetic mechanisms. The aim of the present study is to investigate sensory phenotypes characterizing the presence of concomitant continuous pain in TN.

Methods: The main inclusion criterion was a definite diagnosis of primary TN according to ICHD-3. Each patient underwent 3T MRI scans with sequences dedicated to the study of neurovascular compression, and Quantitative Sensory Testing examination according to the German Research Network on Neuropathic Pain 3 protocol, carried out on both sides of the face.

Results: We enrolled 52 patients with definite TN, including 29 patients (56%) with concomitant continuous pain and 23 with purely paroxysmal pain (44%). All QST parameters had normal mean *Z*-scores values on both sides of the face. CDT was significantly lower in the affected side ($p = 0.02$) in the group of patients with concomitant continuos pain. The correlation analysis between the volume of the affected root and WUR showed a significant negative correlation ($p = 0.01$).

Conclusion: Our findings suggest that concomitant continuous pain in TN may be related to small nerve fibers loss, possibly triggering abnormal activity in denervated trigeminal second-order neurons.

Disclosure: Nothing to disclose.

EPR-320 | Effects of non-pharmacological and non-invasive interventions on chronic deafferentation pain: A meta-analysis

H. Koehler[1]; J. Schmidt[2]
[1]*Department of Neurology, Jena University Hospital, Jena, Germany*; [2]*Department of Psychology, Clinical Psychology, Friedrich Schiller University Jeny, Jena, Germany*

Background and Aims: Deafferentation pain (DP), resulting from damage to the peripheral nervous system, poses a clinical challenge. Pharmacological and invasive approaches often fall short, leading to exploration of alternative therapies like mirror therapy and sensory discrimination training. However, existing studies assess interventions separately for conditions like brachial plexus avulsion (BPA), spinal cord injury (SCI), amputation, or complex regional pain syndrome type II (CRPS II), despite similar pain descriptions. Previous reviews focused on single therapies, lacking comparisons between interventions. This meta-analysis evaluates non-pharmacological,

non-invasive interventions for DP to enhance understanding and guide the development of effective interventions.

Methods: In June 2023, MEDLINE, Web Of Science, PsycINFO, Cochrane CENTRAL, and PubMed were searched for controlled studies evaluating the effects of non-pharmacological and non-invasive interventions on pain intensities in adult patients with chronic DP after SCI, amputation, BPA, or CRPS II. Two reviewers independently screened studies, and network meta-analysis was performed to compare intervention effects. The full protocol is available on PROSPERO (CRD42023431497).

Results: 27 studies evaluating 24 interventions reached qualitative synthesis. Repetitive transcranial magnetic stimulation showed the highest effects for both SCI and amputees. Heterogeneity among studies was high, and certainty of evidence was low. No studies on CRPS II and only 2 studies on BPA evaluated the interventions of interest.

Conclusion: Similar underlying pain mechanisms in considered conditions suggest that interventions promising for DP after SCI and amputation may apply to BPA and CRPS II, where corresponding therapies are yet unexplored. However, higher methodological quality studies are needed for all four conditions.

Disclosure: Nothing to disclose.

EPR-321 | Multicolumn spinal cord stimulation for chronic back and leg pain in patients with failed back surgery syndrome

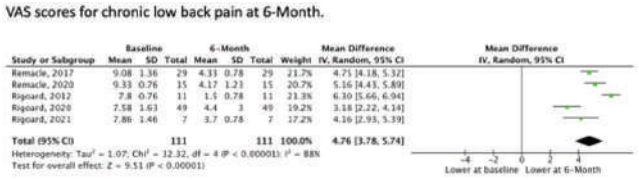
H. Atwan[1]; I. Serag[2]; M. Abouzid[3]

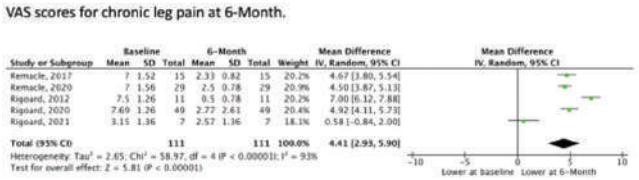
[1]Faculty of Medicine, Assiut University, Assiut, Egypt; [2]Faculty of Medicine, Mansoura University, Mansoura, Egypt; [3]Department of Physical Pharmacy and Pharmacokinetics, Faculty of Pharmacy, Poznan University of Medical Sciences, Poznan, Poland

Background and Aims: Failed Back Surgery Syndrome (FBSS) is a challenging condition characterized by persistent chronic low back pain and leg pain despite surgical interventions. Multicolumn spinal cord stimulation (m-SCS) has emerged as a promising therapeutic approach for managing FBSS-associated pain.

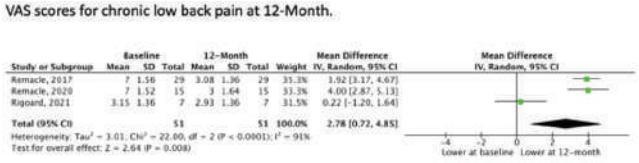
Methods: We aim to analysis the efficacy of m-SCS in alleviating chronic back and leg pain in patients with FBSS. A comprehensive search of electronic databases (PubMed, Web of Science, Scopus, Cochrane Library) was conducted up to October 25th, 2023.

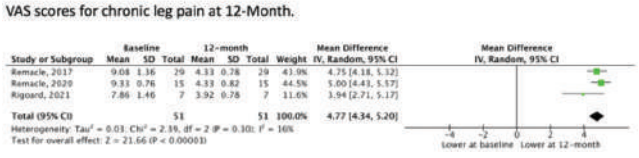
Results: We included 8 articles with 271 patients from 21-center. At 6 months, there were a statistically and clinically significant reduction in the VAS scores for the low back pain (MD, 4.76; 95% CI, 3.78–5.74) and leg pain (MD, 4.41; 95% CI, 2.93–5.90) versus the baseline. Also, at 12 months, there were a statistically and clinically significant reduction in the VAS scores for the low back pain (MD, 4.77; 95% CI, 4.34–5.20) and leg pain (MD, 2.78; 95% CI, 0.72–4.85) versus the baseline.Our meta-analysis demonstrated a significant reduction in both back and leg pain scores among FBSS patients treated with m-SCS compared to the baseline pain scores ($p < 0.05$). Subgroup analyses revealed consistent efficacy across different stimulation parameters and patient demographics. Additionally, improvements in quality-of-life measures and functional outcomes were observed in the m-SCS intervention group.





VAS scores for chronic low back pain and leg pain at 6-month.





VAS scores for chronic low back pain and leg pain at 12-month.

Conclusion: The findings underscore the potential of m-SCS as a valuable therapeutic option in the multidisciplinary approach to FBSS, offering sustained pain relief and improved functional outcomes.

Disclosure: Nothing to disclose.

EPR-322 | Novel electrophysiological and ultrasound biomarkers for trigger point assessment

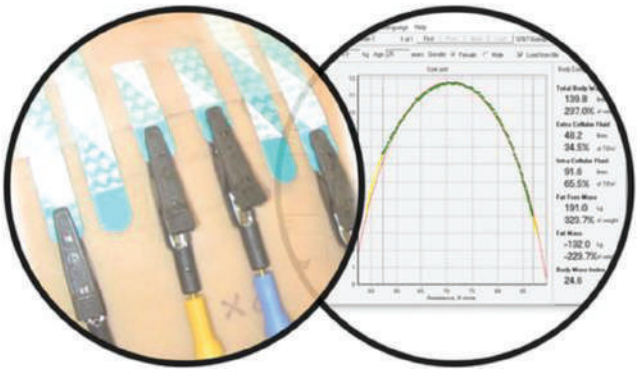
A. Mukushev[1]; A. Nanda[1]; S. Samaan[1]; C. McIlduff[1]; B. Wainger[2]; J. Wu[1]; H. Mu[1]; S. Verga[1]; S. Rutkove[1]

[1]Department of Neurology, Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, MA, USA; [2]Department of Anesthesiology, Critical Care and Pain Medicine, Massachusetts General Hospital, Boston, MA, USA

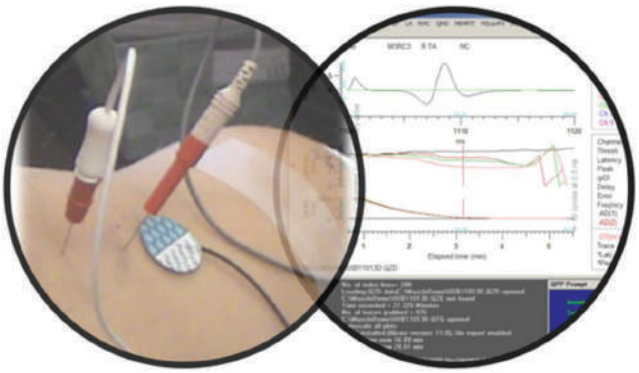
Background and Aims: Although TrPs affect millions of individuals, we do not understand the mechanisms underlying the course of this

condition. Furthermore, most pain studies rely on subjective patient scores as the primary outcome. To address these gaps, we aim to employ three entirely objective and quantitative assessment methodologies to assess these entities. Here we present results from our first group of healthy subjects whose data have been analyzed for repeatability.

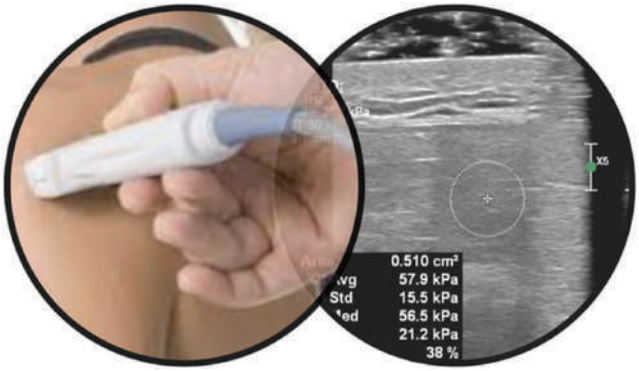
Methods: We performed testing of the three modalities on the right trapezius muscle in healthy participants during two separate visits. Electrical impedance myography (EIM) noninvasively evaluates muscle properties using a painless electrical current. Quantitative muscle ultrasound images translates the brightness of muscle scans into a numerical value, the grayscale level. Myofiber excitability testing (MET) quantifies changes in muscle fiber conduction properties in response to various electrical conditioning stimuli. Intra-class coefficients (ICCs), Bland-Altman analysis and mean percent difference were calculated as a reflection of reliability for each of these modalities.



Electrical impedance myography.



Myofiber excitability test.



Quantitative muscle ultrasound.

Results: Sixteen healthy participants (10 men, 6 women) with mean age ± SD 52.6 ±16.7 years were enrolled. There was a strong intra-class correlation for the EIM phase angle values between first and second ICC = 0.96, and a mean percent difference of 9.35 ±8.89%. Reproducibility of grayscale also demonstrated positive correlation between the visits, ICC = 0.92, with mean percent difference 4.47 ±3.78%, as did MET with mean percent difference 3.47 ±0.37%.

Conclusion: The initial findings indicate the promising use of EIM, grayscale, and MET as potential diagnostic biomarkers for TrPs.

Disclosure: Nothing to disclose.

Marii Skłodowskiej-Curie, Warsaw, Poland; [6]Università degli Studi di Torino, Torino, Italy; [7]Fondazione Policlinico Universitario Agostino Gemelli IRCCS; [8]Centro Parkinson e Parkinsonismi, ASST G.Pini-CTO, Milano, Italy; [9]University Hospital Würzburg and Julius Maximilian University of Würzburg, Würzburg, Germany; [10]Fundacion del Hospital Nacional de Parapléjicos para la Investigacion y la Integracion, Toledo, Spain; [11]Division of Neurosurgery, Department of Surgery, Toronto Western Hospital, University of Toronto, Toronto, Ontario, Canada; [12]Grenoble Institute of Neurosciences, INSERM U1216, University Grenoble Alpes, Grenoble, France; [13]Newronika SpA, Milano, Italy

Background and Aims: Adaptive deep brain stimulation (aDBS) breaks important new ground for patient-personalized neuromodulation treatment, but still needs long-term clinical validation.

Methods: We report an individual comparison between aDBS and conventional DBS (cDBS) of the subthalamic nucleus in 14 patients with Parkinson's disease (PD). Clinical assessment was performed with the UPDRS-III and UDysRS scales and a 3-day diary. Patients were monitored for two weeks in each aDBS or cDBS mode in random order with stimulation delivered with the AlphaDBS device (Newronika SpA, Milan, Italy).

Results: All patients showed significant clinical benefit that was comparable between the two stimulation modes (UPDRS-III % improvement med-off/stim-off to med-on/stim-on cDBS vs. aDBS: 0.66 ±0.15 vs. 0.61 ±0.17; Good-On-Time cDBS vs. aDBS: 11.7 ±4.3 vs. 13.1 ±4.9). Notably, dyskinesias negatively correlated with aDBS-induced UPDRS-III improvement, implying that patients with mild dyskinesias have a greater UPDRS-III improvement (Spearman's ρ: −0.771, $p=0.006$). On the contrary, cDBS-induced UPDRS-III improvement did not correlate with dyskinesias (Spearman's ρ: −0.385, $p=0.282$). In 50% of the patients, the "on time" without dyskinesias in aDBS was >1SD of the average "on-time" without dyskinesia with cDBS. In the end, 90% of patients chose (blinded) preferred aDBS.

Conclusion: We showed that aDBS and cDBS result in similar improvement of PD-related symptoms, with a greater benefit for aDBS in patients with mild dyskinesias. In half of the patients, aDBS provided a greater "on-time" than cDBS, and most patients preferred the adaptive mode.

Disclosure: AP, SM, CC, MA, LK, LR and IUI are funders, employees, or consultant of Newronika SpA. RE, LB, EP, ML, and ARB acted as PI of clinical studies of Newronika SpA. Clinical trial NCT04681534.

EPR-324 | Plasma neurofilament light chain level in isolated REM sleep behavior disorders

A. Calculli[2]; D. Di Martino[2]; G. Ongari[1]; S. Gagliardi[1]; P. Grillo[2]; E. Capriglia[2]; C. Fazio[2]; D. Comolli[2]; M. Terzaghi[1]; A. Pisani[1]

[1]IRCCS Mondino Foundation, Pavia, Italy; [2]Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy

Background and Aims: Rapid-Eye-Movement (REM) sleep behavior disorder (RBD) is recognized as a precursor to α-synucleinopathies, encompassing Parkinson's disease (PD), dementia with Lewy bodies (DLB), and multiple system atrophy (MSA). The isolated RBD (iRBD) population offers an ideal cohort for detecting neurodegenerative biomarkers. This study explores the role of neurofilament light chain proteins (NfLs) in iRBD, PD and MSA.

Methods: Plasma-NfL levels in iRBD, PD, MSA patients, and healthy controls (HC) were assessed using Ella. Statistical analysis employed PRISM9, with data comparisons via the Mann–Whitney and Spearman test.

Results: Plasma-NfL levels were measured in 69 subjects (PD:19, M:14 F:5; iRBD:19, M:18 F:1; MSA:12, M:5 F:7; HC:19, M:14 F:5). Results revealed elevated NfL levels in PD and MSA compared to HC (PD vs. HC $p=0.0005$; MSA vs. HC $p<0.0001$). Notably, iRBD exhibited increased NfL levels compared to HC (iRBD vs. HC $p=0.0392$) and lower than MSA (MSA vs. iRBD $p=0.0472$). No significant difference existed between PD and iRBD ($p=0.8007$). Correlation analyses with continuous variables (UPDRS-III and MMSE) showed no significance. In iRBD, comparative analysis based on hyposmia, constipation, or orthostatic hypotension were not significant.

Conclusion: The findings suggest axonal damage in iRBD, indicating an ongoing neurodegenerative process. Similar NfL levels between PD and iRBD suggest stability during phenoconversion to PD. Elevated NfL levels in iRBD with orthostatic hypotension hint at a potential link to MSA ($p=0.0620$), warranting confirmation with a larger sample size. Plasma-NfLs emerge as promising biomarkers for irreversible CNS damage when combined with clinical and instrumental data.

Disclosure: Nothing to disclose.

EPR-325 | Occipital atrophy as marker for phenoconversion in patients with isolated REM-sleep behaviour disorder

A. Baun[1]; A. Iranzo[2]; M. Terkelsen[1]; M. Stokholm[1]; M. Serradell[2]; M. Otto[3]; K. Svendsen[4]; A. Garrido[5]; D. Vilas[5]; J. Santamaria[2]; A. Møller[6]; C. Gaig[2]; D. Brooks[1]; P. Borghammer[1]; E. Tolosa[5]; S. Eskildsen[6]; N. Pavese[1]

[1]Department of Nuclear Medicine & PET Centre, Aarhus University Hospital, Denmark; [2]Department of Neurology, Hospital Clínic de Barcelona, Spain; [3]Department of Clinical Neurophysiology, Aarhus University Hospital, Denmark; [4]Department of Neurology, Aarhus University Hospital, Denmark; [5]Centro de Investigación Biomédica en Red sobre Enfermedades Neurodegenerativas (CIBERNED), Hospital Clínic, IDIBAPS, Universitat de Barcelona, Catalonia, Spain; [6]Center of Functionally Integrative Neuroscience, Department of Clinical Medicine, Aarhus University

Background and Aims: The cuneus and precuneus are considered important for cognition. In patients with isolated rapid-eye-movement behaviour disorder (iRBD), voxel-based morphometry (VBM) studies report structural changes in these structures, however, not consistently. Here we examined atrophy in the cuneus and precuneus of cognitively normal iRBD patients and tested if this can serve as marker of future phenoconversion to Parkinsonism.

Methods: Using VBM, we analysed magnetic resonance images of 20 iRBD patients and compared them to 36 healthy controls (HC). The iRBD patients had a mean Montreal Cognitive Assessment score of 25.5 (SD 2.46) and a mean Mini Mental State Examination score of 28.2 (SD 1.53). The patients were followed for 8 years ($N=17$). Time-to-event analysis was performed using cox regression.

Results: Eight iRBD patients converted during follow-up; four to dementia with Lewy bodies and four to Parkinson's. VBM showed reduced grey matter volume (GMV) in the cuneus and precuneus of the patients compared to HC. Region of interest analysis confirmed significant reduction in GMV in both the left and right cuneus and precuneus in the patients. Patients with GMV at, or below, the group median in the right cuneus had higher hazards of 13.0 (CI: 1.53–110)

for phenoconversion. Lower right cuneus GMV correlated with shorter time to conversion ($p=0.01$). Lower GMV in left and right precuneus trended to increased hazards at 4.20 (CI: 0.80–22.2) and 4.44 (CI: 0.85–23.2) respectively.

Conclusion: Our findings suggest that cuneus GMV can be used as markers of future phenoconversion in iRBD patients even before onset of cognitive symptoms.

Disclosure: Nothing to disclose.

EPR-326 | Cognitive fluctuations in Parkinson's disease patients without dementia

C. Gasca-Salas[1]; S. Obika[1]; R. Rodríguez-Rojas[1]; B. Fernández-Rodríguez[1]; C. Trompeta[1]; P. Guida[1]; G. Goggani[1]; L. Vela[2]
[1]HM CINAC (Centro Integral de Neurociencias Abarca Campal), Hospital Universitario HM Puerta del Sur, HM Hospitales, Madrid, Spain; [2]Hospital Universitario Fundación Alcorcón, Alcorcón, Madrid, Spain

Background and Aims: Cognitive fluctuations (CF) are spontaneous alterations in cognition, attention, and arousal leading to episodes of perturbed flow of ideas or daytime drowsiness, considered core clinical features of dementia with Lewy bodies and associated with Parkinson's disease (PD) dementia. However, their characteristics remain unexplored in non-demented PD patients. We aimed to identify the frequency of CF, their relationship with neuropsychological tests, and their occurrence in non-demented PD patients who later progress to a worse cognitive state.

Methods: Fifty-one patients underwent clinical and neuropsychological assessments. Administering the CF Scale, a positive answer in three or more of the four items indicated good sensitivity. The Kendall correlation test assessed the relationship between cognitive fluctuations, cognitive tests, and amyloid brain burden (PET). Thirty-eight patients were followed for three years to detect conversion to a more severe cognitive state.

Results: Thirty-two patients scored 0 (62.7%, no positive answers), 11 (21.6%) scored one, and 4 (7.8%) scored two and three points, respectively, on the cognitive fluctuations questionnaire. An association was found between CF and tests of executive function, visual memory, and total amyloid after controlling for the motor-MDS-UPDRS score (confounder). The conversion rate to PD-MCI or dementia at follow-up was higher in patients scoring ≥3 compared to those who did not (100% vs. 23.5%).

Conclusion: Although uncommon in PD patients with dementia, CF, when present, signal an association with progression to a worse cognitive state. This association is reinforced by correlations with lower scores in executive and memory function tests, along with a potential connection with amyloid pathology.

Disclosure: Nothing to disclose.

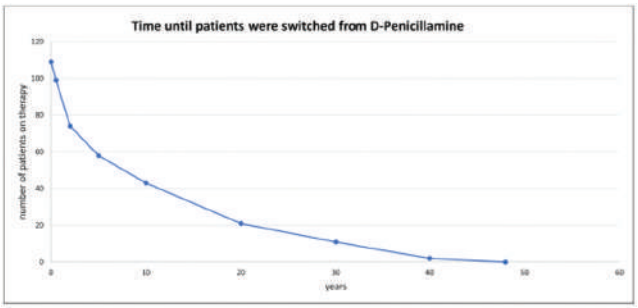
EPR-327 | TRISTAN – retrospective real world data acquisition of Wilson disease patients with neurological symptoms in Germany

C. Hartmann[1]; I. Mohr[2]; J. Wiegand[3]; T. Lang[4]; P. Buggisch[5]; M. Praktiknjo[6]; K. Weiss[7]; F. Tacke[8]
[1]Department of Neurology, Medical Faculty and University Hospital Düsseldorf, Heinrich Heine University Düsseldorf, Germany; [2]Internal Medicine IV, Department of Gastroenterology, University Hospital Heidelberg, Heidelberg, Germany; [3]Division of Hepatology, Department of Medicine II, Leipzig University Medical Centre, Leipzig, Germany; [4]Department of Pediatrics, Starnberg Hospital, Germany; [5]IFi-Institute, Hamburg Germany; [6]Department of Internal Medicine B, University Hospital Münster, Germany; [7]Internal Medicine, Salem Medical Center, Heidelberg, Germany; [8]Department of Hepatology and Gastroenterology, Campus Virchow-Klinikum (CVK) and Campus Charité Mitte (CCM), Berlin, Germany

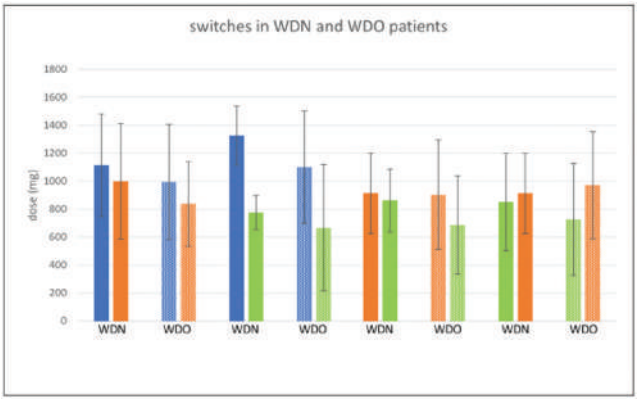
Background and Aims: While D-penicillamine (D-Pen) is recommended as first-line chelating agent for Wilson Disease (WD), administration of trientine (TETA) is a valuable alternative for patients who are intolerant to D-Pen. Since just limited data are available on treatment transitions when switching from D-Pen to TETA and between Trientine formulations, we conducted a retrospective analysis retrieved from 6 specialized WD centres in Germany.

Methods: The study incorporated anonymized data from WD patients receiving TETA with at least one documented follow-up between 2012 and 2021. Information on clinical manifestation and treatment regimen were captured via standardized questionnaires. Patients with an initial neurological affection (WDN) were compared with other types of primary manifestation (WDO).

Results: Our study encompassed data from 143 patients (75 females) with a mean age of 40 (5–85) years. WDN patients ($n=39$) were older at diagnosis than WDO patients (25.0 vs. 14.5). Most patients (88%) underwent 2–4 therapy lines. 32% of patients switched from D-Pen to TETA within the first 2 years, 50% after 7 years of therapy. The conversion factors in WDN and WDO patients were 0.90 and 0.84 for D-Pen to TETA dihydrochloride (TETA-2HCl), 0.59 and 0.60 for D-Pen to TETA-tetrahydrochloride (TETA-4HCl), 0.95 and 0.76 for TETA-2HCl to TETA-4HCl and 1.07 and 1.33 for TETA-4HCl to TETA-2HCl, respectively.



Time until switch from D-Pen.



Conversion factors when switching between treatments in WDN and WDO patients.

Conclusion: Our results emphasize the significance of addressing late-onset complications during D-Pen therapy. Furthermore, this data gives an interesting insight into real-life dosing of chelators and thus might support physicians in future therapy.

Disclosure: This work has been funded by Univar Solutions B.V.

EPR-328 | Comparative study of focused ultrasound unilateral thalamotomy and subthalamotomy for tremor-dominant Parkinson disease

E. Natera-Villalba[1]; E. Natera-Villalba[4]; S. Paschen[2]; S. Paschen[4]; J. Pineda-Pardo[1]; M. del Álamo[1]; R. Rodríguez-Rojas[1]; G. Deuschl[1]; J. Obeso[1]; A. Helmers[3]; A. Helmers[5]; R. Martínez-Fernández[1]; R. Martínez-Fernández[5]

[1]Centro Integral de Neurociencias AC (CINAC), HM Universitario Puerta del Sur, Madrid, Spain; [2]Department of Neurology, University Hospital Schleswig-Holstein, Christian-Albrechts-University, Kiel, Germany; [3]Department of Neurosurgery, University Hospital Schleswig-Holstein, Christian-Albrechts-University, Kiel, Germany; [4]Share first co-author; [5]Share last co-author

Background and Aims: Focused ultrasound thalamotomy (FUS-Vim) is effective in treating Parkinson's disease (PD) tremor. FUS subthalamotomy (FUS-STN) improves PDcardinal features, including tremor.We aimed to compare efficacy in tremor control between FUS-Vim/FUS-STN in tremor-dominant PD (TDPD).

Methods: Retrospective, two-centre study. Medical-refractory TDPD-patients who underwent unilateral FUS-Vim/FUS-STN (2015–2022) were included. TDPD was defined by score = />2 for postural and/or resting tremor on treated-side (t.s.). Data regarding motor status (MDS-UPDRS-III), dopaminergic treatment (LEDD), adverse events were collected at baseline, 4- and12-month post-FUS.

Results: 63TDPD-patients included (23FUS-Vim,40FUS-STN).At baseline, FUS-Vim-patients were older (70.8 ±9.8y [vs.] 58.6 ±8.9y, $p < 0.001$), with equivalent disease progression (6.7 ±3.8y [vs.] 6.1 ±3.4y, $p = 0.525$), t.s.tremor severity (5.6 ±2.3 [vs.] 5.8 ±1.5, $p = 0.267$), total MDS-UPDRS-III (40.3 ±10.6 [vs.] 37.9 ±9.7, $p = 0.37$), and LEDD. (643.5 + 455.7 mg [vs.] 674.2 + 266.3 mg). FUS-STN-patients were more bradykinetic ($p < 0.001$), with more severe t.s. motor status (16.9 ±2.9 [vs.] 18.9 ±3.4, $p = 0.018$). Both groups presented significant improvement in t.s. tremor at 4 and12 month ($p < 0.001$ both, compared to baseline). Whereas benefit was equivalent at 4 months between groups ($p = 0.258$), FUS-Vim improved t.s. tremor less thanFUS-STN at12 months (mean-change 28.2 ±56.7% [vs.] 74.6 ±33.1%, $p < 0.001$), with tremor score in FUS-Vim higher than FUS-STN (3.3 ±2.7 [vs.] 1.5 ±1.8, $p = 0.008$). T.s. rigidity improved at 4 and12 months compared to baseline in both ($p < 0.001$all analyses) with no between-group differences at any timepoint. Improvement in t.s. bradykinesia was observed for both groups at12 months ($p = 0.006$, $p < 0.001$), with higher benefit for FUS-STN (mean-change 14.3 ±71.4% [vs.] 43.1 ±26.9%, $p = 0.025$). At 4 months, FUS-STN group LEDD was reduced compared to FUS-Vim-group ($p = 0.026$), not sustained at12 months ($p = 1.0$). Weight-gain, dyskinesias were more frequent post-FUS-STN ($p = 0.037$, $p = 0.004$); sensory disturbances occurred post-FUS-Vim ($p = 0.004$).Most were mild and resolved by12 months.

Conclusion: InTDPD patients, FUS-STN provides more sustained tremor control and better effect over bradykinesia than FUS-Vim. Adverse events between targets differ in nature but are mostly mild and transient.

Disclosure: Nothing to disclose.

EPR-329 | Advanced DBS programming strategies for unresponsive freezing of gait in real clinical practice

E. Sanesteban Beceiro[1]; V. Gómez Mayordomo[2]; C. Fernández García[3]; A. Fernández Revuelta[1]; E. López Valdés[1]; R. García-Ramos[1]; F. Alonso Frech[1]

[1]Movement Disorders Unit Neurology, Clínico San Carlos Hospital, Madrid, Spain; [2]Neurology Vithas Madrid La Milagrosa University Hospital, Vithas Hospital Group, Madrid, Spain; [3]Neurosurgery, Puerta de Hierro Hospital, Madrid, Spain

Background and Aims: Freezing of gait (FOG) unresponsive to both dopaminergic medication and conventional deep brain stimulation of the subthalamic nucleus (STN-DBS) represents one of the most disabling and unresolved problems of patients with advanced Parkinson's disease (PD). However, existing research indicates that the use of alternative stimulation strategies, such as the use of low-frequency STN-DBS and the stimulation of the substantia nigra pars reticulata (SNr) might provide either a transitory or sustained benefit.

Methods: A retrospective analysis of the real clinical practice in our center regarding the use, safety, and efficacy of two distinct advanced programming strategies for treating refractory FOG. Our treatment algorithm for refractory FOG consisted of two sequential steps: use of high-amplitude low-frequency STN-DBS and use of combined high-frequency STN-DBS with low-frequency SNr-DBS.

Results: 32 PD patients who had undergone bilateral STN-DBS between 2007 and 31 January 2020 (the start of the COVID-19 pandemic) and had developed FOG during this follow-up period were identified. 13 (40.6%) of them developed FOG refractory to conventional DBS. 12 of them were then treated with low-frequency DBS with 5 exhibiting clinical worsening, 3 a transitory (163 ±114 days ~5.4 months) and 4 a sustained improvement in FOG (2196 ±312 days ~6 years). Combined high-frequency STN-DBS with low-frequency SNr-DBS was used in 8 patients with uncontrolled FOG, 2 showed a transitory improvement (55.5 ±35.5 days) and 6 sustained improvements for the time being (690 ±424 days).
Conclusion: Low-frequency STN-DBS and combined high-frequency STN-DBS with low-frequency SNr-DBS seem to be helpful in some patients with refractory FOG.
Disclosure: Nothing to disclose.

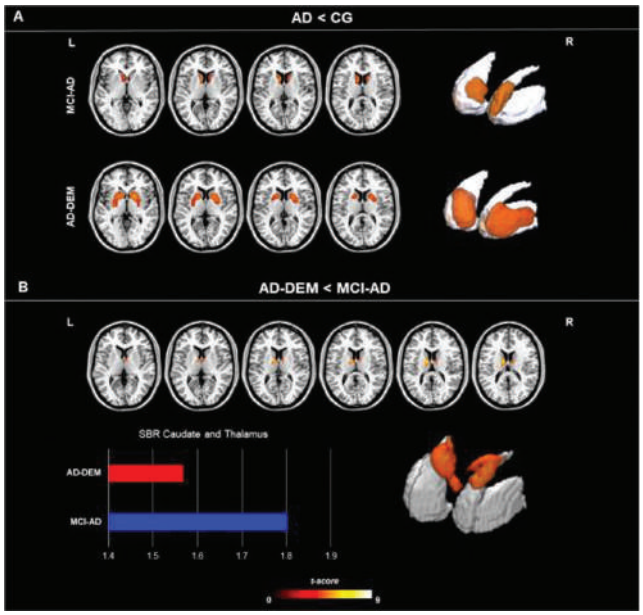
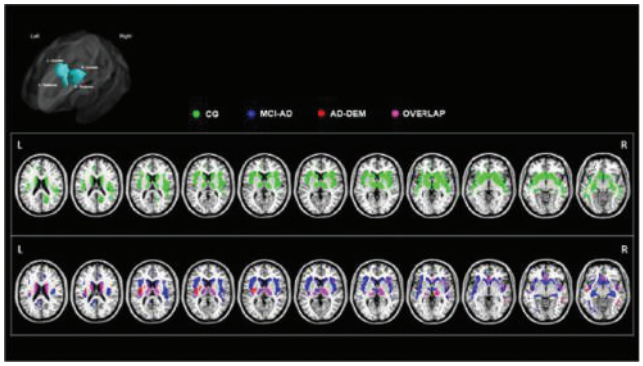
Background and Aims: Both post-mortem and in vivo data argue for dopamine dysfunction in patients with Alzheimer's disease (AD). However, the timing and regional progression of dopaminergic systems alterations in AD are still debated. Aim of the study was to investigate in vivo the pattern of dopaminergic changes and connectivity using DAT-SPECT imaging in patients across the AD spectrum.
Methods: Fifty-nine A+T+N+ AD patients ($n=21$ MCI-AD; $n=38$ AD-DEM) and $n=45$ age and sex-matched controls (CG) entered the study and underwent 123I-FP-CIT dopaminergic imaging. The occipital binding was used as reference region to obtain single-subject binding in different brain regions. Between-groups differences in 123I-FP-CIT binding in both mesolimbic and nigrostriatal dopaminergic pathways were assessed using an ANCOVA test-adjusting for the effect of center of imaging acquisition, age, and sex. Regions resulting from the voxel-wise direct comparison between MCI-AD and AD-DEM were considered as a seed of interest for a voxel-wise interregional correlation analysis.
Results: Both MCI-AD and AD-DEM patients showed dopaminergic depletion within the basal ganglia, whereas cortico-limbic regions (namely hippocampus, amygdala, anterior and middle cingulate, frontal cortex and thalamus) resulted impaired only in the dementia phase. The brain voxel-wise interregional correlation analysis showed a progressive pattern of disruption of caudate/thalamus dopaminergic connectivity to hippocampus and amygdala from MCI-AD to AD-DEM stages.



Voxel-wise 123I-FP-CIT binding differences between groups.



Seed-based connectivity results.
Conclusion: This study indicates basal ganglia dopaminergic alterations and connectivity disruption in the nigrostriatal and mesolimbic

systems already in early stage AD, extending to several cortico-limbic regions in dementia phases.

Disclosure: Nothing to disclose.

Background and Aims: In progressive supranuclear palsy (PSP), subcortical tau can be assessed with the tracer [18F]PI-2620 and cortical neurodegeneration can be measured using cerebral perfusion. Our aim was to examine the relationship of tau and neurodegeneration across PSP categories.

Methods: In progressive supranuclear palsy (PSP), subcortical tau can be assessed with the tracer [18F]PI-2620 and cortical neurodegeneration can be measured using cerebral perfusion. Our aim was to examine the relationship of tau and neurodegeneration across PSP categories.

Results: We found no significant correlation between individual expression of the respective patterns (tau vs. hypoperfusion) across the group (Figure 1B). However, hypoperfusion in prefrontal clusters was associated with tau deposition in all patients ($r = -0.34$, $p = 0.02$) (Figure 1C) and stronger in PSP-RS ($r = -0.63$, $p = 0.005$) (Figure 1D). The multiple regression analysis revealed that tau in GPI was associated with hypoperfusion in the left frontal pole in the complete group and in the left superior frontal gyrus in the PSP-RS group ($p < 0.001$ uncorrected).

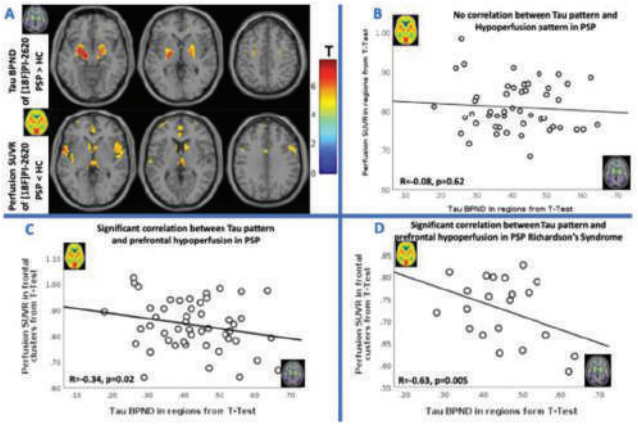

FIGURE 1: The association between pathological tau binding and cerebral hypoperfusion in PSP: A: Two-sample *t*-tests for tau binding potential (upper row) and perfusion SUVR (lower row) between patients and controls for the complete group. Contrasts: Tau.

Conclusion: Subcortical tau is associated with prefrontal hypoperfusion, indicating a restricted remote connection between tau and neurodegeneration. Longitudinal studies are needed to examine whether neurodegeneration follows protein depositions like in Alzheimer's disease or whether neuronal dysfunction occurs in parallel or before tau depositions.

EPR-334 | High-dimensional cellular profiling of actively remyelinating lesions in multiple sclerosis

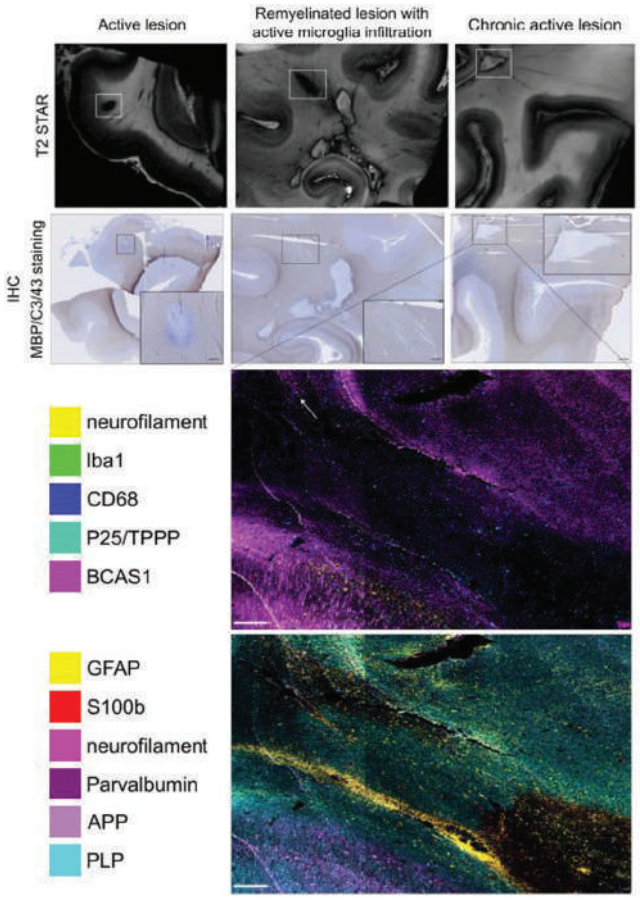
I. Callegari[1]; E. Giacomelli[1]; E. Bartoszek-Kandler[2]; R. Galbusera[1]; D. Gkotsoulias[1]; E. Bahn[3]; M. Ocampo-Pineda[1]; P. Lu[1]; A. Cagol[4]; J. Leupold[5]; B. Dhital[1]; M. Weigel[1]; D. von Elverfeldt[5]; V. Kiselev[5]; C. Stadelmann[3]; C. Granziera[1]

[1]Translational Imaging in Neurology (ThINk) Basel, Department of Biomedical Engineering, Department of Neurology and Research Center for Clinical Neuroimmunology and Neuroscience Basel (RC2NB), University Hospital Basel and University of Basel, Basel, Swit; [2]Department of Biomedicine, Microscopy Core Facility, University of Basel, Switzerland; [3]Institute of Neuropathology, University Medical Center, Göttingen, Germany; [4]Department of Health Sciences, University of Genova, Genova, Italy; [5]Division of Medical Physics, Department of Diagnostic and Interventional Radiology, University Medical Center Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany

Background and Aims: We have previously shown that lesions hyperintense in quantitative susceptibility mapping (QSM) are pathologically either chronic inactive or actively remyelinating. The molecular characteristics of QSM hyperintense lesions are unknown to date.

Methods: In this project we aim at disentangling the structural and cellular composition of QSM hyperintense lesions, by 9.4T qMRI in postmortem brains, and by multiplex imaging mass cytometry (IMC). Based on QSM maps obtained at 3T, blocks containing lesions of interest were acquired with a Bruker ex vivo MRI scanner at 9.4 Tesla, and the resulting MRI measures integrated in the Multi-Omics Factor Analysis v2 statistical framework. Immunohistochemistry for MBP and CR3/43 was used for lesion classification, and the same blocks were next interrogated by IMC to understand the local cellular composition at a high-dimensional level.

Results: We studied 4 individual lesions from 3 blocks of 2 brains. We observed an increased percentage of GFAP+, S100b+ astrocytes in the demyelinated lesion core when compared to the perilesional area. Axonal content was diminished in actively remyelinating lesions. HLA-DR and CD68+ cells correlated with FLASH with TE = 3.8 ms, TI = 270 ms, TR = 1500 ms sequence intensity, suggesting that these sequences are sensitive to the myeloid inflammatory process, while T2* map MGE sequences with TI = 150 ms captured CD68neg high cellularity, suggesting that other cell types might explain this contrast.



Immunohistochemical and IMC correlate of 9.4T MRI T2 star.

Conclusion: These are preliminary results from a newly developed post-mortem high-dimensional imaging approach. We are currently expanding the single-cell profiling towards immune, astrocyte and remyelination markers.

Disclosure: Nothing.

EPR-335 | Functional MRI neurofeedback on functional connectivity and metabolic profiles in patients with visual snow syndrome

L. Michels[1]; P. Stämpfli[2]; K. Weber[3]; R. Schöpfer[1]; R. Mazloum[1]; M. Rosio[1]; L. Disse[3]; N. Zoelch[2]; C. Schankin[4]; F. Fierz[3]

[1]Department of Neuroradiology, University Hospital Zurich, Zurich, Switzerland; [2]Department of Psychiatry, Psychotherapy and Psychosomatics, Psychiatric Hospital, University of Zürich, Zürich, Switzerland; [3]Department of Neurology, University Hospital Zurich, Zurich, Switzerland; [4]Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland

Background and Aims: Visual snow syndrome (VSS) is a burdensome condition with persistent spurious visual phenomena. Neuronally, VSS patients show altered neuronal excitability, increased grey matter volume and functional hyperconnectivity (FC). In this double-blind, placebo-controlled randomized study, we tested if real-time

functional MRI neurofeedback (NFB) will allow patients to downregulate their lingual gyrus activity (outcome), whether this correlates with changes in FC and glutamate level, and a decrease of VSS symptoms.

Methods: In 20 patients with VSS ($\mu = 31.2$ years, 13 male, migraine $n = 9$) and 20 healthy controls. MRI was performed before and acutely after two days of NFB (lingual gyrus [$n = 10$] or gyrus rectus ([$n = 10$] sham region]).

Results: Pre-NFB hyperconnectivity was seen in patients. Five of ten patients downregulated the lingual gyrus. Hyperconnectivity was seen in the sham versus real group after NFB. Higher Puledda scores were related to higher FC. Glutamate levels were lower after NFB in the real group. Regulation success was stronger in patients with a longer persistence of visual snow and higher VSS scores. No improvement in the VSS scores across both groups and within the real NFB group—comparing pre versus post-NFB time points—was found.

Conclusion: Our results indicate that lingual gyrus based NFB minimizes hyperconnectivity and excitability. Although some severely affected patients regulated the lingual gyrus, no improvement in clinical scores was seen. Larger trials (possibly with a more extensive NFB training) are required to judge the value of lingual gyrus based NFB on VSS.

Disclosure: Nothing to disclose.

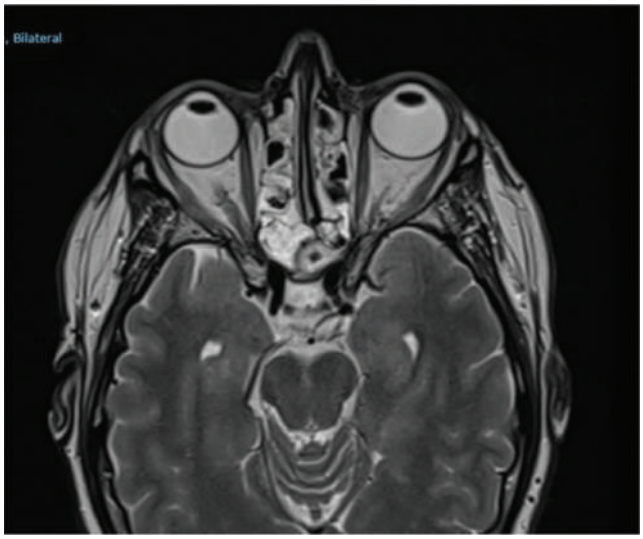
EPR-336 | Rare neurovascular compression syndromes of the brainstem: Beyond trigeminal neuralgia

L. Carazo Barrios; P. Gil Armada; J. Quiles López; V. González Torres
Servicio de Neurología, Complejo Hospitalario de Jaén, España

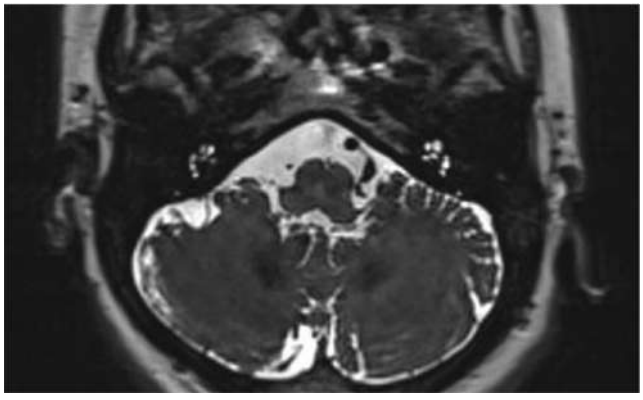
Background and Aims: Neurovascular compression syndromes (NCS) are characterized by the compression of a cranial nerve by an artery. The most common are trigeminal neuralgia and hemifacial spasm, but there are reported cases of rare NCS: glossopharyngeal neuralgia, diplopia due to oculomotor nerve (OMN) compression or vestibular paroxysmia. Magnetic Resonance Imaging (MRI) is a fundamental diagnostic tool. We present a series of 5 cases of rare NCS.

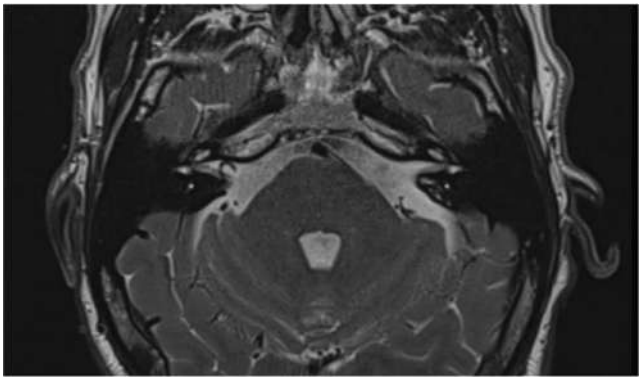
Methods: Case series of 4 males and 1 female, aged between 53 and 70 years old. Two cases of diplopia caused by the compression of the OMN by an aberrant posterior cerebral artery (PCA) and the paraophthalmic internal carotid artery (ICA), two cases of vestibular paroxysmia caused by the compression of the right vestibulocochlear nerve by the inferior cerebellar artery (ICbA) and the anterior inferior cerebellar artery (ICA), and one case of glossopharyngeal neuralgia caused by the compression of the left glossopharyngeal nerve by the posterior inferior cerebellar artery (PICA). See images.

Magnetic resonance imaging (MRI), axial view. Left posterior cerebral artery is aberrant and contacts with the left oculomotor nerve.



Magnetic resonance imaging (MRI), axial view, FIESTA sequence. Right posterior inferior cerebellar artery is in contact and displaces the root zone of the glosopharyngeal nerve.





Magnetic resonance imaging (MRI), axial view. Compression of the right vestibulocochlear nerve by the inferior cerebellar artery (ICbA) that forms a loop and penetrates in the internal auditory canal.

Results: The series presented shows a varied clinical picture of rare NCS. The physiopathology is unclear but could be shared with more frequent NCS like trigeminal neuralgia: vascular compression, demyelination, nucleus excitability and nerve modeling. Clinical characterization of rare NCS allows for early suspicion and optimal use of MRI technique to achieve early diagnosis.

Conclusion: NCS are infrequent disorders with heterogeneous clinical presentations. The mechanisms explaining why certain neurovascular conflicts cause NCS and others are clinically silent are unclear, therefore precise individualized management is lacking. Further clinical descriptions and management oriented research is needed.

Disclosure: Nothing to disclose.

EPR-337 | Brain functional connectivity and cortical neurotransmitter receptor distribution associated to psychotic symptoms in AD

M. Zavarella[1]; S. Basaia[2]; E. Canu[2]; G. Rugarli[1]; G. Cecchetti[3]; E. Spinelli[1]; F. Caso[4]; G. Magnani[4]; M. Filippi[5]; F. Agosta[1]

[1]*Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy;* [2]*Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [3]*Neurophysiology Service, Neurology Unit, and Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute Milan, Italy;* [4]*Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [5]*Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy*

Background and Aims: This study aims to explore resting state functional connectivity (RS-FC) of the CN subregions in AD with (ADps) and without (ADnops) psychotic symptoms, with a focus on the relationship between RS-FC changes and cortical neurotransmitter receptor distribution.

Methods: 68 AD patients underwent clinical and neuropsychological assessment, and MRI. Group was divided in 15 patients with untreated psychotic symptoms (ADps) and 53 ADnops. 53 age-matched controls were also selected. Seed-based RS-FC analysis was performed using CN subregions: dorsal caudate nucleus (dCN), ventral-superior CN (vsCN), and ventral-inferior CN (viCN). In patients, connectivity changes were correlated with neuropsychological performances. Spatial correlations between RS-FC changes and atlas-based nuclear imaging-derived neurotransmitter maps were investigated using JuSpace-toolbox.

Results: Both AD groups showed increased connectivity between each CN-subregions and sensorimotor areas. In both, increased dCN connectivity with sensorimotor regions negatively correlated with memory, visuospatial, and praxis performances. ADps had peculiar reduced RS-FC between dCN and right superior frontal gyrus, vsCN with dorsal and anterior cingulate gyrus bilaterally, and viCN with bilateral inferior temporal gyrus. ADnops had reduced connectivity between dCN and vsCN separately, and right operculum, and between viCN and right supracalcarine area. Regarding CN-subregions connectivity, ADps showed relationship with mu-opioid receptor, glutamate-Receptor-5, and 5HT1a distribution.

Conclusion: This study sheds light on the relevance of understanding CN connectivity and its relationship with psychotic symptoms in AD. The specific relationship between RS-FC of CN subregions and cortical neurotransmitter receptor distribution is relevant therapeutic management implications. Funding. Foundation Research on Alzheimer Disease.

EPR-338 | Brain and spinal cord MRI correlates of motor impairment and vibratory sensation in patients with multiple sclerosis

T. Morozumi[1]; P. Preziosa[2]; A. Meani[1]; G. Pessina[1]; M. Azzimonti[2]; M. Rocca[2]; M. Filippi[3]

[1]*Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [2]*Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy;* [3]*Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy*

Background and Aims: Cervical spinal cord (cSC) focal lesions and volume loss significantly contribute to multiple sclerosis (MS) clinical disability, but their association with specific motor-sensory dysfunction requires further exploration. This study aimed to identify MRI

features of cSC damage associated with increased clinical disability and motor-sensory impairment in MS patients.

Methods: One hundred fifty-one MS patients and 69 age- and sex-matched healthy controls (HC) underwent brain and cSC 3T MRI acquisition and a comprehensive clinical assessment including Expanded Disability Status Scale (EDSS) score, 9-hole peg test (9-HPT), finger tapping test (FTT), timed 25-foot walk test (T25FWT), and vibration detection threshold (VDT). Random forest analyses assessed the predictive value of cSC MRI measures (T2-hyperintense lesion volume [T2-LV], total, grey matter [GM], and white matter [WM] cross-sectional areas [CSA] at C2–C3 level) for EDSS milestones (EDSS ≥ 3.0, 4.0 and 6.0), impaired pyramidal and sensory functional systems (P-FS and S-FS ≥ 2), as well as specific motor and sensory tests.

Results: Various combinations of brain and cSC MRI measures were informative predictors of EDSS milestones (out-of-bag [OOB]-area under the curve [AUC] = 0.879–0.900), VDT (OOB-R^2 = 0.194), and impairment at P-FS (OOB-AUC = 0.820), S-FS (OOB-AUC = 0.795), 9-HPT (OOB-AUC = 0.793), FTT (OOB-AUC = 0.740), and T25FWT (OOB-AUC = 0.825). Notably, cSC GM CSA emerged as the most relevant predictor for most outcomes, except for 9-HPT, where cSC T2-LV demonstrated superior predictive value.

Conclusion: A multiparametric approach including both brain and cSC MRI measures may explain clinical disability in MS with high accuracy. Specifically, cSC GM atrophy represents an impactful pathological substrate contributing to motor-sensory impairment.

EPR-339 | Pattern of cortical BOLD responses in visually induced motion aftereffects (MAE)

S. Becker-Bense[1]; R. Boegle[1,2]; F. Reichl[1]; L. Fabritius[1,2]; M. Dieterich[1,3,4]

[1]German Center for Vertigo and Balance Disorders, University Hospital, LMU Munich, Germany; [2]Department of Neurology, University Hospital, LMU Munich, Germany; [3]Clinical Neuroscience, University of Munich, Germany; [4]Munich Cluster of Systems Neurology (SyNergy), Munich, Germany

Background and Aims: The motion aftereffect (MAE) is a phenomenon of illusory self-motion perception following the end of unidirectional coherent visual motion stimulation. It is attributed to adaptation of neurons and/or mechanisms especially in the temporo-occipital movement-sensitive visual area V5/MT+ causing an inability to promptly react to changed visual input. Aim of our study was to decipher further brain areas involved in MAE processing and their interplay with the vestibular cortical network.

Methods: Twenty-two healthy volunteers underwent 3T fMRI while watching visual motion stimuli (translational, rotational or random direction) as well as static dots, and indicated the end of perceived MAE via button press. Standardized fMRI data preprocessing was performed (SPM12) including group independent component analysis for visual, vestibular and salience network areas with respect to the visual motion and the "pure" MAE period.

Results: All subjects perceived significant MAE after coherent but not after random motion stimulation. BOLD responses in V1 showed none, whereas those in MT+ and salience network areas marked relation to MAE for rotational more than translational stimuli. BOLD responses in the vestibular posterior insula were downregulated bilaterally (rotational > translational) during visual motion stimulation relative to those during random dot and during MAE.

Conclusion: MAE is processed in motion sensitive (MT+) and attention-related areas (salience network), but not in primary visual area V1. Coherent visual motion stimulation, however, induces bilateral downregulation of the vestibular core area in the posterior insula, probably in order to early minimize the intersensory visual-vestibular conflict even so during MAE.

EPR-340 | Trends in incidence and prevalence of multiple sclerosis through five decades in Finland

A. Maunula[1]; M. Sumelahti[2]; M. Viitala[3]; M. Soilu-Hänninen[4]; S. Laakso[5]; S. Atula[6]

[1]Translational Immunology Research Program, University of Helsinki, Helsinki, Finland; HUS Neurocenter, Department of Neurology, Hyvinkää Hospital, Hyvinkää, Finland; [2]Tampere University, Finland, Faculty of Medicine and Healthtechnology; Terveystalo Tampere; [3]Stellar Q Ltd; [4]Clinical Neurosciences, University of Turku, Turku, Finland; Neurocenter, Turku University Hospital, Turku, Finland; [5]Translational Immunology Research Program, University of Helsinki, Helsinki, Finland; Neurocenter, Helsinki University Hospital, Helsinki, Finland; [6]Neurocenter, Helsinki University Hospital, Helsinki, Finland; Department of Clinical Neurosciences, University of Helsinki, Helsinki, Finland

Background and Aims: Impact of the evolution of the diagnostic criteria for multiple sclerosis (MS) on the incidence and prevalence rates of MS in the Nordic countries has, to our knowledge, not been investigated. Our objective is to assess the nationwide MS incidence and prevalence rates in Finland from 1974 to 2021.

Methods: MS patients were identified through the National MS registry and a national social- and healthcare reporting system with ICD-10/ICD-9 codes G35/340. Patients were divided into four subgroups based on the year of MS diagnosis: (1) Time before Poser criteria (1974–1982) (2) Poser criteria (1983–2000) (3) Earlier McDonald criteria (2001–2016) (4) 2017 McDonald criteria (2017–2021) Age-adjusted Incidence and prevalence were calculated per 105 person years with 95% confidence intervals (95% CI).

Results: We observed a significant increase in MS incidence and prevalence during the study period. Over the two periods of McDonald criteria incidence remained stable (9.1 and 8.2; Figure 1) but prevalence increased significantly from 218 (95% CI 214,222) to 241 (95% CI 237,245; Figure 2). Mean age at diagnosis showed no difference, but it was higher among men (Table 1).

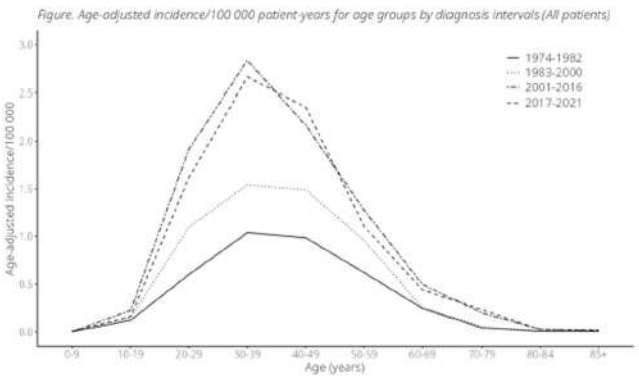

FIGURE 1: Age-adjusted incidence per 105 personyears in different age groups by diagnosis intervals. Age-adjusted incidence increased significantly during the study period, but over the two periods of McDonald criteria incidence remained stable.

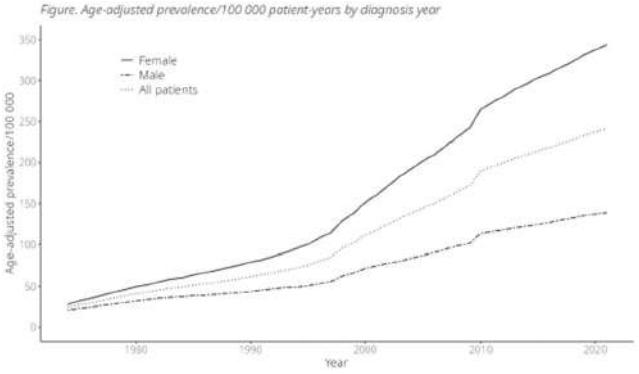

FIGURE 2: Age-adjusted prevalence per 105 person-years by diagnosis year. Age-adjusted incidence increased during the whole study period. Data on prevalence were collected in the years 1974, 2000, 2016 and 2021.

TABLE 1

Table 1. Demographic information and incidence rates per 10 personyears with 95% confidence intervals

	Time before Poser criteria (1974-1982) (n=1558)	Poser criteria (1983-2000) (n=5183)	Earlier McDonald revisions (2001-2016) (n=7758)	Newest McDonald criteria (2017-2021) (n=2276)
Sex (Females); n (%)	955 (61.3 %)	3500 (67.5 %)	5487 (70.7 %)	1581 (69.5 %)
Age at MS diagnosis (years); Mean (SD)	39.5 (12.9)	39.8 (12.1)	39.7 (13.1)	40.6 (13.4)
Females	39.4 (13.0)	39.7 (12.0)	39.4 (13.0)	39.7 (13.0)
Males	39.7 (12.9)	40.0 (12.2)	40.7 (13.2)	42.6 (13.9)
Age-adjusted incidence rate per 10^5 person years (CI)	3.7 (3.5, 3.8)	5.6 (5.4, 5.7)	9.2 (8.9, 9.4)	8.6 (8.3, 9.0)
Females (CI)	4.4 (4.1, 4.7)	7.5 (7.3, 7.8)	13.1 (12.7, 13.4)	12.2 (11.6, 12.8)
Males (CI)	2.9 (2.7, 3.1)	3.6 (3.4, 3.8)	5.3 (5.1, 5.6)	5.2 (4.8, 5.6)
Age-adjusted prevalence rate per 10^5 person years (CI)*	24.3 (22.8, 25.8)	111.4 (108.6, 114.2)	218.0 (214.1, 222.0)	241.3 (237.2, 245.4)
Females (CI)*	27.9 (25.7, 30.1)	151.2 (146.6, 155.8)	308.9 (302.3, 315.5)	343.8 (336.9, 350.7)
Males (CI)*	20.7 (18.7, 22.7)	71.8 (68.6, 74.9)	126.9 (122.6, 131.2)	138.8 (134.4, 143.2)

Footnote to Table 1. *Data on prevalence was collected in the years 1974, 2000, 2016 and 2021

Conclusion: The increasing incidence during the 20th century is most likely due to changes in diagnostic criteria and in the development of magnetic resonance imaging (MRI) technique in the diagnostic set up. The most sensitive diagnostic criteria in 2017 did not further increase the incidence, suggesting also good specificity. Increased prevalence is thought to be the result of increased survival combined with increasing incidence.

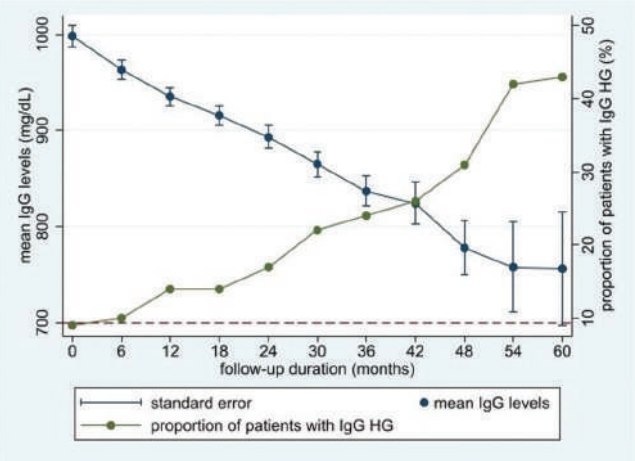
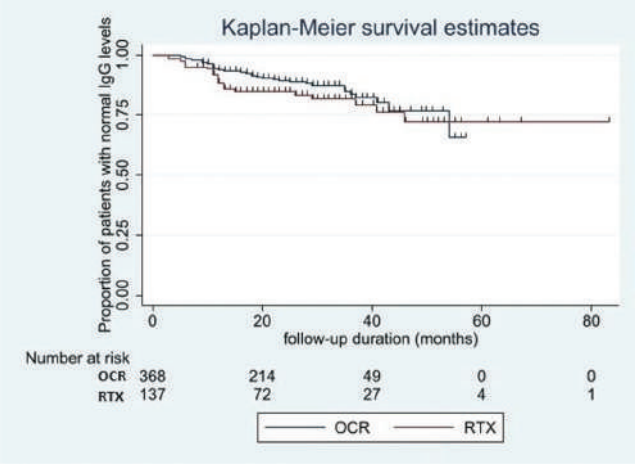
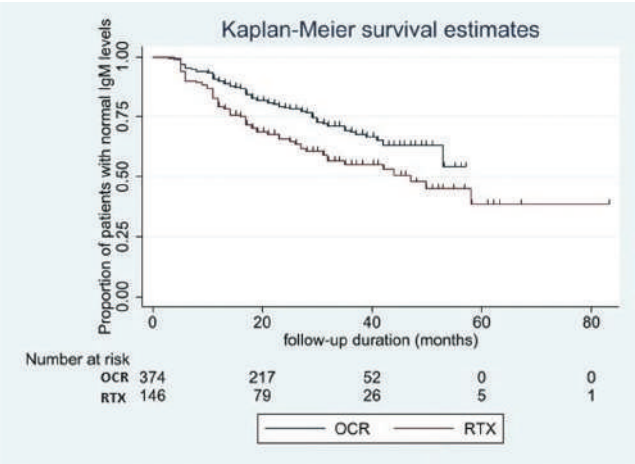
Background and Aims: Hypogammaglobulinemia (HG) is a known side effect of treatment with anti-CD20 monoclonal antibodies, and it is associated with the risk of infections. Aim of this retrospective multicentre study was to assess the frequency of HG in Multiple Sclerosis (MS) and Neuromyelitis Optica Spectrum Disease patients treated with ocrelizumab (OCR) or rituximab (RTX) and its association with the occurrence of infections requiring hospitalization (SI).
Methods: We included 556 patients (190M, 366F) treated for at least one year with either OCR or RTX.
Results: The mean age was 47 years and mean follow-up of 28 months. IgG HG occurred in 20% and IgM HG in 34% of patients. The risk of IgG HG was influenced by an older age (≥50 years) (OR 1.67, 95% CI: 1.08–2.61, $p=0.022$), previous immunosuppressive therapy (OR 1.60, 95% CI: 1.04–2.48, $p=0.033$) and by the number of treatment cycles (OR: 1.19, 95% CI: 1.08–1.31, $p=0.004$). A total of 25 SI occurred (100 person-years rate: 1.8), with a disease phenotype other than relapsing-remitting (OR 1.50, 95% CI: 1.02–2.20; $p=0.039$) and IgG HG (OR 2.65, 95% CI: 1.15–6.12; $p=0.022$) increasing its risk.



Mean IgG levels over time and proportion of patients with IgG HG.



Time to IgG HG, Log-rank: $p=0.170$.



Time to IgM HG, Log rank: $p=0.002$.

Conclusion: IgG and IgM HG occurred in a considerable proportion of patients. IgG HG increased the risk of SI, which were, nevertheless,

relatively infrequent. Our results highlight the importance of monitoring immunoglobulin levels to personalize treatment strategies.

EPR-342 | Relationship between CSF-GFAP and disease burden measures in newly diagnosed MS patients: Impact of age on association

D. Hrych[1]; H. Khouri[1]; G. Kazemi[1]; L. Noskova[2]; J. Motyl[1]; V. Ravano[3]; L. Friedova[1]; J. Krasensky[4]; L. Fialova[2]; T. Kober[3]; M. Andelova[1]; E. Kubala Havrdova[1]; B. Marechal[3]; D. Horakova[1]; M. Vaneckova[4]; T. Uher[1]

[1]Department of Neurology and Center of Clinical Neuroscience, Charles University in Prague, 1st Faculty of Medicine and General University Hospital, Prague, Czechia; [2]Institute of Medical Biochemistry and Laboratory Diagnostics, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czechia; [3]Advanced Clinical Imaging Technology, Siemens Healthineers International AG, Lausanne, Switzerland; [4]Department of Radiology, Charles University in Prague, First Faculty of Medicine and General University Hospital in Prague, Czechia

Background and Aims: Association between astrocytic pathology and disease activity in multiple sclerosis (MS) patients remains to be elucidated.

Methods: We included 70 treatment naive patients with newly diagnosed MS. Glial fibrillary acidic protein in cerebro-spinal fluid (CSF-GFAP) levels were measured using ELISA. All patients were scanned on a single 3T scanner. Spearman correlation and adjusted linear regression were used to analyse associations between CSF-GFAP and disease activity.

Results: Median of age was 32.8 years, median of Expanded Disability Status Scale (EDSS) score was 2.0 and median of CSF-GFAP was 0.62 ng/mL; 72.9% of patients were females. Higher levels of CSF-GFAP were associated with higher: age ($\rho = 0.40$; $p = 0.001$), T2 lesion volume ($\rho = 0.34$; $p = 0.004$), T2 lesion number ($\rho = 0.24$; $p = 0.043$), but lower normalized whole-brain volume ($\rho = -0.29$; $p = 0.015$). Linear regression analyses adjusted for age did not confirm these results. Similarly, higher levels of CSF-GFAP were associated with lower scores in: Symbol Digit Modalities Test (SDMT) ($\rho = -0.32$; $p = 0.013$; $n = 58$), Paced Auditory Serial Addition Test-3s (PASAT-3s) ($\rho = -0.37$; $p = 0.014$; $n = 53$), and Brief Visuospatial Memory Test (BVMTR) ($\rho = -0.36$; $p = 0.007$; $n = 57$), but not California Verbal Learning Test-II (CVLT2). Except from BVMTR ($B = -0.08$; $p = 0.041$), the significance of these associations was no longer observed in linear regression adjusted for age, depression, and time between psychological and biochemical measures. We did not find association between CSF-GFAP and EDSS.

Conclusion: Age plays a crucial role in the relationship between CSF-GFAP, imaging, and cognitive measures, therefore needs to be considered as an important confounder of CSF-GFAP levels.

Background and Aims: Alemtuzumab (ALEM) is an anti-CD52 monoclonal antibody approved for the treatment of Multiple Sclerosis (MS) which showed high efficacy also in the subgroup of highly active patients (pts). We aimed to evaluate efficacy/safety profile of ALEM-treatment in a population of aggressive MS naïve-pts.

Methods: We conducted a multicenter prospective observational study in a cohort of aggressive naïve-pts treated with ALEM in 29 Italian MS Centers, enrolled from October 2015 to February 2019 and followed up until December 2023.

Results: 138 naïve-pts with a mean FU of 78.1 months (SD 12.2) were included. Baseline characteristics are shown in Figure 1. Efficacy data were analyzed starting from the end of a complete therapeutic cycle (year 1 and year2) since the presence of disease activity between the two administrations is not indicative of a therapeutic failure. At 5 years, 50% of pts were NEDA-3 (Figure 2). A multivariate analysis showed that disability progression had a significative correlation with the higher age at disease onset and higher number of T2 spinal cord lesions. 10.9% of pts needed a third cycle of therapy and 31.9% of pts switched to another DMTs. Adverse events were reported in Figure 3.

Figure 1. Baseline disease characteristics

Baseline disease characteristics (138 pts)	
Sex	61,6% F
Mean age at disease onset	30,5 years (SD 8,7)
Mean age at ALEM start	32,1 years (SD 9,1)
Mean disease duration at ALEM start	19,4 months (SD 25,6)
Mean baseline EDSS	2,7 (SD 1,2)
ARR in the last year before ALEM treatment	1,81 (SD 0,94)
Mean n° of T2 lesions at MRI at disease onset	23,5 (SD 22,3)
Mean n° of gd+ lesions at MRI disease onset	4,5 (SD 5,9)
Mean n° of New T2 lesions on baseline MRI	2,81 (SD 4,86)
Mean n° of Gd+ enhancing lesions on baseline MRI	3,41 (SD 5,07)
Mean n° T2 spinal cord lesions	4,82 (SD 3)

FIGURE 1

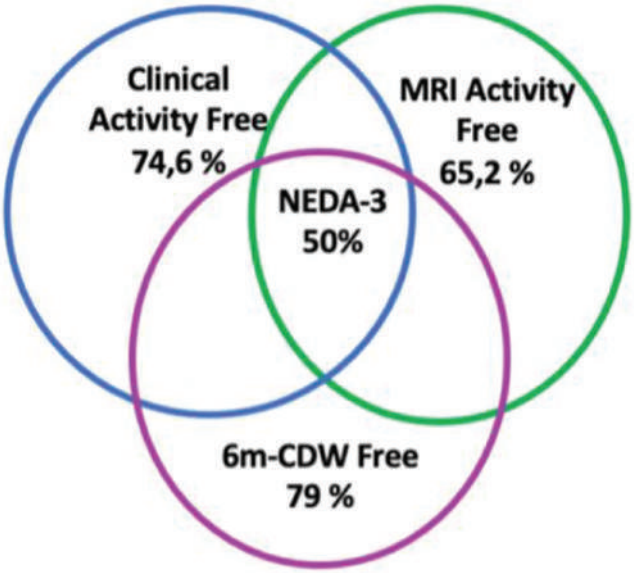

FIGURE 2

Figure 3. Adverse events

Adverse Events of special interest (138 pts)		
Thyroiditis	38 pts, 27,5 %	vs 40 % in CT
Nephropathies	0 pts	
Thrombotic thrombocytopenic purpura	1 pts 0,72%	vs 3% in CT
Infections of special interest	13 pts 9,4 %	
Neoplasia	1 pt 0,72% (death for breast cancer)	
Cardiovascular and pulmonary events	0 pts	
HPV	1 pt 0,72%	
Others autoimmune	2 pts 1,4 %	

FIGURE 3

Conclusion: These results showed that ALEM is highly effective in this population and highlighted that aggressive naïve-pts are ideal candidates for immune system resetting, likely due to young age, short disease duration and low disability. Furthermore, absence of previous immunomodulating/immunosuppressant drugs altering the immune system play a key role in determining effectiveness of this powerful drug. Larger studies are needed to confirm our data.

EPR-344 | Switch from fingolimod to ozanimod for safety or intolerance reasons

E. Signoriello[1]; G. Romano[1]; M. Foschi[2]; A. zanghi[3]; E. D'Amico[3]; R. Fantozzi[4]; D. Centonze[5]; G. Lus[1]

[1]*University of Campania Luigi Vanvitelli;* [2]*University of l'Aquila;* [3]*University of Foggia;* [4]*Neuromed Institute;* [5]*University Tor Vergata, Rome*

Background and Aims: ozanimod is a new generation of sphingosine 1-phosphate (S1P) treatment approved for Multiple Sclerosis (MS) with higher selectivity on S1PR1 and S1PR5, minimizing potential safety concerns around S1P3 receptor activation compared with fingolimod. The objective of the study is to compare the adherence and persistence on treatment in MS patients switched to ozanimod from fingolimod for lymphopenia or liver enzymes increase.

Methods: we retrospectively recruited patients treated with fingolimod that switched to ozanimod for safety reason with at least 12 months of follow-up. We collected demographic, clinical, biochemistry and safety data during fingolimod and after the switch to ozanimod to evaluate the lymphopenia and hypertransaminasemia on fingolimod and ozanimod in order to evaluate the persistence over six months after switch on ozanimod treatment and percentage of NADE (no adverse events) patients during ozanimod.

Results: we recruited 50 RR-MS patients with mean age 42.8 ± 10.21 treated with fingolimod for a mean of 5.6 ys who switched to ozanimod for lymphopenia (85.7%) or hypertransaminasemia (14.2%); 48/50 (96%) of patients persisted on treatment with ozanimod after switch for a mean of 1.2 ys (SD 0.37); we observed a reduction of mean lymphopenia from 0.48 to 0.61 ($p = 0.013$) in all population and reduction of lymphopenic patients from 85.7% on fingolimod to 5% on ozanimod; patients with hypertransaminasemia were 14.2% with fingolimod and 8% on ozanimod disease. Percentage of NADE patients on ozanimod were 82.8%.

Conclusion: Switching from fingolimod to ozanimod might be a good strategy in patients who experienced lymphopenia or hypertransaminasemia during fingolimod therapy.

Disclosure: Nothing to disclose.

EPR-345 | Long term effectiveness and safety of ocrelizumab in multiple sclerosis: A single centre real-world study

L. Moiola; T. Zaccone; S. Guerrieri; I. Gattuso; C. Zanetta; V. Viti; A. Genchi; F. Esposito; A. Nozzolillo; M. Rocca; M. Filippi

[1]*Neurology Department – IRCCS San Raffaele Hospital, Milan, Italy*

Background and Aims: Literature is poor of long-term studies about efficacy and tolerability of ocrelizumab and most data come from open-label extensions of randomized controlled trials and early results from real-world studies. This observational single-centre study aimed to evaluate long-term effectiveness and safety of ocrelizumab treatment in a real-life clinical setting.

Methods: We retrospectively collected data from 244 patients with relapsing multiple sclerosis (RMS) and 71 with primary progressive MS (PPMS) treated with ocrelizumab for at least one year at the MS Centre of San Raffaele Hospital (Milan) up to 31 August 2023.

Results: Patients were followed-up for a mean of 3.95 years (range 1.08–6.82). Ocrelizumab led to a significant reduction in clinical and radiological activity in both RMS and PMS patients; significant Expanded Disability Status Scale (EDSS) worsening despite treatment occurred in PPMS patients. Older age, longer disease duration and higher EDSS at baseline were associated with progression in RMS patients; in PPMS baseline EDSS was instead the only significantly predictor of disability progression. Adverse event profile was consistent with that reported in clinical trials, with hypogammaglobulinemia and recurrent infections being the most frequent. A total of 20 pregnancies occurred in our cohort with outcomes reflecting epidemiology in the general population.

TABLE 1: Clinical and radiological activity before and after ocrelizumab (OCR) treatment.

Table 1. Clinical and radiological activity before and after ocrelizumab (OCR) treatment

		Previous year	During OCR treatment	p-value
Annualized relapse rate (ARR) (mean, 95% CI)	RMS (n=244)	0.41 (0.362 – 0.458)	0.02 (0.008 – 0.025)	<0,001
	PPMS (n=71)	0.07 (0 – 0.160)	0 (0 – 0.016)	0,001
MRI activity (n. patients, 95% CI)	RMS (n=244)	133 (54.5%) (48.2 – 60.8)	50 (20.5%) (15.4 – 25.6)	<0,001
	PPMS (n=69)*	38 (55.1%) (43.0 – 67.1)	16 (23.2%) (13.0 – 33.4)	<0,001

*2 pts without data

TABLE 2: Comparison of OCR effectiveness outcomes between RMS and PPMS groups.

Table 2. Comparison of OCR effectiveness outcomes between RMS and PPMS groups

	RMS (n=244)	PPMS (n=71)	p-value
ARR during the whole follow-up (mean, 95% CI)	0.02 (0.008 – 0.025)	0 (0 – 0.016)	0,074
MRI activity during OCR treatment (% patients, 95% CI)	20.5% (15.4 – 25.6)	22.5% (13.0 – 32.1)	0,710
6 month Confirmed Disability Progression (CDP) Since OCR start to last infusion (% patients, 95% CI)	13.9% (9.1 – 18.8)	46.5% (37.4 – 55.5)	**<0,001**
6 month-Confirmed Disability Improvement (CDI) Since OCR start to last infusion (% patients, 95% CI)	18.2% (13.0 – 23.4)	4.2% (0 – 12.4)	**0,005**
NEDA-3 during the whole follow-up (% patients, 95% CI)	65.2% (59.2 – 71.2)	33.8% (22.7 – 44.9)	**<0,001**

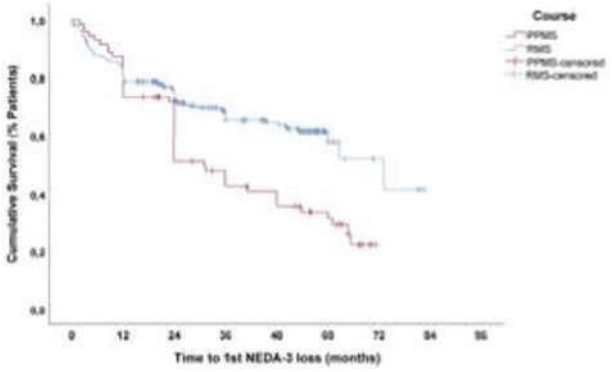

FIGURE 1: Time to loss of NEDA-3 (RMS and PPMS patients).

Conclusion: Ocrelizumab showed a high and long-lasting efficacy on inflammatory disease activity, with greater impact on RMS patients and a favourable safety profile. Treatment start in the early phases of the disease may enhance neuroprotection preventing irreversible disability accumulation.

EPR-346 | The MTHFR A1298C polymorphism is associated with multiple sclerosis severity

G. Abbadessa[1]; S. Bonavita[2]; O. Owain William Howell[3]; M. Ponzano[4]; G. Miele[2]; B. Cooze[3]; A. Signori[4]; M. Risi[1]; R. Magliozzi[5]; E. Maida[2]; I. Farkas[1]; F. Bile[2]; Y. Leung[1]; E. Signoriello[2]; P. Sivrastava[6]; A. Bisecco[2]; E. Nicholas[1]; G. Lus[2]; D. Ridsdale[1]; A. D'Ambrosio[2]; A. Gallo[2]; L. Lavorgna[2]; D. Owen[1]; R. Reynolds[1]; R. Nicholas[1]

[1]Department of Brain Sciences, Imperial College London, London, UK; [2]Department of Advanced Medical and Surgical Sciences, University of Campania Luigi Vanvitelli, Naples, Italy; [3]Institute for Life Sciences, Swansea University, Swansea, UK; [4]Department of Health Sciences, University of Genoa, Genoa, Italy; [5]Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona, Verona, Italy; [6]National Heart & Lung Institute, Imperial College London, London, UK

Background and Aims: The 5–10-methylenetetrahydrofolate reductase (MTHFR) enzyme is critical for cellular homeostasis, orchestrating pivotal processes within the one-carbon metabolic pathway, including the catabolism of methionine and folate, as well as the biosynthesis of nucleic acids and proteins. We aimed to evaluate the association between MTHFR gene variants and Multiple Sclerosis (MS) severity.

Methods: We enrolled two independent populations to investigate the association of MTHFR polymorphisms with MS. An Italian population of 230 MS subjects genotyped for the MTHFR C677T and A1298C polymorphisms at Vanvitelli University (Naples, Italy); clinical data was retrospectively collected for a 5-year follow-up period. A UK cohort of 298 MS brain donors; MTHFR genotypes, clinical, and neuropathological features from this population were retrieved from the UK MS Society Tissue Bank, Imperial College London (London, UK). Logistic, ordered, and Cox regression analyses were employed to explore the associations.

Results: Italian population: The MTHFR A1298C polymorphism was associated, in the recessive model (CC vs. A/C and AA), with more relapses ($p=0.022$), higher EDSS ($p=0.003$), and a higher likelihood of confirmed disability progression ($p=0.010$). UK Population: The MTHFR 1298CC genotype was associated with a lower age at death in recessive and additive models ($p=0.026$, $p=0.037$, respectively); neuropathological evaluation found a higher frequency of active lesions lesions in the recessive and additive models ($p=0.005$, $p=0.002$, respectively), and a higher numbers of infiltrating mononuclear cells in the perivascular and in the meninges ($p=0.048$ recessive, $p=0.037$ additive models) indicating higher levels of inflammation.

Conclusion: These findings strongly support the association between MTHFR A1298C polymorphisms and MS severity.

Disclosure: Nothing to disclose.

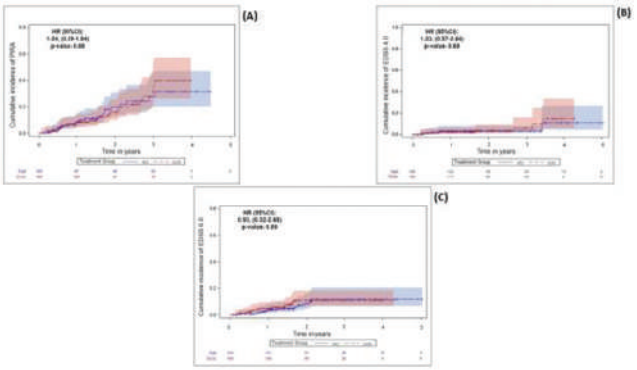
Hospital San Luigi, Orbassano; [16]AORN San G. Moscati di Avellino, Department of Neurology, Avellino, Italy; [17]Foundation Neurological Institute C. Besta; [18]University of Cagliari, Department of Medical Science and Public health, Centro Sclerosi Multipla, Cagliari, Italy; [19]Multiple Sclerosis Clinical Care and Research Center, Federico II University – Department of Neuroscience (NSRO), Naples; [20]Multiple Sclerosis Clinical and Research Unit, University Hospital of Rome Tor Vergata, Rome, Italy; [21]Neurology Unit and MS Center, IRCCS San Raffaele Scientific Institute

Background and Aims: To compare the risk of 6-months confirmed progression independent of relapse activity (PIRA), relapse associated worsening (RAW), and irreversible Expanded Disability Status Scale (EDSS) 4.0 and 6.0 in a real life-cohort of naïve relapsing-remitting multiple sclerosis (RRMS) patients treated with natalizumab (NTZ) or ocrelizumab (OCR).

Methods: RRMS patients with a first visit within one year from disease onset, treated with NTZ or OCR and ≥3 EDSS score evaluations were extracted from the Italian MS and Related Disorders Register. To mitigate the impact of potential biases, pairwise propensity score (PS)-matched analyses were performed. Risk of reaching the outcomes were estimated using multivariable Cox proportional hazards models.

Results: A total of 770 subjects were included (NTZ = 568; OCr = 212). The median (IQR) follow-up after treatment start was 1.63 (0.87–2.72) and 1.60 (0.80–2.68) years, respectively. The PS-matching retrieved 195 pairs. No RAW events were recorded. No differences between the two groups (NTZ – treated group as reference) were found in the risk (HR, 95% CI) of reaching a first PIRA (1.04, 0.59–1.84; $p = 0.88$) event, an irreversible EDSS 4.0 (1.23, 0.57–2.66; $p = 0.60$) and EDSS 6.0 (0.93, 0.32–2.68; $p = 0.89$).



Cumulative incidence of PIRA (A), irreversible EDSS 4.0 (B) and irreversible EDSS 6.0 (C) in NTZ and OCR treated patients.

Conclusion: Both OCR and NTZ strongly suppress RAW events in RRMS patients. In the short-term, the number and the risk of achieving PIRA events, EDSS 4.0 and 6.0 milestones are not significantly different between the two groups. A longer follow-up is essential to confirm the results on disability outcomes.

Disclosure: The authors report no conflicts of interest with respect to the contents of the current study, but note they have received advisory board, speaker honoraria, travel support, research grants or clinical trial support from the manufacturers of DMTs.

EPR-348 | Vagus nerve stimulation improves remyelination in a rat toxic demyelination model

H. Bachmann; E. Carrette; K. Vonck; P. Boon; R. Raedt; G. Laureys

Department of Neurology, Ghent University Hospital, Belgium

Background and Aims: Multiple sclerosis (MS) is a neuroinflammatory and neurodegenerative disease of the central nerve system, characterized by immune-mediated demyelination. Current MS treatments poorly address the chronic inflammation nor offer effective remyelination for axonal protection. Vagus Nerve Stimulation (VNS) shows potential in tackling both neuroinflammation and remyelination in MS. In this preclinical study the effect on remyelination was investigated in a toxic demyelination model.

Methods: In 35 Lewis rats, lysolecithin (LPC) was injected in the corpus callosum to induce a demyelinated lesion. Three days post-injection (dpi), 22/35 rats were perfused to analyse the lesions during demyelination and peak inflammation. 13/35 rats were perfused at 11 dpi to analyse the lesion during remyelination. VNS (0.5sON/29sOFF, 1.0 mA intensity, 30 Hz frequency, 250 μs pulse width) or sham stimulation was performed from two days before injection, until the day of perfusion (either three or 11 dpi). The extent of demyelination was evaluated by a luxol fast blue staining and cresyl violet counterstaining.
Results: At 11 dpi (timepoint of partial remyelination), demyelination was significantly reduced by 57.4% in VNS compared to sham, indicating improved remyelination by VNS. At three dpi (timepoint of demyelination) no significant difference was found between VNS and sham, indicating that VNS does not prevent against the direct demyelinating effects of LPC with the applied stimulation parameters.
Conclusion: Histological evaluation of LPC-induced demyelination showed that VNS significantly improves remyelination, suggesting a possible role for VNS as remyelinating strategy in MS. Further investigation is required.

Neurorehabilitation

EPR-349 | Power of pepper kids robot to train social skills in children with neurological disorders

A. Kolk[2]; A. Roštšinskaja[1]; K. Kits[1]; T. Loit[1]; J. Juhkami[1]; L. Uutsalu[2]; C. Kööp[1]; M. Saard[1]
[1]*Faculty of Medicine, University of Tartu, Tartu, Estonia;* [2]*Department of Pediatrics and Neurology, Tartu University Hospital Children's Clinic, Tartu, Estonia*

Background and Aims: The aim was to investigate child-robot interaction (CRI) in children with neurological disorders (ND) for designing social neurorehabilitation.
Methods: Study took place in Tartu University Children's Clinic. 89 children (4–16 years) participated: 50 with ND, 39 typically developed n control group (CG). 49/89 interacted directly, 40 via video. Interaction was examined in three ways: survey based on four socio-cultural concepts, therapists' observations and children's evaluation of emotional state.

FIGURE 1: Interaction session between child and robot pepper.

Results: Children quickly engaged with Pepper, median contact time was 2.0 [IQR 1.0–3.0] seconds. 93.8% sustained eye contact during whole session (8–10 min). 40% of children with ND believed the robot was very safe compared to 17.9% of CG ($p = 0.025$). Children who communicated with robot through video showed significantly less gesticulations and were more static compared to direct interaction group (55.9% vs. 80%; $p = 0.040$). Direct communication was more effective, but interaction via video also attracted children. 55% of children attributed three or four out of four anthropomorphistic characteristics to Pepper. On Smilyometer, 65 children evaluated their own and Pepper's mood as happy (Mdn 4 out of 5).

FIGURE 2: Child with ND using non-verbal communication with robot Pepper.

Conclusion: Anthropomorphic design of Pepper enhances acceptance, interaction and communication quality in children of all ages. Children found robot friendly, cheerful, smart and safe allowing long-term engagement. In the future, robot Pepper can be used as a therapist to advance children's social skills in neurorehabilitation sessions.

EPR-350 | Validation of the Brief Evaluation of Receptive Aphasia (BERA) tool in post-comatose patients

C. Aubinet[1]; A. Regnier[1]; P. Cardone[1]; N. Lejeune[1]; S. Majerus[2]; O. Gosseries[1]

[1]Coma Science Group, GIGA Consciousness, University of Liège, Liège, Belgium; [2]Psychology and Neuroscience of Cognition Research Unit, University of Liège, Liège, Belgium

Background and Aims: The Brief Evaluation of Receptive Aphasia (BERA) is a new tool to assess receptive phonological, semantic and morphosyntactic abilities in patients with severe brain damage, based on visual fixation of a target image next to a specific distractor. We here aim to provide validation data regarding the administration of the BERA in post-comatose patients, including patients with disorders of consciousness.

Methods: The BERA and Simplified evaluation of CONsciousness disorders scale (SECONDs) were administered to 35 post-comatose patients on two consecutive days, by two blinded raters, to determine the validity and reliability of the BERA. For internal and concurrent validity, versions 1 and 2 of our tool were considered, and BERA results were compared to a language index score extracted from the SECONDs assessment.

Results: The BERA tool showed satisfactory intra- and inter-rater reliability, as well as internal and concurrent validity in patients with and without disorders of consciousness.

Conclusion: This ongoing validation study suggests that the BERA may complement the SECONDs for assessing and diagnosing post-comatose patients. The BERA scores may also indicate selective receptive difficulties for phonological, semantic and morphosyntactic abilities, which would help to orient speech-language therapies.

Disclosure: Nothing to disclose.

EPR-351 | Immersive virtual reality as a complement to physical therapy for Parkinson's disease – A randomized controlled trial

D. Pimenta Silva[1]; F. Pona-Ferreira[2]; B. Santos[2]; C. Correia Rodrigues[3]; A. Xavier[2]; C. Santos Silva[3]; R. Cacho[2]; R. Bouça-Machado[2]; P. Campo-Prieto[4]; J. J. Ferreira[5]

[1]Centro de Estudos Egas Moniz, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; [2]CNS – Campus Neurológico, Torres Vedras, Portugal; [3]Serviço de Neurologia, Departamento de Neurociências e Saúde Mental, Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal; [4]Healthyfit Research Group, University of Vigo. Galicia Sur Health Research Institute (IIS Galicia Sur), SERGAS-UVIGO, Spain; [5]Laboratory of Clinical Pharmacology and Therapeutics, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal

Background and Aims: Virtual reality (VR) can provide intensive motor-cognitive training through multisensory environments, holding potential to complement PD rehabilitation programs.

Methods: In an open-label rater-blinded, randomized-controlled trial, we aimed to assess the efficacy, safety, and usability of combining immersive VR (IVR) with physiotherapy. Thirty PD patients were randomly assigned into two groups: 12-week physiotherapy plus IVR (VRG), or sequential 6-week physiotherapy followed by 6-week physiotherapy plus IVR (SG). Training occurred three times/week. Assessments were conducted on medication at baseline, 6-week, 12-week, and 4-week after intervention ended. Primary outcome was change from baseline to 6-week in TUG with cognitive dual-tasking (TUGcog).

Results: Twenty-nine participants were analyzed. VRG ($n=15$) was younger (median [IQR] age (years) in VRG=61 [58, 66] vs. SG=67.5 [60.5, 71.5]; $p=0.044$) and had higher MDS-UPDRS-3 score (VRG=31 [23, 35.5] vs. SG=22.5 [12, 23.8]; $p=0.008$). No other baseline differences were found. Our primary outcome did not significantly differ between groups [median TUGcog change in VRG = −0.557 [−1.448, 0.422] vs. SG=0.063 [−1.476, 1.157], estimated difference=0.567 (95% CI −1.063; 2.087); $p=0.505$]. Both groups improved in motor, cognitive and QoL measures. Significantly greater changes from baseline to 12-week in SG compared to VRG in TUGcog ($p=0.041$) and TUGmotor ($p=0.020$) suggest added benefits from VR training after 6 weeks of physiotherapy. Adverse events ($n=144$) were mostly mild (68.8%), and more frequently reported during IVR training. IVR was considered easy-to-use.

Conclusion: IVR was safe and usable for PD. Integrating IVR into a PD-specialized program could enhance physiotherapy positive effects, and possibly contribute to more sustained effects. Further research should validate VR's added value in PD rehabilitation.

Disclosure: This work was granted with Prémio João Lobo Antunes – Santa Casa da Misericórdia de Lisboa (grant to DPS).

EPR-352 | Examining EEG asymmetry changes in post-stroke UL rehab with rTMS in late subacute and chronic patients

F. Sánchez Cuesta[1]; C. Del Pozo Rojas[2]; D. Herráez Aguilar[2]; R. Rama[2]; R. Perezzan[2]; Y. González Zamorano[3]; A. Cerezo Zarzuelo[4]; A. Hurtado Martínez[1]; J. Romero Muñoz[1]

[1]Brain Injury and Movement Disorders Neurorehabilitation Group (GINDAT), Institute of Life Sciences, Francisco de Vitoria University, Pozuelo de Alarcón, Spain; [2]Computational Biophysics and Biological Data Analysis Research Group. Institute of Life Sciences, Francisco de Vitoria University, Pozuelo de Alarcón, Spain; [3]Cognitive Neuroscience, Pain and Rehabilitation Research Group (NECODOR), Faculty of Health Sciences, Rey Juan Carlos University, Madrid, Spain; [4]Psycology PhD Programme, Universidad Nacional de Educación a Distancia (UNED), Madrid, Spain

Background and Aims: Interhemispheric rivalry theory suggests inhibition from the unaffected hemisphere hampers recovery after a stroke. This study aims to assess interhemispheric symmetry using EEG properties (entropy, total power, waiting time), and the Brain Symmetry Index (BSI) in response to a neuromodulation protocol stimulating injured hemisphere and inhibiting contralateral.

Methods: Crossover AB/BA clinical trial with 20 participants, Therapy A (bilateral rTMS ×5 weekly sessions ×2 weeks), Therapy B (Therapy A + Motor imagery-EEG-neurofeedback). Patients received concurrent physical and occupational therapy. Fugl Meyer Assessment-Upper Limb (FMA-UL) and 64 electrodes EEG (resting state and finger tapping tasks) were recorded at six time points.

Results: Although functional improvement was observed in both therapies with differences favouring therapy B ($p<0.001$), symmetry differences were not clearly evidenced nor using the selected EEG properties nor BSI in any case ($p>0.05$). No statistically significant correlation was detected between changes in functionality and EEG asymmetry ($p>0.05$).

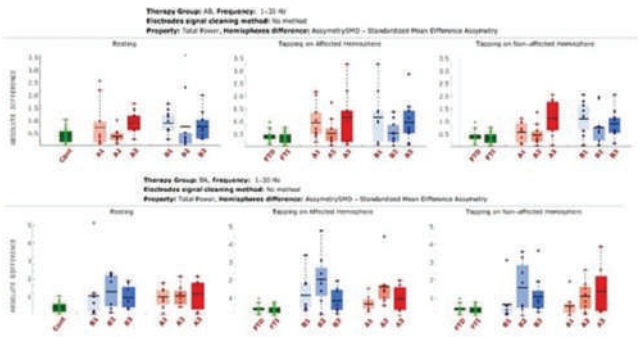

FIGURE 1: AssymetrySMD. Total power.

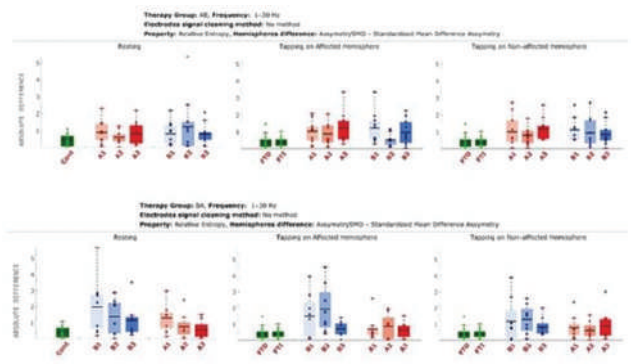

FIGURE 2: AssymetrySMD. Relative entropy.

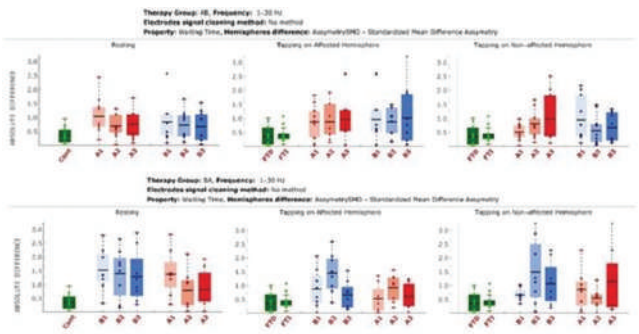

FIGURE 3: AssymetrySMD. Waiting time.

Conclusion: Although the neuromodulation in combination with conventional rehabilitation was effective regarding functional outcomes, it did not reflect in asymmetry changes measured with EEG which indicates that although our protocol was oriented to mitigate the interhemispheric inhibition it might have acted through different yet unveiled mechanisms that deserve further investigation.
Disclosure: There are no conflicts of interest to disclose.

EPR-353 | Nfl quantification in blood as rehabilitation outcome in a cohort of Parkinson's disease (PD) patients

F. La Rosa[1]; M. saresella[1]; I. Marventano[1]; A. Hernis[1]; Saibene[1]; A. Salvatore[1]; A. Castagna[1]; J. Navarro[1]; P. Arcuri[1]; M. Meloni[2]; C. Paola[3]; M. Clerici[1]
[1]IRCCS Fondazione Don Carlo Gnocchi, Milano, Italy; [2]UOC Neurologia, Azienda Ospedaliero-Universitaria, Cagliari, Italy; [3]Neurobiology Laboratory, School of Medicine, University of Study of Milano-Bicocca, Monza, Italy; Milan Center for Neuroscience, University of Study of Milano-Bicocca, Milano, Italy

Background and Aims: Neurofilament-light (Nfl) is a cytoskeletal intermediate filament protein that is expressed in neurons to provide structural support for the axon. Neurofilaments are released into the extracellular space and into the cerebrospinal fluid and blood following neuro-axonal damage or neurodegeneration. Exercises and rehabilitation-therapies were proposed as no-pharmacological treatments to maximize functional capacity, improve quality of life and minimize secondary complications in PD-treatment. The aim of the study is the quantification of plasma-Nfl as a possible rehabilitation outcome to monitor the effectiveness of exercise performed by PD-patients.
Methods: Nfl plasma-concentration was measured by Simoa-assay in 40 PD-patients; they were randomized into two groups of 20-patients: (a) the first formed by PD-patients undergoing an extensive rehabilitation section for 3 months (MAC); compared to (b) the second formed by PD-patients who did not undergo any rehabilitation cycle (CTRL). Patients' plasma was collected from whole-blood and collected for both groups at: (1) baseline (T0) before starting; (2) after 3-months (T1) and (3) after 6-months (T2) of the end of the rehabilitation cycle.
Results: Results have shown (1) significant ($p < 0.05$) decrease in plasma Nfl concentration post-rehabilitation (MAC T1 vs. T0); (2) significant ($p < 0.01$) increase in Nfl release in CTRL (T1 vs. T0). In the MAC patients no significant difference was shown between T1 and T2, instead after 6 months of the end of the rehabilitation activity the Nfl values were equal to the T0 level losing the significant effect that was shown at T1.
Conclusion: Nfl levels could be a rehabilitation outcome for personalize physical activity and rehabilitative-program.
Disclosure: "Nothing to disclose."

EPR-354 | Motor decision-making as a common denominator in motor pathology and a possible rehabilitation target

K. Germanova[1]; K. Panidi[1]; M. Nazarova[2]
[1]Institute for Cognitive Neuroscience, Centre for Cognition and Decision Making, HSE University; [2]Department of Neuroscience and Biomedical Engineering, Aalto University, Helsinki, Finland

Background and Aims: Learned non-use (LNU) is a frequent complication in neurological conditions such as stroke or traumatic brain injury. We suggest that applying neuroeconomic principles to understand patient decision-making in both cognitive and motor domains could be a new fruitful area of LNU research and in motor neurorehabilitation in general.
Methods: We introduced a 'risk-and-reach' task using a touch screen application to study how goal parameters affect motor choices. Tasks involved reaching for iteratively appearing goals, whose position represents different probabilities and rewards. The experiment starts by individualizing each participant's motor abilities and continues with the varying risk-reward scenarios in the motor domain (Figure 1), which is then compared with participant risk preferences in the cognitive domain and questionnaires-based mental traits such as impulsivity and sensation-seeking.

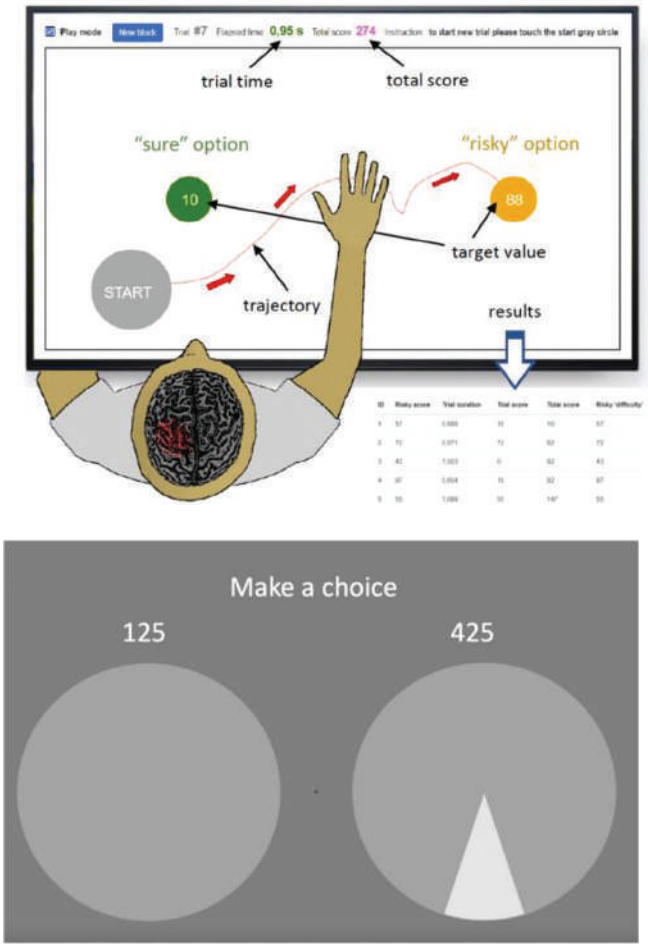

FIGURE 2: Example of a cognitive lottery trial.

Results: Analysis of 20 healthy participants showed that the presence of choice in the motor domain increased movement time ($t = -2.58$, $p = 0.032$). When comparing choices from motor and cognitive lotteries, participants preferred risky options in motor tasks compared to the cognitive ones ($p = 0.001$). Impulsivity and sensation-seeking traits were predictive for higher risky motor choice, while the Bomb Risk Elicitation Task scores predicted aversion to risk in the motor domain.

Conclusion: We showed that the presence of choice in the motor domain invigorates reaching movements. Furthermore, we observed that the motor choices were riskier compared to the cognitive ones. We recommend integrating neuroeconomic parameters in neurorehabilitation tasks. It could provide valuable insight into motor impairment, e.g., LNU, leading to more engaging and ecological interventions.

Disclosure: Nothing to disclose.

EPR-355 | Coordination index to detect cycling characteristics in early Parkinson's disease patients

J. Park[1]; S. Kang[2]; S. Kim[2]; B. Kim[1]

[1]*Department of Neurology, Korea University College of Medicine, Seoul, Korea;* [2]*Department of Biomedical Engineering, Korea University College of Medicine, Seoul, Korea*

Background and Aims: Interestingly, many PD patients, despite experiencing severe freezing of gait, can still ride a bicycle. However, detailed analyses to explore unique cycling characteristics in PD have been limited. This study aims to identify key variables associated with the cycling patterns of PD patients, utilizing the Ultiracer®, an innovative indoor cycling system.

Methods: A prospective study involved 32 PD patients (modified H&Y ≤2) and 42 control participants were evaluated using the Ultiracer® for 15 min at a comfortable speed . The Ultiracer® was equipped with rollers beneath each wheel and a frame-attached rod, enabling medio-lateral sliding and tilting motions, and is outfitted with force-torque sensors. Parameters analyzed included the coordination index, clinical PD data, lower extremity strength, and gait analysis.

Results: The momentum X-axis of the coordination index (CI-Mx), representing roll direction moment, negatively correlated with bicycle velocity in PD patients but not in controls and was significantly higher in PD patients. In a multivariable logistic regression, CI-Mx was a key predictor differentiating PD patients from controls and effectively distinguished between the two groups with high accuracy in receiver operating curve analysis. A significant positive correlation between the coordination index and UPDRS scores in the PD subgroup with less dynamic cycling abilities.

Conclusion: The results suggest that while PD patients retain the ability to cycle, their cycling behaviors differ notably from those of normal controls, particularly with increased CI-Mx. This suggests that the Ultiracer® system provide additional information possibly assisting the diagnostic process for individuals with early-stage PD.

EPR-356 | Association of plasma cholinergic markers with post-stroke walking performance

S. Mitra[1]; T. Darreh-Shori[1]; T. Cederholm[2]; M. Eriksdötter[3]; B. Vahlberg[2]

[1]*NVS Department, Karolinska Institutet, Huddinge, Sweden;* [2]*Department of Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden;* [3]*NVS Department, Karolinska Institutet, Huddinge, Sweden; Theme Inflammation and Aging, Karolinska University Hospital, Huddinge, Sweden*

Background and Aims: Stroke is the second highest cause of mortality and disability worldwide. Physical disability is often reported in post-stroke patients, wherein sedentary behavior might modify the risk of future stroke incidents. We had previously reported that SMS-guided training instructions delivered to stroke patients showed positive clinical outcome in walking performance at 3 month follow-up (The STROKEWALK Study) (1). In this study, we evaluated markers of cholinergic pathway to investigate whether they can serve as indicators of post-stroke recovery in walking ability.

Methods: Post-stroke patients were randomly selected to receive SMS instructions (Intervention group) or not (Control group). Plasma samples were collected at baseline ($n = 28$) and after 3-months follow-up ($n = 28$), respectively. All patients performed the six-minute walking test (6MWT) at baseline and follow-up. Enzyme activity was measured for the cholinergic pathway markers – choline acetyltransferase (ChAT) and butyrylcholinesterase (BChE) and were normalized to total protein content for respective sample. The cholinergic index was determined by calculating the ratio of ChAT/BChE (2).

Results: All patients ($n = 56$) were stratified into those showing clinically relevant improvement in walking ability in 6MWT (≥34-m, Improved group) versus who displayed lesser walking ability (<34-m, Unchanged group). Spearman rank correlation analyses showed association between the changes in cholinergic index and 6MWT performance, respectively from baseline to follow-up, among improved group but not in unchanged group.

Conclusion: Cholinergic index could be a useful biomarker to evaluate post-stroke walking performance. Validation studies are warranted in larger cohorts.

Disclosure: Nothing to disclose.

EPR-357 | Contralateral silent period and its association with upper extremity motor function in people with chronic tetraplegia

T. Arora[1]; J. Liu[2]; Mohan[2]; X. Li[2]; K. O'Laughlin[2]; T. Bennett[2]; Nemunaitis[3]; Bethoux[3]; Pundik[4]; G. Forrest[5]; S. Kirshblum[5]; K. Kilgore[6]; A. Bryden[6]; Henzel[4]; Wang[7]; K. Baker[8]; N. Brihmat[5]; M. Bayram[5]; E. Plow[2]

[1]Department of Neurology, Oslo University Hospital, Oslo, Norway; [2]Department of Biomedical Engineering, Cleveland Clinic Foundation, Ohio, USA; [3]Department of Physical Medicine and Rehabilitation, Cleveland Clinic Foundation, OH, USA; [4]Louis Stokes Cleveland Department of Veterans Affairs Medical Center, Ohio, USA; [5]Department of Physical Medicine and Rehabilitation, Rutgers New Jersey Medical School, New Jersey, USA; [6]Department of Physical Medicine and Rehabilitation, MetroHealth Center for Rehabilitation Research, Ohio, USA; [7]Department of Quantitative Health Sciences, Cleveland Clinic Foundation, Ohio, USA; [8]Department of Neuroscience, School of Medicine, University of Texas RioGrande Valley, RioGrande Valley, Texas, USA

Background and Aims: Contralateral silent period (CSP) is a transcranial magnetic stimulation (TMS)-based measure of corticospinal inhibition that is relevant to motor function but remains poorly understood after spinal cord injury (SCI). To advance the understanding of corticomotor inhibition after SCI, we studied CSP characteristics across muscles with varying degrees of weakness and investigated their relationship with the upper extremity function.

Methods: The data were collected as a part of a multi-site clinical trial (NCT03892746). We investigated CSP onset, offset, duration and depth in the stronger (biceps, muscle power = 3–5) and the weaker (triceps, muscle power = 1–3) muscles and examined their relationship with upper extremity function as assessed using the Capabilities of the Upper Extremity Test (CUE-T).

Results: The participants were 27 adults with chronic C1-C8 SCI (age 48.8 ±16.1 years) and 16 able-bodied (age 33.2 ±11.8 years) controls. Participants with SCI had prolonged CSPs for biceps (83.8 ±45.5 ms vs. 37.0 ±24.5 ms, $p < 0.001$), and delayed (52.4 ±15.0 ms vs. 33.4 ±5.0 ms, $p < 0.001$) and diminished CSPs (38.5 ±24.8% vs. 58.6 ±10.3%, $p = 0.032$) for triceps. Early CSP onset for biceps ($\rho = -0.53$, $p = 0.005$), and prolonged duration ($\rho = 0.74$, $p < 0.001$) and depth ($\rho = 0.73$, $p < 0.001$) for triceps CSP associated with better upper extremity function.

Conclusion: The CSPs in muscles with different extent of weakness following chronic tetraplegia reflect changes in corticospinal inhibition in relation to the neural level of injury. Individuals with better corticospinal inhibitory profiles as indicated by earlier onset, longer, and deeper CSPs for weaker muscles demonstrate better upper extremity function.

Disclosure: This work was supported by The Assistant Secretary of Defense for Health Affairs endorsed by the Department of Defense through the Spinal Cord Injury Research Program under Award No. W81XWH1810530.

Neuro-ophthalmology/neuro-otology

EPR-358 | Prevalence and functional impact of vestibular symptoms in patients with migraine: A cross-sectional study

A. Jaimes[1]; A. Gómez[1]; O. Pajares[1]; J. Rodriguez-Vico[1]; J. Serratosa[2]; J. Porta-Etessam[3]

[1]Headache Unit, Neurology Department, Fundación Jiménez Díaz University Hospital; [2]Epilepsy Unit, Neurology Department, Fundación Jiménez Díaz University Hospital; [3]Headache Unit, Neurology Department, Hospital Clínico San Carlos

Background and Aims: Dizziness is a common symptom in migraine patients, impacting daily life. This study aimed to assess the prevalence and impact of this symptom in migraine patients.

Methods: This cross-sectional study surveyed patients and family members from both the headache unit and neurology clinic.

Results: A total of 388 participants were included, with 274 (70.6%) having migraine and 114 (29.4%) serving as controls. Mean age was 41.9 years (±13.3), with females comprising 76.8%. Baseline characteristics are summarized in Table 1. Moderate and severe anxiety prevalence was higher in migraine patients (20.1% and 17.5%, respectively) than controls (9.6% and 2.6%). Additionally, 27.7% of migraine patients reported persistent photophobia, 24.5% persistent phonophobia, and 25.2% persistent osmophobia. Vestibular symptoms were more prevalent in migraine patients (54%) than controls (15%; OR 6.7, 95% CI 3.8–11.8; $p < 0.001$). Analysis of the Dizziness Handicap Inventory (DHI) showed severe functional and emotional handicaps in 23%, and severe physical handicaps in 54.7%. Logistic regression analysis revealed a significant association between dizziness and persistent photophobia, higher HIT-6 scores, unilateral pain, headache exacerbated by movement, nausea, and elevated anxiety levels.

^Chronological association with migraine attacks, *Calculated on the 148 migraine patients with dizziness

Conclusion: Migraine patients are six times more likely to experience dizziness than healthy controls. Since dizziness mainly occurs during migraine attacks and factors like higher headache burden and symptoms of central sensitization, such as persistent photophobia and nausea, increase the likelihood of dizziness, it's plausible that dizziness is linked to central sensitization. These symptoms notably impact overall quality of life, as shown by the DHI scale.

EPR-359 | Differentiating vestibular from somatosensory disequilibrium: Postural sway signatures while standing on foam

A. Gamvroula[1]; E. Karagianni[1]; M. Kouvli[1]; T. Kalamatianos[1]; G. Stranjalis[1]; M. Skoularidou[1]; E. Anagnostou[1]

[1]*Department of Neurology, Eginition Hospital, National and Kapodistrian University of Athens, Greece*

Background and Aims: Standing on foam with eyes closed, the vestibular Romberg test (vRt), is employed in the clinical assessment of peripheral vestibulopathy. Nevertheless there is lack of evidence regarding whether and to what extent vRt can effectively differentiate between (somato)sensory and vestibular causes of balance impairment.

Methods: Static balance was assessed in 39 patients with peripheral vestibulopathy (PV), 30 patients with pure sensory neuropathy (SN) and 30 healthy controls (C) while standing on firm surface or foam with eyes open or closed. Postural sway was analyzed by means of linear (sway area and standard deviation) and nonlinear (Shannon entropy) time and frequency domain metrics. The latter was based on comparisons of the percentage of energy in each of three frequency bands: low (0–0.5 Hz), middle (0.5–2 Hz) and high frequency (2–20 Hz).

Results: The majority of linear sway metrics were found to be greater in both PV and sensory neuropathy SN compared to controls C. Romberg quotients (eyes closed/eyes open on firm support) of linear sway metrics showed significant differences between SN and C, as well as between SN and PV. In contrast, vestibular Romberg quotients (eyes closed/eyes open on foam) were found to be similar in PV, SN, and C. A modified Romberg quotient (eyes closed on foam/eyes closed on firm support) did, however, reveal some notable differences between PV and SN.

Conclusion: The classical vRt proves fruitless in discriminating between PV and SN. However, comparing standing on firm support or foam, while keeping the eyes closed, appears to be a suitable test for distinguishing PV from SN.

Disclosure: Nothing to disclose.

EPR-360 | Auditory dysfunction and its relationship with cognitive impairment and MRI morphometry data in Parkinson's disease

A. Chumak[1]; O. Alenikova[2]; L. Parkhach[3]; M. Dymkovskaya[4]

[1]*Neurology Department, Republican Research and Clinical Center of Neurology and Neurosurgery, Minsk, Belarus;* [2]*Neurology Department, Republican Research and Clinical Center of Neurology and Neurosurgery, Minsk, Belarus;* [3]*Neurology Department, Republican Research and Clinical Center of Neurology and Neurosurgery, Minsk, Belarus;* [4]*Neurology Department, Republican Research and Clinical Center of Neurology and Neurosurgery, Minsk, Belarus*

Background and Aims: Among sensory dysfunctions, auditory processing has received increasing interest as it may contribute to

dementia in PD. Additionally to well-known a neuroprotective role of dopamine in the peripheral auditory system, efferent auditory pathways from different cortical regions also protect and provide modulation for auditory nerves and cochlea. Since there is PD-related neurodegeneration, we investigated the relationship between auditory dysfunction, cognitive deficits and MRI changes in PD patients.
Methods: Participants included 34 non-demented PD patients and 30 age-matched controls. To assess hearing we used Speech, Spatial and Qualities of Hearing (SSQ) questionnaire. Audiometric evaluation consisted of pure tone audiometry (PTA), auditory brainstem response (ABR) and Otoacoustic Emissions (DPOAE). We also applied MRI voxel-based morphometry and neuropsychological tests.
Results: PTA revealed slight decrease in hearing at high frequencies in 5 PDpatients and 4 controls. Despite this, PDpatients performed worse on the SSQ, indicating significant problems to hear speech in a variety of competing contexts. ABR reviled the I–V interval increase reflecting a slowdown in signal transmission throughout the auditory pathway in PD. DPOAE responses were reduced in PDpatients indicating involvement the efferent olivocochlear system (Table 1). DPOAE date correlated with the TMT and MoCA as well as volume in the auditory association cortex, cingulate cortex, insula and amygdala (Table 2).

TABLE 1: Comparative assessment of the PD patients group and the control group.

Parameters	PD patients group n = 34	Control group n = 30
	Median (IQR)	
Age, years	63 (57 68)	60 (55 70)

EPR-361 | Diagnostic role of biceps muscle biopsy in progressive external ophthalmoplegia

A. Colpak[1]; M. Cakan[1]; H. Kilic[2]; Z. Ergul Ulger[1]; C. Bekircan-Kurt[1]; Y. Kocaefe[2]; S. Erdem Ozdamar[1]; E. Tan[1]
[1]*Department of Neurology Faculty of Medicine, Hacettepe University, Ankara, Turkey;* [2]*Department of Medical Biology, Faculty of Medicine, Hacettepe University, Ankara, Turkey*

Background and Aims: Mitochondrial diseases are a heterogeneous group of disorders characterized by alterations in oxidative phosphorylation and caused by mutations in nuclear or mitochondrial genes. Tissues that require more oxygen, such as the extraocular eye muscles, are more likely to be affected. Progressive External Ophthalmoplegia (PEO) is one of the mitochondrial disorders which should be considered in patients with pupil sparing symmetric ophthalmoplegia and ptosis. We aimed to determine the diagnostic rate of muscle biopsy and its correlation with genetic tests in our PEO patient group.
Methods: We retrospectively reviewed the clinical and laboratory findings of patients who undergone biceps muscle biopsy with the suspicion of PEO between 2019 and 2023.
Results: A total of 96 patients had biceps muscle biopsies with the suspicion of mitochondrial myopathy due to negative mitochondrial mutation in serum samples. Of these 96 patients, 33 had ptosis/ophthalmoplegia or both. Although the clinical features of the patients

were typical for PEO, mitochondrial cytopathy was present only in 10 out of 33 (33%). Genetic testing for mitochondrial DNA mutations was done in all biopsy samples and common deletion was detected in 4 of 10 patients with mitochondrial cytopathy (40%). In addition, 7 out of 23 patients with normal muscle biopsy were also positive for common deletion in muscle samples (30.4%).

Conclusion: In patients with PEO, negative genetic testing of the serum and negative extremity muscle biopsy do not rule out the diagnosis. Genetic testing of affected muscles may be considered.

Disclosure: Nothing to disclose.

EPR-362 | Visually induced motion aftereffects (MAE) in patients with functional vertigo

F. Reichl[1]; R. Boegle[1]; M. Maywald[3]; L. Fabritius[2]; M. Dieterich[1]; S. Becker-Bense[1]

[1]*German Center for Vertigo and Balance Disorders, University Hospital, LMU Munich, Germany*; [2]*Department of Neurology, University Hospital, LMU Munich, Germany*; [3]*Department of Psychiatry, University Hospital, LMU Munich, Germany*

Background and Aims: Variants of the motion aftereffect (MAE), an illusory self-motion percept after prolonged exposure to coherent moving visual pattern, was extensively studied in healthy subjects and suspected to involve not only visual motion-sensitive, but also vestibular areas in terms of a central visual-vestibular interplay. Aim of our study was to psychophysically evaluate the MAE in patients with functional vertigo (persistent perceptual-postural vertigo, PPPD [1]) that typically present with increased symptom [1] Staab, Jeffrey P. et al. 2017.

Methods: Twenty PPPD patients and 10 healthy controls (HC) watched visual motion stimulation of different directions (translational, rotational or random dots) and speeds (angular velocity 7–210°/s) repeatedly presented. Subjects indicated the end of perceived MAE via button press.

Results: All participants perceived significant MAE in opposite direction following rotational and translational stimulation. With random dot motion HC reported no MAE, but a quarter of the PPPD patients unspecific aftereffects without systematic direction. With translational stimulation, the MAE duration increased with increasing angular velocity over both groups typically up to a maximum at ≥120°/s. With rotational stimulation MAE was the longest in HC at 90–120°/s, whereas PPPD patients with high symptom severity showed maximum duration at lower angular velocities (<90°/s) that came near to the HC curve with decreasing symptom severity.

Conclusion: Compared to HC, the peak inducing angular velocity of rotational MAE is lowered in functional vertigo syndromes (PPPD) as a function of their symptom severity, probably reflecting their increased sensitivity to typically slowly moving visual stimuli in everyday life.

Disclosure: This work was supported by the Deutsche Stiftung Neurologie (DSN) (project 80766113), and the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) under Germany's Excellence Strategy (Munich Cluster for Systems Neurology: EXC 2145 SyNergy to MD.

EPR-363 | Retinal oxygen saturation in patients with RVCL-S, a monogenic small vessel disease

I. de Boer[1]; W. Winter[1]; M. Al-Nofal[2]; A. Wilms[1]; N. Pelzer[1]; A. Zamanipoor Najafabadi[2]; I. Notting[2]; G. Terwindt[1]

[1]*Department of Neurology, Leiden University Medical Center, Leiden, The Netherlands*; [2]*Department of Ophthalmology, Leiden University Medical Center, Leiden, The Netherlands*

Background and Aims: Investigating mutation carriers with retinal vasculopathy with cerebral leukoencephalopathy and systemic manifestations (RVCL-S) provides an opportunity to discover biomarkers during both the pre-symptomatic and symptomatic phases of cerebral small vessel disease. RVCL-S is an autosomal dominant small vessel disease caused by mutations in TREX1. As oxygen saturation measurements have shown potential to detect retinal and vascular changes in several neurodegenerative diseases, we aimed to determine if retinal oxygen saturation differs between RVCL-S patients and controls.

Methods: Retinal oxygen saturation was assessed in 17 eyes from RVCL-S patients and 19 eyes from controls by using a non-invasive measuring tool (Oxymap T1 retinal oximeter). Mean arterial and venular oxygen saturation and arteriovenous difference per eye were measured, as well as vessel calibre.

Results: No differences in arterial oxygen saturation were found between RVCL-S patients and controls (median [IQR]: 94.5% [92.7–98.9] vs. 93.4% [87.2–98.3], p-value = 0.12). However, the venular oxygen saturation of RVCL-S patients was considerably higher than in control patients, median of 71.5% [IQR: 55.0–77.2] and 55.5% [IQR: 51.2–59.9] respectively (p-value < 0.001). In line with these findings, the arteriovenous difference was decreased in RVCL-S patients (median [IQR]: 22.6% [18.5–38.3] vs. 38.5% [34.1–39.9], p-value < 0.001). Finally, RVCL-S patients exhibited a reduced calibre in both arterial and venular vessels.

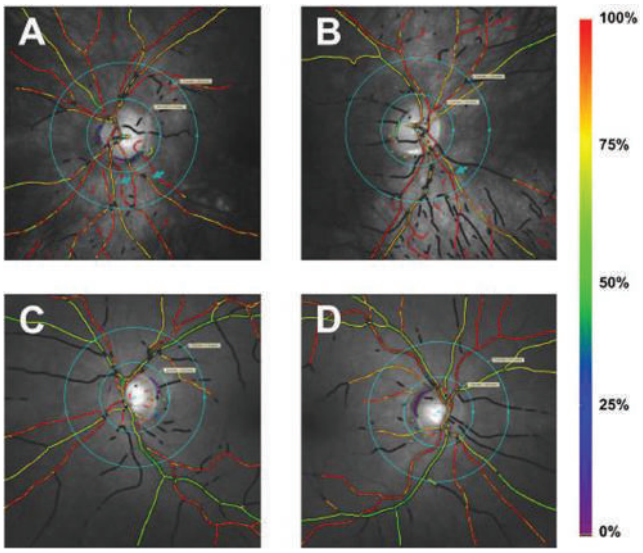

FIGURE 1: Pseudo colour fundus map of RVCL-S patient and control. Retinal oximetry images of the left (A) and right (B) eye of a RVCL-S patient and the left (C) and right (D) eye of a control individual are shown.

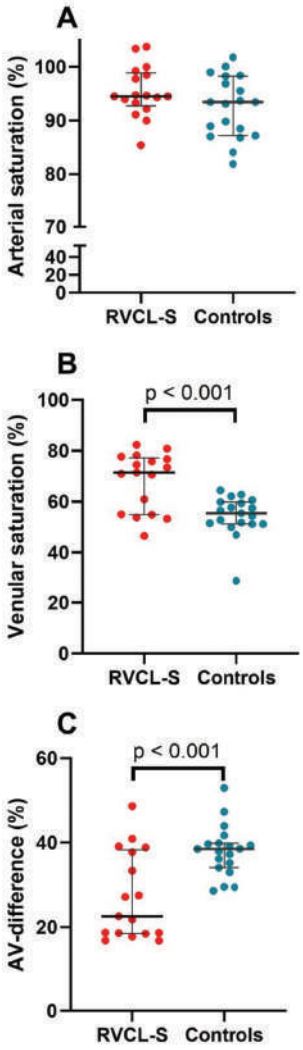

FIGURE 2: Retinal oxygen saturation in RVCL-S. Arterial (A) and venular oxygen saturation (B) and arteriovenous difference (AV-difference) (C) in RVCL-S patients and controls. Thickened line displays the median and the bars the interquartile range.

Conclusion: Retinal oximetry measurements have great potential to serve as (early) biomarkers for RVCL-S. Such precise objective instruments may also provide important non-invasive tools in determining disease activity for follow-up of common small vessel diseases.

EPR-364 | Breaking new ground in vestibular migraine treatment with CGRP-based therapies

D. Pawar[1]; D. GR[2]; D. Pawar[3]; N. Nandvikar[4]; M. Shouka[5]
[1]*Specialist Neurologist, Aster Gardens Specialty Clinic, Dubai, UAE;* [2]*Consultant ENT, Institute of ENT, Head and Neck Surgery, MGM Healthcare Pvt Ltd, Chennai, India;* [3]*Advance American Heart Association Instructor, Al Fajer Training Institute, Dubai, UAE;* [4]*Prin. K. M. Kundnani College of Pharmacy, Mumbai, India;* [5]*Audiologist, Aster Gardens Specialty Clinic, Dubai, UAE*

Background and Aims: Vestibular migraine (VM) is a complex neurological condition characterized by a combination of headache and vestibular symptoms. Despite its prevalence, treatments for VM are limited and the recommendations are borrowed from migraine sphere. Recent advancements have highlighted the role of Calcitonin Gene-Related Peptide (CGRP) in migraine and VM, suggesting a potential breakthrough in treatment with anti-CGRP drugs.

Methods: This retrospective study, conducted at Aster Gardens Specialty Clinic, Dubai, evaluated the efficacy of CGRP-based therapies in VM. Total 12 patients (Mean 37.83 years, 7 females, 5 male) with VM were selected, excluding those with therapy duration less than 3 months or confounding medical conditions. Interventions included Erenumab, Rimegepant, and Eptinezumab, with treatment tailored as per FDA-approved dosing guidelines. Assessment tools like MIDAS and Dizziness Handicap Inventory (DHI) scores, alongside numerical (1–10) scale and subjective improvement were used for baseline and post-treatment evaluations at 3 months. Data analysis was performed using IBM SPSS software, ensuring ethical compliance and security.

Results: Statistically significant improvements were noted in headache and vestibular symptoms over 3 months, as shown by decreased MIDAS and DHI scores. Headache symptoms improved in 50% of patients, while 75% reported significant improvement in vestibular symptoms. Results demonstrate the potential of CGRP therapies in managing VM, aligning with recent literature on their effectiveness in migraine treatment.

Conclusion: Present study reinforces the efficacy of CGRP-based therapies in treating VM, advocating for the inclusion of CGRP therapies in standard treatment protocols and highlighting need for further research in this area.

Disclosure: None.

EPR-365 | Activation of the CD40/CD154 pathway in Muller cells induces ocular hypertension-induced death of retinal ganglion cells

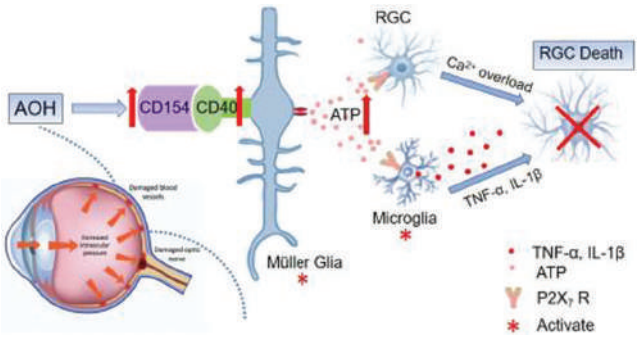
Y. Xu[1]; W. Liang[1]; A. Feng[1]; Y. Huang[1]; A. Li[1]; H. Hu[2]
[1]*Guangdong-Hong Kong-Macau Institute of CNS Regeneration, Jinan University, Guangzhou, China;* [2]*Shenzhen Eye Hospital, Jinan University, Shenzhen, China*

Background and Aims: In glaucoma, high ocular hypertension causes death in retinal ganglion cells (RGCs) that eventually leads to blindness. In this study, we explored whether activation of CD40 receptor with its ligand CD154, can participate in ocular hypertension-triggered ATP release from Muller glial cells, which subsequently trigger RGC death.

Methods: Acute ocular hypertension (AOH) was established in C57BL/6J mice. Then the survival of RGCs and reactivity of glial cells were examined by immunostaining and western blotting. The expression of CD40, CD154, P2X7R (ATP receptor) and several inflammation-related cytokines were measured by qPCR. The in vitro experiments on the Muller cell line using CoCl2 to induce hypoxia were also performed, with the changes in CD40 expression and ATP levels quantified.

Results: After AOH insult, the RGC survival decreased sharply within 1–4 days. The retinal expression of CD40, P2X7R, TNF-a and IL-1b were transiently increased at 1 day post-surgery and then returned to the level of sham control, whereas the microglia and Muller cells remained activated for 7 days. Meanwhile, the serum concentration of CD154 slightly increased after AOH. The hypoxia caused an up-regulation of CD40 in Muller cells in vitro, and exogenous addition of CD154 proteins to the CoCl2-treated Muller cells triggered ATP release.

Conclusion: AOH-induced RGC death may be mediated by the activation of CD40, P2X7R and inflammation. Co-activation of CD40 and CD154 triggers the release of ATP from Muller cells in vitro. Whether the CD40/CD154 pathway also participates in glaucomatous pathogenesis in vivo is under investigation using CD40-null mice.



Graphic Abstract: In glaucoma, increased intraocular pressure induces the co-activation of CD40 and CD154 in Muller cells, which

triggers the release of ATP that further activates P2X7R on both RGCs and microglia that lead to RGC death.

Disclosure: Nothing to disclose.

EPR-366 | Evaluation of retinal changes in patients with chronic migraine

Y. Walha[1]; M. Rekik[1]; K. Moalla[2]; S. Kammoun[1]; A. Trigui[1]; M. Damak[2]; C. Mhiri[2]

[1]*Ophthalmology Department*, *Habib Bourguiba Hospital*, *Sfax*, *Tunisia*; [2]*Neurology Department*, *Habib Bourguiba Hospital*, *Sfax*, *Tunisia*

Background and Aims: Few studies have assessed the retinal changes in patients with migraine using optical coherence tomography (OCT). We investigate changes in macular thickness (MT) through OCT in migraine patients with and without aura compared to healthy controls.

Methods: This is a cross-sectional case-control study conducted at the Ophthalmology and Neurology Departments of the Habib Bourguiba University Hospital in Sfax. This study included migraine patients and control subjects. All patients and controls underwent a complete ophthalmological examination. OCT was used to measure average MT and pericentral quadrants conforming to the segmentation of the Early Treatment Diabetic Retinopathy Study.

Results: One hundred and twenty eyes from 60 patients (60 eyes in the migraine without aura (MWoA) and 60 eyes in the migraine with aura (MWA) were included. Control group included 30 age and gender matched healthy participants (60 eyes). The mean age of patients was 37.2 years, with a sex ratio (M/F) of 0.22. OCT revealed that MT thickness were significantly reduced in MWoA and MWA groups compared with the control group ($p < 0.001$), with the exception of the foveal thickness in the MWoA and MWA groups compared with the control group. We found a significant decrease in parafoveal thickness in the MWA group compared to the MWoA group in the superior and temporal quadrant.

Conclusion: MT are significantly thinner in patients with migraine. Our findings could be explained by hypoperfusion and retrograde trans-neuronal degeneration related to this disease.

Disclosure: "Nothing to disclose."

Ageing and dementia 1

EPO-001 | Development of small molecules promoting tau clearance in Alzheimer disease

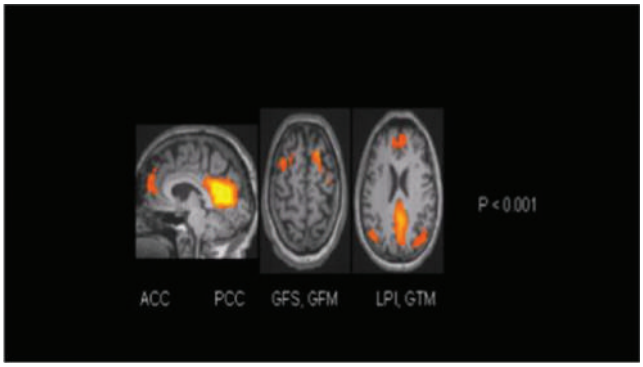
L. Wang[1]; R. Kumar[1,2]; P. Pavlov[1]; B. Winblad[1,3]
[1]*Division of Neurogeriatrics, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Solna, Sweden;* [2]*Department of Pharmaceutical Engineering and Technology, Indian Institute of Technology (BHU), Varanasi, India;* [3]*Theme Inflammation and Aging, Karolinska University Hospital, Huddinge, Sweden*

Background and Aims: A major pathological hallmark of Alzheimer disease (AD) is the intracellular accumulations of neurofibrillary tangles composed of paired helical filaments (PHFs) of tau protein. Lowered efficiency of degradation pathways, such as ubiquitin proteasome system, further exacerbates the aggregated tau accumulation. Proteolysis-Targeting Chimeras (PROTACs) are heterobifunctional molecules that can bring E3 ligase into the vicinity of protein of interest, leading to protein ubiquitination, followed by proteasomal degradation. Since 2016, PROTACs have been applied to resolve tau pathologies. Most of these PROTACs have only been evaluated in cell models and the exploration is still at the early stage. In this study, we aim to perform intensive research to develop novel small-molecule PROTACs to initiate tau degradation for AD treatment.
Methods: We screened a library of tau binders from a public database (bindingdb.org) by performing global molecular docking into the 3D structure of PHFs. The top ranked compounds were selected to design new PROTACs, with different linkers connected to the ligands binding to E3 ligase, for instance cereblon and carboxyl terminus of Hsp70 interacting protein (CHIP). We are performing modeling of the ternary complex (tau-PROTACs-E3 ligase) and the highly scored PROTACs will be synthesised. Their protein binding affinities and tau-reducing effects will be evaluated in cell models.
Results: We perform the development of small-molecule PROTACs according to the methods listed above. We selected the top ranked tau binders and designed new PROTACs.
Conclusion: The hit PROTACs will move on to in vivo study and provide pre-clinical evidence for novel treatment of AD tauopathies.
Disclosure: The authors declare no conflict of interest.

EPO-002 | Functional connectivity as biomarker of neurodegenerative disease

A. Medvedeva
First Moscow State Medical University, Russia

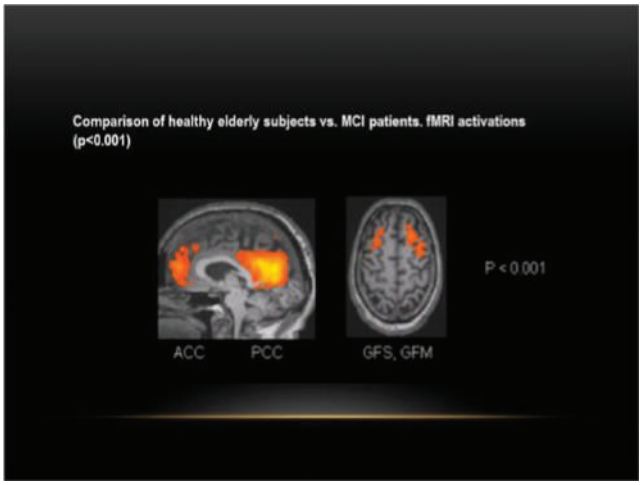
Background and Aims: Alzheimer's disease (AD) selectively involves cerebral neuronal networks. The aim was to correlate fMRI patterns and EEG-coherence in Alzheimer's disease (AD), amnestic Mild cognitive impairment (aMCI), non amnestic Mild cognitive impairment (nMCI), Frontotemporal Dementia (FTG) and controls.
Methods: 90 patients with AD, 90 aMCI, 85 nMCI, 60 FTD patients and 90 age-matched controls underwent fMRI (3 Tesla, TRIO, Siemens) and resting EEG-recordings (NeuroScan Synamps System). EEGs were recorded using a standard protocol and montage. Coherences between regions of interest, based on fMRI activation patterns were calculated.



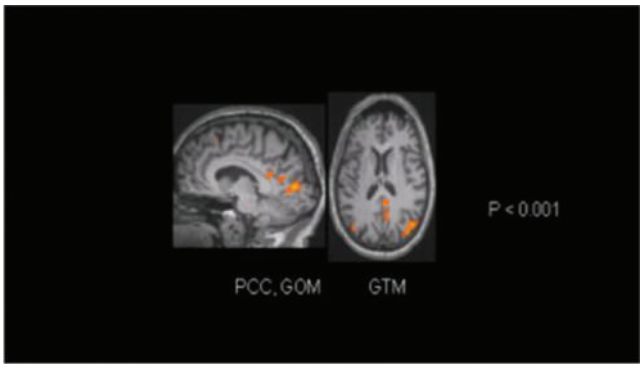
Comparison of controls vs. AD patients. fMRI activations ($p < 0.001$)

Results: There were significant differences between AD and aMCI for theta coherences between anterior cingulate gyrus (ACC) and left temporal gyrus (LTG) (AD < aMCI, $p < 0.05$) Fig.2; between AD and controls for theta between ACC and right temporal gyrus, between ACC and left hippocampus, and between ACC and right parietal gyrus (AD < controls, $p < 0.01$) Fig. 1. aMCI-subjects showed reduced coherence compared with controls between ACC and left frontal superior gyrus within delta, theta and alpha1-band. Theta coherence was significantly between anterior and posterior cingulate gyrus, between right and LTG (aMCI < controls, $p < 0.05$) Fig. 3. There were significant differences between FTG and controls, between

ACC and left temporal gyrus in delta and theta (FTG < controls, $p < 0.05$). There were not found significant differences between AD, FTD and nMCI.



Comparison of controls vs. aMCI patients. fMRI activations ($p < 0.001$)



Comparison of aMCI vs. AD patients. fMRI activations ($p < 0.001$)

Conclusion: EEG coherence seems to be a useful approach, which helps to detect the early stage of cognitive decline.

Background and Aims: To investigate microstructural gray matter (GM) and white matter (WM) alterations in FTLD patients and to develop machine learning (ML) algorithm that classifies patients according to NODDI metrics and neuropsychological data.

Methods: Thirty-five behavioral-variant frontotemporal dementia (bvFTD), 20 semantic-variant primary progressive aphasia (svPPA), 14 nonfluent-variant primary progressive aphasia (nfvPPA), 9 semantic-bvFTD (sbvFTD) and 48 controls performed multi-shell diffusion-brain MRI. Fractional anisotropy (FA), Intra-cellular Volume Fraction (ICVF) and Orientation Dispersion Index (ODI) maps were estimated. GM and WM comparisons between FTLD groups were performed. ML algorithm was trained on (i) mean GM/WM values of FA, ICVF and ODI maps subdivided in brain lobes and (ii) neuropsychological data.

Results: FA maps showed widespread WM damage in FTLD patients relative to controls. ICVF maps showed damage in FTLD patients relative to controls in frontotemporal for bvFTD, left temporal-frontal for svPPA and nfvPPA, right temporal for sbvFTD. ODI maps showed a GM reduction with a similar ICVF-GM pattern. WM alterations in patients relative to controls was observed: (i) WM reduction in corpus callosum and corona radiata (bvFTD, svPPA, nfvPPA) and right corona radiata (sbvFTD); (ii) WM increase in temporo-occipital WM bundles (bvFTD) and stria-terminalis (svPPA). ML model

(ICVF + ODI + neuropsychological data) showed a 95.9% accuracy in the classification of each patient syndrome.

Conclusion: NODDI and ML algorithm hold potential for advancing our understanding of FTLD pathology and facilitating diagnosis, personalized treatment strategies at individual-level. EPO-004 | Aging features through connectome analysis and advanced diffusion-weighted metrics with a machine learning approach

S. Basaia[1]; S. Pisano[2]; E. Sibilla[1]; E. Spinelli[3]; E. Canu[1]; M. Filippi[4]; F. Agosta[3]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; [2]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Neurology Department, Istituto Clinico S. Anna Hospital, Brescia, Italy; [3]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy; [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: To develop machine learning algorithm combining connectome analysis and advanced diffusion-weighted metrics to classify different features underlying aging process.

Methods: Forty-eight young-controls (YC), 20–31 years, 21 middle-aged [MC] and 44 elderly-controls [EC], 41–85 years, underwent brain multi-shell diffusion-MRI and cognitive evaluation. Fractional anisotropy (FA), Intra-cellular Volume Fraction (ICVF) and Orientation Dispersion Index (ODI) maps were estimated. TBSS and connectomics were performed. Support-vector-machine (SVM) model trained on FA, ICVF and ODI values of all connections resulted different in TBSS and connectomics, was used for the identification of features (TBSS- or connectome-related) of aging process. Features that better distinguished three groups were used as variables in a multivariate polynomial regression to predict subject's age. Correlation coefficient between the predicted age by the model and the age of the subjects.

Results: SVM models showed 99.7% and 100% accuracy in the classification of YC relative to MC/EC, ODI values of TBSS-related connections as best selected feature. SVM models demonstrated 83.4% accuracy between MC-EC groups, identifying FA connections values as the most informative feature for classification. Mean ODI of TBSS- and FA of connectome-related connections were inserted in the multivariate polynomial regression to predict subject's age. Correlation analysis indicated relationship between age-predicted and actual age of subjects ($r = 0.93$; $p < 0.001$).

Conclusion: Combination of SVM and neuroimaging achieved high accuracy in group classification and age prediction, highlighting the potential for understanding brain connectivity patterns and age-related changes. EPO-005 | Clinical characteristics and biomarker profile in early and late-onset Alzheimer's disease: The Shanghai Memory Study

J. Wu; Z. Xiao; X. Ma; X. Zhou; D. Ding; Q. Zhao
Institute of Neurology, Huashan Hospital, Fudan University, Shanghai, China

Background and Aims: Early-onset Alzheimer's disease (EOAD) constitutes approximately 5%–10% of Alzheimer's disease (AD). Its difference with Late-onset Alzheimer's disease (LOAD) was not well documented. The current study explored their characteristics covering clinical, neuropsychological and biomarker profiles.

Methods: Ninety-ninety patients with LOAD and 104 with EOAD were enrolled from a Chinese hospital-based cohort, the Shanghai Memory Study. Clinical features, cognitive performance, and full-panel of plasma biomarker were compared cross-sectionally. Disease progression and longitudinal cognition change were analyzed as well.

Results: Results: Patients with EOAD presented more severe impairment in global cognition, attention, and language function (all $p<0.05$). Levels of plasma Aβ40, Aβ42, Aβ42/Aβ40, and neurofilament light (NfL) were higher in the LOAD group, while plasma p-tau181 concentration was higher in the EOAD group (all $p<0.05$). After adjusting for age, gender, disease severity, and comorbid disease, younger age at onset (AAO) was associated with lower levels of plasma Aβ40 (B = 1.827, 95% CI 1.205 to 2.450, $p<0.001$), Aβ42 (B = 0.106, 95% CI 0.064 to 0.147, $p<0.001$), and NfL (B = 0.280, 95% CI 0.145 to 0.415, $p<0.001$), while with higher concentrations of p-tau181 (B = −0.040, 95% CI −0.069 to −0.012, $p=0.006$). The level of plasma p-tau181 was significantly correlated with global cognition, memory, attention, and visuospatial function in patients with EOAD, but not in LOAD.

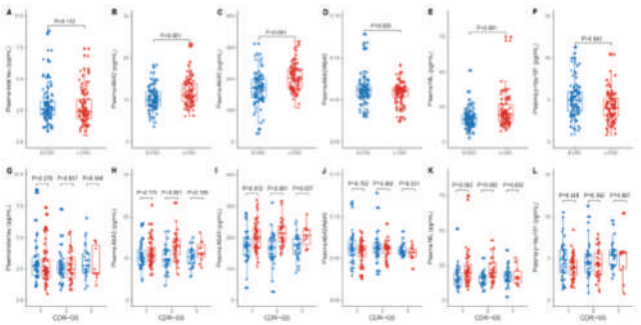

FIGURE 1 Concentrations of plasma biomarkers among patients with different age-at onset and disease severity.

TABLE 2 multiple linear regression of plasma biomarkers and age at onset Note: a mode 1, data were adjusted for CDR-global score, gender, education duration, and APOE genotype; b in model 2, data were adjusted for gender, education duration, CDR-glo.

Plasma biomarkers	Model 1[a]		Model 2[b]	
	B (95%CI)	P value	B (95%CI)	P value
total-tau	-0.011 (-0.033, 0.010)	0.285	-0.017 (-0.038, 0.004)	0.107
Aβ42	0.117 (0.075, 0.160)	<0.001*	0.106 (0.064, 0.147)	<0.001*
Aβ40	2.095 (1.429, 2.760)	<0.001*	1.827 (1.205, 2.450)	<0.001*
Aβ42/Aβ40	0 (0,0)	0.076	0 (0, 0)	0.140
NfL	0.303 (0.166, 0.441)	<0.001*	0.280 (0.145, 0.415)	<0.001*
P-tau181	-0.040 (-0.068, -0.012)	0.006*	-0.040 (-0.069, -0.012)	0.006*

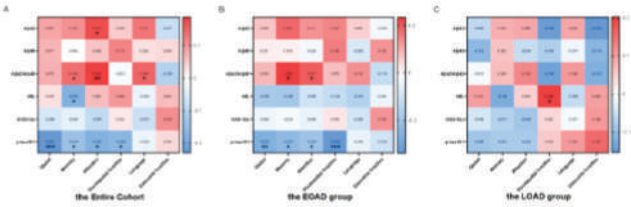

FIGURE 2 correlations between plasma biomarker concentrations and cognitive domains. Note: The plasma biomarkers concentrations were log transformed. A, correlations between plasma biomarker concentrations and cognitive domains in all participants; B, co.

Conclusion: Conclusion: Patients with EOAD differed from LOAD in cognitive performance and biomarker profile. Plasma p-tau181 level showed more tremendous change in EOAD.

Disclosure: Nothing to disclose.

EPO-006 | Sleep disturbances and the impact in neuropsychiatric symptoms in Alzheimer's disease

C. Fernandes[1]; D. Valente[2]; I. Carvalho[1]; F. Gomes[1]; F. Barros[1]; C. Bernardes[1]; P. Faustino[1]; J. Durães[3]; M. Lima[4]; I. Baldeiras[4]; M. Tábuas-Pereira[3]; I. Santana[3]
[1]Neurology Department, Hospitalar and University Center Coimbra, Coimbra, Portugal; [2]Neurology Department, Hospitalar and University Center os Algarve, Faro, Portugal; [3]Neurology Department, Hospitalar and University Center Coimbra, Coimbra, Portugal; CIBB – Center for Innovative Biomedicine and Biotechnology, University of Coimbra, Coimbra, Portugal; Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [4]Neurology Department, Hospitalar and University Center Coimbra, Coimbra, Portugal and CIBB – Center for Innovative Biomedicine and Biotechnology, University of Coimbra, Coimbra, Portugal

Background and Aims: Sleep disturbances are common in Alzheimer's disease (AD), contributing to accelerate cognitive deterioration and

progression of neuropsychiatric symptoms (NPS). Understanding the sleep disturbances in AD can expand our knowledge and improve treatment of NPS. Evaluate the association between sleep disturbances and NPS in patients with AD.

Methods: We performed a cross-sectional study, including patients with the diagnosis of AD supported by biomarkers. NPS were assessed with Frontal Behavioral Inventory (FBI) and Neuropsychiatric Inventory (NPI). Sleep disturbances were evaluated with Pittsburgh Sleep Quality Index (PSQI), STOP-BANG score, Epworth scale (ES) and REM Behavior Disorder screening questionnaire (RBDSQ). Statistical analysis comprised univariate analysis and statistical significance was set at $p<0.05$.

Results: We included 61 patients (68.9% female) with average age of onset of 64.2(±6.8) years. The median education was 4.0 (IQR=5.0) and MMSE of 20 (IQR=8). According to the STOP-BANG score, 11 patients (21.2%) were at intermediate or higher risk of obstructive sleep apnea (OSA) and 18 patients (29.5%) reported sleep disturbances in PSQI (score >5). Total PSQI scores were correlated with FBI indifference ($r=0.031$; $p=0.012$), inattention ($r=0.380$; $p=0.006$), aphasia ($r=0.429$; $p=0.002$) and perseveration ($r=0.294$; $p=0.038$). STOP-BANG score was correlated with FBI indifference ($r=0.290$; $p=0.043$), logopenia ($r=0.358$; $p=0.012$), aphasia ($r=0.513$; $p<0.001$), perseveration ($r=0.440$; $p=0.002$), comprehension deficit ($r=0.316$; $p=0.027$), hyperorality ($r=0.498$; $p<0.001$) and utilization behaviors ($r=0.295$; $p=0.038$). No correlation was found between NPS symptoms and ES and RBDSQ.

Conclusion: Sleep disturbances were associated with NPS frontal dysfunction showing that sleep quality influences the diurnal function of AD patients. Interestingly, patients at higher risk of OSA presented with more prominent frontal features suggesting a possible pattern of AD phenotype related to hypoxia, meriting further studies.

Disclosure: Nothing to disclose.

EPO-007 | Effect of Aβ on Alzheimer's disease tau spreading

F. Nabizadeh
School of Medicine, Iran University of Medical Sciences, Tehran, Iran

Background and Aims: Alzheimer's disease (AD) is characterized by the accumulation of Amyloid-beta (Aβ) plaques initiated approximately two decades before the symptom onset followed by buildup and spreading of neurofibrillary tau aggregates. Although it has been suggested that the Aβ amplifies tau spreading the observed spatial disparity called it into question. Yet it is unclear how neocortical Aβ remotely affects early pathological tau, triggering it to leave the early formation area, and how Aβ facilitates tau aggregate spreading throughout cortical regions. I aimed to investigate how Aβ can facilitate tau spreading through neuronal connections in the AD pathological process by combining fMRI normative connectomes and longitudinal in vivo molecular imaging data.

Methods: In total, the imaging data of 317 participants including, 173 Aβ-negative non-demented and 144 Aβ-positive non-demented participants have entered the study from ADNI. Furthermore, normative resting-state fMRI connectomes were used to model tau spreading through functional connections.

Results: It was observed that the Aβ in regions with the highest deposition (Aβ epicenter) is remotely associated with connectivity-based spreading of tau pathology. Moreover, Aβ in regions that exhibit the highest tau pathology (tau epicenter) is associated with increased connectivity-based tau spreading to non-epicenter regions.

Conclusion: The findings provide a further explanation for a long-standing question of how Aβ can affect tau aggregate spreading through neuronal connections despite spatial incongruity. The results suggest that Aβ pathology can remotely and locally facilitate connectivity-based spreading of tau aggregates.

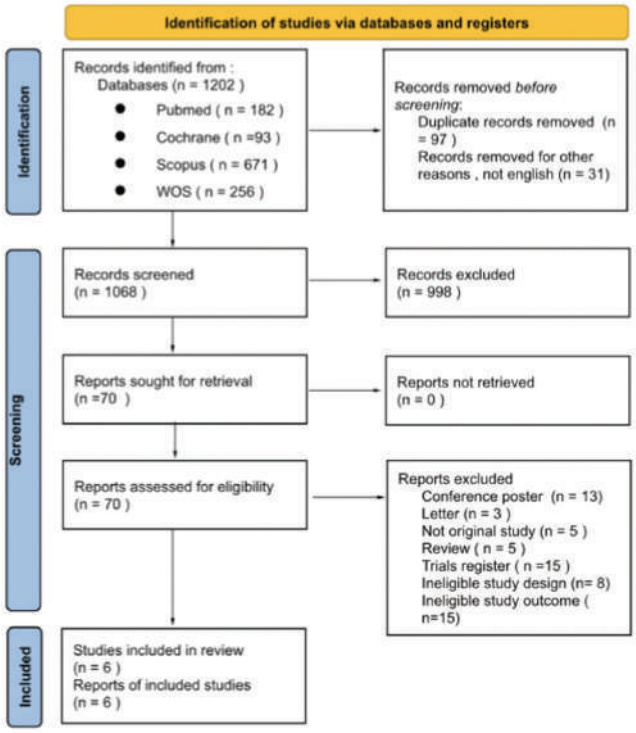
Disclosure: Nothing to disclose.

EPO-008 | Solanezumab treatment for Alzheimer disease: Meta analysis for non expedition trials

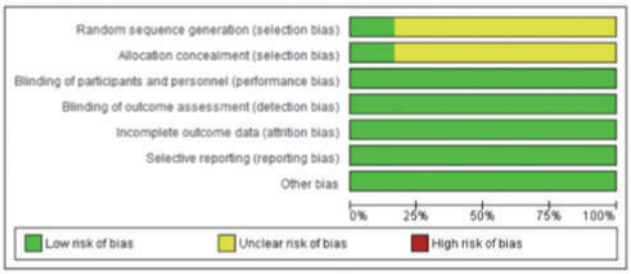
A. Al Wssawi; H. Talib Hashim
University of Warith Al-Anbiyaa, College of Medicine

Background and Aims: Solanezumab, a monoclonal antibody, has shown promise in treating Alzheimer's disease by targeting beta-amyloid plaques, potentially slowing cognitive decline. Despite mixed initial trials, ongoing research indicates potential benefits.

Methods: It is a systematic review and meta-analysis. We included only RCTs for Non-EXPEDITION Trials. 1202 records were screened based on our search strategy on main database (Pubmed, Scopus, WOS, Cochrane). Continuous Outcomes were pooled using Random Effects, Inverse Variance and Mean Difference.



Flow chart of study selection and included study based on PRISMA



ROB for included study

Results: 6 RCTs, 4956 participant used Solanezumab. 5 RCTs included, outcome of (ADAS-Cog14, ADAS-Cog11, MMSE, CDR-SB Score), intervention number in each Trial (n1 = 578, n2 = 102, n3 = 50, n4 = 1057, n5 = 659). Improvements in cognitive subscale of the Alzheimer's Disease Assessment Scale (ADAS-cog14) were observed by 5 studies. The overall pooled results showed that Solanezumab is associated with a significant reduction in ADAS- Cog 14 scores as compared to placebo. (MD −1.18, 95% CI (−1.96, −0.40); $p = 0.003$, $I^2 = 0\%$). Improvements in cognitive subscale of the Alzheimer's Disease Assessment Scale (ADAS-cog11) were observed by 2 studies. Pooled analysis showed that Solanezumab is associated with a significant reduction in ADAS- Cog 11 scores as compared to placebo. (MD −1.68, 95% CI (−2.80, −0.55); $p = 0.003$, $I^2 = 0\%$).

Baseline characteristic of included study

Conclusion: Solanezumab treatment for Alzheimer's disease presents a promising avenue in the quest for effective interventions. While its ability to halt or reverse the disease remains uncertain, it offers hope by targeting the underlying amyloid plaques, a key hallmark of Alzheimer's.

Disclosure: Nothing to disclose.

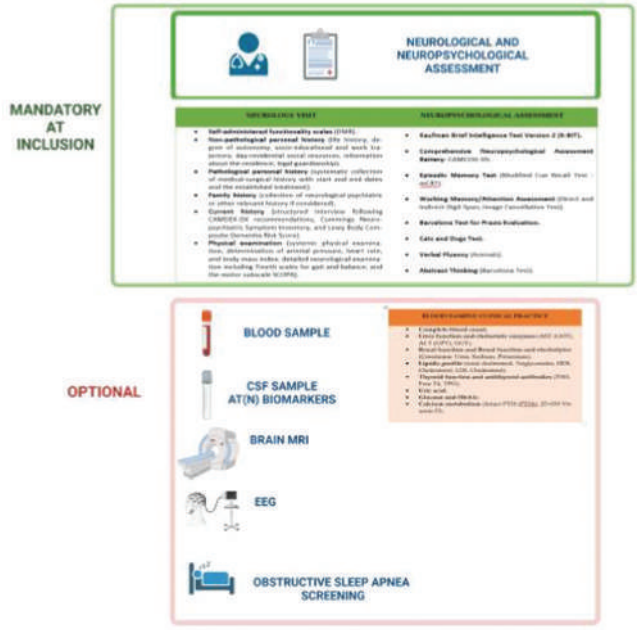
EPO-009 | Gender disparities in down syndrome-associated Alzheimer's disease and related pathologies

M. Altuna[1]; A. Estanga[1]; J. Saldias[1]; M. Cañada[1]; A. Garrido[2]; M. Echeverria[2]; J. Larrea[3]; M. García-Sebastián[1]

[1]Cita Alzheimer Foundation, Donostia, Spain; [2]Osakidetza Basque Health Service, Donostialdea Integrated Health Organisation, Clinical Biochemistry Department, Donostia, Spain; [3]Osakidetza Basque Health Service, Donostialdea Integrated Health Organisation, Radiology Department, Donostia, Spain

Background and Aims: Down syndrome (DS) constitutes a genetically determined form of Alzheimer's disease (DSAD). While gender differences in risk factors and the clinical course of Alzheimer's have been identified in the general population, this aspect remains unexplored in DS. Our primary aim is to investigate gender influences on DSAD diagnosis and related comorbidities in DS.

Methods: Observational cross-sectional study in a population-based cohort of adults with DS, regardless of intellectual disability (ID) and cognitive status, with dual purposes (clinical and research), from January to December 2023. Conducted adapted neurological-neuropsychological evaluations to determine ID and cognitive status in relation to DSAD. Optional procedures included brain MRI, lumbar puncture for AT(N) biomarker study, and blood analysis, addressing both clinical and research objectives.



Protocol of baseline visit of clinical and research cohort of adults with DS

Results: Recruited 115 participants, 46.9% women, average age 46.32 years (25–65). No gender differences in ID (89.9% mild to moderate) or cognitive status for DSAD (35.6% symptomatic). Similarly, no distinctions in age of cognitive symptom onset (51.1 ± 5.4 years), prodromal (51.4 ± 4.7 years), and DSAD dementia (53.6 ± 5.7 years) diagnosis; and or global cognition, episodic memory, neuropsychiatric inventory, functional autonomy scales, and quantitative neurological assessment (balance, gait scales, and screening for rigid-akinetic syndrome) scores. No differences observed in epilepsy and obstructive sleep apnea prevalence. The only comorbidities with statistically significant differences (more prevalent in women) were hypothyroidism and vitamin D deficiency.

		FEMALE	MALE	
Number of adults with DS		54 (46.9 %)	61 (53.1%)	
ID	Mild	45.7%	37.4%	p = 0.48
	Moderate	47.8%	50%	
	Severe/Profound	6.5%	12.6%	
Diagnosis 1st visit	aDS	60.9%	66.7%	p = 0.29
	pAD	15.2%	5.6%	
	dAD	23.9%	27.8%	
Age 1st visit (mean + SD)		46.9 +/- 9.5 years	45.8 +/- 9.3 years	p = 0.57
Age DSAD symptoms onset		50.9 +/- 5.4 years	51.3 +/- 5.3 years	p= 0.46
Age prodromal DSAD		51.2 +/- 4.7 years	51.5 +/- 4.7 years	p= 0.93
Age dementia DSAD		53.4 +/- 5.7 years	53.4 +/- 5.6 years	p= 0.91
Epilepsy		18.4%	17.5%	p= 0.45
Sleep apnea syndrome		20.4%	24.6%	p= 0.79
Neuropsychiatric symptomatology		28.3%	24.1%	p= 0.63
Hypothyroidism		56.5%	38.9%	p= 0.05
Vitamin D deficiency		45.7%	27.8%	p= 0.05

Down syndrome population data

Conclusion: The influence of gender on the clinical course of symptomatic Alzheimer's and more frequent comorbidities may be lesser, possibly not significant, in genetically determined forms, or at least in DSAD.

Disclosure: Nothing to disclose.

EPO-010 | MHC-II receptor enrichment in locus coeruleus since Alzheimer's disease early stages

N. Rabaneda Lombarte[1]; F. Pereira[2]; A. Ehrenberg[2]; V. Paes[3]; C. Suemoto[4]; R. Leite[4]; R. Rodriguez[4]; R. Ferretti-Rebustini[4]; E. Ferrioli[4]; R. Nitrini[4]; W. Jacob-Filho[4]; C. Pasqualucci[4]; W. Seeley[5]; S. Spina[5]; B. Miller[6]; L. Grinberg[7]

[1]Department of Neurosciences, Hospital Universitari Germans Trias i Pujol, Barcelona, Spain; [2]Department of Neurology, Memory and Aging Center, Weill Institute for Neurosciences, University of California, San Francisco, California, USA; [3]Department of Pathology, University of Sao Paulo Medical School, Sao Paulo, Brazil; [4]Division of Geriatrics, University of Sao Paulo Medical School, Sao Paulo, Brazil; [5]Department of Pathology and Global Brain Health Institute, University of California, San Francisco, California, USA; [6]Department of Neurology, Memory and Aging Center, Weill Institute for Neurosciences, and Global Brain Health Institute, University of California, San Francisco, California, USA; [7]Department of Pathology, University of Sao Paulo Medical School, Brazil. Department of Pathology and Neurology, Memory and Aging Center, Weill Institute for Neurosciences, and Global Brain Health Institute, University of California, San Francisco, USA

Background and Aims: The locus coeruleus (LC), a key noradrenergic nucleus for memory and arousal, is an early-damaged region in Alzheimer's disease (AD) with tau vulnerability. The molecular mechanism for this remains unclear. We conducted RNA analysis on LC and substantia nigra (SN), a less vulnerable nucleus, in subjects at progressive AD stages, to explore the molecular basis of LC's selective vulnerability to AD-tau.

Methods: RNA sequencing was conducted on RNA extracted from the LC and SN regions of postmortem brains belonging to healthy controls (HC; $n = 11$) and AD patients ($n = 40$) across distinct Braak stages (BB) (Fig. 1).

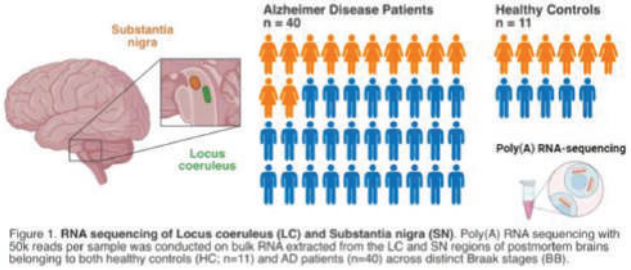


Figure 1. **RNA sequencing of Locus coeruleus (LC) and Substantia nigra (SN)**. Poly(A) RNA sequencing with 50k reads per sample was conducted on bulk RNA extracted from the LC and SN regions of postmortem brains belonging to both healthy controls (HC; n=11) and AD patients (n=40) across distinct Braak stages (BB).

FIGURE 1

Results: Genes linked to the MHC-II receptor ontology term showed upregulation from the initial BB in the LC (Fig. 2). Notably, the expression of HLA-DQB1 gene, a key player in the immune system,

exhibits a 1-fold increase at BB 1 compared to BB 0. In BB 2 and BB 3 cases, an increase in the expression of CD4 and HLA-DRA genes was observed compared to HC. In the advanced stages of the disease (BB 4–6), all MHC-II genes exhibited higher RNA expression compared to HC. Notably, the SN showed none of these changes.

BB1		BB2		BB3		BB4-6	
LC	SN	LC	SN	LC	SN	LC	SN
HLA-DQB1↑	HLA-DQB1	HLA-DQB1	HLA-DQB1	HLA-DQB1↑	HLA-DQB1	HLA-DQB1↑	HLA-DQB1
HLA-DRA ↑	HLA-DRA	HLA-DRA ↑	HLA-DRA	HLA-DRA ↑	HLA-DRA	HLA-DRA ↑	HLA-DRA
HLA-DRB1↑	HLA-DRB1	HLA-DRB1	HLA-DRB1	HLA-DRB1	HLA-DRB1	HLA-DRB1↑	HLA-DRB1
CD4 ↑	CD4	CD4 ↑	CD4	CD4 ↑	CD4	CD4 ↑	CD4
CD74 ↑	CD74	CD74	CD74	CD74	CD74	CD74 ↑	CD74

Figure 2. **Genes linked to the MHC-II receptor gene ontology term fold-change**. Genes in green had no significant fold-change between Braak Stage (BB) indicated in first row and BB 0, while genes in blue had an increased fold-change in BB (indicated in the first row) and BB 0. The comparison was performed in Braak-by-Braak manner, employing a linear regression test for gene differential expression, while accounting for the Braak Stage and correcting for Sex and Age of Death.

FIGURE 2

Conclusion: Multiple lines of evidence back MHC-II involvement in AD. This study uniquely shows early MHC-II activation, especially in the vulnerable human brain region. This suggests therapeutic potential in modulating this axis for AD treatment and offers insights into unknown disease origins. Further research is crucial to validate these findings and explore the earliest AD stages in subcortical nuclei.

Disclosure: NRL was a recipient of the "Rotación Externa de Formación en Neurología" grant from the Spanish Society of Neurology.

EPO-011 | Combined plasma biomarkers for the diagnosis of Alzheimer's Disease in clinical scenario

A. Pilotto[1]; A. Galli[1]; C. Trasciatti[1]; V. Quaresima[1]; C. Tolassi[1]; M. Parigi[2]; A. Rizzardi[1]; S. Caratozzolo[1]; A. Benussi[1]; S. Giliani[2]; K. Blennov[3]; N. Ashton[4]; H. Zetterberg[5]; A. Padovani[1]

[1]Neurology Unit, University and ASST SPedali CIvili of Brescia, Brescia, Italy; [2]Nocivelli Institute, ASST Spedali CIvili of Brescia, Brescia, italy; [3]University of Gothenborg, GOthenborg, Sweden; [4]University of Moelndal, Moelndal, Sweden; [5]Wallenberg Institute, University of GOthenborg, Sweden

Background and Aims: The implementation of plasma biomarkers in clinical settings is pivotal for a rapid screening and diagnosis, as well as for tracking disease progression reducing the costs and burden of CSF assessments. Aim of the study was to evaluate the ability of plasma markers to discriminated Alzheimer's disease (AD) and both healthy controls (HC) and other neurodegenerative diseases (NDD).

Methods: The cross-sectional study included patients with AD (A+T+N+), patients with non-AD NDD, and healthy controls. Each patient underwent standard core-standard CSF analyses, plasma p-tau181, p-tau 217, Aβ42, and Aβ40 were measured using single molecule arrays (SIMOA) analyses. The ability of blood-based biomarkers to detect AD pathology was assessed by using ROC and linear regression analyses.

Results: two-hundred eighty-six individuals, namely 124 AD, 50 NDD, and 112 HC entered the study. P-tau 181, p-tau 217, p-tau 181/Aβ42 ratio, and p-tau 217/ Aβ42 ratio levels were elevated in AD compared to NDD and HC. P-tau 217 biomarker showed the highest area under the receiver operating curve (AUC) for identifying AD from HC (AUC = 0.933), compared to p-Tau 181 (AUC = 0.88) and other considered biomarkers. p-tau 217/ Aβ42 ratio exhibited the highest AUC for identifying AD from NDD (AUC = 0.858).

Conclusion: plasma p-tau 217 was the most accurate biomarker in ruling out AD individuals from HC, whereas its combination with Aβ42 was the best biomarker in identifying AD from other neurodegenerative diseases.

Disclosure: None.

EPO-012 | Primary progressive aphasia in Italian and English: A cross-linguistic cohort study

S. Mazzeo[1]; C. Hardy[2]; J. Jiang[2]; C. Morinelli[3]; V. Moschini[3]; J. Johnson[2]; A. Chokesuwattanaskul[4]; A. Volkmer[5]; J. Rohrer[2]; A. Ingannato[6]; S. Bagnoli[6]; S. Padiglioni[3]; B. Nacmias[6]; S. Sorbi[6]; V. Bessi[6]; J. Warren[2]

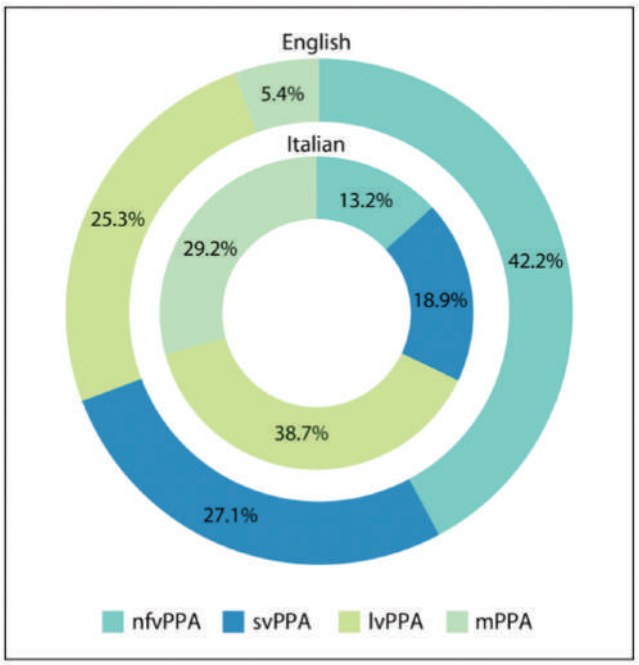
[1]Research and Innovation Centre for Dementia-CRIDEM, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy; Vita-Salute San Raffaele University, Milan, Italy; [2]Dementia Research Centre, Department of Neurodegenerative Disease, UCL Queen Square Institute of Neurology, University College London, London, UK; [3]Research and Innovation Centre for Dementia-CRIDEM, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy; [4]Division of Neurology, Department of Internal Medicine, King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand; [5]Department of Psychology & Language Sciences, University College London, London, UK; [6]Department of Neuroscience, Psychology, Drug Research and Child Health, University of Florence, Azienda Ospedaliera-Universitaria Careggi, Florence, Italy

Background and Aims: Primary Progressive Aphasia (PPA) is a neurodegenerative disorder primarily affecting language abilities, with clinical variants (nonfluent/agrammatic variant [nfvPPA], semantic variant [svPPA], logopenic variant [lvPPA], and mixed-PPA [mPPA]) categorized based on linguistic features. This study aims to compare PPA cohorts of native speakers of English and Italian.

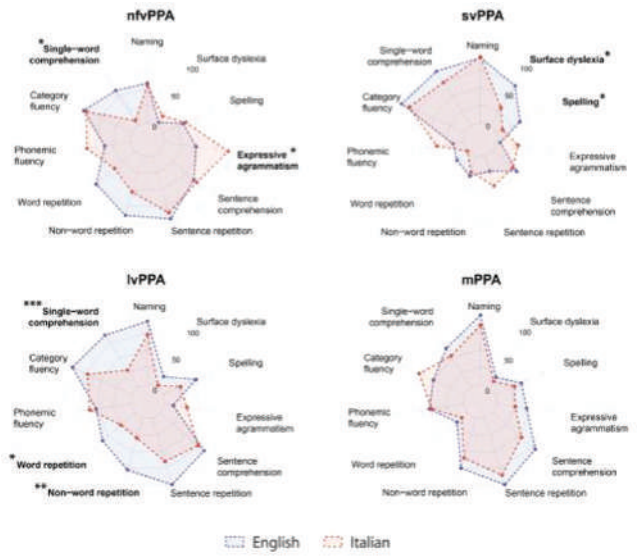
Methods: We considered 166 English participants (70 nfvPPA, 45 svPPA, 42 lvPPA, 9 mPPA) and 106 Italian participants (14 nfvPPA, 20 svPPA, 42 lvPPA, 31 mPPA). Starting from the neuropsychological battery used to assess patients, we extracted one test for each cognitive and linguistic function that can be compared between cohorts. Comparisons were adjusted for symptom duration and Mini-mental State Examination.

Results: The English cohort included a higher proportion of nfvPPA patients (42% vs. 13%, $p < 0.001$), while the Italian cohort showed higher proportions of lvPPA (25% vs. 38%, $p = 0.019$) and mPPA (5% vs. 29%, $p < 0.001$) (Fig. 1). English nfvPPA patients were more frequently impaired in single-word comprehension (60% vs. 8%, $p = 0.013$), while Italian nfvPPA patients exhibited more agrammatism

(46% vs. 93%, $p=0.015$). English svPPA had a higher proportion of surface dyslexia (68% vs. 30%, $p=0.046$) and spelling impairment (38% vs. 10%, $p=0.021$). English lvPPA had broader impairments, including single-word comprehension (89% vs. 29%, $p<0.001$), repetition of words (61% vs. 26%, $p=0.03$), nonverbal working memory (69% vs. 36%, $p=0.005$), and visuospatial perception (89% vs. 25%, $p<0.001$) (Fig. 2).



Donut plots showing proportion of PPA variants in English and Italian cohorts. Significant differences between cohorts are coded as follows: *$p<0.05$ ***$p<0.001$



Profiles of neurolinguistic and general cognitive impairment in the Italian and English cohorts. Significant differences between cohorts are coded as follows: *$p<0.05$; **$p<0.01$; ***$p<0.001$

Conclusion: Language-specific characteristics impact the clinical presentation of PPA. Cultural and linguistic nuances should be considered in PPA diagnosis and management, calling for more tailored assessments and criteria.

Background and Aims: Recently, diagnostic criteria have been proposed for a variant of frontotemporal dementia (FTD) showing distinctive right temporal damage, named semantic behavioural variant FTD (sbvFTD). Our aim was to describe longitudinal patterns of disease progression for each FTD syndrome, with a particular focus on sbvFTD.

Methods: Our cohort included a total of 59 FTD patients with a diagnosis of behavioral variant of FTD (bvFTD, $n=38$), sbvFTD ($n=8$), or semantic variant of primary progressive aphasia (svPPA, $n=13$), who underwent at least two MRI scans on a 3T scanner. Fifty-two healthy controls underwent the same protocol. Cortical thickness analyses were performed at baseline and longitudinally to describe cortical atrophy progression.

Results: At baseline, patients with sbvFTD had an intermediate atrophy pattern between bvFTD and svPPA, with right-predominant temporal pole involvement associated to significant right frontal atrophy. Longitudinally, bvFTD patients were found to progress

widely bilaterally, while svPPA continued steady progression restricted to the temporal lobes, and sbvFTD showed progression only in the left temporal lobe with limited further volume loss in the right hemisphere.

Conclusion: Our study has characterized structural neuroimaging hallmarks of each FTD variant and recognized variant-specific patterns of disease progression. These findings could aid in the identification of imaging biomarkers able to improve FTD diagnosis and prognostic stratification. Moreover, our results singled out sbvFTD as a relatively distinct entity. Funding. Supported by European Research Council (StG-2016_714388_NeuroTRACK); Foundation Research on Alzheimer Disease; Next Generation EU/National Recovery and Resilience Plan, Investment PE8-Project Age-It.

Background and Aims: Semantic behavioral variant of frontotemporal dementia (sbvFTD) is a neurodegenerative condition presenting with specific behavioral and semantic derangements and predominant atrophy of the right anterior temporal lobe (rATL). Our objective was to evaluate clinical, neuropsychological, neuroimaging and genetic features of an Italian sbvFTD cohort, defined according to recently proposed guidelines, compared to semantic variant primary progressive aphasia (svPPA) and behavioral variant FTD (bvFTD) patients.

Methods: Fifteen sbvFTD, 63 bvFTD and 25 svPPA patients and 40 healthy controls were enrolled. Patients underwent clinical, cognitive evaluations and brain MRI. Emerging symptoms of sbvFTD patients were recorded. Grey matter atrophy was investigated using voxel-based morphometry.

Results: sbvFTD patients developed early person-specific semantic knowledge loss (67%), object semantic loss (67%), complex compulsions and rigid thought process (60%). Sequentially, additional behavioral symptoms emerged (apathy/inertia, loss of empathy, anxiety, suspiciousness). sbvFTD patients showed sparing of attentive and executive functions, especially compared to bvFTD, and better performance at language tests, compared to svPPA. sbvFTD had predominant rATL atrophy, almost specular to svPPA. Three sbvFTD patients showed pathogenic genetic variants.

Conclusion: We applied sbvFTD diagnostic guidelines to an Italian cohort, demonstrating that the presence of two out of three core diagnostic criteria (person-specific semantic knowledge loss, mental

rigidity and loss of empathy), along with the evidence of preserved executive functions and frontal lobes at MRI should prompt a diagnosis of sbvFTD. Funding. This study was supported by European Research Council (StG-2016_714388_NeuroTRACK); Foundation Research on Alzheimer Disease; Next Generation EU/National Recovery and Resilience Plan, Investment PE8-Project Age-It.

EPO-015 | Gantenerumab for early Alzheimer's disease: A systematic review and meta-analysis

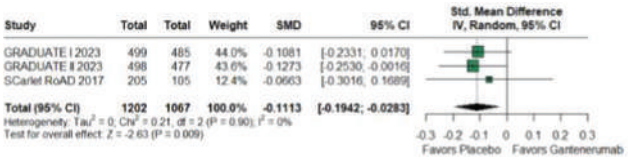
A. Menegaz de Almeida[1]; M. G. H. S. J. Leite[2]; L. Moreira Lopes[3]; P. L. Gomes Lima[4]; M. L. Siegloch Barros[4]; S. L. Rocha Pinheiro[5]; Í. Barros Andrade[6]; P. Viana[7]; V. Morbach[8]; R. de Oliveira[9]; A. C. Pinheiro[10]

[1]Federal University of Mato Grosso, Sinop, Brazil; [2]Santa Marcelina University, São Paulo, Brazil; [3]Sciences Medical School of Santos, Santos, Brazil; [4]Federal University of Acre, Rio Branco, Brazil; [5]Federal University of Bahia, Anísio Teixeira, Brazil; [6]Faculdade de Saúde Santo Agostinho, Vitória da Conquista, Brazil; [7]Extremo Sul University, Criciúma, Brazil; [8]Feevale University, Novo Hamburgo, Brazil; [9]Department of Medicine, Federal University of Mato Grosso, Sinop, Brazil, [10]Department of Neurology, Massachusetts General Hospital, Brigham and Woman's Hospital, Harvard Medical School, Boston, MA

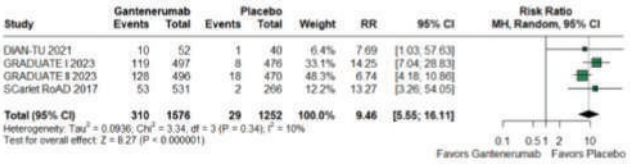
Background and Aims: Gantenerumab is a monoclonal antibody targeting amyloid β protein (Aβ) in early Alzheimer's disease (AD). Hence, we sought to evaluate gantenerumab safety and efficacy in early AD patients.

Methods: MEDLINE, Embase, and Cochrane databases were systematically searched until December 02, 2023. Data were examined using the Mantel-Haenszel method and 95% confidence intervals (CIs). Heterogeneity was assessed using I^2 statistics. Meta-regression analysis was conducted to evaluate a possible link between baseline Clinical Dementia Rating Scale – Sum of Boxes (CDR-SB) and amyloid-related imaging abnormalities (ARIA) at follow-up. R, version 4.2.3, was used for statistical analysis.

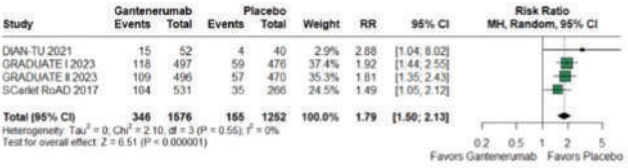
Results: A total of 4 RCTs and 2848 patients were included, of whom 1580 (55%) received subcutaneous gantenerumab. Concerning clinical scores, the placebo group achieved better rates of change in the Disease Assessment Scale (ADAS-Cog13) (SMD −0.1113; 95% CI −0.1942 to −0.0283; $p=0.009$; $I^2=0\%$). Gantenerumab was strongly associated with the occurrence of ARIA-E and ARIA-H: (19.67% vs. 2.31%; RR 9.46; 95% CI 5.55–16.11; $p=<0.000001$; $I^2=10\%$) and (21.95% vs. 12.38%; RR 1.79; 95% CI 1.50–2.13; $p=<0.000001$; $I^2=0\%$), respectively. Only injection site events showed a statistically significant difference between groups, tending towards the placebo group (17.64% vs. 7.53%; RR 2.23; 95% CI 1.81–2.73; $p=<0.000001$; $I^2=61\%$). The meta regression between baseline CDR-SB and ARIA showed no significant link.



ADAS-Cog 13



ARIA-E



ARIA-H

Conclusion: In this meta-analysis, consistent results suggest that gantenerumab is not safe and efficient for early AD, showing no improvement in clinical scores for AD and being associated with the occurrence of ARIA-E, ARIA-H, and injection site events.

Autonomic nervous system diseases 1

EPO-016 | Haemodynamic determinants of supine hypertension in patients with classical orthostatic hypotension

A. van der Stam[1]; B. Gagaouzova[2]; F. Kerkhof[2]; I. van Rossum[2]; S. Shmuely[1]; R. Reijntjes[2]; M. van Houwelingen[3]; R. Thijs[2]; G. van Dijk[2]

[1]Department of Neurology, Donders Institute for Brain, Cognition and Behavior, Radboud University Medical Center, Nijmegen, The Netherlands; [2]Department of Neurology, Leiden University Medical Center, Leiden, The Netherlands; [3]Department of Experimental Cardiology, Erasmus Medical Center, Rotterdam, The Netherlands

Background and Aims: The underlying mechanisms of, and relation between supine hypertension (SH), classical orthostatic hypotension (cOH), and the severity of the orthostatic systolic blood pressure (SBP) fall are currently largely unknown. We investigated the relative importance of heart rate (HR), stroke volume (SV) and total peripheral resistance (TPR) to these issues.

Methods: Tilt table tests recorded with beat-to-beat BP recordings (Finapres NOVA and BMEye Nexfin) were assessed and divided in four groups: Controls without SH (SH−; i.e., supine SBP < 140 mmHg) ($n = 19$), controls/SH+ ($n = 61$), cOH/SH− ($n = 30$) and cOH/SH+ ($n = 50$). We used linear regression to relate cOH severity to supine SBP, and used the logratio method to analyse the relative contributions of hemodynamic parameters to upright BP. We used a p value of 0.003 after Bonferroni correction.

Results: In both patients and controls high supine SBP was caused by high TPR (Figure 1). The orthostatic SBP fall increased with supine SBP in patients (Figure 2). The main difference in the upright position between cOH/SH+ and cOH/SH− patients was TPRLR, which was higher in cOH/SH− than in cOH/SH+ ($p < 0.002$). A secondary difference was that SVLR decreased more in cOH/SH− than in cOH/SH+ ($p < 0.003$) (Figure 3). HRLR had similar relative contributions to orthostatic SBP ($p = 0.028$) (Figure 3).

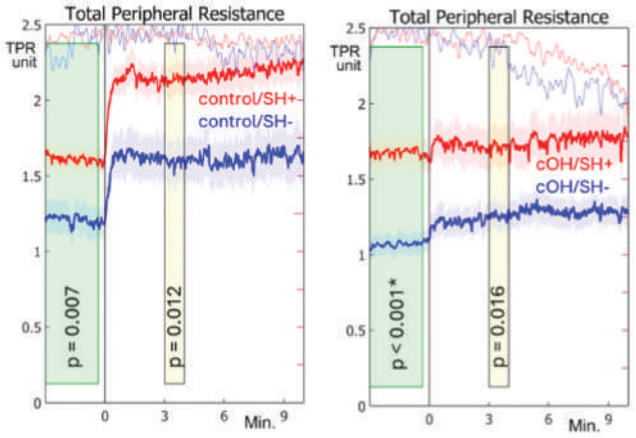

FIGURE 1 Measured total peripheral resistance (TPR) over time. The black line indicates completion of tilt. Both orthostatic hypotension (cOH) patients and controls are divided by the SBP>140 mmHg criterion for supine hypertension (SH). * = Significant.

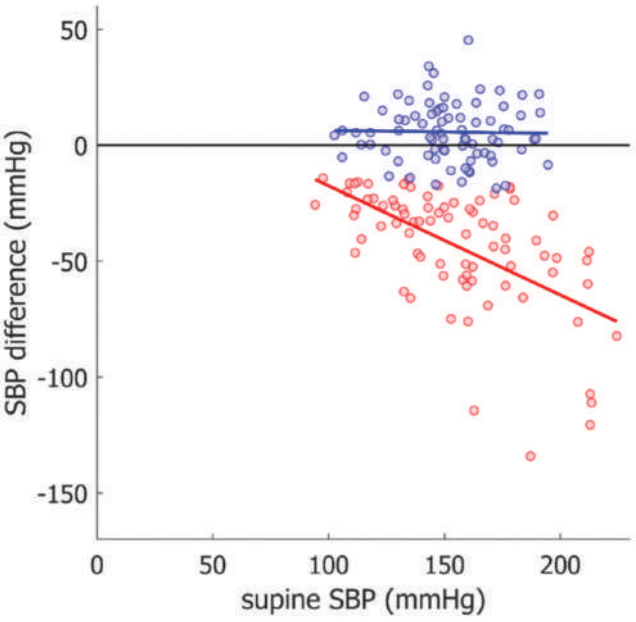

FIGURE 2 Relationship between the blood pressure fall three minutes after tilt and the supine blood pressure for controls (blue) and orthostatic hypotension patients (red).

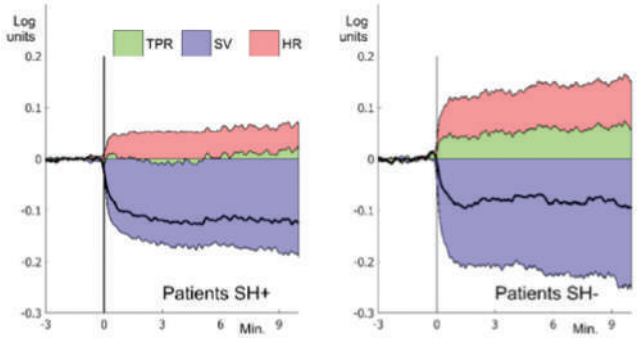

FIGURE 3 Relative contributions of the three hemodynamic parameters to orthostatic blood pressure. Orthostatic hypotension patients are divided by the SBP>140 mmHg criterion for supine hypertension (SH). The black line shows the mean arterial pressure.

Conclusion: High supine TPR explained SH; a failure to increase TPR explained the orthostatic SBP fall. The latter was likely due to autonomic failure, which can however not directly explain high supine TPR. Explaining this requires other mechanisms, such as residual sympathetic tone, denervation supersensitivity or humoral factors.

EPO-017 | Morphological and functional assessment of the vagus nerve in multiple sclerosis

A. Abicic[1]; I. Adamec[2]; M. Krbot Skorić[2]; A. Junaković[2]; A. Karić[2]; M. Habek[2]
[1]*Department of Neurology, General Hospital Zabok, Zabok, Croatia;* [2]*Department of Neurology, University Hospital Centre Zagreb, Zagreb, Croatia*

Background and Aims: Autonomic dysfunction (AD) has been linked to vagal nerve atrophy in some neurodegenerative diseases, but atrophy of the vagus nerve in multiple sclerosis (MS) and its association with AD has not been studied. The aim of this study was to determine the relationship between the cross-sectional area (CSA) of the vagus nerve and parasympathetic function in people with MS (pwMS) and healthy controls (HC).
Methods: 40 pwMS (65.0% females, 36.03±9.08 years) and 39 HC (79.5% females, 38.23±7.19 years) were enrolled. The subjects underwent an ultrasound of the vagus nerve and testing of the parasympathetic nervous system was evaluated with the respiratory sinus arrhythmia (RSA), Valsalva ratio (VR) and heart rate variability (HRV).
Results: The mean vagal CSA in pwMS was 1.98±0.44 mm^2 on the right and 1.72±0.39 mm^2 on the left side. The mean vagal CSA in the HC group was 2.08±0.53 mm^2 on the right and 1.73±0.36 mm^2 on the left side. There was no significant difference between the two groups in right ($p=0.33$) or left ($p=0.90$) vagal CSA. In the HC, there was significant correlation between right vagal CSA and RSA (rp=0.330, $p=0.040$), and right-left vagal CSA ratio and RSA (rp=0.345, $p=0.031$). The right-left vagal CSA ratio correlated with the LF/HF (rp=0.322, $p=0.049$). No correlation was observed in pwMS.
Conclusion: The ultrasound characteristics of the vagal nerves correlate with the parasympathetic nervous system measures in HC. This correlation was not observed in pwMS.
Disclosure: Nothing to disclose.

EPO-018 | Peripheral visual exploration in postural tachycardia syndrome is reduced during standing: The cause of tunnel vision?

B. Rodriguez[1]; L. Pantano[1]; T. Nef[2]; R. Müri[2]; W. Z'Graggen[1]
[1]*Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland;* [2]*Gerontechnology and Rehabilitation Group, ARTORG Center for Biomedical Engineering Research, University of Bern, Bern, Switzerland*

Background and Aims: Patients with postural tachycardia syndrome (POTS) report strongly disturbing visual symptoms such as tunnel vision and focusing problems in everyday life, but this phenomenon has not yet received any attention from research. The aim of this study was to characterise visual symptoms in POTS and to investigate possible underlying pathophysiological mechanisms.
Methods: Fifteen patients with POTS and 15 healthy controls were included in this study. Hemodynamics, (visual) symptoms, eye movements and pupil diameter were measured in all participants during free exploration of images in the supine position and during 60° head-up tilt using continuous cardiovascular monitoring, subjective symptom assessment and eye tracking.
Results: During head-up tilt, patients with POTS showed a reduced number and duration of fixations as well as a reduced number, peak velocity and amplitude of saccades compared to their supine eye movements and to those of healthy subjects. This reduction in visual exploration occurred mainly in the peripheral two-thirds of the visual field and paralleled the onset of subjective visual symptoms. There were no differences in the saccade main sequence between the two groups in either body position. The pupil diameter of patients increased excessively during head-up tilt.

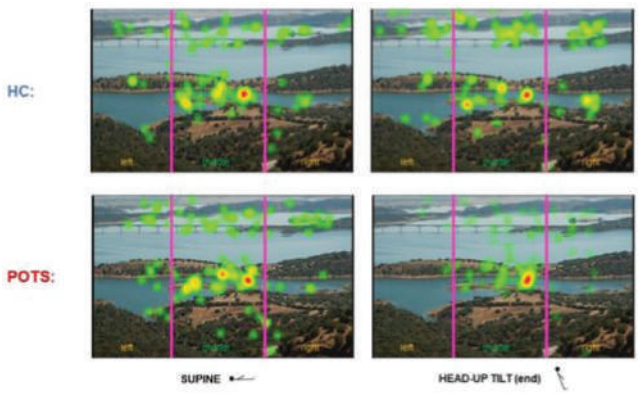

Illustration of fixations. The darker the marking, the more strongly the area was fixated. The image was divided into three areas of interest, whereby the values of the left and right areas were cumulated and used as "periphery" for further analysis.

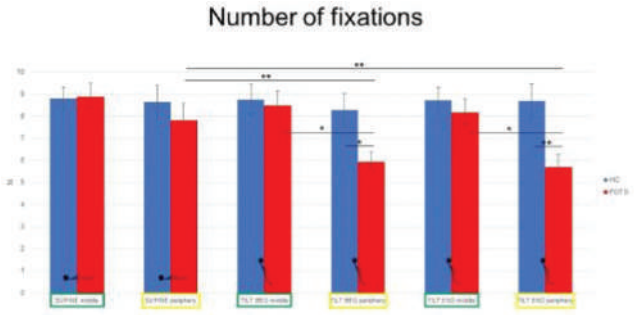
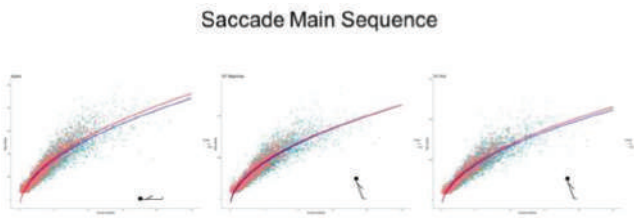


Bar graphs showing the number of fixations of POTS (red) and healthy controls (blue) in the supine position, during the first and last half of a ten-minute 60° head-up tilt. Values are given as means ± S.E.M. *$p \leq 0.05$, **$p \leq 0.01$.



Saccade main sequence (relationship of saccade peak velocity (degrees/second) and amplitude (degrees)) shown for POTS (red) and healthy controls (blue) in the supine position, during the first and last half of a ten-minute 60° head-up tilt.

Conclusion: Patients with POTS have a reduced exploration of the peripheral visual field exclusively in the upright body position, possibly leading to tunnel vision. Since the saccade main sequence was normal in patients in both body positions, the reduction of peripheral visual exploration is likely due to a position-dependent dysfunction of the frontal eye field.

Disclosure: Nothing to disclose.

EPO-019 | Autonomic dysfunction in people with multiple sclerosis: A 6-year longitudinal study

B. Ruška[1]; L. Crnošija[2]; I. Adamec[2]; A. Junaković[2]; B. Barun[2]; T. Gabelić[2]; M. Krbot Skorić[2]; M. Habek[3]

[1]*Department of Neurology, Sveti Duh University Hospital, Zagreb, Croatia;* [2]*Department of Neurology, University Hospital Center Zagreb, Zagreb, Croatia;* [3]*School of Medicine, University of Zagreb, Zagreb, Croatia*

Background and Aims: The aim of this study was to investigate the evolution of autonomic dysfunction in pwMS over a six-year follow-up.

Methods: This was a prospective cohort study in which 121 consecutive pwMS (85 females, age at baseline 32.2 ± 8.7 years) were enrolled at the time of diagnosis and evaluated every two years for six years. ANS symptoms were evaluated with the Composite Autonomic Symptom Score (COMPASS-31). Heart rate (HR) and blood pressure (BP) responses to the Valsalva maneuver, HR response to deep breathing (RSA), BP response to passive tilt and quantitative sudomotor axon reflex test (QSART) were performed with CNSystems Task Force® Monitor device. The severity and distribution of ANS function was quantified using adrenergic (AI), cardiovagal (CI) and sudomotor (SI) indices of the Composite Autonomic Severity Scale (CASS).

Results: There was no significant change in the frequency of autonomic symptoms measured with COMPASS-31 over the years ($p = 0.454$). During the follow-up, there was a significant progression of autonomic dysfunction (31% of pwMS experienced conversion of the CASS score from 0 at baseline to >0 at year 6, $p = 0.038$). This difference was mainly driven by progression of parasympathetic (19% of pwMS experienced conversion of the CI from 0 at baseline to >0 at year 6, $p = 0.001$) and sudomotor (32% of pwMS experienced conversion of the SI from 0 at baseline to >0 at year 6, $p = 0.003$) dysfunction. Increase in age was an independent predictor of progression of autonomic dysfunction (Exp(B) 1.107, 95% CI 1.038–1.180).

Conclusion: Substantial proportion of pwMS experience progression of autonomic dysfunction over time.

Disclosure: Nothing to disclose.

EPO-020 | Delayed orthostatic hypotension in Parkinson's disease and in the aging general population

B. Calió[1]; F. Leys[1]; G. Matteucci[2]; N. Campese[1]; G. Rivasi[2]; G. Goebel[1]; G. Testa[2]; R. Granata[1]; S. Duerr[1]; J. Ndayisaba[1]; K. Radl[1]; M. Thurner[1]; K. Seppi[1]; W. Poewe[1]; S. Kiechl[1]; A. Ungar[2]; G. Wenning[1]; M. Rafanelli[2]; A. Fanciulli[1]

[1]*Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria;* [2]*Department of Geriatrics, Careggi University Hospital, Florence, Italy*

Background and Aims: Delayed orthostatic hypotension (dOH) is considered a prodromal form of classic OH (cOH), but its frequency and associated clinical features in Parkinson's disease (PD) and aging individuals are not well known.

Methods: We retrospectively studied individuals with PD and age-matched aging individuals without parkinsonism referred to the Innsbruck and Florence dysautonomia centers for head-up tilt-test under continuous noninvasive blood pressure (BP) monitoring. In both study cohorts, we reviewed the medical records of the 6 months preceding and following the examination for history of syncope and falls.

Results: Two-hundred thirteen individuals with PD [35% women; 73(69; 76) years of age; 6 (3; 10) years of disease duration] and 213 age-matched aging individuals [45% women; 73(69; 77) years of age] were included. DOH occurred in 18% of patients with PD and 9% of the aging individuals, and was significantly associated with a diagnosis of PD [OR = 2.69 (95% C.I.: 1.3–5.7), $p = 0.010$]. Patients with PD had a more severe systolic BP fall during prolonged head-up tilt

with respect to aging individuals ($p < 0.001$). Syncope and syncope-related falls history were more frequent in the aging individuals ($p < 0.001$).

Conclusion: Delayed OH is more common in PD than in aging individuals. In PD, the systolic BP fall drives dOH development and the slow onset of symptoms may reduce the occurrence of syncope-related falls. Nonetheless, due to the frequency of dOH and its potential progression into cOH, a closer monitoring of the affected individuals should be considered.

Disclosure: Nothing to disclose.

EPO-021 | Long-term efficacy of antihypotensive drugs for neurogenic OH: Real-world data in patients with alpha-synucleinopathies

S. Sajeev[1]; G. Chiaro[1]; S. Johnstone[1]; G. Ingle[1]; V. Iodice[2]
[1]*Autonomic Unit, The National Hospital for Neurology and Neurosurgery, UCLH NHS Trust, London, UK;* [2]*Department of Brain Repair and Rehabilitation, UCL Queen Square Institute of Neurology, University College London, UK*

Background and Aims: Treatment of neurogenic orthostatic-hypotension (nOH) relies on consensus-based approaches; real-world data on long-term efficacy and safety are lacking. We evaluated response to anti-hypotensives in a longitudinal cohort of patients with synuclein-related nOH (PAF, PD, DLB and MSA).

Methods: Severity of cardiovascular autonomic failure was assessed with autonomic function testing. Response to medications was measured with a semi-composite questionnaire assessing the number of falls/month and hospitalizations/trimester, the burden of orthostatic symptoms, quality of life (OHQ, SF-36, PGI scale) and BP monitoring (with structured diary and ambulatory monitoring). Demographic measures are reported as median + IQR, all other measures as mean ± SD.

Results: 101 patients completed the questionnaire (49-PAF, 27-PD, 21-MSA and 4-DLB). 61 patients were on long-term treatment (26 on one, 35 on multiple anti-hypotensives); 40 on non-pharmacological measures, due to early-stage disease, severe supine-hypertension, immobilization, or medication unresponsiveness. Number of falls and hospital admission were 2 ± 12 and 0.3 ± 1 respectively. The OHQ composite score (range 1–10) was 7.24 ± 1.7. SF36 physical and mental composite scores (range: 0–100) were 33.2 ± 37.5 and 38.9 ± 37.8 respectively. PGI score (range: 1–7) was 4.7 ± 1.4. The magnitude of nOH was 56/27 (±34/19) mmHg in treated patients, compared to 29/6 (±22/11) mmHg in those untreated.

Conclusion: Despite multiple anti-hypotensive use, two-thirds of patients were significantly symptomatic with nOH, as corroborated by falls rates and hospital admissions. These findings emphasized the critical nature of nOH, its current gaps in pharmacological management and its profound impact on patients' daily functioning.

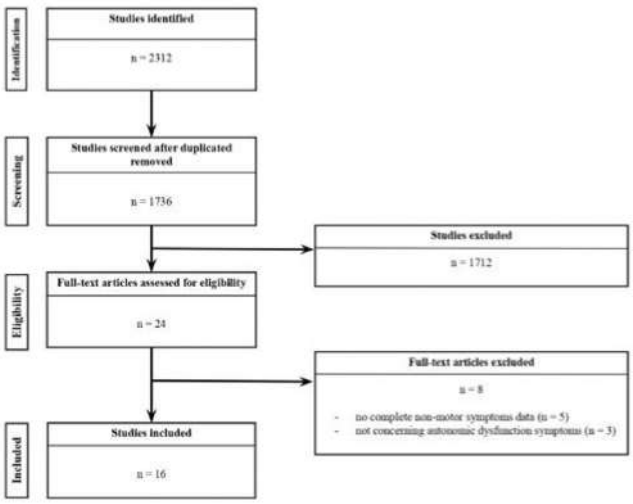
Disclosure: Nothing to disclose.

EPO-022 | A systematic review of the effects of LCIG infusion on autonomic symptoms in advanced Parkinson's disease

S. Galli[1]; L. De Carolis[1]; E. Bianchini[1]; M. Alborghetti[1]; B. Calió[2]; P. Pacilio[1]; A. Fanciulli[2]; F. Pontieri[1]; D. Rinaldi[1]
[1]*Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Sapienza University of Rome, Rome, Italy;* [2]*Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria*

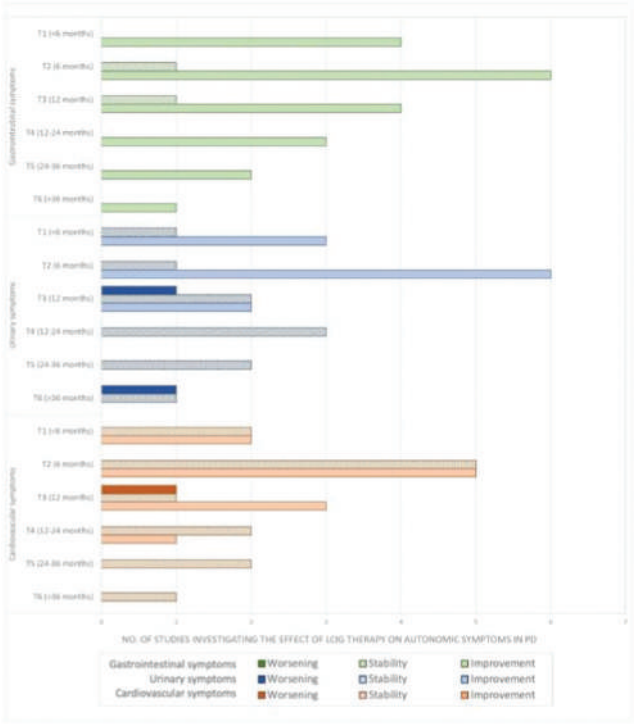
Background and Aims: Autonomic dysfunction significantly affects Parkinson's disease (PD) patients' quality of life, especially in the advanced stages. Levodopa/carbidopa intestinal gel (LCIG) infusion represents an established therapeutic approach for advanced PD characterized by severe motor complications and is considerably helpful in addressing some non-motor symptoms (NMS). However, the impact of LCIG on autonomic symptoms remains less elucidated. We conducted a systematic review to investigate the influence of LCIG therapy on autonomic dysfunction in patients with PD.

Methods: Following the PRISMA guidelines, we systematically searched Pubmed for studies reporting autonomic outcome measures in LCIG-treated PD patients published between January 2005 and June 2023 (Figure 1).

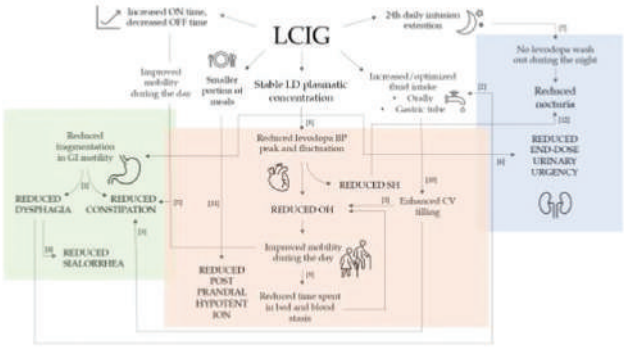


Flowchart of the systematic review process.

Results: Among the 2,312 studies identified, 16 met the inclusion criteria and underwent quality assessment and data extraction, encompassing a cohort of 1,361 patients with Parkinson's disease (PD) (Figure 2). Thirteen studies reported improvement or stability in gastrointestinal, urinary, and cardiovascular symptoms throughout the interventional period. Conversely, one study reported worsening cardiovascular symptoms, while two studies observed worsening urological symptoms. Regarding safety, seven studies reported gastrointestinal (8.4%), urinary (0.5%), cardiovascular (1.1%), and autonomic LCIG-related AEs.



Number of studies reporting improvement, stability, or worsening of gastrointestinal, urinary, and cardiovascular symptoms at each timepoints.



Proposed mechanisms for LCIG's beneficial effects on autonomic symptoms in PD.

Conclusion: LCIG infusion is relatively safe and may help reduce autonomic symptoms burden in advanced PD.
Disclosure: Nothing to disclose.

EPO-023 | Characterize autonomic involvement and its correlation with electrophysiological parameters in various subtypes of GBS

P. Majumdar; A. Das
All India Institute of Medical Sciences, New Delhi

Background and Aims: GBS is an inflammatory demyelinating disorder of peripheral nerves. About 2/3 rd of patients of GBS have autonomic dysfunction. No studies have clearly mentioned type and severity of autonomic dysfunction in different types of GBS.
Methods: This was a prospective cohort study in which 68 patients of GBS underwent clinical workup along with autonomic function testing (heart rate variability with deep breathing, orthostatic blood pressure measurement, isometric handgrip test, cold pressor test and valsalva manoeuvre). The study was done in All India Institute of Medical Sciences, New Delhi. Autonomic function tests were done at two times, at admission and at 15th day. Primary outcome was to determine the predominant pattern of autonomic dysfunction in subtypes of GBS.
Results: 71 patients were screened for eligibility and 68 patients completed the study. At baseline, 79% of patient had dysfunction on laboratory autonomic function tests while only 25% had positive scores on Composite Autonomic Symptom Score (COMPASS-31). Sympathetic dysfunction was the predominant abnormality accounting for 85.71% patients in AIDP group and 68.18% patients in axonal group (AMAN and AMSAN) combined. There was no correlation of any pattern of autonomic dysfunction with degree of axonal involvement ($p = 0.681$).
Conclusion: This study showed that sympathetic dysfunction is the predominant pattern of autonomic involvement in GBS patients. No correlation could be found out between types of autonomic dysfunction and variants of GBS/degree of axonal involvement in axonal variants.
Disclosure: Nothing to disclose.

EPO-024 | Nuclear imaging and autonomic biomarkers predict phenoconversion in pure autonomic failure

G. Chiaro[1]; R. Alnasser Alsukhni[1]; G. Ingle[1]; K. Bhatia[2]; C. Mathias[3]; J. Bomanji[4]; V. Iodice[1]
[1]*Autonomic Unit, National Hospital for Neurology and Neurosurgery, London, UK;* [2]*Department of Clinical and Movement Neurosciences, UCL Queen Square Institute of Neurology, University College London, London, UK;* [3]*UCL Queen Square Institute of Neurology, Faculty of Brain Sciences, University College London, London, UK;* [4]*Institute of Nuclear Medicine, UCLH NHS Foundation Trust, London, UK*

Background and Aims: Abnormal DaTSCAN is a potential biomarker of central nervous system involvement in pure autonomic failure (PAF) and can predict phenoconversion to more widespread alpha-synucleinopathies. We aimed to describe whether combining DaTSCAN, MIBG cardiac scintigraphy and autonomic biomarkers can help assess likelihood of phenoconversion.
Methods: As part of our longitudinal program on alpha-synucleinopathies, the Queen Square Autonomic Prodromal Project (QSA-PRODROMAL), a subgroup of consecutive patients with an initial diagnosis of PAF underwent a multimodal assessment with cardiovascular autonomic function performed with Finapres NOVA, DaTSCAN and cardiac MIBG.

Results: 23 PAF patients with available DaTSCAN and cardiac MIBG were included. Within a median disease duration of 8 (IQR 6–12) years, 6 patients phenoconverted: 2 to Lewy body disorders ([LBD], 1 to Parkinson's disease and 1 to dementia with Lewy bodies), 1 to multiple system atrophy (MSA), and 2 met the research criteria for possible prodromal MSA. Nuclear imaging was abnormal up to 4 years prior to phenoconversion. Both LBD had abnormal DaTSCAN and cardiac MIBG with low supine plasma noradrenaline levels (<200 pg/ml). MSA had abnormal DaTSCAN, normal cardiac MIBG and normal supine plasma noradrenaline levels (>200 pg/mL). The 2 possible prodromal MSA had preserved cardiac innervation and either normal (cerebellar) or abnormal (parkinsonian) DaTSCAN, depending on their clinical phenotype.

Conclusion: The combination of DaTSCAN, cardiac MIBG and catecholamine profiles identified PAF patients at risk of developing other alpha-synucleinopathies and helped predate their phenoconversion by up to 4 years.

Disclosure: The authors have nothing to disclose.

EPO-025 | Pain subtypes and sleep dysfunction in Parkinson's disease

I. Murasan[1]; S. Diaconu[1,2]; D. Rusu[1,2]; B. Opritoiu[1,2]; L. Ungureanu[1,2]; B. Ciopleias[1,2]; C. Kakucs[1,2]; C. Falup-Pecurariu[1,2]
[1]*Department of Neurology, County Clinic Hospital, Brasov, Romania;* [2]*Faculty of Medicine, Transilvania University, Brasov, Romania*

Background and Aims: In Parkinson's disease (PD), sleep is often affected, pain being among the possible causes. This can lead to difficulties in initiating and maintaining sleep, one of the consequences being sleep fragmentation. We aimed to characterize the link between pain and sleep dysfunction in patients with Parkinson's disease.

Methods: 131 PD patients were enrolled in this case-control study. Pain domains (according to the King's Parkinson's Disease Pain Scale-KPPS) were analyzed according to the presence of sleep disturbances. Based on a Pittsburgh Sleep Quality Index (PSQI) score >5, patients with PD were considered "bad sleepers", and those with a score ≤5 were considered "good sleepers".

Results: 33 (25.19%) patients fell into the "good sleepers" category, and 98 (74.8%) into the "bad sleepers" category. "Bad sleepers" patients presented more significant pain than "good sleepers" for all the component domains of the KPPS scale, the results for the following domains being statistically significant: musculoskeletal pain (5.48 ± 3.50 vs. 2.70 ± 2.67, $p < 0.001$), chronic pain – respectively central pain (1.19 ± 2.01 vs. 0.15 ± 0.71, $p = 0.004$), nocturnal pain – respectively pain in relation to akinesia (2.26 ± 2.74 vs. 0.64 ± 1.22, $p = 0.001$) and radicular pain (4.35 ± 4.20 vs. 2.45 ± 3.55, $p = 0.022$).

Conclusion: The majority of the patients assessed have a diminished quality of sleep. In their case, pain is more prominent than in individuals with uninterrupted sleep. Focusing on treatment of pain would potentially improve the sleep of these PD patients.

Disclosure: Nothing to disclose.

EPO-026 | Circadian rhythm in patients with hereditary transthyretin amyloidosis and asymptomatic mutation carriers

L. Sander[1]; G. Chiaro[2]; A. Torrente[3]; G. Ingle[2]; A. Carr[4]; C. Whelan[5]; J. Gillmore[5]; M. Reilly[4]; C. Mathias[6]; V. Iodice[1]
[1]*Autonomic Unit, The National Hospital for Neurology and Neurosurgery, London, UK; Department of Brain, Repair and Rehabilitation, University College London Queen Square Institute of Neurology, London, UK;* [2]*Autonomic Unit, The National Hospital for Neurology and Neurosurgery, London, UK;* [3]*Autonomic Unit, The National Hospital for Neurology and Neurosurgery, London, UK; Department of Biomedicine, Neuroscience and Advanced Diagnostics (Bi.N.D.), University of Palermo, Palermo, Italy;* [4]*Centre for Neuromuscular Diseases, Department of Neuromuscular Diseases, UCL Queen Square Institute of Neurology and the National Hospital of Neurology and Neurosurgery, London, UK;* [5]*National Amyloidosis Centre, Division of Medicine, University College London, London, UK;* [6]*Department of Brain, Repair and Rehabilitation, University College London Queen Square Institute of Neurology, London, UK*

Background and Aims: Hereditary or variant transthyretin amyloidosis (ATTRv) is a life-threatening disease with effective disease modifying treatments (DMT). Cardiovascular autonomic failure is a key feature. Abnormal circadian blood pressure (BP) rhythm might represent a risk factor for cardiovascular events. This study evaluates BP profile in ATTRv patients and carriers.

Methods: 97 patients with ATTRv and 12 TTR mutation carriers underwent ambulatory 24h BP measurements (ABPM; 29% females, mean age 58y, range 28–78 y, 43% T60A mutation). Dipping profile was defined according to the consensus criteria. Autonomic function testing (AFT) included tilt table/standing/pressor tests, heart rate responses to Valsalva Manoeuvre and deep breathing using Finapres NOVA.

Results: 54/97 patients were on treatment affecting BP (22 on pressor agents, 39 on antihypertensives), carriers had no treatments affecting BP. 74/109 subjects showed an abnormal dipping profile: 53 had reduced dipping, 21 were non- or reversed dippers. 4/74 subjects were carriers (all reduced dippers): three had mild AFT impairment, one was normal. 6/8 carriers with normal ABPM showed abnormal AFT. Only two carriers and two patients had unremarkable autonomic assessment throughout. No significant dipping profile difference was found at first assessment in patients with (12/97) or without DMT.

Conclusion: Pathologic BP profiles are common in ATTRv and may be an early feature in certain carriers. Both ABPM and AFT are needed to detect subtle autonomic impairment. ABPM might be a useful screening tool but does not allow for quantitative parasympathetic/

sympathetic assessment requiring formal AFT. Longitudinal studies are needed to investigate changes in circadian rhythm and their response to DMT.

Disclosure: LS holds a grant from the University of Basel, Switzerland. GC, AT, GTI, CA, CJW, MMR, CJM: nothing to disclose. JDG provides consultancy for Alnylam, AstraZeneca, Bridgebio, Ionis, Intellia and ATTRalus. VI is supported by the National Institute for Health Research, University College London Hospitals Biomedical Research Centre.

EPO-027 | Sympathetic dysfunction as an early autonomic indicator in Parkinson's disease without orthostatic hypotension

J. Park[1]; L. Okamoto[2]; I. Biaggioni[2]; B. Kim[1]
[1]*Department of Neurology, Korea University Medicine, Seoul, Korea;* [2]*Division of Clinical Pharmacology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN, USA*

Background and Aims: This study aimed to evaluate the characteristics of autonomic dysfunction in drug-naïve patients with early-stage PD without orthostatic hypotension (OH) by analyzing Valsalva maneuver (VM) parameters.

Methods: Drug-naïve patients without orthostatic hypotension ($n=61$) and controls ($n=20$) were retrospectively analyze. The patients were subcategorized into early-PD ($n=35$) and mid-PD ($n=26$) groups based on the Hoehn and Yahr staging. VM parameters driven by Finapres®, including changes in systolic blood pressure at late phase 2 (ΔSBPVM2), ΔHRVM3, Valsalva ratio (VR), pressure recovery time, adrenergic baroreflex sensitivity, and vagal baroreflex sensitivity, were assessed.

Results: In the early-PD group, ΔSBPVM2, a marker of sympathetic function, was significantly lower compared to that in controls (risk ratio = 0.95, $p=0.027$). Receiver operating characteristic (ROC) curve analysis showed an optimal cutoff value of −10 mmHg for ΔSBPVM2 ($p=0.002$, area under the curve [AUC]: 0.737) and 17 mmHg for ΔDBPVM2 ($p=0.002$, AUC: 0.736). VR and age exhibited an inverse relationship with Unified Parkinson's Disease Rating Scale Part 3 scores (VR: $p=0.038$, $\beta=-28.61$; age: $p=0.027$, $\beta=0.35$) in the multivariable regression analysis.

Conclusion: The ΔBPVM2 parameter of the VM may help detect autonomic nervous system involvement in early-PD without OH. Our results suggest that sympathetic dysfunction is an early manifestation of autonomic dysfunction in patients with PD.

Disclosure: Nothing to disclose.

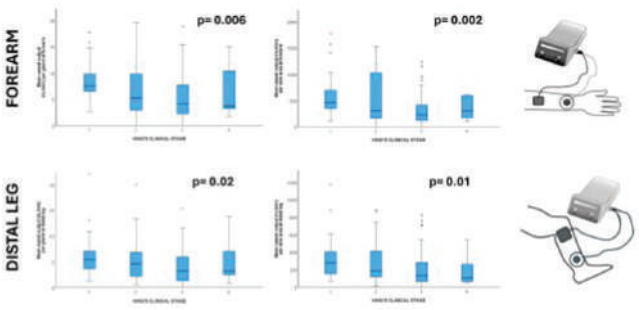
EPO-028 | Longitudinal assessment of sudomotor dysregulation in amyotrophic lateral sclerosis: A multimodal functional study

R. Dubbioso[1]; V. Provitera[2]; M. Nolano[2]
[1]*Department of Neurosciences, Reproductive Sciences and Odontostomatology, University of Naples Federico II,* [2]*stituti Clinici Scientifici Maugeri IRCCS, Skin Biopsy Lab, Neurological Rehabilitation Unit of Telese Terme Institute*

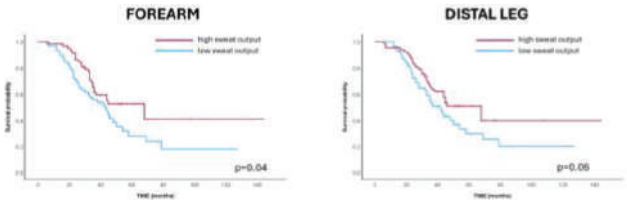
Background and Aims: Among autonomic complaints, sudomotor symptoms have been described in approximately one-quarter of patients with amyotrophic lateral sclerosis (ALS). However, no study has systematically investigated their correlations with the onset and severity of the disease, as well as progression over time. Here we used a multimodal approach to answer these questions in a large cohort of ALS patients

Methods: Patients underwent functional assessment of sudomotor dysfunction by clinical questionnaires and dedicated instruments, such as sympathetic-skin-response (SSR) and dynamic-sweat-test (DST) recorded at upper and lower limbs at recruitment, after 6 and 12 months.

Results: ALS patients ($n=125$), compared with HC ($n=30$), complained of more thermoregulatory symptoms ($p=0.001$), with a significant reduction in sweat output at DST and SSR amplitude at upper and lower limbs (all $p<0.05$). Across clinical stages, patients displayed a significant reduction in overall sweat output (all $p<0.02$), a result confirmed by longitudinal study ($p<0.001$). Bulbar onset patients showed more autonomic symptoms and thermoregulatory disturbances than spinal onset patients, interestingly functional study disclosed significant difference for SSR, but not for DST between the two groups, suggesting an impairment of central-brainstem circuits underlying thermoregulatory dysfunction in the bulbar phenotype. Finally, survival analysis showed that reduction of total sweat output at upper limb was significantly associated with poor prognosis ($p=0.04$).



DYNAMIC SWEAT TEST ACROSS CLINICAL STAGES IN ALS PATIENTS



Kaplan-Meier curves of survival probability of ALS patients stratified according to the total sweat output at the dynamic sweat test

Conclusion: Sudomotor disturbance is part of the non-motor symptoms of ALS patients, worsening in parallel with motor disability and being more pronounced in bulbar phenotype. Functional assessment of sudomotor dysregulation could be considered as a potential biomarker of disease progression in ALS.
Disclosure: None.

EPO-029 | Association of fibromyalgia severity with patients' mood, sleep quality, quality of life and autonomic dysfunction

R. Singh[1]; N. Rai[2]; J. Rai[3]; A. Pathak[3]
[1]*Professor, Department of Physiology, AIIMS Bhopal;* [2]*Visiting faculty, Department of Neurology, AIIMS Bhopal;* [3]*JRF, Department of Physiology, AIIMS Bhopal*

Background and Aims: Fibromyalgia syndrome is a musculoskeletal disorder characterized by widespread pain. Pain limits their daily activities, affecting their mood and quality of life. Autonomic derangements have also been shown to be associated with FMS. This study was done to explore the association of autonomic dysfunction, sleep quality and mood with increasing severity of fibromyalgia and its impact on their quality of life
Methods: Hundred adult fibromyalgia patients, as per ACR 2010 criteria, were evaluated for sleep quality, Quality of life, Pain, Mood, and FMS severity using validated questionnaires. They were also evaluated for autonomic functions using heart rate variability and Ewing's battery of tests.
Results: Pain scores on VAS were 6.80±1.58 and 54.10±14.33 on global pain scale. Mean FIQR score was 50.62±13.68, poor sleep quality. Mean depression, anxiety, and stress scores as assessed by DASS-21 were 10.04±4.59, 8.33±4.48, and 10.75±4.66, respectively. Autonomic dysfunction was observed in less than 50% of patients, but no significant correlation was found between FMS severity and level of AD. An increasing trend of depression, anxiety, stress, was observed with increase in FMS severity. Sleep quality and quality of life deteriorated with increasing severity of FMS.
Conclusion: Pain increased with increasing severity of FMS but there is no association of FMS severity with autonomic dysfunction. There is a deterioration in mood, sleep quality as well as quality of life of patients with increasing severity. The causal association of autonomic dysfunction observed in a few of the patients needs further exploration in a follow-up study.
Disclosure: Nothing to disclose.

EPO-030 | Autonomic function as predictor of cognitive impairment following deep brain stimulation in Parkinson's disease

V. Cabreira; M. Rosas; E. Azevedo; P. Castro
Neurology Department, Centro Hospitalar Universitario de Sao Joao, Porto, Portugal

Background and Aims: Parkinson's disease (PD) affects over 4 million people older than 50. While deep brain stimulation (DBS) is an established treatment for motor complications in PD, mechanisms explaining cognitive dysfunction post-DBS remain incompletely understood. Our aim is to investigate whether baseline autonomic function is associated with cognitive impairment post-DBS in PD.
Methods: Prospective cohort study. STN-DBS surgery candidates were recruited between 2016 and 2019, and submitted to baseline neurological, autonomic (non-invasive Finometer device (Finapres) and 3-lead ECG), and comprehensive neuropsychological assessments. A follow-up autonomic and cognitive assessment was conducted 6–12 months post-surgery. An adaptation of the Ewing battery of autonomic tests was followed. The high frequency component of RRi variability (HFRR) (parasympathetic tone), the low frequency component of SAP variability (LFSAP) (sympathetic tone) and baroreceptor gain were used for analysis. Cognitive change scores (T1-T2) were computed and assumed as dependent variable in a regression model, using baseline demographics and quantitative scores on autonomic non-invasive tests as independent variables.
Results: 38 patients were included. Phonetic verbal fluency ($p=0.013$), Frontal Assessment Battery (FAB) ($p=0.008$) and Trail Making test part B ($p=0.035$) deteriorated post-DBS. LFSAP was associated with a worse FAB score post-DBS, even after adjustment for age and disease duration ($p=0.022$) (Figure 1). Both variables were correlated ($r=0.416$; $p=0.035$). This seems independent from a DBS effect on autonomic function.

Table 1. Analysis of cognitive impact of deep brain stimulation (DBS) in this PD patient group. Performance on a neuropsychological battery of tests (mean and SD) pre- and post-DBS is shown. Higher scores indicate better performance, except for Trail Making Test A and B, where higher scores (longer time to complete the task) indicate poorer performance. Bold indicates statistically significant *p*-value ($p < .05$).

	Pre-DBS	post-DBS	paired t-test
MoCA	24.2 (2.7)	25.4 (2.6)	p=0.385
Frontal assessment battery (FAB)	14.1 (2.1)	11.2 (3.2)	p=0.008
Semantic verbal fluency	15.6 (4.7)	12.6 (5.0)	p=0.207
Phonetic verbal fluency	33.0 (9.3)	26.9 (11.5)	p=0.013
Wechsler memory scale	12.1 (2.6)	21.4 (32.9)	p=0.046
Digit span memory test	9.6 (1.9)	8.6 (1.9)	p=0.276
Progressive matrices de raven (PM47)	25.4 (5.4)	26.0 (5.3)	p=0.338
Figure copy test	11.5 (1.8)	11.4 (1.7)	p=0.885
Trail making test part A	85.3 (43.8)	107.1 (69.1)	p=0.099
Trail making test part B	249.3 (222.7)	351.9 (235.4)	p=0.035
Boston naming test	43.5 (22.5)	53.8 (7.5)	p=0.059
Clock drawing	3.8 (1.5)	3.4 (1.3)	p=0.705

Table 2. Mean and SD of the autonomic parameters values pre-surgery and post-surgery. HFRR for high frequency RR variability, LFSAP for low frequency systolic arterial pressure, BRG for baroreceptor alpha-index gain and HR for heart rate. DBS – deep brain stimulation[surgery.

	HFRR (sec2)	LFSAP (mmHg2)	BRG	HR (bpm)
Pre-DBS	186.7 (236.8)	4.9 (5.5)	5.2 (3.6)	70.3 (10.8)
Post-DBS	111.1 (108.2)	3.4 (2.5)	3.7 (3.1)	71.3 (10.5)
Paired t-test pre- vs post-DBS	p=0.080	p=0.295	p=0.043	p=0.658

Conclusion: The identification of treatable targets and useful biomarkers of cognitive dysfunction after DBS helps identifying whose patients are specifically vulnerable for accelerated cognitive decline post-DBS, allowing for better patient selection and prognostic information.

Disclosure: Nothing to disclose.

Puca" AOU Consorziale Policlinico, Bari, Italy, [10]Department of Neurology, Casa sollievo della sofferenza, San Giovanni Rotondo, Italy; [11]Department of Neuroscience, Azienda Ospedaliera Universitaria Integrata Verona, Verona, [12]Department of Neurology and Stroke Unit, AORN Antonio Cardarelli, Naples, Italy, [13]Department of Neurology, Di Venere Hospital, Bari, Italy, [14]Department of Human neurosciences, University of Rome La Sapienza, Rome, Italy

Background and Aims: It is unclear whether the aetiology of minor stroke or TIA affects the effectiveness of short-term dual antiplatelet treatment (DAPT). This study aims to analyse the aetiology of first and recurrent events and their predictive value in a real-world population of patients treated with DAPT.

Methods: The real-life study on short-term DAPT in Patients with ischemic stroke or TIA (READAPT) prospectively included, from February 2021 to February 2023, patients with minor stroke or high-risk TIA receiving DAPT. We determined the aetiology of index and recurrent cerebral ischemic events. Cox regression analysis identified predictors of ischaemic recurrence.

Results: Among 1920 patients with ischaemic stroke or TIA (65.4% male, median age 72 years) the index event was undetermined in 830 cases (43.2%), lacunar in 534 (27.8%), atherothrombotic in 452 (23.5%) and other determined cause in 104 (5.4%). Sixty-four patients (3.3%) had a 90-day recurrent ischaemic stroke or TIA. There were no differences among the different aetiologic groups in recurrent events. Among the 64 patients with recurrences, the distribution of aetiologies was different for the recurrent event as compared to the index events (undetermined 46.9% vs 34.4% large vessel 29.7% vs 21.8%; lacunar 18.8% vs 31.2%; other 4.7% vs 6.3%; cardioembolic 0 vs 6.3%; $p=0.001$).

Conclusion: Our data suggest that there is no difference in the risk of recurrent events according to stroke aetiology of the index event in patients treated with short-term DAPT. Recurrent events have a different aetiological distribution of index events.

Disclosure: Nothing to disclose.

EPO-032 | Exploring the prognostic role of fibrinogen in ischemic stroke

A. Maruccia[1]; M. Pugliatti[2]; F. Colucci[2]

[1]Residency School of Neurology, Department of Neuroscience and Rehabilitation, University of Ferrara, Italy; [2]Department of Neuroscience and Rehabilitation, University of Ferrara, Italy; S. Anna University Hospital, Ferrara, Italy

Background and Aims: Several biomarkers might play a prognostic role in stroke. We explored the prognostic role of plasma fibrinogen levels (PFL) at stroke onset on residual disability and risk of hemorrhagic infarction in incident patients with ischemic stroke (IS).

Methods: Historical cohort study design. Data on comorbidities, National Institutes of Health Stroke Scale (NIHSS) on admission, PFL at stroke onset (<300 mg/dL, >=300 mg/dL) and modified Rankin Scale (mRS) before and after 3 months were collected, as well as hemorrhagic conversion among patients treated with Intravenous Thrombolysis (IVT). 'mRS difference' was computed between mRS at 3-months after stroke and onset. ANCOVA and logistic regression were used.

Results: 241 men and 203 women aged 66.9 ± 13.1 and 72.1 ± 14.2 years, respectively, were enrolled. PFL directly correlated with age at stroke onset ($p=0.043$). No difference in the distribution of PFL by site of lesion, TOAST and Oxfordshire Community Stroke Project classification, indication to thromboarteriectomy and NIHSS were detected. Inverse association was found between PFL

and IVT indication [aOR=0.46 (95% CI: 0.30, 0.72, $p=0.001$)]. In IVT treated patients, mean mRS difference was higher in subjects with high PFL after adjusting for age, onset NIHSS, diabetes mellitus, smoking habit (1.39 vs 1.33, $p=0.000013$). No association of PFL with hemorrhagic infarct conversion was found.

Conclusion: In IS patients, high PFL are associated to reduced indication to IVT and increased disability at 3 months after stroke. The prognostic role of PFL at stroke onset may depend on age and NIHSS at onset. PFL was not associated with an increased risk of post-treatment hemorrhagic infarction.

Disclosure: Nothing to disclose.

EPO-033 | Diagnostic utility of Vessel Wall MR Imaging in patients with Acute Ischemic Stroke

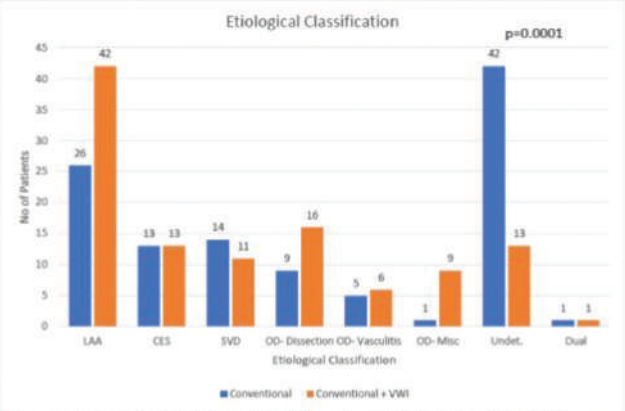
A. Mohan[1]; M. Srivastava[1]; M. Salunkhe[1]; V. Goel[2]; R. Bhatia[1]; A. Garg[2]; L. Joseph[2]; S. Jain[2]; M. Singh[1]; A. Pandit[1]; V. VY[1]; R. Rajan[1]; A. Gupta[1]

[1]Department of Neurology, All India Institute of Medical Sciences, New Delhi, India; [2]Department of Neuroimaging and Interventional Neuroradiology, All India Institute of Medical Sciences, New Delhi, India

Background and Aims: There is a need for better investigations to elucidate the etiology of stroke. High-Resolution Vessel Wall MRI is emerging imaging technique used to help understand the etiopathogenesis of acute ischemic stroke (AIS). Studies describing various findings have not yet clarified the exact utility of VW-MRI to subtype AIS. Current study was undertaken to evaluate the diagnostic utility of VW-MRI in patients with AIS.

Methods: A single-centre, prospective study recruited patients with AIS within 30 days. A team of stroke neurologists classified the etiology of AIS before and after VW-MRI. Subsequent statistical analysis was done to look for the proportion of patients with a change in etiological classification before and after VW-MRI and factors associated with the same.

Results: A total of 111 patients were recruited with a median age of 50.5 years (IQR: 38–60 years) and 72.4 % of the study population were males. The incorporation of VW-MRI resulted in change in etiological classification in 38 out of 111 (34.3%) ($p=0.0001$) patients. A baseline etiological classification of undetermined as per traditional luminal imaging modalities was found to be a strong predictor of change in etiological classification post VW-MRI (OR: 38.7; 95% CI: 2.7–555.7)



Data represented as n(%); LAA : Large Artery Atherosclerosis; CES: Cardioembolic Stroke; SVD: Small Vessel Disease; OD: Other Determined.

FIGURE Etiological Classification Before and After Vessel Wall MR Imaging

TABLE Univariate Logistic Regression for change in Etiological classification after VW- MRI

Factors	Change in Etiological Classification			
	No	Yes	OR (95% CI)	p-value
Sex				
Male	54	26	1.38 (0.55-3.51)	0.49
Female	23	8	**0.34 (0.15-0.77)**	**0.01**

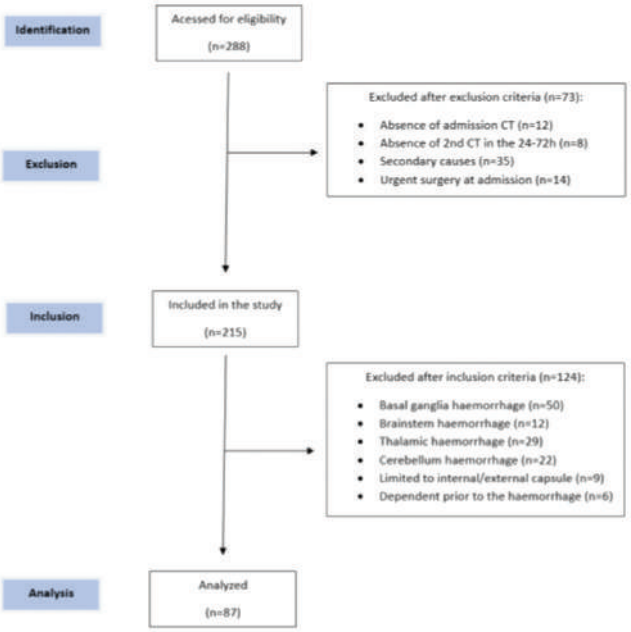
EPO-034 | **Perihematomal edema impact in the 3 years follow-up of lobar intracerebral haemorrhage**

B. Carvalho[1]; C. Pisco[2]; L. Fonseca[3]; P. Castro[1]
[1]*Department of Neurology, Centro Hospitalar Universitário de Sã João, Porto, Portugal;* [2]*Department of Clinical Neurosciences and Mental Health, Faculty of Medicine, University of Porto, Porto, Portugal;* [3]*Stroke Unit and Department of Internal Medicine, Centro Hospitalar Universitário de São João, Porto, Portugal*

Background and Aims: Spontaneous intracerebral hemorrhage (ICH) is a leading cause of non-ischemic strokes with substantial impact on morbidity and mortality. While perihematomal edema (PHE) is recognized as indicator of secondary brain injury and has been linked to increased neurological disability, there is a paucity of long-term follow-up studies exploring these associations. This study aims to address this gap and evaluate the enduring impact of PHE on the outcomes of ICH patients.

Methods: A retrospective cohort study at Centro Hospitalar Universitário São João, Porto, Portugal, included 87 lobar primary ICH patients from 2014 and 2020. We evaluated absolute (PHE), relative (rPHE) perihematomal edema, and edema extension distance (EED) measured at admission computer tomography (CT) scan and 24–72 hours post-ICH. Primary outcomes were 3-year survival and favorable functional outcome (FO) defined as modified Rankin Scale 0–3.

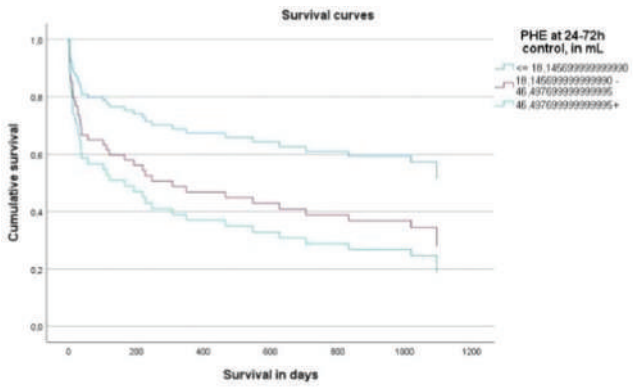


Patient selection flowchart

Results: Median age was 74.0 years (interquartile range 66–82), with 51.7% male. After 3 years, 40.2% were alive, 14.9% had a favorable FO. PHE at 24–72 h negatively correlated with survival in days (Cox regression hazard ratio 2.520, 95% CI 1.118–5.681, $p = 0.026$), but not rPHE or EED. An inverse correlation of EED at 24–72 hours to a better FO was also observed (OR 0.055, 95% CI 0.004–0.788, $p = 0.033$).

Variables	(n= 87)
Demographic and clinical	
Male sex – n (%)	45 (51.7)
Age, Years – median (IQR)	74 (66-82)
Previous mRS – median (IQR)	1 (1-2)
Hypertension – n (%)	59 (67.8)
Dyslipidemia – n (%)	43 (49.4)
Diabetes – n (%)	23 (26.4)
Smoker – n (%)	18 (20.7)
Previous alcohol abuse – n (%)	9 (10.3)
Antiplatelets – n (%)	26 (29.9)
Anticoagulant -n (%)	18 (20.7)
Statins – n (%)	37 (42.5)
Atrial fibrillation – n(%)	16 (18,4)
Hematoma characteristics	
Hematoma volume at admission, mL – median (IQR)	21.25 (6.89–35.95)
PHE at admission, mL – median (IQR)	25.40 (8.49-50.16)
PHE at control, mL – median (IQR)	33.99 (13.19-60.76)
rPHE at admission – median (IQR)	1.22 (0.66-2.72)
rPHE at control – median (IQR)	1.09 (0.67-2.32)
EED at admission, mL – median (IQR)	0.56 (0.29-0.80)
EED at admission, mL – median (IQR)	0.59 (0.30-0.83)
Follow-up outcomes	
Death at 3 years – n(%)	52 (59.8%)
Independence at 3 years (mRS 0-3) – n(%)	21 (24.1%)

Demographic characteristics and follow-up



Survival curve for PHE at control

Conclusion: PHE appeared to predict early mortality in lobar ICH. Given the observed tendency towards better functional outcomes (FO) in patients with low EED, recognizing PHE as an early death predictor emphasizes the necessity for further research to understand its role in influencing patient outcomes.

Disclosure: Nothing to disclose.

EPO-035 | Clonal hematopoiesis of indeterminate potential (CHIP) in ischemic stroke etiology

C. Lázaro Hernández[1]; P. Lozano Iragüen[2]; M. Montoro Gómez[3]; L. Palomo Sanchis[3]; J. Campos Zarraquiños[3]; Á. García-Tornel García-Camba[1]; J. Juega Mariño[1]; J. Pagola Pérez de la Blanca[1]; C. Molina Cateriano[1]; M. Rubiera del Fueyo[1]

[1]*Neurology Department, Vall d'Hebron University Hospital, Barcelona, Spain;* [2]*Neurology Department, Clínica Dávila, University of the Andes. Santiago, Chile;* [3]*Hematology Department, Vall d'Hebron University Hospital, Barcelona, Spain*

Background and Aims: Clonal Hematopoiesis of Indeterminate Potential (CHIP) is characterized by the presence of somatic mutations in peripheral blood cells without evidence of a hematological neoplasm. Recent research has associated CHIP with cardiovascular disease and stroke. The objective of our study is to evaluate the relationship of CHIP with the etiology of the ischemic stroke and how its measurement could contribute to the study of stroke causes.

Methods: Prospective observational study of consecutive patients who suffered an ischemic stroke between September 2021 and August 2022. After complete work-up, patients were classified as cardioembolic (CE), atherothrombotic (AT) and cryptogenic (CRYP) stroke. Patients with double mechanism, incomplete study or active neoplasia were excluded. During hospital admission, 13 genes related to CHIP were analysed. A variant allele fraction of >1% was considered positive.

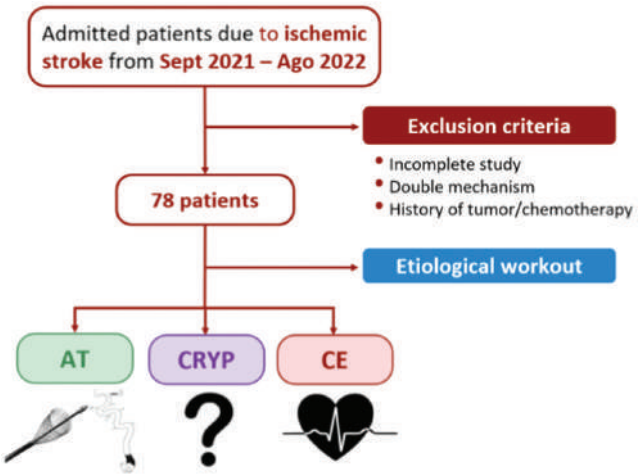


FIGURE 1 Methodology of the study with the corresponding exclusion criteria. AT = Atherothrombotic; CRYP = Cryptogenic; CE = Cardioembolic.

Results: Samples from 78 patients (50% women, mean age 73.4 years) were analysed and etiologically classified as: 37 CE (47.5%), 33 AT (42.3%) and 8 CRYP (10.3 %). Twenty-eight patients had CHIP (35.9%), of which the predominating mutations were: DNMT3A

(35.7%), TET2 (32.1%) and PPM1D (14.3%). Patients with CE stroke had a higher frequency of CHIP and less mutation heterogenicity (Figure 2). In the multivariate analysis, the TET2 mutation was associated with CE etiology after adjusting by age, coronary artery disease and classic cardiovascular risk factors (OR 20.9; $p=0.016$) (Figure 3).

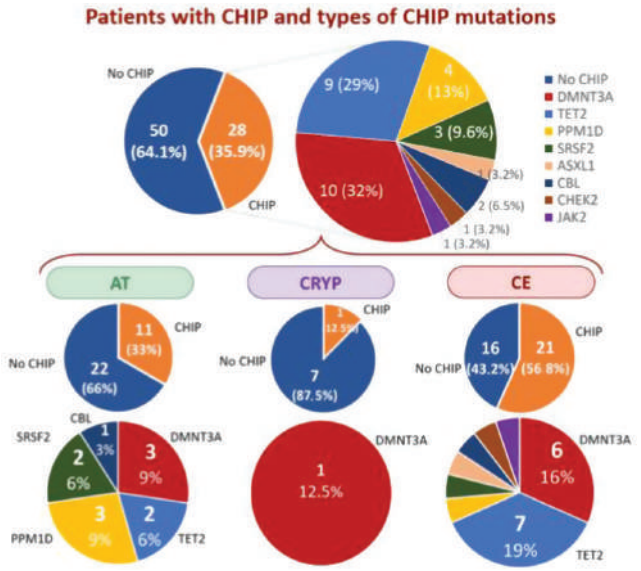

FIGURE 2 Frequency of CHIP and the different mutations according to the etiological diagnosis. It can be observed how patients with CE stroke had a higher frequency of CHIP and less mutation heterogenicity.

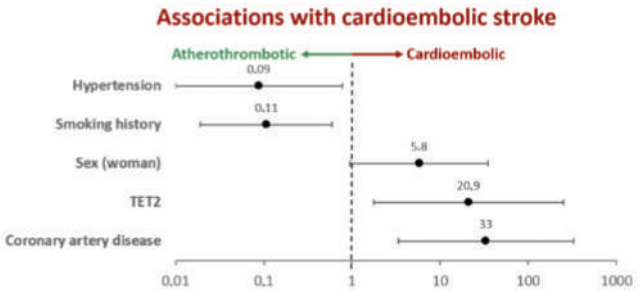

FIGURE 3 Forest plot of the multivariate analysis. In which it is shown the association between cardioembolic stroke and the presence of the TET2 mutation.

Conclusion: CHIP is frequently found in patients with ischemic stroke. The presence of the TET2 mutation was associated with CE stroke and could potentially facilitate the etiological diagnosis of stroke.

Disclosure: Nothing to disclose.

EPO-036 | Exploring sex disparities in ischemic stroke treatment and functional outcomes

A. Cabral[1]; P. Almeida[1]; T. Gregório[2]; M. Rocha[2]; H. Costa[2]; L. Paredes[2]; M. Veloso[2]; P. Barros[2]

[1]*Neurology Department, ULS Gaia Espinho, Porto, Portugal;* [2]*Stroke Unit, ULS Gaia Espinho, Porto, Portugal*

Background and Aims: Females face worse functional recovery after stroke. While poorer health, older age and greater stroke severity could explain this, some population studies have shown that accessibility and timeliness of treatment also play a role. We aimed to assess sex-related disparities in stroke treatment and functional outcomes within our population.

Methods: This retrospective, single-center study included acute ischemic stroke patients treated with thrombolysis and/or thrombectomy from January 2015 to December 2022 at our stroke center. The primary outcome was functional status at 3-month follow-up, while the secondary outcome was time from symptom onset to final reperfusion therapy (TSOFT). Bivariate analysis comparing female and male patients was followed by binary logistic and linear regression to identify predictors of functional outcome and TSOFT, respectively.

Results: 1219 patients were included (54% females, mean age 74 years). Females were older, had worse baseline functional status and higher NIHSS scores at admission. Bivariate analysis showed that females were more likely to have unfavorable functional outcomes (OR 1.367; 95% CI 1.092–1.713) and significantly longer TSOFT (228 versus 200 min; $p=0.002$). However, after adjusting for confounders, female sex itself did not correlate with worse functional outcomes (aOR 1.237; 95% CI 0.926–1.646), while longer TSOFT did (aOR 2.177; 95% CI 1.302–3.641). Additionally, linear regression analysis indicated a significant association between female gender and longer TSOFT, even after adjusting for confounders (B = −0.055, $p=0.003$, 95% CI [−0.091, −0.019]).

Conclusion: Our findings suggest female stroke patients experience delays in treatment, and that these contribute to worse functional outcomes.

Disclosure: Nothing to disclose.

EPO-037 | Factors associated with fast infarct growth and its impact on patients treated with Mechanical Thrombectomy

D. Wróbel[1]; P. Wrona[2]; B. Łasocha[3]; P. Brzegowy[3]; T. Popiela[3]; G. Kapral[1]; J. Staniszewska[1]; M. Derechowska[1]; A. Słowik[2]

[1]*Student Scientific Group in Cerebrovascular Diseases, Jagiellonian University Medical College, Krakow Poland;* [2]*Department of Neurology, Jagiellonian University Medical College, Krakow, Poland;* [3]*Department of Radiology, Jagiellonian University Medical College, Krakow, Poland*

Background and Aims: Infarct growth rate varies significantly between stroke patients. Fast infarct growth (FIG) is associated with more severe neurological deterioration within time lapse between

stroke onset and neurological procedures; that information may be crucial for Mechanical Thrombectomy (MT) decision-making process. We aimed to identify factors associated with FIG.

Methods: We retrospectively analyzed 641 consecutive patients with AIS in anterior circulation treated with MT in Comprehensive Stroke Center in University Hospital, Cracow (2019–2023). In all patients we obtained pre-stroke risk factors and performed computed tomography perfusion (CTP) followed by post-processing analysis with RAPID software. FIG was identified if ratio of CTP-derived cerebral blood flow <30% volume/time from last known well to imaging exceeded 10ml/h. We included 151 (23.56%) patients with FIG and 490 (76.44%) without.

Results: Patients with FIG were more frequently males (58.3% vs 46.9%, $p=0.015$), had significantly lower time from last known well to imaging (135 [84–213]min vs 249.5 [189–302]min, $p<0.001$), higher NIHSS on admission (18 [15–21] vs 15 [10–19], $p<0.001$) and higher hypoperfusion intensity ratio (HIR, defined as T10max to T6max volumes ratio) (0.57 [0.47–0.68] vs 0.3 [0.15–0.44], $p<0.001$). After multivariate analysis, each increase of 0.1 in HIR increased odds for FIG 2.02 (1.76–2.33, $p<0.001$). Moreover, FIG was linked with 0.57 (0.35–0.93, $p=0.024$) lower odds for obtaining functional independency at day 90, after adjusting for confounders.

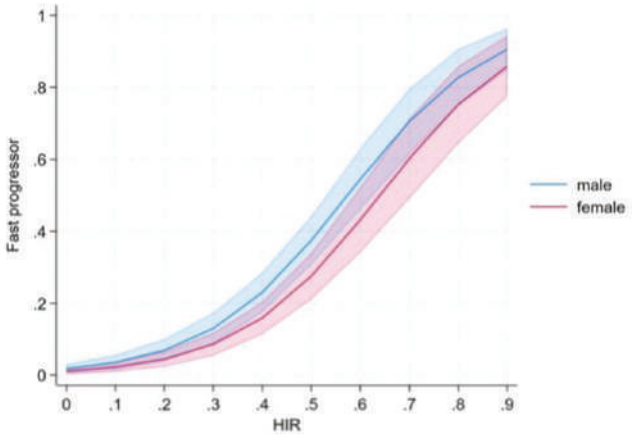

FIGURE 1 Association of hypoperfusion intensity ratio and probability of FIG (fast infarct growth) according to patient sex.

Conclusion: Higher HIR (denoting less robust leptomeningeal collaterals) and male sex are associated with FIG. Although patients with FIG may have lower time from last known well to admission, they present more severe neurological symptoms and worse long-term prognosis.

Disclosure: ERA-NET-NEURON/21/2020 iBioStroke grant.

TABLE 1 Comparison of patients with and without FIG.

	Patients without FIG (N=490)	Patients with FIG (N=151)	*P* value
Demographics			
Male, n (%)	**230 (46,9)**	**88 (58,3)**	**0.015**
Age, years, median [IQR]	72 [60-65]	69 [61-80]	0.203
Stroke risk factors

EPO-038 | **Admission blood pressure: Causes and consequences in large vessel occlusion stroke**

J. Donnelly[1]; D. Campbell[2]; P. Barber[3]

[1]*Department of Neurology, Auckland City Hospital, New Zealand;*

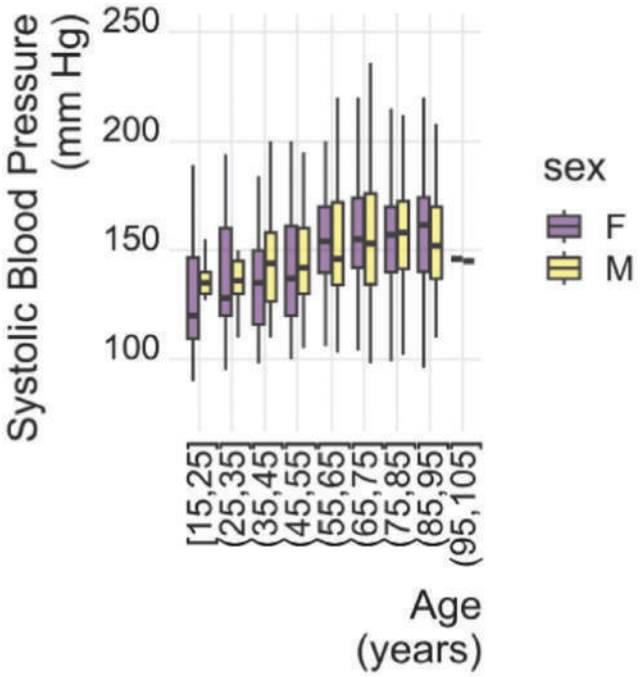
[2]*Department of Anaesthesiology, University of Auckland, New Zealand;*

[3]*Department of Medicine, University of Auckland, New Zealand*

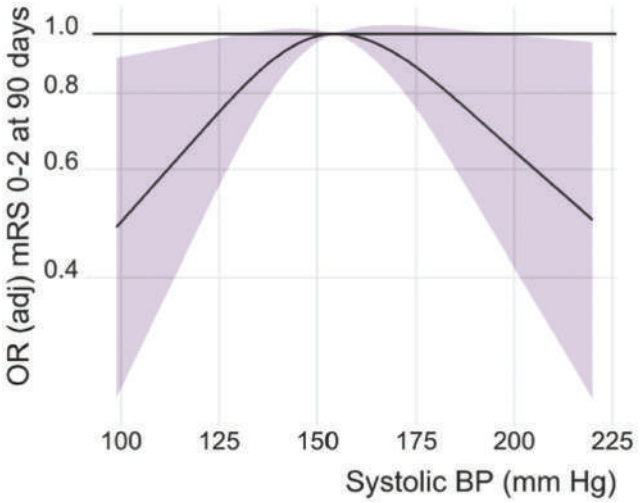
Background and Aims: The influence of sex and age on admission blood pressure and how admission blood pressure relates to clinical outcome (modified rankin score at 90 days – mRS-90) in stroke patients treated with endovascular thrombectomy is unclear.

Methods: Retrospective analysis was performed on patients with stroke receiving clot retrieval. Systolic blood pressure was assessed as the first recorded value. Outcome was assessed by the modified Rankin scale (mRS) score with mRS of 0 to 2 denoting functional independence. A multivariable binary logistic regression was created.

Results: In a cohort of 1079 stroke patients treated with clot retrieval, systolic blood pressure was dependent on age ($p<0.0001$) and there was a significant interaction of sex with females less than 50 years old presenting with lower blood pressure. Multivariable logistic regression revealed a quadratic relationship with both low and high admission systolic blood pressure associated with decreased odds of functional independence.



Relationship between age, sex and admission systolic blood pressure in stroke patients treated with endovascular thrombectomy



Adjusted odds ratio of admission systolic blood pressure in predicting functional independence in stroke patients treated with endovascular thrombectomy

Conclusion: Further investigation into sex differences in blood pressure control and early stroke pathophysiology is required.

Disclosure: Nothing to disclose.

EPO-039 | Renal function and Neurofilament Light chain serum concentrations in ischemic stroke

F. Ferrari[1]; F. Mazzacane[1]; N. Loizzo[2]; S. Scaranzin[3]; C. Morandi[3]; M. Gastaldi[3]; A. Persico[2]; A. Cavallini[2]

[1]Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; [2]Cerebrovascular Disease & Stroke Unit, IRCCS Neurological Institute Foundation Mondino, Pavia, Italy; [3]Neuroimmunology Unit, IRCCS Neurological Institute Foundation Mondino, Pavia, Italy

Background and Aims: Neurofilament Light chain (NfL) is a leading biomarker of long-term stroke patients' prognosis. Next step is to evaluate if NfL could be effectively employed as candidate surrogate end-point in stroke studies. An accurate identification of potentially confounding factors is required. This longitudinal prospective observational study investigates the correlations between NfL serum concentrations and renal function in ischemic stroke patients.

Methods: We included patients with stroke at neuroimaging, 18-80 years, onset <24h, NIHSS >1, pre-stroke mRS < 2. Exclusion criteria: TIA/previous stroke/TBI/other neurological disease, chronic immunosuppression, pregnancy, severe chronic kidney disease (eGFR < 30mL/min). Patients were treated as standard of care; serum creatinine was measured on admission blood tests. NfL serum concentrations were determined with Ella Automated-Immunoassay-System on samples collected within 24h from onset (T0), after 3–5 days (T1) and 7 ± 2 days (T2).

Results: At present, 43 patients have been enrolled (12 females, median age 64y[IQR18.5]. At onset, 53.5% had NIHSS 1–4, 39.5% NIHSS 5–15, 7% NIHSS>16. NfL median values were lower at T0

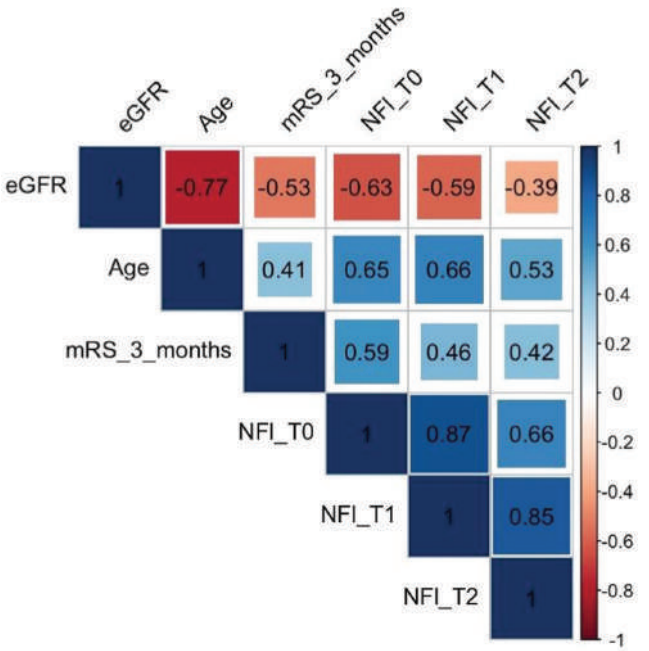


FIGURE 1 Correlation matrix between eGFR, age, mRS at 3 months, NfL.

(35.9pg/mL [IQR49.05]) vs T1 (66.1pg/mL [IQR97.25]; $p = 0.003$) and T2 (122pg/mL [IQR170.25]; $p < 0.001$). NfL at all time-points correlated positively with age and mRS at 3 months, and negatively with eGFR (T0 and T1 $p < 0.001$, T2 $p = 0.01$; Figure 1). Correlation analysis showed a negative linear relationship between eGFR and NfL at all time-points ($p \leq 0.01$; Figure 2).

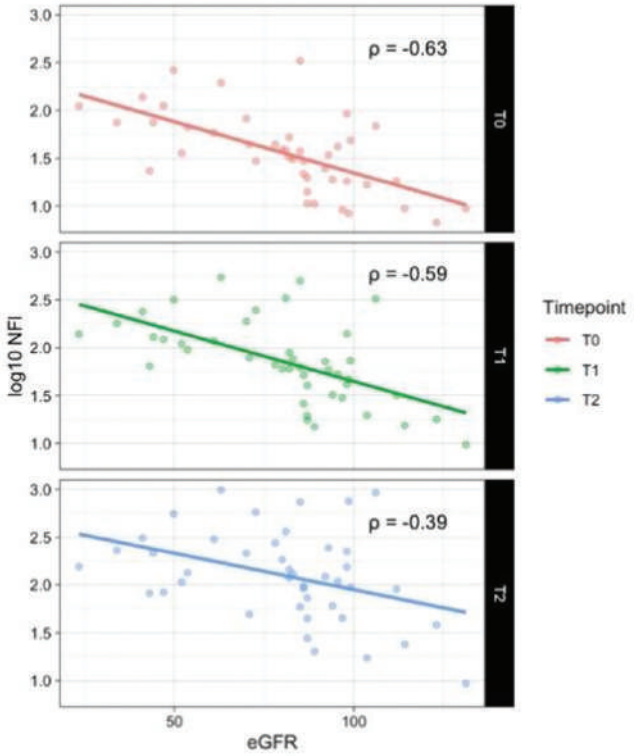

FIGURE 2 Correlations between eGFR and NfL at the three time-points.

Conclusion: NfL serum levels are inversely correlated with renal function in ischemic stroke patients and this variable should be considered in future studies as a potential source of bias in this population.

Disclosure: This study was supported by the Italian Ministry of Health "Ricerca Corrente 2022–2024" granted to IRCCS Mondino Foundation.

EPO-040 | New metrics of hypoxic burden predict recurrent cardio-cerebro-vascular events following ischemic stroke

I. Filchenko[1]; X. Yang[1]; S. Baillieul[2]; A. Brill[3]; C. Bernasconi[1]; M. Schmidt[1]; C. Bassetti[1]

[1]*Department of Neurology, Inselspital, Bern University Hospital, University of Bern;* [2]*Univ. Grenoble Alpes, Inserm, U1300, CHU Grenoble Alpes, Service Universitaire de Pneumologie Physiologie;* [3]*Department for Pulmonary Medicine, Allergology and Clinical Immunology, Inselspital, Bern University Hospital, University of Bern*

Background and Aims: Considering the limitations of conventional metrics of sleep-disordered breathing (SDB), novel physiologically informed metrics are needed to better predict the risk of cardio-cerebrovascular events (CCVE) associated with SDB. In this study, we suggest the use of new metrics of hypoxic burden to predict CCVE in stroke patients.

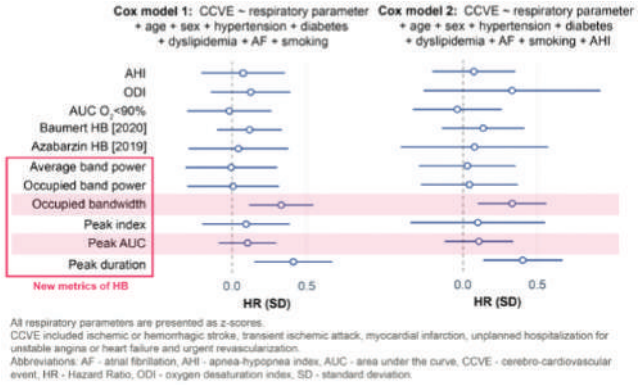
Methods: This is an exploratory analysis of the prospective observational longitudinal Sleep Deficiency & Stroke Outcome Study (ClinicalTrials.gov Identifier: NCT02559739). In acute ischemic stroke patients, hypoxic burden metrics were computed based on the oximetry signal from the respiratory polygraphy within the first week post-stroke. Recurrent CCVE were recorded over a 3-year follow-up. Cox regression with adjustment for vascular risk factors was used to investigate the prognostic value of 48 cardiovascular parameters regarding CCVEs.

Results: Out of 447 recruited patients, 347 were included in this analysis (Figure 1). 15% developed a future CCVE (mean observation time is 648 days). The 99% occupied bandwidth and negative peak duration significantly predicted vascular risk, whereas no associations were significant for apnea-hypopnea index (AHI), oxygen desaturation index (ODI), area under curve following non-specific desaturation <90%, or hypoxic burden parameters according to Azarbarzin and Baumert (Figure 2). The 99% occupied bandwidth and negative peak duration were not significantly associated with AHI or ODI (Figure 3).

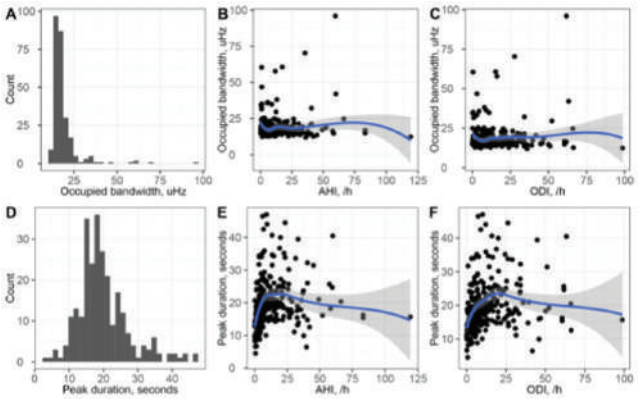
Parameter	Value
Age, years	65.10 [56.10, 73.70]
Sex (female)	125 (36.0%)
TIA	56 (16.1%)
NIHSS at admission, points	2.00 [0.00, 4.00]
NIHSS at discharge, points	0.00 [0.00, 2.00]
mRS at subacute stroke	0.00 [0.00, 1.00]
Intravascular stroke treatment	79 (22.8%)
Hypertension	200 (58.3%)
Diabetes	46 (13.3%)
Dyslipidemia	200 (59.3%)
Obesity	67 (19.5%)
Atrial fibrillation	33 (9.7%)
Current smoking	85 (24.8%)
AHI, /h	7.30 [3.50, 18.40]
AHI≥20/h	73 (22.7%)

Abbreviations: AHI – apnea-hypopnea index, NIHSS – National Institute of Health Stroke Scale, mRS – modified Rankin Scale, TIA – transient ischemic attack.

Patient characteristics.



Coefficient plots of Cox regression models showing the association of respiratory parameters at acute stroke with the vascular risk.



Properties of hypoxic burden metrics: histograms and associations with AHI and ODI.

Conclusion: Among investigated parameters, 99% occupied bandwidth and negative peak duration emerge as the most robust predictors of CCVE after stroke. Future studies should further validate the predictive ability of these markers.

Disclosure: Swiss National Science Foundation grant #320030_149752.

EPO-041 | Endovascular treatment in medium vessel occlusion: Experience from a stroke unit

F. Assis Jacinto[1]; M. Lima[2]; P. Bem[2]; V. Tedim Cruz[1]; C. Duque[1]
[1]*Neurology Department, Hospital Pedro Hispano, Matosinhos, Portugal;* [2]*Neuroradiology Department, Hospital Pedro Hispano, Matosinhos, Portugal*

Background and Aims: Medium vessel occlusion (MeVO) accounts for 25–40% of ischemic strokes with visible vessel occlusion. The endovascular treatment's (EVT) efficacy and safety hasn't been confirmed in MeVOs. We aim to evaluate the functional outcome of MeVOs that received EVT.

Methods: One-year retrospective study, with descriptive and comparative analysis.

Results: From 40 patients admitted, 10 (25%) received EVT (all with M2 occlusion). The median age was 76.5 years ([Q3-Q1]: [85.75–61.5]). The median time from symptom onset to admission was 442.5 ([Q3-Q1]: [840–117.5]) minutes with a median NIHSS at admission of 7 ([Q3-Q1]: [11.75–3]). Median ASPECTS was 9 ([Q3-Q1]: [10–8]) with Tan collateral score of 3 in 10 patients. 15 patients received acute revascularization treatment: 7 EVT, 5 iv thrombolysis (rtPA) and 3 rtPA plus EVT. The median door-in-door-out time was 86 ([Q3-Q1]: [139.5–71]) minutes and the median door-to-needle time was 136 ([Q3-Q1]: [193–133]) minutes. After EVT, 8 (20%) patients had a TICI 2b. At discharge, the median NIHSS was 2 ([Q3-Q1]: [5.75–0]). The median mRS at 90 days was 3 ([Q3-Q1]: [4–1]). EVT isn't related with mRS at 90 days (p 0.920). EVT is related with a greater variation between NIHSS at admission and at discharge (p 0.014). A favourable mRS at 90 days was significantly related with a lower NIHSS at discharge (p 0.032).

Conclusion: Despite the absence of direct correlation between EVT and favourable functional outcomes at 90 days, EVT is significantly correlated to a greater variation between NIHSS at admission and at discharge suggesting a possible efficacy of this procedure in MeVOs.

Disclosure: Nothing to disclose.

EPO-042 | Dynamic outcome prediction of alteplase-treated acute ischemic stroke patients: A machine learning approach

I. Petrović[1]; S. Njegovan[2]; O. Tomašević[2]; S. Rajić[1]; D. Vlahović[1]; Z. Božić[3]; I. Milosavljević[1]; A. Balenović[1]; Ž. Živanović[1]
[1]*Faculty of Medicine, University of Novi Sad;* [2]*Department of Systems, Signals and Control Engineering, Faculty of Technical Sciences, University of Novi Sad, Novi Sad, Serbia;* [3]*Neurology Clinic, University Clinical Center of Vojvodina, Novi Sad, Serbia*

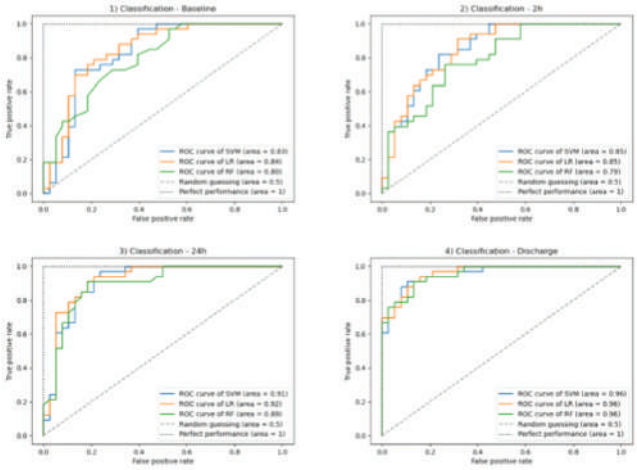
Background and Aims: Numerous factors impact the functional outcomes of acute ischemic stroke (AIS) patients treated with intravenous thrombolysis (IVT). Currently, there is a lack of predictive models incorporating clinically relevant features at various time points. This study aimed to develop a machine-learning model for dynamic prediction of functional outcomes.

Methods: Retrospective analysis involved alteplase-treated AIS patients at the University Neurology Clinic of Vojvodina (Novi Sad, Serbia) from December 2008 to December 2022. Clinical data were categorized into four groups based on collection time: Baseline, 2-h, 24-h, and Discharge features. These were utilized as input for the model. The 90-day modified Rankin scale (mRS), as an outcome measure, determined favorable (mRS ≤2) and unfavorable outcomes (mRS ≥3). The main classifier evaluation parameter was the area under the receiver operating characteristic (AUC-ROC) curve.

Results: The study comprised 355 patients (average age 66.4 years, 64% male), with 55% achieving a favorable outcome. Models demonstrated good discrimination on the testing set (AUC = 0.80–0.96), with the highest values in the 24-h (AUC = 0.89–0.91) and discharge models (AUC = 0.96).

Models and Selected Features								
Baseline		2-hour		24-hour		Discharge	
1. Age 2. Baseline Systolic Blood Pressure 3. ASPECTS 4. Baseline NIHSS 5. Baseline Hemoglobin 6. Baseline Glycemia 7. Platelet count 8. Usage of Acetylsalicylic acid 9. Onset to treatment time 10. Door to CT time 11. Type of hyperlipidemia 12. OCSP type of stroke		1. Age 2. ASPECTS 3. Baseline NIHSS 4. Baseline Hemoglobin 5. Baseline Glycemia 6. Platelet count 7. Usage of Acetylsalicylic acid 8. Onset to treatment time 9. Door to CT time 10. 2-hour NIHSS 11. Type of hyperlipidemia 12. OCSP type of stroke		1. Age 2. Baseline Glycemia 3. Platelet Count 4. Door to Needle time 5. 2-hour NIHSS 6. 24-hour NIHSS 7. Post-tPA Diastolic Blood Pressure 8. OCSP type of stroke		1. Age 2. Baseline glycemia 3. 24-h NIHSS 4. 24-h NIHSS 5. Door-to-needle time 6. OCSP type of stroke 7. Discharge NIHSS 8. Discharge treatment 9. Length of hospitalization	
Classifier	Evaluation metrics							
	AUC	Accuracy	AUC	Accuracy	AUC	Accuracy	AUC	Accuracy
SVM	0.83	0.76	0.85	0.78	0.91	0.87	0.96	0.90
Logistic Regression	0.84	0.79	0.85	0.76	0.92	0.85	0.96	0.89
Random Forest	0.80	0.72	0.79	0.75	0.89	0.83	0.96	0.87

Selected features and Evaluation metrics



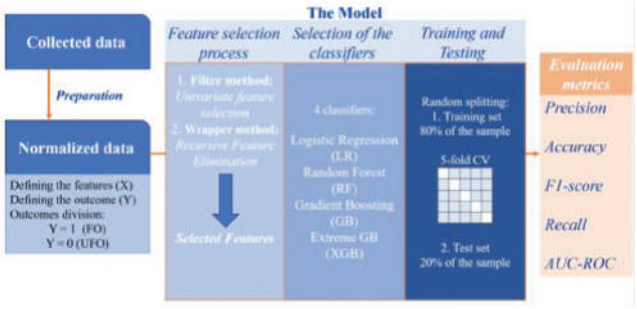
AUC-ROC curves

Conclusion: The baseline model is applicable for predicting clinical outcomes before IVT, aiding in decision-making for its initiation, while other models enhance predictive accuracy for post-IVT clinical outcomes, allowing timely adaptations in treatment approaches.
Disclosure: Nothing to disclose.

EPO-043 | The outcome prediction of ischemic stroke patients with atrial fibrillation: An interpretable machine learning study

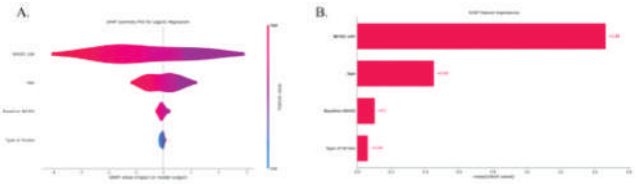
I. Petrović[1]; M. Ivanišević[2]; A. Balenović[1]; I. Milosavljević[1]; S. Rajić[1]; D. Vlahović[1]; Z. Božić[3]; Ž. Živanović[1]
[1]*Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia;* [2]*Faculty of Medicine, University of Belgrade, Belgrade, Serbia;* [3]*Neurology Clinic, University Clinical Center of Vojvodina, Novi Sad, Serbia*

Background and Aims: Considering that patients with atrial fibrillation (AF) can also achieve favorable outcomes, there is a noticeable literature gap in identifying contributing factors and prediction possibilities for this group. The aim was to utilize interpretable machine learning (IML) to analyze the functional outcomes of stroke patients with admission AF.
Methods: We included 381 alteplase-treated acute ischemic stroke (AIS) patients, out of which AF was registered in 29% during admission. Based on the 90-day modified Rankin Scale (mRS) value, two groups were made: a favorable outcome group (mRS ≤2), and an unfavorable outcome group (mRS ≥3). 63 features were used as input for the analysis and model build-up. The decision-making process was better understood through the interpretation packages.

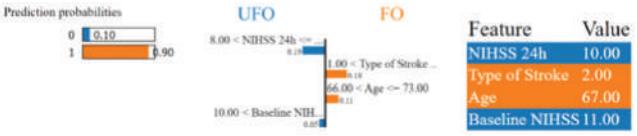


Machine Learning Model Build-Up Process

Results: In the AF group ($n = 109$), a favorable outcome was achieved in 55% of patients, and 4 selected distinguishing variables were: the patient's age, the baseline and 24-h value of NIHSS (National Institutes of Health Stroke Scale), and the type of stroke determined by OCSP (Oxfordshire Community Stroke Project). Logistic regression showed high predictive power (AUC = 0.922), and the interpretation packages revealed a 24-h NIHSS value as the most influential factor.



SHAP analysis results – the whole group-level interpretation



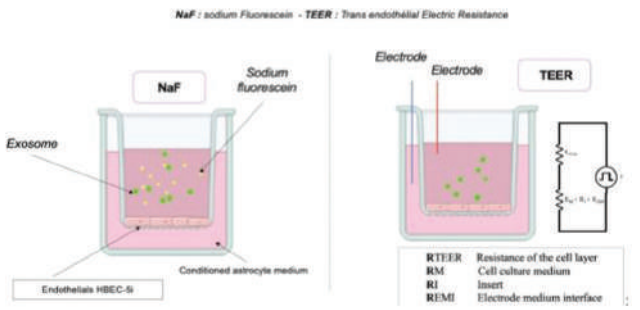
LIME analysis results – the individual-level interpretation

Conclusion: By focusing on alteplase-treated ischemic stroke patients with admission AF, this study identified younger age, lower baseline and 24-h NIHSS values, and OCSP types of AIS other than TACI as important predictors of a favorable 90-day functional outcome. IML can enhance trust and aid in understanding the decision-making 'black box' of machine learning.
Disclosure: Nothing to disclose.

EPO-044 | Endovascular treatment in ischemic stroke with isolated anterior cerebral artery occlusion

J. Mayol[1]; M. Rodrigo-Gisbert[1]; M. Olivé-Gadea[1]; F. Rizzo[1]; F. Diana[2]; M. Rubiera[1]; C. Molina[1]; A. Tomasello[2]; M. Ribó[1]; M. Requena[1]
[1]*Stroke Unit, Department of Neurology, Hospital Universitari Vall d'Hebron, Barcelona, Spain;* [2]*Department of Neuroradiology, Hospital Universitari Vall d'Hebron, Barcelona, Spain*

Background and Aims: Limited data exist on endovascular treatment (EVT) for anterior cerebral artery (ACA) occlusion-associated ischemic stroke, leading to variability in therapeutic decisions. Therefore, we aim to evaluate EVT safety and efficacy in patients with ACA occlusions compared with best medical treatment (BMT).
Methods: Retrospective cross-sectional study involving consecutive patients presenting with isolated ACA occlusion stroke from November-2015 to November-2023. The study delineated baseline clinico-radiological characteristics and treatment-related factors. Primary safety outcomes included symptomatic intracerebral hemorrhage (sICH) and 90-day mortality. Secondary outcome was functional independence (90-day mRS = 0–2).
Results: Among the 68 patients, 41 (60.3%) underwent EVT. Median age was 78 (IQR 73–84) years [EVT 77, IQR 68–84 vs BMT 84, IQR 73–89; $p = 0.137$]. Median NIHSS score was 9 (IQR 5–16) [EVT 9, IQR 7–17 vs BMT 7, IQR 4–16; $p = 0.478$]. No statistically significant differences were observed between patients undergoing EVT or BMT in sICH rate (EVT 10.5% vs BMT 4.5%, OR 1.179, 95% CI 0.078–17.84; $p = 0.905$), 90-day mortality (EVT 26.3% vs BMT 29.3%, OR 1.874, 95% CI 0.372–9.443; $p = 0.447$), or functional independence (EVT 36.4% vs BMT 25.0%, OR 0.774, 95% CI 0.078–7.634; $p = 0.826$). Among patients undergoing EVT, cardioembolic stroke showed higher odds of functional independence than other etiologies (OR 5.54, 95% CI 1.095–27.99; $p = 0.038$).



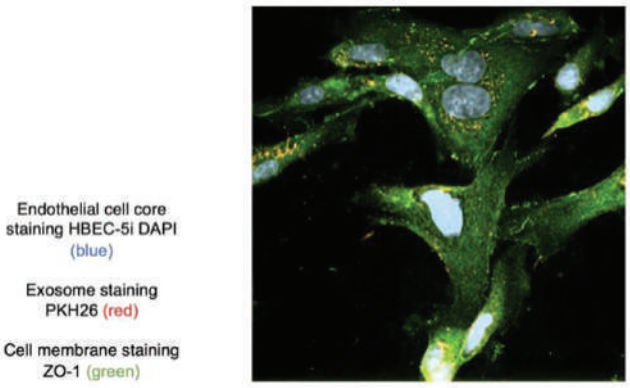
Method for permeability testing when exosomes are in contact with the BBB model

Conclusion: In our series, EVT for isolated ACA occlusion stroke was safe, although it did not significantly modify outcomes. Within EVT patients, cardioembolic stroke showed greater benefits. Ongoing randomized clinical trials will determine EVT efficacy for ACA occlusions.
Disclosure: Nothing to disclose.

EPO-045 | Obstructive sleep apnea syndrome: A cerebrovascular risk factor, linked to Alzheimer's disease

P. Guillot[1]; F. Roche[2]; N. Barth[3]; N. Perek[4]
[1]*Université Jean Monnet, Saint-Etienne, France;* [2]*CHU, Saint-Etienne, France;* [3]*INSERM, U1059, SAINBIOSE, Université de Lyon, Saint-Etienne, France;* [4]*Gérontopôle AURA, 25 boulevard Pasteur, Saint-Etienne, France*

Background and Aims: Some studies have shown a link between obstructive sleep apnea syndrome (OSA) and Alzheimer's disease (AD). Our aim is to show that OSA is associated with cognitive disorders and has biological similarities with AD.
Methods: Isolation, characterization and quantification of exosomes from blood sera of non-AD apneic elderly subjects ($n = 15$); non-AD non-apneic elderly controls ($n = 15$) and AD elderly subjects (in progress, currently $n = 10$). Establishment of an in vitro BBB model whose permeability will be measured in contact with exosomes from each group.
Results: After isolation by precipitation and chromatography, characterization of exosomes by Western blot (WB) and ELISA using anti-CD81, CD63 and CD9 antibodies showed that apneic subjects had a high level of exosomes similar to AD patients. In addition, the exosomes of apneic subjects contained TAU and beta-Amyloid proteins in almost the same quantities as those of AD patients. The in vitro BBB model (monoculture of endothelial cells in astrocyte-conditioned medium) showed an increase in permeability of the model in contact with exosomes from apneic subjects similar to AD subjects. However, patients with very severe apnea induced a greater alteration of the BBB than AD patients.



Imaging exosomes in contact with endothelial cells

Conclusion: Analysis of exosomes from the 3 groups showed similarities between the apneic and AD groups compared with controls, suggesting that OSA may be a factor in the development of AD.

Clinical neurophysiology

EPO-046 | A new way to modulate somatosensory cortex: High frequency tACS matching individual evoked HFOs frequency

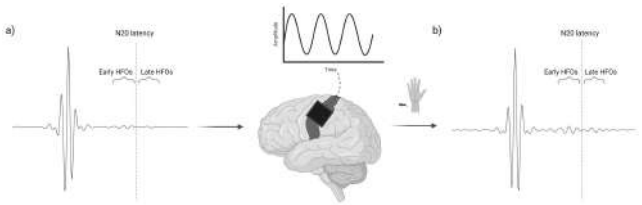
A. Cruciani[1]; G. Pellegrino[2]; A. Todisco[1]; F. Motolese[1]; M. Sferruzzi[1]; D. Norata[1]; F. Santoro[1]; G. Musumeci[1]; M. Rossi[1]; F. Pilato[1]; V. Di Lazzaro[1]; F. Capone[1]

[1]*Department of Medicine and Surgery, Unit of Neurology, Neurophysiology, Neurobiology, and Psychiatry, Università Campus Bio-Medico di Roma, Roma, Italy*; [2]*Epilepsy program, Schulich School of Medicine and Dentistry, Western University, London, Ontario, Canada*

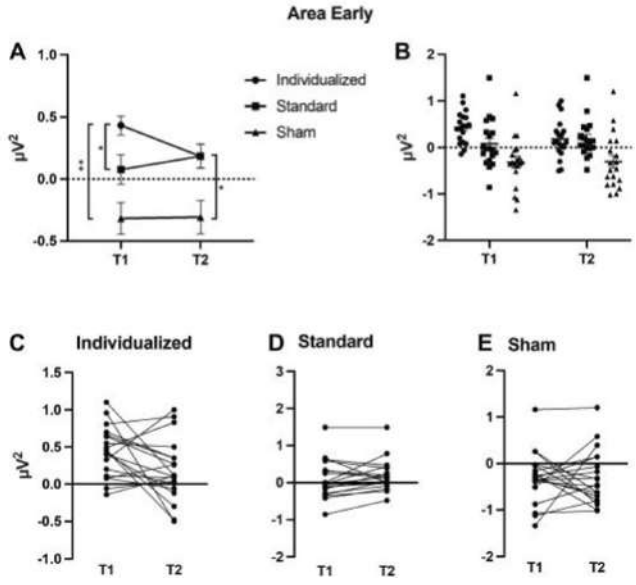
Background and Aims: Transcranial Alternating Current Stimulation (tACS) modulates brain activity non-invasively through electrical currents, with established effects on the primary motor cortex. This study explores the entrainment effects of tACS on the somatosensory system, particularly on evoked high-frequency oscillations (HFOs), comparing individualized, standard (600 Hz), and sham settings in healthy subjects.

Methods: The study involved three blocks, each a week apart and randomized among participants: Individualized tACS at the individual's HFOs rhythm, Standard tACS at 600 Hz, and Sham stimulation. Nineteen healthy participants underwent median nerve stimulation, and somatosensory evoked potentials (SEPs) were recorded before tACS (T0), immediately after tACS (T1), and 10 minutes after tACS (T2). High-frequency oscillations (HFOs) were identified and analyzed using a customized MATLAB pipeline. tACS was administered. Statistical analysis assessed differences across stimulations in delta values (T1-T0, T2-T0) using one-way repeated measure ANOVA and post-hoc comparisons.

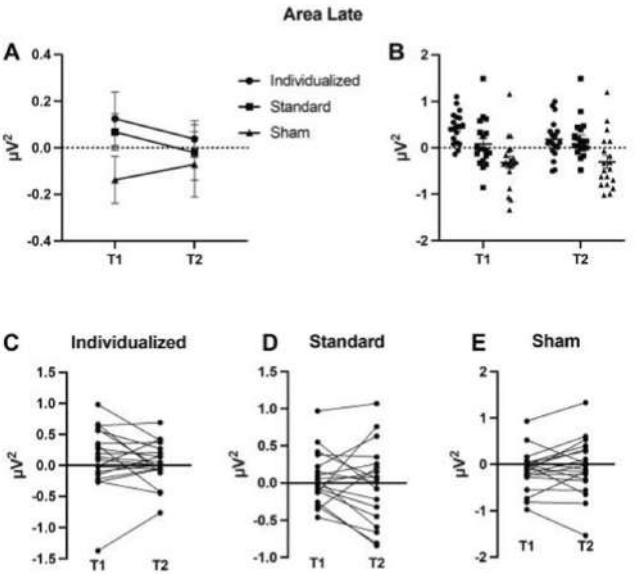
Results: Comparing T0 to T1 and T0 to T2 we found that Individualized tACS significantly increased Area Early compared to Standard and Sham, but no differences were observed between Standard and Sham. Area Late, N20 amplitude, and N20 latency showed no significant effects across stimulations at both time points (T1, T2).



Schematic representation of tACS delivered over left S1. Representative HFOs from subject 7: a) HFOs before tACS (T0); b) HFOs immediately after individualized tACS (T1)



Effects of different tACS stimulations on Area Early



Effects of different tACS stimulations on Area Late

Conclusion: Concluding, we here provide the first evidence that tACS tuned to the individual HFOs frequency modulates the thalamocortical activity in a frequency- and time-specific manner. Multiple studies have demonstrated dysregulation of HFOs in various pathological conditions. Accordingly, the evidence of individualized tACS capacity to influence somatosensory system could potentially pave the way for novel therapeutic applications.

EPO-047 | EEG and brain MRI alterations in transient global amnesia: The impact of time and gender

C. Ferrazzoli[1]; A. Castelli[1]; V. Ferrazzoli[2]; A. Pagano[1]; G. Di Mauro[1]; C. Liguori[1]; N. Mercuri[1]; F. Placidi[1]; F. Izzi[1]
[1]*Epilepsy Center, Neurology Unit, Department of Systems Medicine, University of Rome Tor Vergata, Rome;* [2]*Diagnostic Imaging Unit, Department of Biomedicine and Prevention, University of Rome Tor Vergata, Rome*

Background and Aims: The aim of the study is to evaluate the prevalence and characteristics of EEG and Brain MRI findings in patients with transient global amnesia (TGA).
Methods: This single-center observational retrospective study examined adult inpatients admitted at Policlinico Tor Vergata (2013–2023) with transient global amnesia (TGA), diagnosed according to Hodges and Warlow criteria. Only patients who underwent both EEG and brain MRI were included.
Results: Of 69 patients meeting criteria (41 females, 28 males; mean age 62.38 ± 9.20 years), TGA symptoms lasted 5.46 ± 6.14 hours. EEG abnormalities occurred in 68.1% of patients, predominantly bilateral (38.3% left, 51% bilateral, 10% right, $p = 0.002$). Focal slowing was observed in 33.3%, and interictal epileptiform abnormalities in 34.8%. Epileptiform changes were more frequent in females than males (46.3% vs. 17.86%, $p < 0.05$). EEG latency from TGA was shorter in the epileptiform group (47 ± 22.63 vs. 61.86 ± 36.6 hours, $p = 0.013$). Brain MRI revealed DWI positive lesions in 23.2% (left prevalence 11/16, bilateral 4/16, right 1/16, $p = 0.007$). DWI-positive patients had a shorter time interval from attack to MRI (82 ± 27.66 vs. 101.43 ± 45.54 hours, $p < 0.05$). No significant correlation existed between DWI positivity and EEG alterations or lateralization.
Conclusion: The study affirms timing importance, with shorter intervals correlating with increased EEG and MR-DWI findings in TGA. Left-sided DWI lesion dominance was noted, consistent with prior studies. No lateralization of EEG abnormalities was found, and MRI and EEG results showed no significant association. Additionally, a significant correlation between gender and paroxysmal EEG abnormalities suggests a potential gender-specific etiology in TGA, warranting further investigation.
Disclosure: Nothing to disclose.

EPO-048 | Investigating the working mechanism of transcranial direct current stimulation

E. Lescrauwaet[1]; M. Sprengers[1]; E. Carrette[1]; C. Algoet[1]; A. Mertens[1]; D. Klooster[2]; R. Raedt[1]; P. Boon[1]; K. Vonck[1]
[1]*4brain, Department of Neurology, Reference Center for Refractory Epilepsy, Ghent University Hospital, Ghent, Belgium;* [2]*Department of Electrical Engineering, Eindhoven University of Technology, Eindhoven, The Netherlands*

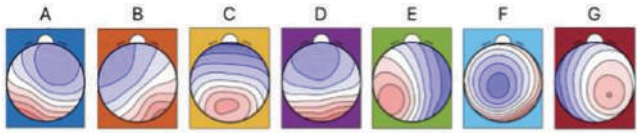
Background and Aims: Transcranial Direct Current Stimulation (tDCS) is used to modulate neuronal activity but its exact mechanism of action (MOA) is unclear, hampering its clinical applicability. This study investigates tDCS modulation of the corticospinal neurotransmission and its MOA. By anesthetizing the scalp before applying tDCS and by applying tDCS to the cheeks, we investigated whether stimulation of peripheral and/or cranial nerves substantially contributes to the effects of tDCS.
Methods: In a randomized cross-over study, 4 conditions were compared in 19 healthy volunteers: (1) anodal tDCS (a-tDCS) over the motor cortex, (2) a-tDCS over the motor cortex with a locally applied anesthetic on the scalp, (3) a-tDCS over the cheek region and (4) sham a-tDCS over the motor cortex. Motor evoked potentials (MEPs) were measured before and up to 1 h after a-tDCS. A questionnaire was used to assess the tolerability of a-tDCS.
Results: A significant MEP amplitude increase compared to baseline was found from 30 to 60 min after motor cortex a-tDCS. When applying a-tDCS over the motor cortex with a local anesthetic applied, only a non-significant small increase in MEP amplitude compared to baseline was observed. The questionnaire demonstrated that side effects are significantly lower when the local anesthetic was applied before a-tDCS administration.
Conclusion: The significant MEP amplitude increase observed post a-tDCS supports the modulatory effects of tDCS. The absence of significant modulation when a local anesthetic was applied suggests that effects of tDCS are not solely established through direct cortical stimulation, but stimulation of peripheral and/or cranial nerves might contribute to tDCS-induced modulation
Disclosure: Nothing to disclose.

EPO-049 | Exploring brain network dynamics in parkinson's patients with visual hallucinations: An EEG microstate approach

E. Toplutaş[1]; R. Uysal Kaba[2]; B. Güntekin[3]; L. Hanoğlu[1]
[1]*Department of Neurology, Istanbul Medipol University, Istanbul, Turkey;* [2]*Institute of Neuroscience, Istanbul Medipol University, Istanbul, Turkey;* [3]*Department of Biophysics, Istanbul Medipol University, Istanbul, Turkey*

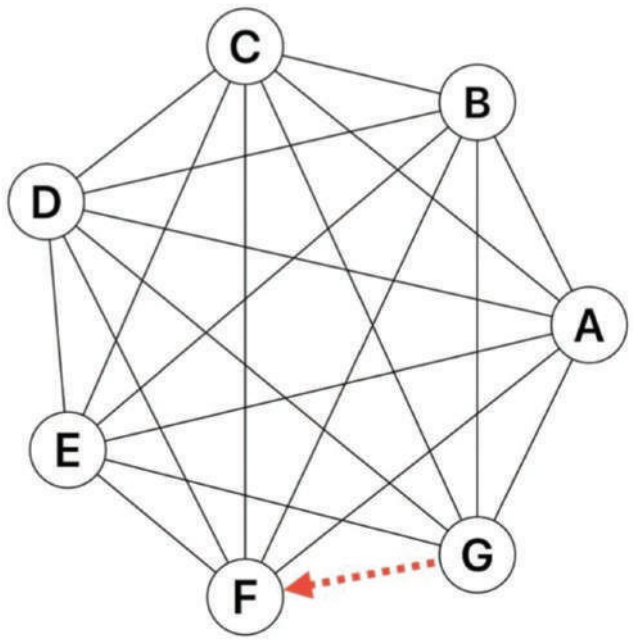
Background and Aims: In this study, we explore the realm of Parkinson's disease (PD), focusing on the manifestation of visual hallucinations (VH), a symptom often overshadowed yet critical in understanding the disease's complexity. Our aim is to elucidate the alterations in brain networks among PD patients experiencing VH, utilizing EEG microstate analysis. This approach offers a window into the neurophysiological processes underpinning these hallucinatory experiences.
Methods: Our cohort consisted of 19 PD patients reporting VH and a matched group of 20 PD patients without such symptoms. The matching criteria included age, gender, educational level, cognitive performance, and PD motor scores. We captured the brain's electrical activity through 5-min EEG recordings in a resting state with eyes

closed. The analysis of EEG microstates was conducted using templates derived from healthy controls, segmented into seven distinct topographical maps.



The analysis of EEG microstates was conducted using templates derived from healthy controls, segmented into seven distinct topographical maps.

Results: Between the two groups, statistical analysis revealed no significant differences in demographics, cognitive assessments, or motor scores. When examining the EEG microstate parameters, including duration, occurrence, and coverage, the results were consistent across all seven microstates, showing no notable variations. However, a significant finding emerged in the transition probabilities, with the VH group exhibiting a markedly lower frequency of transitions from microstate G to microstate F ($p < 0.001$).



The probabilities of microstate transitions are illustrated here, with the VH group exhibiting a significantly lower frequency of transitions from microstate G to microstate F ($p < 0.001$).

Conclusion: This study explores at EEG microstate alterations in PD patients who have VH, providing information on the neurophysiological processes that underpin these phenomena. The findings give a more advanced understanding of the disease's neural origins than just symptomatology.

Disclosure: There are no conflicts of interest.

Background and Aims: Aim of this study is to demonstrate that TMS-evoked potentials (TEPs) can track neurodegeneration within cortical networks in Alzheimer's disease (AD).

Methods: We collected TEPs, resting state functional MRI (rs-fMRI), diffusion tensor imaging (DTI), and an extended neuropsychological evaluation in AD cases at various stages of the disease and healthy controls. TEPs were elicited by stimulating the parietal nodes of the default mode network (DMN) and the frontal nodes of the executive control network (ECN). We tested for differences in cognition, WM microstructural tract integrity and early TEP amplitudes (<50 ms) across groups.

Results: Two early TEP components generated for DMN stimulation, i.e., P20P and N20F, showed significantly higher amplitude after left stimulation than after right stimulation in mild cognitive impairment (MCI) due to AD, and not in other groups. Moreover, the N20F following a left DMN stimulation was stronger in MCI patients compared to healthy controls and to AD patients in dementia stage.

Conclusion: In the early stages of the disease, AD is associated with asymmetric alterations of neurophysiological responses in the DMN, in line with previously reported vulnerability of this network and of the left hemisphere in AD cases. The increased TEP responses only in the MCI group indicate that neurophysiological alterations within the DMN are not linearly related with the disease staging. Early TEP components from DMN stimulation have the potential to differentiate MCI due to AD from healthy individuals. Funding: Italian Ministry

EPO-051 | Repetitive transcranial magnetic stimulation of the supplementary motor complex: What is known?

K. Germanova[1]; K. Panidi[1]; M. Nazarova[2]
[1]*Institute for Cognitive Neuroscience, Centre for Cognition and Decision Making, HSE University*; [2]*Department of Neuroscience and Biomedical Engineering, Aalto University, Finland*

Background and Aims: The supplementary motor complex (SMC), consisting of the pre-SMA and SMA-proper, contributes to a wide variety of brain functions. Non-invasive brain stimulation over both pre-SMA and SMA-proper areas effectively modulated different aspects of neurological and psychiatric disorders. In this review, we focused on studies with repetitive transcranial magnetic stimulation (rTMS) applied to these regions in both healthy individuals and clinical populations.

Methods: We collected original studies in English from the PubMed, Cochrane, and Scopus databases (PROSPERO ID – CRD42020141289) categorizing them into (1) studies on healthy volunteers and (2) studies on patients. From each study, we extracted: demographics, the function investigated, stimulation parameters including TMS coil targeting approach, and the primary outcomes.

Results: The final sample included 129 articles: 68 studies performed on healthy and 61 studies on clinical populations. Notably, the majority of studies focused on the SMA-proper rather than the pre-SMA. In the healthy participants, the SMA-proper was stimulated aiming to influence both motor (65% of papers) and cognitive processes (25% of papers), 10% of the article reported only neurophysiological findings. The pre-SMA stimulation was also applied aiming to modulate primarily motor function (79%). In the clinical population, both regions were stimulated to mitigate motor impairment symptoms. The SMA-proper was mostly stimulated in patients with Parkinson's disease (>40% of papers), while the pre-SMA – in patients with obsessive-compulsive disorder.

Conclusion: We suggest that SMA-proper/pre-SMA is a promising target for TMS for various neuropsychiatric conditions. Nevertheless, further research is needed to understand the interhemispheric and SMA/pre-SMA effect differences.

Disclosure: Nothing to disclose.

EPO-052 | Dopaminergic therapy and swallowing physiology in patients with Parkinson's disease: An electrophysiological study

G. Cosentino[1]; M. Todisco[2]; M. Rossi[3]; G. Belluscio[3]; S. Malaspina[3]; M. Avenali[1]; C. Pacchetti[2]; R. Zangaglia[2]; M. Fresia[2]; F. Valentino[2]
[1]*University of Pavia. IRCCS Mondino Foundation*; [2]*IRCCS Mondino Foundation*; [3]*University of Pavia*

Background and Aims: Though dopaminergic therapy is the gold-standard treatment for PD, its effects on the swallowing function are still debated. Objective of the study is to assess the swallowing function through an electrokinesigraphic approach in a group of non-dysphagic PD patients with motor complications evaluated both in off- and on-therapy.

Methods: the repeated swallowing of a liquid bolus was performed while recording the following parameters: i) surface electromyographic activity of the submental-suprahyoid muscles (sh-EMG), involved both in the oral and pharyngeal phases of swallowing); ii) intraswallowing apneic pause (AP); iii) pharyngo-laryngeal mechanogram (PLM). Amplitude, duration and area of the recorded signals and time intervals were calculated using the Matlab platform. All patients were assessed both in on- and off-medication state.

Results: 11 patients (64 ± 6.4, 4F/7M) were enrolled and completed the experimental assessments. A significant ($p < .05$) shortening of the interval between the inspiratory and expiratory peaks following the swallowing act and the end of the AP was observed in the on- vs. off-medication state. Better but not statistically significant swallowing performances were also observed in patients when on-medication, in particular we observed a shorter oro-pharyngeal delay ($p = .11$) and a larger area of the PLM ($p = .017$)

Conclusion: dopamine therapy can improve the synergy between breathing and swallowing in accordance to previous findings that dopaminergic treatment can improve pulmonary function tests. However, based on these preliminary results in a small group of non-dysphagic PD patients, no significant changes in the other aspects of the oral and pharyngeal phases of swallowing were observed.

Disclosure: None.

EPO-053 | Neurophysiological evidence on the intravenous methylprednisolone use in spinal surgery

J. Park; K. Kwak; J. Park; D. Kim; H. Eom; Y. Park
Department of Rehabilitation Medicine, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea

Background and Aims: Research suggests corticosteroids post-spinal injury might increase side effects without benefits, highlighting a lack of symptom or electrophysiological controls. The hypothesis is that intravenous methylprednisolone (IVMP) could restore surgery-induced MEP amplitude reduction in a range-dependent manner, potentially improving postoperative motor scores.

Methods: This study reviewed spinal surgery patients with neurophysiological monitoring at a tertiary hospital, 2017–2023. Patients with over 50% MEP reduction were categorized into steroid and non-steroid groups upon surgeon's decision. MEP monitoring occurred at set intervals post-event, with examining MEP restoration and its correlation with motor recovery across defined MEP decline ranges. Statistical methods like T-tests and Pearson's correlation evaluated the effect of MEP recovery on motor outcomes.

Results: The analysis included 100 patients (71, steroid; 29, non-steroid group), with 807 muscles examined (524, steroid; 183 non-steroid group) (Table 1). The steroid group demonstrated higher MEP amplitudes (%) compared to the non-steroid group exclusively in the −100% to −80% MEP reduction range (Figure 1). A significant correlation was identified between the recovery of MEP amplitude and motor score improvement within the −80% to −50% reduction range (Table 2). For cases with complete MEP loss (-100%), no recovery in MEP or motor function was observed (Figure 1 and Table 2).

MEP, motor evoked potential; ΔMotor = Motor score of postoperative day 1 - Motor score of preoperative day 1; SD, standard deviation. Pearson's correlation analysis was applied. $P < 0.05$, statistically significant.

r, Pearson's correlation coefficient between ΔMEP and ΔMotor. *, $P < 0.05$; **, $P < 0.01$; ***, $P < 0.001$.

Conclusion: This current study is the first to investigate the effects of IVMP on the deterioration degree of MEP waves, and it further explores the impact of IVMP on postoperative motor outcomes in relation to the degree of MEP deterioration.

Disclosure: Nothing to disclose.

EPO-054 | Detection of electrophysiological markers indicating neuropathy in children and adolescents diagnosed with type 1 DM

M. İnci[1]; A. Poyraz[2]; G. Şirin[1]; E. Sarban[3]; M. Yıldız[3]; F. Baş[3]; E. Kocasoy Orhan[1]

[1]*Istanbul University, Istanbul Faculty of Medicine, Department of Neurology;* [2]*Istanbul University, Istanbul Faculty of Medicine, Department of Neurosurgery;* [3]*Istanbul University, Istanbul Faculty of Medicine, Department of Pediatric Endocrinology*

Background and Aims: We aimed to investigate the temporal changes and patterns of involvement in nerve conduction studies and autonomic tests in children and adolescents diagnosed with type 1 diabetes mellitus (T1DM).

Methods: We conducted nerve conduction studies and autonomic tests twice, with a one-year interval, on 63 patients aged between 8 and 18, with a minimum disease duration of 2 years, all diagnosed with T1DM. Demographic and clinical findings were assessed, and the study design is summarized in Figure 1.

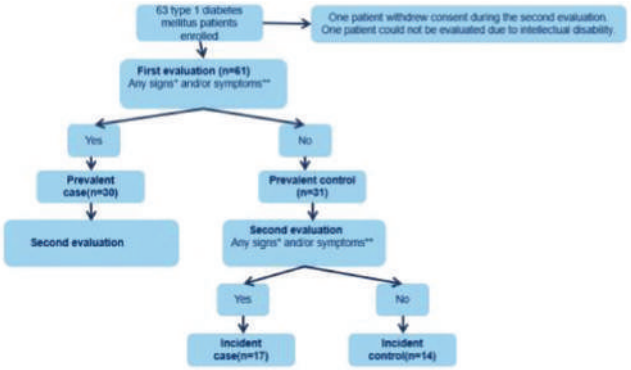

FIGURE 1 Diagram of the study design *associated with polyneuropathy, **according to Diabetic Neuropathy Symptom Score (DNS)

Results: No pathological findings consistent with the classical signs of neuropathy were observed in the parameters of nerve conduction studies. The most frequently abnormal parameters were peroneal F persistence (38.1%) and minimum F latency (30.2%), R-R interval variability (RRIV) (21%), and tibial minimum F latency (11.1%). Sural sensory peak latency and peroneal motor distal latency were found to be longer in both prevalent and incident case groups compared to the incident control group ($p < 0.05$). When the prevalent case group was compared with the prevalent control group, RRIV was lower, and sympathetic skin response (SSR) latency was longer in both upper and lower extremities ($p < 0.05$).

Conclusion: Monitoring latencies and conduction velocities in sensory and motor nerves may be more guiding in understanding the development of polyneuropathy. In addition, it seems useful to include SSR and RRIV examinations, which are parameters not frequently evaluated, in polyneuropathy research protocols in this group.

Disclosure: None of the authors has any conflict of interest to disclose.

EPO-055 | Difference in electromyographic features of dystonic and essential tremor: A pilot study

M. Minár[1]; S. Kajan[2]; Z. Košutzká[1]

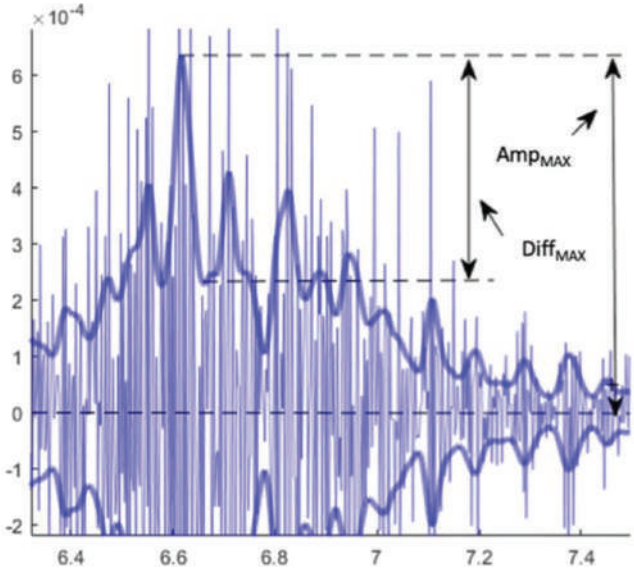
[1]*Second Department of Neurology, Faculty of Medicine, Comenius University Bratislava, Slovakia;* [2]*Institute of Robotics and Cybernetics, Faculty of Electrical Engineering and Information Technology, Slovak University of Technology in Bratislava, Bratislava, Slovakia*

Background and Aims: Many patients with dystonic tremor (DT) – especially in the form of bilateral upper limb action tremor – are

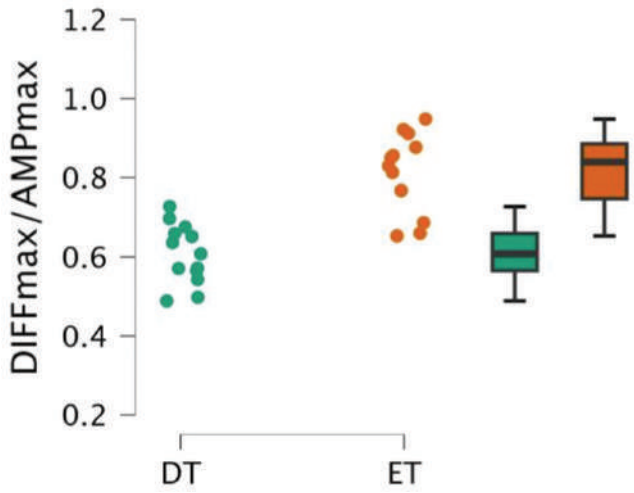
misdiagnosed as having essential tremor (ET). We aimed to find specific objective electromyographic (EMG) features of DT.

Methods: We examined 25 patients with upper limb tremor referred to our laboratory with a working diagnosis of ET. Surface EMG data were recorded from the extensor and flexor carpi radialis (ECR, FCR), first dorsal interosseus muscle and accelerometer placed on the index finger of a more affected limb by the Neurosoft®Neuro-MEP-8 EMG.

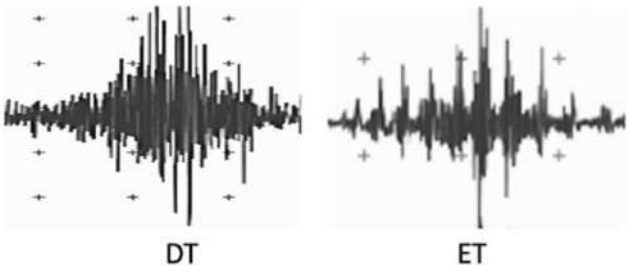
Results: None of the patients presented with obvious clinical features of dystonia. In 13 patients, we detected antagonist co-contraction, motor overflow, mirror dystonia, null point, and/or myoclonic jerks on EMG, thus suggesting the diagnosis of DT. From objectively measured parameters, these patients had a significantly lower ratio between maximum peak difference (measured between the highest and lowest point of discharge spike), and its maximum negative amplitude (DIFFmax/AMPmax; 0.607 ± 0.075, vs. 0.815 ± 0.102, $p < 0.001$, Cohen's $d = 2.333$). It indicates that isolated tremor bursts on EMG are less prominent in DT, perhaps due to rising from the background of sustained muscle contractions (dystonia). None of the other parameters differed significantly.



Measured parameters



Difference between ET and DT



Examples of patients with DT and ET

Conclusion: Surface EMG might help to verify subclinical dystonic activity and thus distinguish clinically similar tremors. In addition, measurable parameters might be used in the objective assessment of tremor types and they can become a part of the diagnostic process using deep learning methods.

Disclosure: This study was supported by the Grant of the Ministry of Education, Science, Research and Sport of the Slovak Republic (VEGA Nr. 1/0527/22).

EPO-056 | Reference values for near fiber EMG measures in upper and lower limb muscles

O. Garnes-Camarena[1]; I. Mahillo-Fernandez[2]; O. Lorenzo[2]; R. Mandeville[3]; D. Stashuk[4]

[1]Jimenez Diaz Foundation University Hospital, Madrid, Spain; [2]Jimenez Diaz Foundation Research Institute, Madrid, Spain; [3]Beth Israel Deaconess Medical Center, Boston (MA), USA; [4]Systems Desing Engineering, University of Waterloo, Ontario, Canada

Background and Aims: Near-fiber MUP (NF-MUP) analysis provides novel and useful information on motor unit potential (MUP) temporal dispersion (NFM-Dispersion) and instability (NF-MUP segment jitter (NFM-SJ)) from signals acquired during routine EMG protocols. NFM-Dispersion is the spread in the times with which muscle fiber action potentials (MFAP) pass the recording electrode, whereas NFM-SJ reflect the temporal inconsistencies in their generation.

Methods: NFM-Dispersion and NFM-SJ reference values were determined for six muscles (deltoid, biceps, triceps, vastus lateralis, tibialis anterior and medial gastrocnemius), based on a sample size of 20 control cases each with a minimum of 20 MUPs per muscle (age 23–79 y-o). The EMG signals used were acquired using a standard needle EMG examination protocol. DQEMG (Decomposition-based Quantitative EMG) software was used for the calculation of NF-MUP parameters. Reference values were defined using a method based on the e-norm (Jabre, 2015) and e-ref (Nandedkar, 2018) methods.

Results: The distribution of values by quartiles indicated a small variability between subjects, with low standard errors and narrow confidence intervals. The analysis of values above the defined reference values indicated that NF-MUP parameters are highly clustered and close to the reference values. Considering all of the MUPs for each respective group of control muscles, the percentage of unstable MUPs ranged between 4.9 and 11.2%, and the percentage of dispersed MUPs from 5.2 to 13.4%.

TABLE 1 NFM-SJ reference values.

Muscle	Q1 (μs) /SE	Mean (μs) /SE	Std	Q2 (μs) /SE	Q3 (μs) /SE	E-Ref (μs)	95th P (μs)

TABLE 2 NFM-Dispersion reference values.

Muscle	Q1 (ms)/SE	Mean (ms) /SE	Std	Q2 (ms) /SE	Q3 (ms) /SE	E-Ref (ms)	95th P (ms)
Deltoid	0.7/0.07	1.5/0.09	1.2	1.3/0.08	2.1/0.1	3	3.8
Biceps	0.6/0.06	1.2/0.08	1.2	1/0.06	1.7/0.08	3	3.1
Triceps	0.8/0.08	1.7/0.09	1.2	1.4/0.09	2.1/0.14	3	4.1
Vastus L	0.5/0.11	1.2/0.11	1.1	1/0.12	1.8/0.14	3	3.4
Tibialis A	0.4/0.08	1.3/0.09	1.5	1/0.09	1.8/0.14	3	4.1
M Gastroc	0.7/0.13	1.6/0.12	1.2	1.4/0.14	2.3/0.14	3	3.7

Conclusion: NFM-Dispersion and NFM-SJ stability measures, extracted from regular EMG signals, are useful and solid parameters that can augment the current understanding of neuromuscular disorders.

Disclosure: Nothing to disclose.

EPO-057 | Introduction to near fiber EMG, a novel way to measure motor unit electrophysiological properties

D. Stashuk[1]; O. Garnes-Camarena[2]; R. Mandeville[3]

[1]Systems Desing Engineering, University of Waterloo, Ontario, Canada; [2]Jimenez Diaz Foundation University Hospital, Madrid, Spain; [3]Beth Israel Deaconess Medical Center, Boston (MA), USA

Background and Aims: Motor Unit Potential (MUP) complexity and instability are key parts of EMG examinations, whose assessment can be time-consuming or subjective. We introduce a novel and semi-automated way of measuring MUP complexity and instability, based on Near Fiber (NF) EMG concepts. A NF-MUP is the summation of the muscle fibre potentials of fibers near the recording electrode (NF-MFPs). The temporal dispersion and instability of NF-MFPs are new clinically useful MU characteristics that can be quantified using NF-MUP parameters.

Methods: Aspects of novel signal processing algorithms used to extract MUP trains, estimate MUP and NF-MUP templates and select isolated NF MUPs for complexity and instability analysis as well as new quantitative measures to characterize sampled MUs will be described, demonstrated, and discussed.

Results: NFEMG has been used to study and assess several neuromuscular diseases. It has been used to detect increased MUP complexity and instability in CIDP, ALS, GBS, and diabetic neuropathy. In addition, it can be used to diagnose MG with similar accuracy as provided by SFEMG.

Conclusion: NF EMG offers an exciting new, rapid, and comprehensive evaluation of MUP complexity and instability that promises to significantly advance the diagnosis and monitoring of neuromuscular diseases.

Disclosure: Nothing to disclose.

EPO-058 | Sural-to-medial femoral cutaneous amplitude ratio in early diagnosis of uremic neuropathy

Ş. Deveci[1]; Z. Matur[2]; D. Mermi Dibek[1]; A. Öge[3]

[1]University of Health Sciences Turkey, Basaksehir Cam and Sakura City Hospital, Clinic of Neurology, Istanbul, Turkey; [2]Bezmialem Vakif University Faculty of Medicine, Department of Neurology, Istanbul, Turkey; [3]Istanbul University, Istanbul Faculty of Medicine, Department of Neurology, Istanbul, Turkey

Background and Aims: Chronic Renal Failure (CRF) is typically associated with length-dependent axonal polyneuropathy and secondary demyelination. This study aimed to clinically and electrophysiologically assess CRF patients experiencing polyneuropathy-related complaints before initiating dialysis. The sural-to-medial femoral cutaneous nerve action potential (NAP) amplitude ratio (SMFCAR) was evaluated for its sensitivity and specificity in early electrophysiological diagnosis.

Methods: The study included 32 CRF patients (mean age 60.0 ± 9.6 years) and 30 age and sex-matched controls (58.9 ± 6.6 years). Assessments encompassed neurological examination, Michigan Neuropathy Screening Instrument (MNSI) A-B, and Semmes-Weinstein monofilament (10 g–5.07 mm) test. Radial, median, ulnar, medial femoral cutaneous, sural, and superficial peroneal sensory; median, ulnar, tibial, and peroneal motor conduction studies were performed. Sural-to-radial amplitude ratio (SRAR) and SFMCAR were calculated, and their diagnostic sensitivities were compared.

Results: The patients were in the CRF stages of 3 (59.4%), 4 (34.4%), and 5 (6.3%). The average CRF duration was 54.3 ± 46.1 (8–276) months. MNSI-B indicated clinical polyneuropathy in 59% of the patients, while routine nerve conduction studies diagnosed it in 72%. Median SRAR and SMFCAR values were significantly lower in patients than controls ($p < 0.001$ for both). At 90% specificity, SMFCAR's cut-off was <2.8 with a sensitivity of 59%, while SRAR's was <0.77 with a sensitivity of 35%.

Conclusion: In some CRF patients with symptoms compatible with length-dependent polyneuropathy, peripheral nerve involvement might be in a stage that cannot be detected by routine examination and electrophysiology. SMFCAR may be a useful alternative to SRAR in the early diagnosis.
Disclosure: Nothing to disclose.

EPO-059 | Subclinical epileptic activity and cognitive decline in Parkinson's disease and atypical parkinsonisms

T. Jesus[1]; R. Peralta[2]; A. Franco[2]; S. Parreira[2]; A. Oliveira[1]; A. Horváth[3]; C. Bentes[2]
[1]*Neurology Department of Hospital de Vila Franca de Xira, Unidade Local de Saúde Estuário do Tejo, Vila Franca de Xira, Portugal;* [2]*EEG and Sleep Laboratory-Neurophysiology Monitoring Unit of Hospital Santa Maria, Unidade Local de Saúde de Santa Maria, Lisbon, Portugal;* [3]*Neurocognitive Research Center, National Institute of Mental Health, Budapest, Hungary*

Background and Aims: Subclinical epileptiform activity (SEA) are epileptic discharges that occur without clinical seizures. There is evidence that SEA might be associated with accelerated cognitive decline in Alzheimer's disease (AD). Its occurrence and clinical correlates in parkinsonian syndromes have not been studied yet. Our primary aim was to study the frequency of SEA in parkinsonian patients. The secondary aim was to compare clinical and demographic characteristics in patients with and without SEA and characterize SEA morphologically.
Methods: Retrospective cross-sectional study. We examined patients with parkinsonian syndromes who underwent level 1/2 polysomnography between 1/1/2018 and 31/05/2022. Demographic information, diagnosis, and presence of mild cognitive impairment/dementia were obtained by chart review. Electroencephalogram (8 channels) was manually analysed for SEA, defined as paroxysms that fulfilled ≥4/6 epileptic discharge criteria according to the International Federation of Clinical Neurophysiology, confirmed by 3 epileptologists/neurophysiologists. Non-parametric statistical analysis was performed.
Results: 26 polysomnographies were reviewed (15 Parkinson's disease, 6 Multiple system atrophy, 2 Dementia with Lewy bodies, 2 vascular parkinsonism and 1 progressive supranuclear palsy). 14 patients had SEA (54%). There were no statistically significant differences between patients with SEA (median age 72yrs, 64% women, 36% with cognitive decline) and without (median age 64yrs, 67% women, 25% with cognitive decline). SEA's main location was temporal and temporo-occipital.
Conclusion: Our SEA prevalence was similar to studies with AD patients, and higher than data published from healthy controls (5–25%). Although it is a small heterogenous sample, with few EEG channels, it suggests that SEA is frequent in other neurodegenerative disorders.
Disclosure: Nothing to disclose.

EPO-060 | New national reference limits for nerve conduction studies

T. Szczepanski[1]; K. Nilsen[1]; P. Omland[2]
[1]*Department of Neurology and Clinical Neurophysiology, Oslo University Hospital, Oslo, Norway;* [2]*Department of Neurology and Clinical Neurophysiology, St. Olavs Hospital, Trondheim, Norway*

Background and Aims: Reference limits are important for correctly interpreting nerve conduction studies (NCS). Because reference limits for NCS are dependent of the examining procedure and the equipment settings used, laboratory-specific reference limits are needed. However, creating such reference limits with traditional methods is expensive and time-consuming. We present reference limits for NCS using a more practical approach – extrapolated norms (e-norms) – using historical measurements from the world's largest database of NCS.
Methods: We applied the e-norms algorithm on 2 143 280 Norwegian historical NCS measurements (conduction velocities, amplitudes, distal latencies) from 1998 to 2023 for the motor Peroneal, Tibial, Median and Ulnar nerves and the sensory Sural, Superficial Peroneal, Medial Plantar, Median, Ulnar and Radial nerves. Age was stratified into decades starting from the age of 20 up to the age of 99. Height was stratified into three brackets: 150–170 cm, 170–180 cm and 180–200 cm.
Results: The stratification gave in total 630 reference limits. In general, the reference limits decreased with age and height for conduction velocities and amplitudes, and increased for latencies. The values were close to the currently used limits derived by traditional methods. Ten references limits for nerves in the lower extremities could not be reliable calculated.
Conclusion: We have calculated new national reference limits for NCS in Norway (published at https://www.ous-research.no/digmine). Compared to the reference limits already in use, the reference limits produced by the e-norms algorithm are similar. In addition, the algorithm also produced reference limits for age groups where high quality reference limits are currently lacking.
Disclosure: Nothing to disclose.

EPO-061 | COVID-19 vaccination response in participants receiving efgartigimod IV or Efgartigimod PH20 SC in ADAPT+ or ADAPT-SC+

F. Saccà[1]; J. Howard Jr.[2]; J. Sleasman[3]; F. Gistelinck[4]; P. Duncombe[4]; B. Van Hoorick[4]; S. Steeland[4]; R. Mantegazza[5]; J. De Bleecker[6]; A. Azar[7]; K. Winthrop[8]

[1]GENESIS Department, Federico II University of Naples, Naples, Italy; [2]Department of Neurology, The University of North Carolina, Chapel Hill, North Carolina, USA; [3]Division of Allergy, Immunology, and Pulmonary Medicine, Duke University School of Medicine, Durham, North Carolina, USA; [4]Argenx, Ghent, Belgium; [5]Department of Neuroimmunology and Neuromuscular Diseases, Fondazione Istituto Neurologico Carlo Besta, Milan, Italy; [6]Department of Neurology, Ghent University Hospital, Ghent, Belgium; [7]Division of Allergy and Clinical Immunology, Johns Hopkins University School of Medicine, Baltimore, Maryland, USA; [8]Division of Infectious Disease, Oregon Health and Science University, Portland, Oregon, USA; Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy

Background and Aims: Patients with generalised myasthenia gravis (gMG) experience greater risk of adverse outcomes from respiratory infections, including COVID-19. Some immunosuppressive therapies used in gMG management increase risk of infection and impair vaccine responses. We investigated the effect of treatment with efgartigimod [administered intravenously (IV) or subcutaneously (SC, coformulated with recombinant human hyaluronidase PH20), a human IgG1 antibody Fc-fragment that reduces total and pathogenic IgG levels through neonatal Fc receptor blockade, on humoral immune responses to COVID-19 vaccination in participants with gMG.

Methods: In ADAPT+ (completed) and ADAPT-SC+ (ongoing open-label extension), efgartigimod IV (10 mg/kg) or efgartigimod PH20 SC (1000 mg) were administered in cycles of 4 once-weekly infusions/injections. Among other COVID-19 receptor binding domain-specific IgGs, SARS-CoV-2-IgG-RBD responses were assessed, nominally, at prevaccination, ≥4 weeks after vaccination, and subsequently at 1 week after fourth efgartigimod PH20 SC injection (when total IgG levels were maximally reduced, Figure). One sample was collected if postvaccination time points coincided with each other.

Results: Eighteen participants in ADAPT-SC+ (Table) received a COVID-19 vaccine during or after a cycle. For 78% ($n = 14/18$) of participants, this was their second or third vaccine dose. A 35.9-fold increase in SARS-CoV-2-IgG-RBD levels occurred from prevaccination to ≥4 weeks postvaccination (Figure). Similarly, from prevaccination to 1 week after the fourth efgartigimod PH20 SC injection, a 33.8-fold increase emerged (Figure). Similar results were observed with efgartigimod IV during ADAPT+.

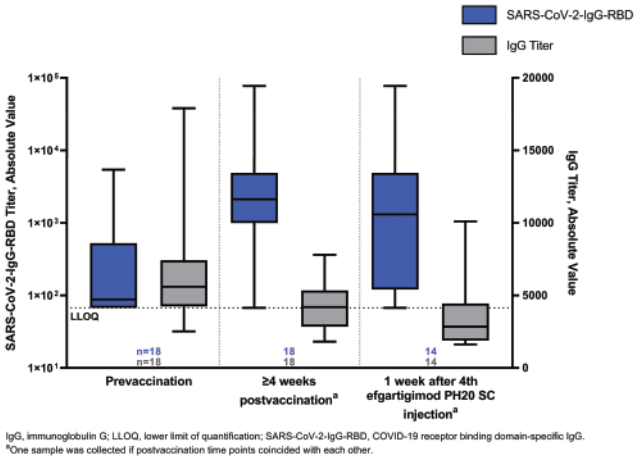

FIGURE Absolute Values of SARS-CoV-2-IgG-RBD Titer and Total IgG Titer

TABLE Participant Characteristics

Characteristic	Participants (N=18)
Age (y), mean (SD)	53.9 (11.7)
Age category, n (%)	
18-64 y	15 (83.3)
≥65 y	3 (16.7)
Sex, n (%)	
Female	10 (55.6)
Male	8 (44.4)
Body mass index (kg/m), mean (SD)	28.3 (6.2)

Conclusion: Consistent with efgartigimod IV results, participants receiving efgartigimod PH20 SC were able to mount antigen-specific IgG responses to COVID-19 immunisation, even when total IgG levels were maximally reduced.

EPO-062 | Primary angiitis of the central nervous system: The experience of a tertiary center

R. Lopes[1]; D. Costa[1]; I. Almeida[1]; R. Taipa[2]; A. Sousa[3]; E. Santos[1]; R. Samões[1]

[1]Neurology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal; [2]Neuropathology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal; [3]Neurophisiology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal

Background and Aims: Primary Angiitis of Central Nervous System (PACNS) is a rare inflammatory disorder affecting blood vessels in CNS without systemic involvement that exhibits a range of presentations. We aimed to characterize the population of patients with PACNS in a tertiary center.

Methods: Retrospective analysis of patients in Neuroimmunology outpatient clinic diagnosed according to Rice and Scolding (2020) criteria. Demographic, clinical, laboratory, imaging, and histological data were recorded.

Results: Twelve patients were included (male-to-female ratio 1:1.4) with an average age of symptom onset at 50.8 ± 16 years and diagnosis at 53.8 ± 13 years. Half were classified as definitive diagnosis, the remaining six as possible. Most frequent presenting symptoms were cognitive impairment (42%), stroke/focal neurological deficits (33%). Over the course of the disease, 66% also developed headache. MRI was abnormal in all 12 cases, with ischemic lesions (66%), microhemorrhages (33%) as the most frequent changes. Abnormalities in CSF were found in 82%, with lymphocytic pleocytosis in 54% (average 15.2 cells/μL), elevated protein levels in 45% (average 0.6 g/L), oligoclonal bands in 36%. Classical angiography was positive in 100% (5/5), and histological results in 75% (6/8) with prevalence of lymphocytic vasculitis. The treatments used were mainly corticosteroids (92%) and cyclophosphamide (75%). The patients were followed for an average of 8.4 ± 7 years, 33% with a Rankin scale ≥3. Despite treatment, gradual clinical deterioration was observed in 42% and sequelae cognitive impairment in 50%.

Conclusion: This analysis reveals a variety of clinical, radiological, and histological findings showing the complexity of the disorder. The severity of the condition despite treatment is also highlighted.

Disclosure: Nothing to disclose.

EPO-063 | CD20 T lymphocytes in multiple sclerosis: Impact on neuropsychological findings

A. Esposito[1]; A. Spiezia[1]; F. Falco[1]; F. Lamagna[2]; M. Eliano[1]; M. Petracca[3]; C. Di Monaco[1]; V. Nicolella[1]; F. Novarella[1]; R. Lanzillo[1]; M. Moccia[4]; V. Brescia Morra[1]; A. Carotenuto[1]

[1]*Department of Neurosciences, Reproductive and Odontostomatological Sciences, Federico II University, Naples, Italy;* [2]*Department of Psychology, Università degli Studi della Campania 'L. Vanvitelli';* [3]*Department of Human Neurosciences, Sapienza University, Rome, Italy;* [4]*Department of Molecular Medicine and Medical Biotechnology, Federico II University of Naples, Italy*

Background and Aims: Some T lymphocytes show molecular signature also for B lymphocytes (CD20)CD20 T lymphocytes may play a pivotal role in multiple sclerosis pathology, especially at progressive stages. This would suggest that CD20 T lymphocytes might be a marker of central nervous system (SNC) compartmentalized inflammation. We aim to investigate the correlation between CD20 T lymphocytes in peripheral blood in MS patients with neuropsychological features (i.e. cognition, depression, anxiety, fatigue and sleep quality).

Methods: We enrolled 90 MS patients. Each patient underwent cognitive assessment (BICAMS) and psychometric assessment (i.e. MFIS, BAI, BDI, PSQI). Cognitive status was defined through the cerebral functioning score (CSF). For each patient we performed blood sample collection to assess CD20 T lymphocytes and neurofilaments (NFL) levels.

Results: Forty-four out of 90 patients were relapsing-remitting (49%), 46 were progressive patients (51%). Seventy patients (18.9%) showed CD20 T lymphocytes in peripheral blood with a mean level of 0.38 ± 1.2. Patient with CD20 T lymphocytes were more likely to be in progressive patients (76.5% vs 23.5% of relapsing MS patients, $p = 0.02$), and showed a higher EDSS (3.5 vs 6, $p = 0.001$). Moreover, patients with CD20 T lymphocytes showed worse cognitive functioning ($p = 0.004$), higher global fatigue symptoms ($p = 0.02$) higher cognitive fatigue ($p = 0.01$), higher psychosocial fatigue ($p = 0.005$) and a trend toward worse sleep quality ($p = 0.06$). Conversely, NFL levels were not associated with CD20 T lymphocytes.

Conclusion: The presence of CD20 T lymphocytes in peripheral blood of MS patients, could possibly reflect an ongoing neurodegenerative process independent from inflammatory activity resulting in worse neuropsychological functioning.

EPO-064 | Intravenous vs subcutaneous natalizumab in the treatment of multiple sclerosis, a cohort study

S. Costa[1]; D. Costa[1]; A. Sousa[2]; R. Samões[1]; E. Santos[1]

[1]*Neurology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal;* [2]*Neurophysiology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal*

Background and Aims: Subcutaneous (SC) natalizumab has been recently approved for multiple sclerosis treatment. There are few studies comparing clinical effectiveness and safety of subcutaneous and intravenous Natalizumab.

Methods: Retrospective study of multiple sclerosis patients followed at a Portuguese tertiary center, currently under treatment with Natalizumab (NTZ). Analysis of efficacy and safety of intravenous (iv) and subcutaneous (sc) formulations.

Results: Data were collected from 59 patients of which 12 were treated with iv NTZ (group 1), 36 with iv and then formulation was switched to sc NTZ (group 2), and 11 with sc NTZ (group 3). At baseline, patients from group 1, 2 and 3, had respectively a median

EDSS of 2.0 [IQR: 0–4.5], 1.5 [IQR: 0–6.0] and 1.0 [IQR: 0–2]. ARR (Annualized relapse rate) was 1.0 in all groups. Patients from group 1 (5/41.7%) group 2 (16/44.4%), and group 3 (6/54.5%) had disease activity on CE-MRI. Patients from group 1, 2 and 3, had respectively a median of 4 [IQR: 1.0–14.0], 3 [IQR: 1.0–13.0], and 1.0 [IQR: 1.0–2.0] years of treatment. After treatment, median EDSS was 2.0 [IQR: 0–4.5] in group 1 and 2, and 1.5 [IQR: 1–2] in group 3, and median ARR was 0 in all groups. One patient (8.3%) of group 1 (3 years of NTZ) and 2(18.1%) patients of group 3 (1 year of NTZ) had disease activity on CE-MRI. Both formulations were well-tolerated. Only two patients presented minor gastrointestinal side effects and discontinued sc formulation. Three patients refused to switch to sc NTZ.

Conclusion: Both formulations of NTZ seem to be comparable in safety and in stabilizing the disease.

Disclosure: All authors declare that they have no conflicts of interest related to the manuscript.

EPO-065 | Crohn-related CRION case report: When optic neuropathy is not synonymous with demyelinating disease

G. Mignani[1]; N. Giannini[1]; G. Bellini[1]; M. Bellini[2]; G. Siciliano[1]; L. Pasquali[1]

[1]*Department of Neurological Sciences, University of Pisa, Pisa, Italy;* [2]*Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy*

Background and Aims: Among the extra-intestinal manifestations in Crohn's disease, Chronic Relapsing Inflammatory Optic Neuropathy (CRION) is an inflammatory optic neuropathy characterized by a strong responsiveness to steroids.

Methods: A 22-year-old woman suffering from Crohn's disease since 2014, undergoing multiple ileal resections, on Vedolizumab therapy. Since March 2023, during a flare-up of IBD (and Vedolizumab suspension) she began to experience bilateral eyelid edema, photophobia, and pain during eye movements. She underwent endocrinological examination suspecting Graves' disease (negative autoantibodies, no hormonal profile alterations) and Ophthalmic examination (chemosis, conjunctival hyperemia, tearing). Brain MRI showed bilateral edematous impregnation of periocular soft tissues, lacrimal glands, perisclera tissues, lateral rectus muscles, and a swollen (non-enhancing) appearance of the optic chiasm. Blood tests were normal. She went to the emergency department where a neurologist initiated high-dose steroid therapy, with symptoms remission. A flare was observed upon tapering the dose, prompting the resumption of steroid therapy. Cervical spine MRI was negative and cerebrospinal fluid analysis showed no oligoclonal bands, negative viral and bacterial meningitis panel, polyclonal immunoglobulins, and 106 mg/dL protein. Anti-AQP4, anti-MOG, complement factors, myositis-associated autoantibodies, ANA, AMA, LKM, and ENA were negative.

Results: In IBD, optic neuropathy may be ischemic (not detected during ophthalmic examination), reactive to anti-TNF drugs (unlikely due to Vedolizumab therapy), demyelinating (ruled out by diagnostic workup), associated with rheumatological disease (excluded), or CRION. The latter seems most likely in this patient.

Conclusion: Timely diagnosis of CRION leads to rapid reversal with steroid therapy, avoiding permanent visual sequelae.

Disclosure: No disclosures.

EPO-066 | Evaluation of parameters affecting sexual dysfunction in multiple sclerosis: A preliminary study

Ö. Totuk; M. Türkkol; H. Güdek; D. Çetinkaya Tezer; İ. Güngör Doğan; Ş. Şahin; S. Demir

Neurology Clinic, Şehit Prof. Dr. İlhan Varank Sancaktepe Training and Research Hospital, İstanbul, Turkey

Background and Aims: This study aimed to analyze the factors affecting sexual dysfunction (SD) in Multiple Sclerosis (MS) which is one of the most important causes of disability in young adults.

Methods: Volunteers diagnosed with MS were included in the study. The Arizona Sexual Experiences Scale (ASEX), Beck Depression Inventory (BDI) and Short-Form Health Survey (SF-12) were used to screen for possible SD, assess depression and evaluate quality of life (QoL) respectively. MS types and disease-modifying drugs (DMDs) used by patients were recorded. Disease durations were divided into four groups (1–3, 4–6, 7–9, ≥10 years).

Results: Socio-demographic information of 418 MS patients is shown in Table 1. A positive correlation was found between ASES and BDI scores and a negative correlation with SF-12. Multivariate variance analysis showed significant effects of BDI scores, gender and disease duration on SD. Women had higher ASES scores than men. As BDI scores increased, a significant increase in ASES was observed. SD was found in all disease duration groups, being more pronounced in the 1–3 and 4–6 year diagnosis groups. Age, MS type, DMD's used, education duration and SF-12 levels had no significant effect on ASES scores.

Parameter	Score
Age, mean (Years)	37.99 ± 10.01
Age range (Years)	(min: 18 - max: 66)
Female, n (%)	291 (69.6%)
MS diagnosis duration (years)	7.76 ± 6.64
(min: 1, max: 36)	
MS Type (n)	RRMS*: 133
	Progressive MS**: 285
Education (%)	Primary School (8.1%)
	Secondary School (6.2%)
	High School (26.8%)
	University (48.1%)
	Master's Degree (10.8%)

*RRMS: Relapsing-Remitting Multiple Sclerosis

**Progressive MS: Progressive Multiple Sclerosis

Sociodemographic Data of Patients

Conclusion: The study supports the literature in finding SD more common and associated with depression in women compared to men. SD and depression were more intense in patient groups diagnosed for up to six years, possibly due to changes in coping mechanisms over the years. Further studies are needed.
Disclosure: Nothing to disclose.

EPO-067 | The use of diffusion tensor tomography to assess the pyramidal system in patients with multiple sclerosis

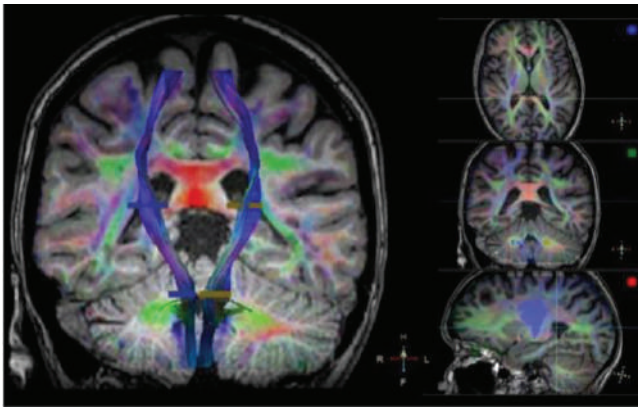
A. Peshkin[1]; S. Kotov[2]; G. Toniya[3]
[1]*Multiple Sclerosis Centre, Moscow Regional Clinical and Research Institute, Moscow, Russian Federation;* [2]*Department of Neurology, Moscow Regional Clinical and Research Institute, Moscow, Russian Federation;* [3]*Department of Radiology, Moscow Regional Clinical and Research Institute, Moscow, Russian Federation*

Background and Aims: The corticospinal tract (CSC) forms the basis of motor neurophysiology. The aim – to study CST in patients with highly active Multiple sclerosis (MS) during period of switching therapy.
Methods: 24 patients with MS were examined. Depending on severity of violations of pyramidal functional system (PFS) according to EDSS, patients were divided into 2 groups, group 1—17 patients with score of 0–2.5 points, group 2—7 patients with score of >=3 points. Diffusion tensor images (DTI) were processed using the DTI FiberTrak software.
Results: There was a decrease in the volume of pyramidal tract in patients of group 2 ($p < 0.001$), an asymmetry of indicator was found, in several patients – decrease on the clinically intact side, which may indicate visually undetectable signs of damage to pyramidal tract. There was a distinct tendency towards decrease in fractional anisotropy and a decrease in length of pyramidal tract as pyramidal deficit increases ($p < 0.001$). Negative correlations were found between indicators of neurological deficit and volume and length of the pyramidal tract, as well as a direct correlation of duration of course of MS with apparent diffusion coefficient (ADC) and the reverse – with fractional anisotropy.

Table 1.
Demographic indicators of the examined patients

Indicator	All patients n=24	1st group n=17	2nd group n=7
Sex M/F	7/17	6/11	1/6
Age M+/-σ	38,4+/-10,3	37,6+/-9,6	39,8+/-11,5
Duration of the disease M+/-σ	5,6+/-3,7	5,6+/-4,1	5,5+/-3,0
Type of MS	RRMS – 20 SPMS – 4	RRMS – 16 SPMS – 1	RRMS – 4 SPMS – 3
EDSS, score Me [Q1, Q3]	2,0 [1,5; 3,5]	1,5 [1,5; 2,0]	4,5 [3,5; 5,5]
Pyramidal functional system, score Me [Q1, Q3]	1,0[1,0; 3,0]	1,0 [0,0; 1,0]	3,0 [3,0; 3,0]

Patient data



Visualization of CST using DTI

Table 2.
Indicators of diffusion tensor examination of the pyramidal tract in patients with MS

Indicator	1st group n=17	2nd group n=7	Control group n=5
Volume of the pyramid tract (V), mm³	7414+/-1490 **p1-2<0,001**	5 650+/-1 828	7252+/-1025 p1-K=0,543 p2-K=0,018
Fractional anisotropy (FA)	0,515+/-0,031 p1-2=0,296	0,504+/-0,016	0,524+/-0,009 p1-K=0,045 **p2-K <0,001**
Apparent diffusion coefficient (ADC), 10^ (-3) mm²/sec	0,826+/-0,052 p1-2=0,113	0,857+/-0,065	0,807+/-0,02 p1-K=0,574 **p2-K=0,01**
The length of the pyramid tract (L), mm	123,5+/-12,4 p1-2=0,04	116,4+/-4,7	133,5+/-7,1 **p1-K=0,001** **p2-K<0,001**

Note: p1-2 is an indicator of the statistical significance of differences between groups 1 and 2, p1-K is an indicator of the statistical significance of differences between 1 and control groups, p2–K is an indicator of the statistical significance of differences between 2 and control groups. Statistically significant indicators are indicated in bold.

DTI results

Conclusion: The revealed decrease in volume and length of pyramidal tract, an increase in ADC, the asymmetry of these indicators, correlations with level of pyramidal insufficiency, EDSS and duration of the course of MS, obviously, can serve as additional criteria for assessing dynamics of disease and effectiveness of therapy.
Disclosure: Nothing to disclose.

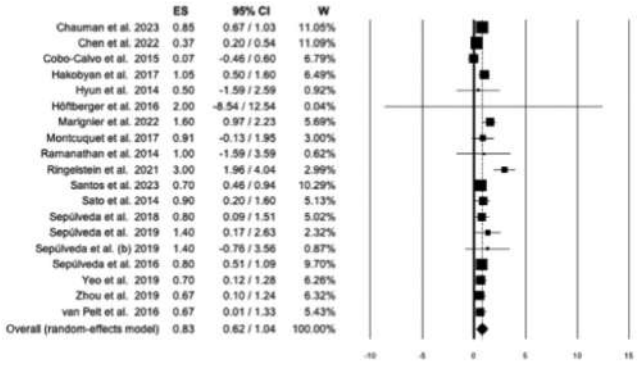
EPO-068 | Characterizing double-negative neuromyelitis optica spectrum disorder: A systematic review and meta-analysis

A. Malvaso[1]; G. Greco[2]; E. Ballante[3]; P. Businaro[2]; C. Morandi[2]; S. Scaranzin[2]; S. Masciocchi[2]; E. Marchioni[4]; D. Franciotta[2]; M. Gastaldi[2]
[1]*Department of Brain and Behavioral Sciences, IRCCS "C. Mondino" National Neurological Institute, University of Pavia, Pavia, Italy; Neuroimmunology Research Unit, IRCCS "C. Mondino" National Neurological Institute, Pavia, Italy;* [2]*Neuroimmunology Research Unit, IRCCS "C. Mondino" National Neurological Institute, Pavia, Italy;* [3]*Political and Social Science Department, University of Pavia; BioData Science Unit, Mondino Foundation;* [4]*Neurooncology and Neuroinflammation Unit, IRCCS "C. Mondino" National Neurological Institute, Pavia, Italy*

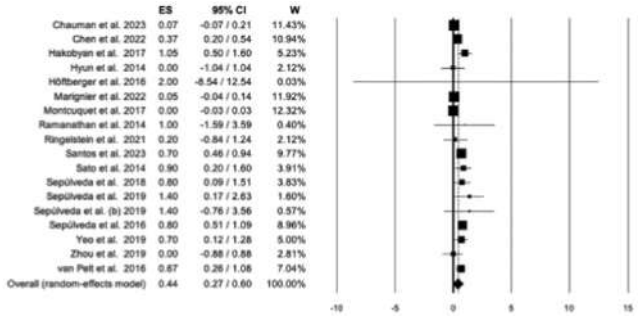
Background and Aims: Neuromyelitis-optica spectrum disorders (NMOSD) usually associate with aquaporin-4 (AQP4) or myelin oligodendrocyte glycoprotein (MOG) antibodies. Seronegative-NMOSD (SN-NMOSD) has been described, but the clinical-therapeutic profile is poorly defined.

Methods: We searched PubMed, Scopus and Google Scholar databases for studies reporting SN-NMOSD patients, on which anti-MOG-Abs and AQP4-Abs were tested. PRISMA guidelines and methodological quality control were assessed. Fixed or random-effects models were used to pool results across studies.

Results: We included 36/1027 articles screened and analyzed 591 SN-NMOSD patients (mean age: 30.3 [range 6–78]; female:male ratio; 2:1). Disease course was relapsing in 66% of cases. Brain MRI at onset showed brain abnormalities in 165/241 patients (69%) including tumefactive brain lesions in 19/241 (8%). Spinal cord MRI showed cervicothoracic lesions (99/241, 41%) and LETM (89/241, 37%). CSF analysis showed OCBs in 58/300 patients (19.3%). Mean annualized relapse ratio (ARR) was 0.77 (95% CI 0.10–1.8), and was higher in patients with late onset (>50 years, $p<0.001$). Mean EDSS and late-onset were associated with a relapsing course ($p<0.05$). Relapsing SN-NMOSD patients had a higher ARR and a worse outcome compared to AQP4-NMOSD or MOG-NMOSD. Among relapsing patients, 147/247 (60%) received a disease-modifying treatment (DMT). The administration of any DMT led to a reduction of ARR (pre-treatment: 0.83 ± 0.21 [95% CI 0.62–1.04, $I^2=66.19\%$, $p<0.0001$]; post-treatment: 0.44 ± 0.17 [95% CI 0.27–0.60, $I^2=85.81\%$, $p<0.0001$]).



Forest plot with random-effects models used to pool results of pre-treatment ARR across studies, including early and late-onset NMOSD.



Forest plot with random-effects models used to pool results of post-treatment ARR across studies, including early and late-onset NMOSD.

Conclusion: DN-NMOSD is a severe condition with distinctive features compared to AQP4-NMOSD. The administration of DMTs seems to be effective in this group of patients, but randomized clinical trials are needed.

Disclosure: The authors declare no conflicts of interest.

EPO-069 | Characterization of EEG patterns in a cohort of patients with autoimmune encephalitis

J. Moura[1]; G. Videira[1]; J. Lopes[1]; J. Freitas[2]; E. Coutinho[3]; R. Samões[1]; E. Santos[1]

[1]Neurology Department, Unidade Local de Saúde Santo António, Porto, Portugal; [2]Neurophysiology Department, Unidade Local de Saúde Santo António, Porto, Portugal; [3]Centro de Neurociências e Biologia Celular, Universidade de Coimbra (CNC-UC), Coimbra, Portugal

Background and Aims: Variable EEG features associated with autoimmune encephalitis (AIE) have been reported in the literature, the diagnostic/prognostic value of which remains unknown. We aim to describe the EEG features from an institutional AIE cohort.

Methods: Retrospective review of the clinical and EEG features of AIE patients (according to Graus criteria) diagnosed between 2000 and 2023.

Results: In total, 49 AIE cases were identified (57.1% male) including 30.6% anti-NMDAr, 26.5% anti-GAD65 and 26.5% seronegative. EEG abnormalities were present in 81.6%: 71.4% had slow activity and 46.9% had focal epileptiform activity. These mostly involved the temporal region (59.6% and 69.6%, respectively). The extreme-delta brush pattern was present in 3 EEGs. Two patients presented with non-convulsive status epilepticus. An abnormal EEG was present in 78.6% of patients with normal brain MRI (49.0%), corresponding to

44.8% of the cohort. The presence of any EEG abnormality was associated with seizures at presentation ($p=0.022$). Even in patients without seizures, the EEG was abnormal in 65.0%. We found no significant difference in the EEG features when comparing serogroups, including seropositive vs. seronegative and intracellular vs. surface antibodies. The presence of slow activity was associated with an increased recurrence rate ($p=0.027$) in AIE with intracellular antibodies, when diffuse, and with increased disability after 6.0 (3.0–8.0) years in AIE with intracellular antibodies ($p=0.042$), when focal temporal.

Conclusion: EEG abnormalities are common in AIE, even in cases with normal brain MRI or without clinical seizures. The presence of slow activity may be a prognostic factor, depending on the antibody type.

Disclosure: The authors have nothing to disclose.

EPO-070 | The familiarity of romanian psychiatrists with anti-*N*-methyl-D-aspartate receptor encephalitis: A web-based study

D. Pavăl[1]; N. Gherghel-Pavăl[2]; O. Căpățînă[1]; I. Micluția[1]

[1]*Department of Psychiatry, "Iuliu Haţieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania;* [2]*Romanian Association for Autoimmune Encephalitis, Cluj-Napoca, Romania*

Background and Aims: Psychiatrists are often the first to be consulted in patients with anti-*N*-methyl-D-aspartate receptor (anti-NMDAR) encephalitis. Thus, they need to be aware of clinical features, differential diagnoses, and treatment options for patients affected by this condition. In this study, we aimed to investigate the familiarity of Romanian psychiatrists with anti-NMDAR encephalitis.

Methods: We recruited psychiatrists from Romania and conducted a cross-sectional observational study by using a web-based survey.

Results: 111 psychiatrists completed the survey, of whom 47 (42.34%) were specialists, while 64 (57.66%) were trainees. The median length of training for specialists was ten years (IQR 9.5), while for trainees was 2.5 years (IQR 3). In total, 31 (27.93%) psychiatrists encountered a case of anti-NMDAR encephalitis, with no significant difference between specialists and trainees. 31 (27.93%) psychiatrists were either unaware of the disorder or only knew its name, while 77 (69.37%) had knowledge of an outline of it. Only 3 (2.7%) psychiatrists had comprehensive knowledge of the disorder. Respondents with a higher awareness level had undergone significantly longer training ($p=0.014$). Unsurprisingly, having encountered a case significantly influenced awareness levels ($p<0.001$). There were no significant differences between specialists and trainees regarding specific knowledge about anti-NMDAR encephalitis. However, higher awareness levels and having encountered a case significantly influenced answer accuracy for questions regarding psychiatric presentation and epidemiological features.

Conclusion: Our study indicates that Romanian psychiatrists have suboptimal knowledge of anti-NMDAR encephalitis, highlighting the need for improved awareness of this disorder.

Disclosure: Nothing to disclose.

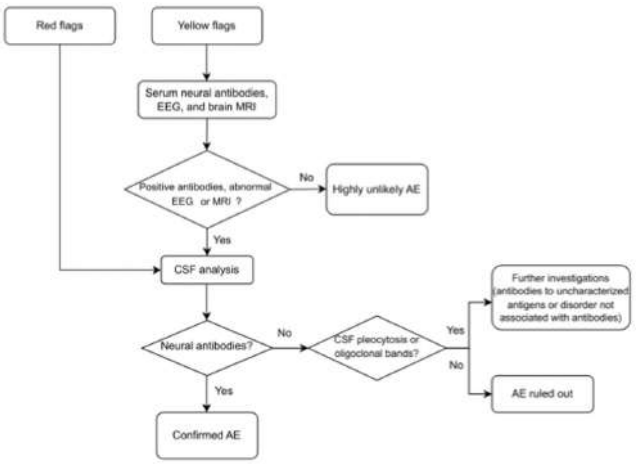
EPO-071 | Neural antibodies in first-episode psychosis patients with warning signs for autoimmune encephalitis

D. Pavăl[1]; N. Gherghel-Pavăl[2]; O. Căpățînă[1]; A. Stan[3]; L. Raduly[4]; L. Budișan[4]; I. Micluția[1]

[1]*Department of Psychiatry, "Iuliu Haţieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania;* [2]*Romanian Association for Autoimmune Encephalitis, Cluj-Napoca, Romania;* [3]*Department of Neurology, "Iuliu Haţieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania;* [4]*Research Center for Functional Genomics, Biomedicine and Translational Medicine, "Iuliu Haţieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania*

Background and Aims: While autoimmune encephalitis (AE) remains an essential differential diagnosis in first-episode psychosis (FEP), testing all FEP patients for neural antibodies is not feasible in real-world clinical practice. Thus, some researchers suggest selective testing in patients with warning signs of AE. Moreover, criteria have been proposed for a category of so-called autoimmune psychosis (AP). Here, we aimed to determine the prevalence of AE in a cohort of patients with FEP.

Methods: To achieve our objective, we used a phenotype-driven algorithm. Initially, we screened patients for "yellow" and "red flags" indicating low or high pre-test probability warning signs for AE, respectively. We also evaluated patients for previously proposed warning signs and AP criteria. Next, patients with red flags underwent cerebrospinal fluid analysis (including neural antibodies), while patients with yellow flags underwent tests for serum neural antibodies, EEG, and brain MRI.

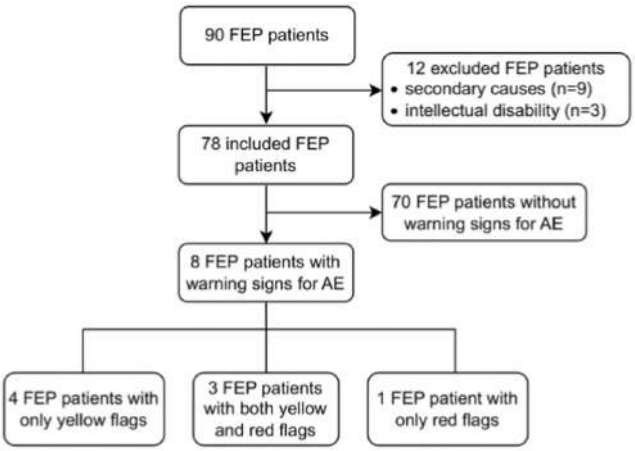


A phenotype-driven algorithmic approach for detecting autoimmune encephalitis in patients with first-episode psychosis. Abbreviations: AE, autoimmune encephalitis; CSF, cerebrospinal fluid.

Yellow flags (↓ pre-test probability for autoimmune encephalitis)	**Red flags** (↑ pre-test probability for autoimmune encephalitis)
• Rapid progression of psychosis (despite antipsychotic treatment) • Insufficient response to antipsychotics • Persistent hyponatremia (not explained by side-effects of medication) • Other autoimmune disorders (such as systemic lupus erythematosus or autoimmune thyroiditis)	• Altered level of consciousness • Severe or disproportionate cognitive dysfunction • Movement disorder (catatonia, dyskinesia, and/or dystonia) • Autonomic dysfunction • Focal neurological signs • Aphasia, decreased verbal output and/or unexplained dysarthria • Persistent headache • Seizures • Intolerance to antipsychotics or neuroleptic malignant syndrome
	Comorbidities: • Viral prodrome (mild fever, malaise, anorexia, and/or headache) • Recently diagnosed or active tumor (such as ovarian teratoma or thymoma) • Recent (<3 months) history of viral encephalitis
	History of autoimmune encephalitis

Warning signs for autoimmune encephalitis in patients with first-episode psychosis were defined as "yellow" (low pre-test probability) and "red flags" (high pre-test probability).

Results: We screened 78 patients with FEP and found that eight (10.3%) had at least one warning sign for AE: four (5.13%) patients had at least one red flag, while four (5.13%) had only yellow flags. Four (5.13%) patients met the criteria for possible AP. Two patients (2.56%) had anti-NMDAR encephalitis, while the remaining six (7.69%) received a primary psychiatric disorder diagnosis. The AP criteria failed to identify patients with definite AP due to a lack of paraclinical criteria.



Selection and inclusion of patients with first-episode psychosis and warning signs for autoimmune encephalitis.

Conclusion: Our study emphasizes the significance of including AE in the differential diagnosis of FEP.

Disclosure: This work was supported by the Iuliu Hațieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania (grants no. 881/41/12.01.2022 and 772/32/11.01.2023).

EPO-072 | Update of the treatment of pediatric neuromyelitis optica spectrum disorders

M. Elkhooly[1]; F. Bao[2]; S. sriwastava[3]; M. Ismail[4]
[1]*Department of Neurology, Southern Illinois University School of Medicine, Springfield, IL, USA; Department of Neurology, Wayne State University, Detroit, MI, USA; Department of Neurology and Psychiatry, Minia University, Minia, Egypt;* [2]*Department of Neurology, Wayne State University, Detroit, MI, USA;* [3]*Department of Neurology, McGovern Medical School, Houston, Texas, USA;* [4]*Department of Neurology and Psychiatry, Minia University, Minia, Egypt*

Background and Aims: Neuromyelitis Optica Spectrum Disorders (NMOSDs) is a collection of inflammatory and demyelinating disorders affecting the central nervous system. Given the severity and recurrence nature of the attacks, effective and safe treatment modalities are crucial. This study aims to provide an update on the current and emerging therapies for NMOSDs in the pediatric population.
Methods: We conducted a comprehensive analysis of the existing medications utilized in the treatment of pediatric NMO, encompassing both those currently being investigated in clinical trials for pediatric NMO on clinicaltrials.gov and the NIH website, as well as articles published on PubMed and Embase since 2008.
Results: A total of 15 studies have been conducted to examine the effects of 7 distinct drugs. A total of 231 patients were enrolled / anticipated to be enrolled, with 139 receiving Azathioprine, 21 receiving rituximab, 24 receiving mycophenolate mofetil, 12 receiving eculizumab, 15 receiving Inebilizumab, 12 receiving Ravulizumab, and 8 receiving Satralizumab. Azathioprine, mycophenolate mofetil, and rituximab are commonly utilized and generally regarded as safe. Various monoclonal antibodies, such as eculizumab, Inebilizumab, Ravulizumab, and Satralizumab, are currently undergoing testing to determine their effectiveness and safety.
Conclusion: Pediatric NMO treatment is still challenging, further clinical trials and research are warranted.
Disclosure: None.

EPO-073 | Characterization of neuropeptide cortistatin in multiple sclerosis patients

C. Adan[1]; R. Luque Huertas[2]; R. Piñar Morales[1]; F. Barrero Hernández[1]; E. González-Rey[4]
[1]*Clínico San Cecilio University Hospital, Granada, Spain;* [2]*Maimonides Biomedical Research Institute, Cell Biology, Physiology and Immunology, Córdoba, Spain*

Background and Aims: Multiple sclerosis (MS) diagnosis is based on clinical, radiological and biochemical criteria. However, it is necessary to find specific and reliable biomarkers to assess disease activity. We hypothesize that endogenous neuroimmune mediators could

be a new type of molecules which address the progression of this autoimmune disorder.

Methods: To assess the potential of cortistatin (CST), an anti-inflammatory and neuroprotective neuropeptide crucial in neuroimmune interactions, as a peripheral biomarker, blood samples were taken from patients with relapsing-remitting MS. CST levels were analyzed in plasma and serum. We also evaluated by a microfluidic qPCR the gene expression of CST and specific receptors as well as the relationship of CST and the immune response in peripheral mononuclear blood cells isolated from MS patients.

Results: We observed that, although CST levels were unchanged in plasma they were significantly reduced in serum from MS patients compared to healthy controls. Of note, we found that CST was highly susceptible to degradation in serum. We also demonstrated that immunomodulatory therapies did not affect CST plasma levels, except for patients treated with beta interferon, they showed increased plasma CST. Interestingly, we found that the gene expression of CST and related peptides were similar between patients and controls, while expression for the GPR107 receptor, a recently discovered receptor in the somatostatin system, was significantly downregulated in MS patients.

Conclusion: Our results suggest that the CST system could be altered in MS patients. However, further studies are needed to determine its role during the pathogenesis of MS and its relationship with current treatments.

Disclosure: The author declares no conflicts of interest.

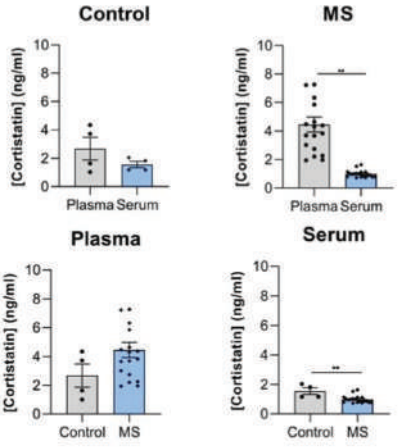


Figure 1. Variation of CST levels in plasma and serum. The comparison between plasma and serum CST levels of healthy **controls** and patients with **MS**, and between healthy controls and MS in **plasma** and **serum** is shown. Data are presented as mean ± SEM. **P < .01

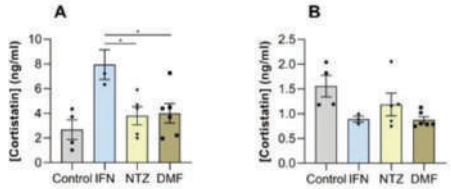

Figure 2. Levels of CST in the different therapies. The comparison between plasma **(A)** and serum **(B)** CST levels of MS patients distributed according to their disease modifying therapies is shown. IFN: interferon-β1a; NTZ, natalizumab; DMF: dimethyl fumarate. Data are presented as mean ± SEM. *P < .05

FIGURE 1

EPO-074 | The role of innovative therapies in refractory myasthenia gravis: Are they interchangeable and safe? A case-series

A. Sarnataro[1]; C. Pane[1]; N. Cuomo[1]; M. Campanile[1]; G. Puorro[1]; A. Marsili[1]; F. Saccà[2]; M. Garibaldi[3]; L. Fiondi[4]
[1]NSRO Department, Federico II University, Naples, Italy; [2]GENESIS Department, Federico II University, Naples, Italy; [3]Neuromuscular and Rare Disease Centre, Sant'Andrea Hospital, Rome, Italy; [4]Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Faculty of Medicine and Psychology, SAPIENZA University of Rome, Rome, Italy

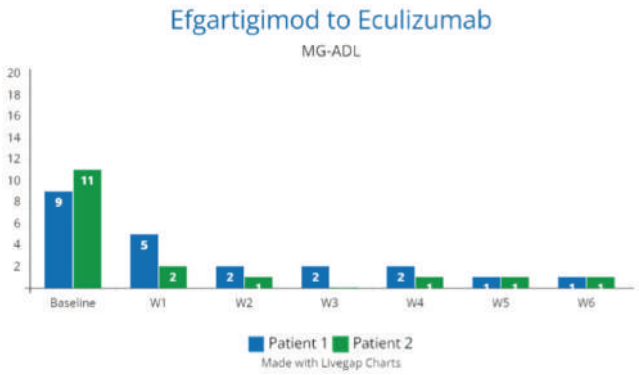
Background and Aims: Myasthenia Gravis (MG) therapies have dramatically changed in the last few years with the introduction of complement inhibitors and neonatal Fc receptor blockers. There are no data available on retreatment options in non-responder patient. We performed a case-series including four patients treated with innovative therapies that underwent a switch from anti-complement to FcRn blockers and viceversa.

Methods: We enrolled 4 patients with refractory MG treated with Efgartigimod (Pt. 1 and Pt. 2) and Ravulizumab (Pt. 3 and Pt. 4).They all underwent major clinical deterioration and switched to therapies with a different mechanism of action. We performed MG-ADL at the baseline and weekly, QMG at the baseline and after induction period of Eculizumab and cycle 1 of Efgartigimod and then every 3 months.

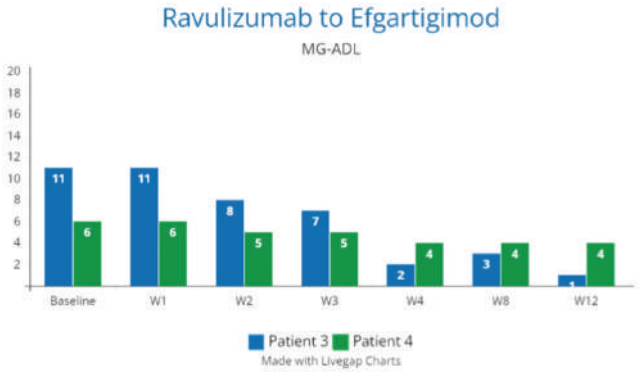
	AGE	SEX	AGE ONSET	DISEASE DURATION	MFGA	THERAPY SWITCH
Patient 1	46 y.o.	F	36 y.o.	10 years	IIIb	Efga -> Ecu
Patient 2	47 y.o.	F	26 y.o.	21 years	IIIb	Efga -> Ecu
Patient 3	33 y.o.	F	23 y.o.	10 years	IIIb	Ravu -> Efga
Patient 4	51 y.o.	F	28 y.o.	23 years	IIIb	Ravu -> Efga

Patients' characteristics description

Results: In the group of patients switching from Efgartigimod to Eculizumab we observed a mean MG-ADL reduction of 9 and a QMG reduction of 8.5 points after the induction period. Patients remained in the Minimal Symptom Expression for all the maintenance period. Ravulizumab to Efgartigimod switching group observed a MG-ADL global reduction of 5.5 points and a QMG reduction of 4 points after cycle 1. No major adverse events were observed except for Pt .4 who suffered from systemic infection. Efgartigimod was suspended and readministered after the resolution of the infection.



Efgartigimod to Eculizumab Group MG-ADL



Ravulizumab to Efgartigimod Group MG-ADL

Conclusion: Switch between innovative treatments with different mechanism of action proved to be a successful strategy in non-responders. Both Eculizumab and Efgartigimod succeeded in improving clinical status after few weeks of treatment. Further data collection is needed to assess the long-term efficacy of therapeutic switches.

Disclosure: Nothing to disclose.

EPO-075 | Cerebrospinal fluid interleukin-6 as a potential biomarker in CNS neuroinflammatory diseases: A real world analysis

E. Virgilio[1]; P. Garelli[2]; A. Dutto[1]; L. Giordano[1]; I. Pastore[1]; F. Franchino[1]; G. Micca[3]; G. Visconti Rossi[3]; M. Capobianco[1]
[1]Neurology Unit, Department of Medicine, ASO Santa Croce e Carle, Cuneo, Italy; [2]MS Center and Neurologia I U, Dipartimento di Neuroscienze e Salute Mentale, A.O.U. Città della Salute e della Scienza di Torino, Torino, Italy/Dipartimento di Neuroscienze "Rita Levi Montalcini," Università di Torino, Torino, Italy; [3]Clinical Biochemistry, ASO Santa Croce e Carle, Cuneo, Italy

Background and Aims: Interleukin-6 (IL-6) pathways have recently been described in the pathogenesis of neuromyelitis optica spectrum disorder (NMOSD). Some data suggest that CSF IL-6 may be a short-term prognostic biomarker in NMOSD. However, whereas various cytokines would be involved in the pathogenesis of inflammatory disease, the differences in cerebrospinal fluid (CSF) cytokines between different inflammatory diseases remain unclear. We aimed to compare CSF IL-6 levels among various neurological inflammatory disorders and to explore the relationship between CSF IL-6 and various intrathecal immunoglobulin (Ig) indexes.

Methods: From May 2023 we prospectively obtained IL-6 levels in consecutive CSF samples in patients suspected of an inflammatory disease of the CNS. IL-6 has been tested by commercially available ECLIA Kit. We also collected CSF cell count, protein levels, quantitative IgG indexes such as Link Index and Kappa-free-light-chain Index using nephelometry, and oligoclonal band (OB) status using isoelectrofocusing on agarose gel.

Results: So far, 20 patients (13 female, 10MS, 4 NMOSD/MOGAD, 2 clinically isolated syndrome and 4 non-inflammatory controls), with a mean age of 42.5 years (SD 13.4) were enrolled. Patients with NMOSD/MOGAD showed higher IL-6 levels compared to MS (35.25 ± 33.14 vs 4.98 ± *p*: 0.05 pg/ml). An inverse correlation of IL-6 levels was observed with Link Index (*r*: −0.56 *p*: 0.01), Kappa-Index (*r*: −0.29 *p*: 0.2) and patients without OB displayed higher levels of CSF IL-6 (17.15 ± 23.21 vs 4.93 ± 2.15 *p*: 0.05 pg/ml).

Conclusion: Our preliminary data support the potential of CSF IL-6 as a diagnostic biomarker in CNS inflammatory diseases. We plan to confirm our observation on a larger sample size.

Disclosure: Nothing to disclose.

EPO-076 | Prevalence and pattern of cognitive impairment in patients awaiting kidney and liver transplantation

A. Golenia[1]; P. Olejnik[1]; M. Grusiecka-Stańczyk[2]; N. Żołek[3]; E. Wojtaszek[4]; P. Żebrowski[4]; J. Raszeja-Wyszomirska[2]; J. Małyszko[4]

[1]*Department of Neurology, Medical University of Warsaw, Warsaw, Poland;* [2]*Department of Hepatology, Transplantology, and Internal Medicine, Medical University of Warsaw, Warsaw, Poland;* [3]*Institute of Fundamental Technological Research, Polish Academy of Sciences, Warsaw, Poland;* [4]*Department of Nephrology, Dialysis and Internal Medicine, Medical University of Warsaw, Warsaw, Poland*

Background and Aims: Cognitive impairment (CI) is common in both end-stage kidney disease (ESKD) and end-stage liver disease (ESLD). The goal of the study was to assess the prevalence and pattern of CI in patients awaiting kidney and liver transplantation.

Methods: In this cross-sectional, prospective study, 27 consecutive patients with ESKD and 27 consecutive patients with ESLD due to alcoholic liver disease, all currently on transplant waiting lists, were screened for cognitive decline using the Addenbrooke's Cognitive Examination. Medical history, demographics and laboratory test results were also collected.

Results: The prevalence of CI among patients with ESKD and ESLD was 27% and 88%, respectively. In both groups, the most impaired cognitive domain was memory and additionally verbal fluency in patients with ESRD and visuospatial abilities in patients with ESLD. The most statistically significant increase in the prevalence of CI was found in patients with fewer years of schooling, in both ESLD and ESKD populations, and in elderly patients, but only in the ESLD group. Additionally, better cognitive functioning in ESKD patients was associated with higher levels of total lymphocyte count and alanine transaminase (ALT), and in ESLD patients with higher levels of ALT and aspartate transaminase.

Conclusion: The prevalence of CI, especially in patients with ESLD, is high and may negatively affecting the transplantation process. Routine screening tests in this group would contribute to the implementation of effective treatments and facilitate the provision of specialized health care.

Disclosure: Nothing to disclose.

EPO-077 | A case of phonagnosia in a patient carrying C9orf72 gene mutation

E. Stanitsa; L. Apostolakopoulou; E. Angelopoulou; V. Konstadinides; R. Antonellou; G. Velonakis; G. Karadima; G. Koutsis; L. Stefanis; S. Papageorgiou

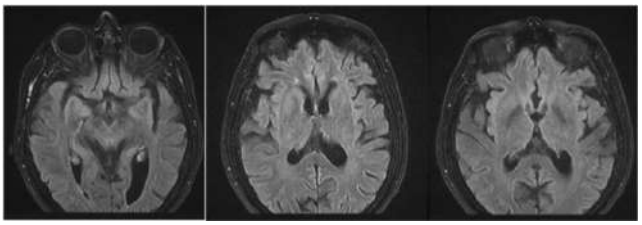
Department of Neurology, Eginition University Hospital, Athens, Greece

Background and Aims: Phonagnosia is a rare selective impairment of familiar voice recognition, with relative intact comprehension and recognition of faces. Compared to prosopagnosia, phonagnosia has been infrequently described in neurodegenerative diseases, and relative genetic evidence is scant.

Methods: We describe a case of a 56 years-old female patient, a primary school teacher, mainly presenting with progressive difficulty in recognizing familiar voices through the telephone, with intact recognition of familiar faces. Difficulties in concentration, visuospatial abilities, low information processing speed and apathy were also reported by her husband. Family history was positive for amyotrophic lateral sclerosis.

Results: Neurological examination was normal. MMSE was 26/20, and FAB was 13/18. The extensive neuropsychological examination revealed deficits in attention, executive function, visuospatial perception and memory, as well as impaired phonological and semantic verbal fluency. Brain MRI showed mild generalized cortical and hippocampal atrophy. Routine blood tests and electroencephalogram were normal. Audiological and ophthalmological evaluation was normal. CSF examination revealed normal TAU, p-tau and β-amyloid levels. Genetic analysis revealed C9orf72 expansion mutation. Phonagnosia was confirmed experimentally, by examining familiar voice recognition in a small sample of cognitively normal individuals

of similar age. Recently, another case of progressive phonagnosia was described in a patient with a C9orf72 expansion and frontotemporal dementia.



Brain MRI (FLAIR) of our patient demonstrating mild generalized cortical and hippocampal atrophy

Conclusion: To our knowledge this is the second case report of a patient with C9orf72 mutation presenting with phonagnosia. This might be partially explained by the overload of the neural network processing voices – due to her professional activity, combined with genetic mechanisms.

Disclosure: None.

EPO-078 | Unveiling constructional apraxia in huntington's disease through neurophysiological markers

A. Giglio; A. De Rosa; G. De Michele

Department of Neurosciences and Reproductive and Odontostomatological Sciences, Federico II University, Naples, Italy

Background and Aims: This study investigates constructional apraxia (CA) in HD, a feature insufficiently explored. Our aim is to unravel CA's cognitive underpinnings within the HD population, shedding light on potential associated cognitive markers.

Methods: Seventy HD patients from the Enroll-HD study were recruited, meeting specific inclusion criteria including a positive molecular HD test, clinically evident neurocognitive disease, ≥2 years of formal education, and the absence of other cognitive-impairing neurological disorders. Comprehensive assessments encompassed neuropsychological, psychiatric, motor, and functional evaluations. CA presence and type were determined via a copying task.

Results: Unexpectedly, 32 HD participants exhibited constructional apraxia (CA), yet no significant differences emerged between CA and no-CA groups in demographic, clinical, motor, or functional aspects (all $p > 0.05$). MANOVA revealed overall non-significant neuropsychological differences, but AC participants scored significantly lower on Symbol digit modality test, Stroop-color word – reading, Stroop-color word – interference, and Phonological verbal fluency tests (all $p < 0.05$). Logistic regression, statistically significant (X^2 [8] = 7.625, $p = 0.006$; Cox & Snell $R^2 = 0.057$), linked AC only to Stroop-color word – interference test (Wald: 7.166, $p = 0.007$, OR: 0.955, 95% CI: 0.924–0.988).

Background and Aims: CogEx (ClinicalTrials.gov, NCT03679468) was a randomized, sham-controlled trial determining effectiveness of cognitive rehabilitation (CR) and aerobic exercise (EX) in progressive multiple sclerosis (PMS). We present volumetric MRI and task-related functional MRI (fMRI) findings.

Methods: Participants were randomized (1:1:1:1) to "CR-plus-EX", "CR-plus-sham-EX (EX-S)", "EX-plus-sham-CR (CR-S)", and "CR-S-plus-EX-S" and attended 12-week intervention. Physical/cognitive assessments were performed at baseline, immediately after intervention (week-12) and 6 months post-intervention (month-9). MRI sub-study participants underwent volumetric MRI and fMRI (Go-NoGo task).

Results: 104 PMS participated in the MRI sub-study ("CR-plus-EX": $n=25$; "CR-plus-EX-S": $n=28$; "CR-S-plus-EX": $n=25$; "CR-S-plus-EX-S": $n=26$); 88 (85%) completed baseline and week-12 volumetric MRI and 84 (81%) completed Go-NoGo fMRI. At week-12 and month-9, no differences were found among interventions for symbol-digit modalities test (SDMT) correct responses, nor for SDMT, California verbal learning test (CVLT) and brief visuospatial memory test *Z*-scores ($p=$ range 0.12–0.94). Time-by-treatment interactions for changes at week-12 vs baseline of normalized grey matter (NGMV) ($p=0.10$) and cortical GM (NcGMV) ($p=0.10$) volumes were not significant. However, they became significant ($p=0.04$; $p=0.02$, respectively) when comparing all patients performing CR vs those performing CR-S. "CR-plus-EX-S" patients exhibited Go-NoGo-related fMRI activity increase ($p<0.05$, corrected) at week-12 vs baseline in bilateral insular regions. In all CR patients, increased NGMV ($r=0.42$, $p=0.004$) and NcGMV ($r=0.36$, $p=0.01$) at week-12 vs baseline correlated with increased CVLT Z-score.

Conclusion: Conclusions. CR modulated GM volumes and insular fMRI activity in PMS. Funding. Funded by the MS Society of Canada (grant #EGID3185). Ancillary funding from CMSC, Danish MS Society, and National MS Society.

EPO-080 | Altered cognition in Parkinson patients with depression compared to major depressive individuals

B. Yulug[1]; S. Cankaya[1]; E. Ozdemir Oktem[1]; A. Ozsimsek[1]; C. Sayman[1]; D. Sayman[1]; R. Karaca[1]; U. Duran[1]; L. Hanoglu[2]

[1]Department of Neurology, Alanya Alaaddin Keykubat University, Antalya, Turkey; [2]Research Institute for Health Sciences and Technologies (SABITA), Clinical Electrophysiology, Neuroimaging and Neuromodulation Laboratory, Istanbul Medipol University, Istanbul, Turkey

Background and Aims: The interaction of depression heralding PD and incidental depression after the diagnosis of PD is complex requiring a unified pathophysiological model of depression in PD. Here we explored the connectivity and cognitive differences between PD patients (with and without depression), Control and MDD patients. Our results indicate considerable cognitive and connectivity differences between PD and MDD patients suggesting a compensatory phase specific to PD, regardless of the pathophysiology of depression.

Methods: 38 Parkinson's outpatients (aged 49–86 years; 23 depressive (PDD) and 15 non depressive (PND)) and 46 healthy controls (aged 20–81 years; 22 depressive (MDD) and 24 non depressive (ND)) were recruited by their clinicians. We applied MMSE, MOCA and HDRS test to all the participants for cognitive and depression assessment.

Results: There was significant difference in terms of age ($p < .001$), education years ($p = 0.009$) and HDRS scores ($p < .001$). After adjusting age and education years, our findings revealed significant differences in orientation ($p = 0.050$) and abstraction ($p = 0.005$) scores which are subtests of MOCA without any difference in MOCA scores between PDD and MDD groups. We also observed that the MDD patients were clearly impaired on tests known to assess non-verbal primary memory, as well as verbal and non-verbal episodic memory compared to non-demented PD, a finding that has been confirmed both in non-depressed and depressed PD compared to MDD ($p < .005$).

Conclusion: Our study revealed valuable findings considering cognitive impairment in PD patients with depression compared to major depressive disorder (MDD). We believe that our results hold a clinicaş value for the literature.

Disclosure: Nothing to disclose.

EPO-081 | The affective and cognitive theory of mind and associated brain functional alterations in patients with PPA

Background and Aims: We aimed to investigate cognitive and affective theory of mind (ToM) abilities in semantic (svPPA) and nonfluent (nfvPPA) variants of primary progressive aphasia, compared to other frontotemporal lobar degeneration (FTLD) cases, such as behavioral (bvFTD) and right temporal variants (rtvFTD). Moreover, this study explored the neural correlates of affective and cognitive ToM alterations in these FTLD syndromes.

Methods: Sixty-seven FTLD patients (14 nfvPPA, 17 svPPA, 23 bvFTD and 13 rtvFTD) and 98 healthy controls underwent neuropsychological evaluation, structural and resting-state functional MRI. Based on literature, two regions of interest (medial prefrontal cortex-lmPFC and right supramarginal gyrus-rSMG) were created as main nodes for affective and cognitive ToM, and RS functional connectivity (RS-FC) networks were obtained. Using graph analysis and connectomics, global and regional functional brain connectivity were assessed and compared between groups. Patients underwent the affective (SET-EA) and cognitive (SET-IA) ToM subtests of the Story-Based Empathy Task (SET), and their performances were compared across groups.

Results: Affective and cognitive ToM abilities as measured by the SET appeared similarly impaired in all patients' groups, including PPA. Significant regional RS-FC alterations within both affective and cognitive networks were observed in each group of patients as compared with healthy controls.

Conclusion: These findings suggest a deterioration of affective and cognitive ToM skills in FTLD patients, including PPA, which seems to be related to similar functional connectivity alterations. The present study emphasizes the importance of socio-cognitive features in the early detection of FTLD conditions. Funding. European Research Council (StG-2016_714388_NeuroTRACK); Foundation Research on Alzheimer Disease.

EPO-082 | Improving cognitive functions in healthy subjects using tACS and individual theta frequency

B. Yuluğ[1]; C. Sayman[1]; S. Cankaya[1]; E. Ozdemir Oktem[1]; A. Ozsimsek[1]; A. Berekelia[2]; U. Duran[1]; D. Sayman[1]; R. Karaca[1]; L. Ipek[1]; L. Hanoglu[3]

[1]*Alanya Alaaddin Keykubat University, Department of Neurology and Neuroscience, Antalya, Turkey*; [2]*Bahcesehir University, Department of Neurology, Istanbul, Turkey*; [3]*Istanbul Medipol University, Department of Neurology, Istanbul, Turkey*

Background and Aims: Transcranial Alternating Current Stimulation (tACS), a non-invasive method, aims to enhance cognitive abilities in healthy individuals and those with cognitive challenges by replicating brain activity. Beyond cognitive neuroscience, it shows promise for psychiatric issues like schizophrenia. This study explores tACS effects on eight healthy individuals aged 26 to 34.

Methods: Cognitive assessments (MMSE, MoCA, STROOP test, trail making parts A and B, short-term memory, Recall, Wechsler memory scale), EEG scans, and depression level evaluations conducted before and after tACS stimulation. Personalized tACS stimulation was administered to the dorsolateral prefrontal cortex (DLPFC) area, utilizing individual theta frequency (ITF) determined with MetLab. The 20-minute sessions, spanning five days, employed a 2 mA sinusoidal oscillating current at minus one ITF (4–8 Hz) to enhance cognitive functions. Post-stimulation, participants underwent the same battery of cognitive tests and EEG scans.

Results: The statistical analysis, utilizing paired samples T-test with a significance threshold of $p < 0.005$, revealed no significant change in depression levels ($p = 0.439$). While Wechsler memory scale, MoCA, MMSE, and STROOP tests exhibited no noteworthy differences, there were significant improvements in short-term memory ($p = 0.041$) and trail making part B ($p = 0.008$) (Table 1).

Conclusion: In conclusion, tACS, a well-established non-invasive brain stimulation technique, has demonstrated cognitive benefits in various conditions. This study reinforces existing literature, indicating notable enhancements in short-term memory and executive function (trail making) after five days of tACS stimulation. Further investigations should involve larger participant groups to consolidate and expand upon these findings.

Disclosure: Nothing to disclose.

EPO-083 | Effects of episodic and chronic tension type headache on cognition and empathic neural responses: A fMRI study

B. Yulug[1]; S. Cankaya[1]; C. Sayman[1]; E. Ozdemir Oktem[1]; A. Ozsimsek[1]; U. Aylak[2]; B. Ayyıldız[3]; D. Sayman[1]; R. Karaca[1]; A. Aktürk[1]; L. Hanoglu[4]; A. Velioğlu[5]

[1]*Alanya Alaaddin Keykubat University, Department of Neurology and Neuroscience, Antalya, Turkey*; [2]*Bahcesehir University, Department of Neurology, Istanbul, Turkey*; [3]*Anatomy PhD Program, Graduate School of Health Sciences, Kocaeli University, Istanbul, Turkey*; [4]*Istanbul Medipol University, Department of Neurology, Istanbul, Turkey*; [5]*Center for Psychiatric Neuroscience, Feinstein Institute for Medical Research, Manhasset, New York, USA*

Background and Aims: This study delves into tension-type headache (TTH), emphasizing its prevalence and impact on health and daily life. The evolving understanding of TTH's neurological basis, particularly altered central pain perception, prompts a need for comprehensive studies on mood, cognitive function, and pain empathy. The study aims to evaluate cognitive and empathic neuroimaging correlates of TTH, addressing the lack of integrated studies in this area.

Methods: The enrollment comprised 102 participants (46 TTH patients, 41 healthy controls) from Alanya University, diagnosed following International Headache Committee criteria. Exclusion criteria covered various conditions, and ethical approval was obtained. Structural and resting-state fMRI scans were conducted with specific parameters.

Results: Analyzing demographic and clinical data, age differences were nonsignificant ($p > 0.05$), while education years significantly varied ($p < 0.001$). MOCA scores exhibited a significant difference ($p < 0.05$), with tension-type headache patients scoring lower. Subgroup analysis of episodic and chronic patients revealed no significant differences in neurocognitive tests, volume, or connectivity ($p > 0.05$).

Conclusion: The study proposed a potential reverse causal relationship, suggesting individuals with higher empathy levels might be more susceptible to developing TTH. The decline in cognitive scores correlated with increased headache intensity, indicating a complex interaction between acute headache episodes, pain processing, and cognition. fMRI results demonstrated changes in brain regions associated with acute pain, impacting executive functions and highlighting the cost of cognition during acute pain episodes. It provides valuable insights into the intricate relationship between TTH, cognitive function and pain empathy, contributing to the understanding of the neurological underpinnings of TTH and its broader implications.

Disclosure: Nothing to disclose.

EPO-084 | Neurocognitive correlates of awareness of everyday functioning in middle-aged and older adults with HIV

A. Jacob[1]; M. Crowe[1]; V. Del Bene[2]; P. Fazeli[3]; D. Stavrinos[4]; D. Vance[3]
[1]*Department of Psychology, University of Alabama at Birmingham, Birmingham, Alabama, USA*; [2]*Department of Neurology, University of Alabama at Birmingham, Birmingham, Alabama, USA*; [3]*School of Nursing, University of Alabama at Birmingham*; [4]*Institute of Social Science Research, University of Alabama, Tuscaloosa, Alabama, USA*

Background and Aims: People living with HIV (PLWH) are vulnerable for cognitive decline and are at greater risk for impaired everyday functioning; however, they may lack self-awareness of such impairments. We examined neuropsychological correlates of self-awareness of everyday functioning in PLWH.
Methods: In this cross-sectional study, 260 PLWH (40+ years) completed a comprehensive assessment including neuropsychological tests as well as self-report (i.e., Lawton and Brody IADL Questionnaire) and performance-based measures of everyday functioning (i.e., Timed Instrumental Activities of Daily Living). Self-awareness of functional status was calculated in the domains of medication management, financial management, telephone use, and grocery shopping. An algorithm was developed to classify accurate reporters, under-reporters, and over-reporters using cut-offs between actual performance vs self-reported performance. Multinomial and binomial logistic regression equations were used.
Results: For financial management, participants with higher scores in executive function/attention were less likely to be under-reporters, while participants with higher depression were more likely to over-report difficulties. For medication management, word-reading emerged as the only significant predictor of inaccurate vs accurate reporting. For telephone use, participants who scored higher on executive function/attention and word-reading were less likely to under-report difficulties. For grocery shopping, those of non-white race had increased risk for inaccurate reporting.
Conclusion: Factors that impact self-awareness of deficits may vary based on the functional domain and factors beyond cognitive function, such as mood and social factors, and should be included when examining awareness of functional difficulties. These results support the use of a domain level approach to examining awareness of functional difficulties in PLWH.
Disclosure: Nothing to disclose.

EPO-085 | From vision to language: Neuropsychological profile in a cohort of patients with Posterior Cortical Atrophy

E. Bergamin[1]; L. Giampietri[2]; M. Del Chicca[1]; V. Nicoletti[2]; S. Cintoli[2]; G. Spadoni[2]; F. Baldacci[1]; G. Siciliano[1]; G. Tognoni[2]
[1]*Department of Neuroscience, University of Pisa, Pisa, Italy*; [2]*Department of Medical Specialties, Neurology Unit, AOUP, Pisa, Italy*

Background and Aims: The aim of this study was to analyze the neuropsychological profile of a group of patients with Posterior Cortical Atrophy (PCA) due to Alzheimer's disease (AD). Unlike typical AD, memory, insight and judgement are relatively preserved until latter stages but patients commonly report early language difficulties. However, some inconsistencies exist among the cognitive features described.
Methods: Clinical features and neuropsychological profile of 22 subjects (13 females) aged between 49 and 73 years (61.13 ± 7.04) with PCA due to AD have been analyzed. Each patient underwent a battery of neuropsychological tests, brain MRI, brain [18F]FDG-PET and alternatively amyloid-PET or research for AD biomarkers on CSF. A voxel-based analysis of [18F]FDG-PET compared with normal control subjects has been performed for 14 patients.
Results: All patients showed impairment in visual-perceptual, visual-spatial abilities and visuospatial memory. Variable language impairment was detected in 68% of patients. At voxel-based analysis of [18F]FDG-PET the evaluation of semantic fluency positively correlated with hypometabolism in the left angular gyrus ($p < 0.001$) and Progressive Matrices Test positively correlated with hypometabolism in inferior and superior left parietal gyrus ($p < 0.001$).
Conclusion: A considerable variability in the language profile was found: specifically, in some patients an impairment of semantic verbal fluency was observed, while in others a logopenic phenotype was detected, in agreement with the literature. The positive correlations found for semantic fluency and Progressive Matrices Test are consistent with the existing literature. Further studies are needed to characterize the progressive evolution of the neuropsychological profile of PCA.
Disclosure: The authors have nothing to disclose.

EPO-086 | Sex differences in neuropsychological profile in behavioural frontotemporal dementia

F. Menegon[1]; F. De Marchi[1]; A. Baj[1]; M. Sacchetti[2]; G. Decaroli[3]; P. Serra[4]; B. Sarasso[4]; C. Comi[3]; G. Tondo[3]
[1]*Department of Translational Medicine, University of Piemonte Orientale, Neurology Unit, Azienda Ospedaliero-Universitaria Maggiore della Carità, Novara, Italy*; [2]*Department of Clinical Psychology, Azienda Ospedaliero-Universitaria Maggiore della Carità, Novara, Italy*; [3]*Department of Translational Medicine, University of Piemonte Orientale, Neurology Unit, S. Andrea Hospital, Vercelli, Italy*; [4]*Neurology Unit, S. Andrea Hospital, Vercelli, Italy*

Background and Aims: Behavioral variant (bvFTD) is the most common form of frontotemporal dementia (FTD), presenting with executive deficits and behavioural changes. Sex differences in prevalence, clinical characteristics, and biomarkers, have been described in several neurodegenerative diseases, including FTD. A previous study reported worse executive and language performances in FTD females than males, but these findings are still sparse and need further characterization.

Methods: We included 20 patients (12 females, 8 males, age-matched) diagnosed with bvFTD at the Memory Clinics of Novara and Vercelli, Piedmont, Italy. All patients underwent a neurological and neuropsychological evaluation at baseline, to characterize the clinical presentation. Patients also underwent a brain MRI and FDG-PET scan, and a lumbar puncture to support clinical diagnosis. In familial cases, mutations in genes frequently associated with FTD were investigated.

Results: In our cohort, sex did not influence global cognition, evaluated with the Mini Mental State Examination and the Montreal Cognitive Assessment (MOCA). When considering specific cognitive domains, we observed better performance in females compared to males in working memory (i.e., corrected Reverse Digit Span, $p=0.0198$), and language (i.e., MOCA denomination subscore, $p=0.03$).

Conclusion: From our preliminary data, sex might have a role in determining the type of neuropsychological impairment in bvFTD, with females performing better than males in language and working memory tests. These results confirm that sex may play a role in influencing clinical phenotype in bvFTD, supporting the hypothesis of sex as a pivotal variable for biological and clinical differences in neurodegenerative diseases.

Disclosure: Nothing to disclose.

EPO-087 | QEEG connectivity markers to predict post-stroke cognitive impairment: A pilot study

H. Dragoș[1]; L. Livint Popa[1]; D. Muresanu[2]
[1]*Department of Neurosciences, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania;* [2]*RoNeuro Institute for Neurological Research and Diagnostic, Cluj-Napoca, Cluj, Romania*

Background and Aims: Post-stroke cognitive impairment (PSCI) occurs in about 20% of acute ischemic stroke (AIS) patients within the first months and is associated with poor long-term prognosis. AIS lesion seems to cause a change in the low-frequency resting state networks, resulting in increased local connectivity, associated with a global disconnection and a disruption of subcortical-cortical or cortico-cortical interactions. This study aimed to develop a predictive model incorporating quantitative EEG connectivity markers to accurately predict PSCI six months after AIS.

Methods: Data were collected from 30 patients with symptomatic supratentorial AIS confirmed by brain MRI without a history of cognitive impairment or dementia. Resting-state EEG was recorded within the first seven days after AIS onset. Relative power for delta, theta, alpha, and beta bands, delta/alpha ratio, coherence, and phase-locking value were computed. Neuropsychological assessments consisting of the Montreal Cognitive Assessment test, Digit Symbol, Digit Backward, Stroop Color-Word Test, and Rey Auditory Verbal Learning test were performed one and six months after AIS.

Results: Delta/alpha ratio and relative theta frequency power were independent predictors for PSCI, suggesting the association between post-stroke alpha slowing and PSCI, which may be mediated by attentional dysfunction.

Conclusion: QEEG markers seem to be a useful tool to inform early prognostication of PSCI, particularly when cognitive function cannot be adequately assessed.

Disclosure: Nothing to disclose.

EPO-088 | Indicators of cognitive status and quality of life in patients with dystrophic myotonia (DM)

E. Malhina[1]; Y. Rushkevich[1]; S. Likhachev[1]; M. Dymkovskaya[1]; A. Gusina[2]; O. Haliyeyskaya[1]
[1]*Republican Scientific and Practical Center of Neurology and Neurosurgery, Minsk, Belarus;* [2]*Republican Scientific and Practical Center "Mother and Child", Minsk, Belarus*

Background and Aims: Dystrophic myotonia (DM) is a rare multisystem autosomal dominant disease. This is the most common genetic form of muscular dystrophy in adults. Clinical manifestations are varied. Intellectual impairments are observed in all forms of DM. Purpose. Study of the characteristics of cognitive status and quality of life (QoL) in patients with DM.

Methods: 21 patients with a genetically confirmed diagnosis of DM: 3 male and 18 female, ME 45.0[39.0;52.0] years (14 – type DM1, 7 – type DM2). 33 healthy controls (HC): 11 male, 31 female. ME 45.0[38.0;53.0] years.

Results: According to the MoCA, a decrease in scores was found in patients with DM (Me 27.0[25.0;29.0]) compared to the HC (Me 30.0[28.5;30.0]), (U, $p=0.007$). When studying the MoCA subtests, patients with DM revealed a decrease in "attention" indicators (U, $p=0.04$); "delayed reproduction" (U, $p=0.054$). The SF-36 assessment showed that in patients with DM there is a dominant decrease in the general indicator of the physical component of health (Me 34.0[29.1; 38.5]) compared to the HC (Me 30.0[45.1; 56.1]), (U, $p=0.013$). A defect was identified in the subscales "physical functioning" (U, $p=0.0025$), "general health" (U, $p=0.048$) and "vital activity" (U, $p=0.046$).

Conclusion: Patients with DM have cognitive impairment with a predominance in the "attention" and "delayed recall" subtests. A decrease in QoL indicators was revealed in terms of physical functioning", "general health" and "life activity". The data obtained reflect the importance of cognitive testing and the study of QoL in patients with DM for the correction of identified disorders.

Disclosure: The authors have nothing to disclose.

EPO-089 | Cognitive decline in patients with diabetes mellitus type 2: The validity of PS-test

Y. Laykova; E. Gorobets; R. Esin; R. Gamirova
Kazan Federal University

Background and Aims: The objective of the study was to determine the validity of the tool for the early detection of cognitive impairment in patients with type 2 diabetes mellitus (DM).
Methods: The study group (SG) involved 102 patients (67 women, 35 men) with diabetes mellitus type 2, average age 67.5±8.1. The comparison group (CG) included 89 respondents aged 64.3±9.5 years (51 women, 38 men). Both groups were assessed by Montreal Cognitive Assessment (MoCA) test and by the specific tool for cognitive assessment in DM (PS-test) worked out by the authors. Statistic methods: nonparametric statistical estimation methods suitable for samples that do not follow a normal distribution; the Mann-Whitney test; Spearman test.
Results: The MoCA test results revealed statistically significant difference (SSD) between SG and CG. The average MoCA test score in SG was 21.07±0.36, in CG – 28.75±0.15 ($p<0.001$). SSD was revealed also as a result of PS-test performing. The average paremiological test score in SG was 14.46±0.38, in CG – 19.84±0.04. According to the Chaddock scale, the obtained correlation coefficient $r=0.8858$ corresponds to a high degree. The level of significance of the correlation is confirmed by the p value <0.0001. Thus, the developed test correlates well with the MoCA test chosen as an external reference criterion, which proves the validity of this tool.
Conclusion: PS-test can be used in clinical practice for early reveal of cognitive decline in patients with DM type 2.
Disclosure: The reported study was funded by Russian Foundation for Basic Research (RFBR) according to the research project no. 20-312-90044.

EPO-090 | Deciphering the decline in dementia diagnoses: A 2015–2022 analysis in Sweden

B. Winblad
Division of Neurogeriatrics, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden

Background and Aims: This study investigates age-standardized rates of dementia diagnoses in Sweden among individuals aged 65 and older from 2015 to 2022, focusing on three primary diagnoses—F00 (Alzheimer's disease), F01 (Vascular dementia), and F03 (Unspecified dementia). The primary objective is to analyze trends, emphasizing the significant decrease post-2019.
Methods: Data sourced from national healthcare records includes age-standardized rates measured as dementia diagnoses per 100,000 inhabitants for individuals aged 65 and older. Gender-specific trends for F00, F01, and F03 are analyzed using descriptive statistics and Poisson regression.
Results: For F00 dementia diagnoses, both males and females exhibit a consistent decline from 2015 to 2019, followed by a substantial reduction post-2019. Males experience a decline from 7.4 to 6.6, while females have a notable drop from 7.3 to 3.9. Similarly, F01 vascular dementia diagnoses demonstrate a substantial decrease in both genders post-2019. Males witness a decline from 110.6 to 78.3, while females see a drop from 91.1 to 63.9. Additionally, F03 unspecified dementia diagnoses portray a consistent decline from 2015 to 2019, with a further reduction post-2019. Males decrease from 161.1 to 135.3, while females drop from 138.0 to 115.6.
Conclusion: Findings reveal a substantial post-2019 decrease in dementia diagnoses, possibly impacting healthcare planning and resource allocation. Adaptability in healthcare systems is crucial for addressing the evolving needs of the aging population due to COVID-19 infection. One conclusion could be that demented persons did not get satisfactory assessment and care during the COVID period. Further research is needed to explore contributing factors.
Disclosure: The authors declare no conflicts of interest or financial relationships that could bias the study's results or interpretation.

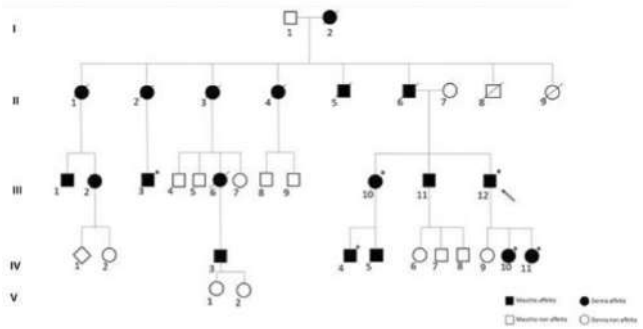
EPO-091 | Autosomal dominant SPG18: A large Italian family

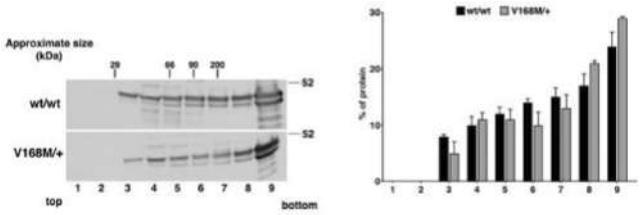
N. Cuomo[1]; A. Trinchillo[1]; V. Valente[2]; M. Esposito[3]; M. Migliaccio[4]; A. Iovino[1]; P. Michele[2]; C. Caccavale[1]; C. Nocerino[1]; E. Salvatore[5]; G. Pierantoni[2]; V. Menchise[6]; S. Paladino[2]; C. Criscuolo[5]
[1]*Department of Neurosciences, Reproductive Sciences and Odontostomatology, University Federico II of Naples, Naples, Italy;* [2]*Department of Molecular Medicine and Medical Biotechnology, University of Naples Federico II, Naples, Italy;* [3]*Clinical Neurophysiology Unit, Cardarelli Hospital, Naples, Italy;* [4]*IRCCS SDN SYNLAB, Naples, Italy;* [5]*CDCD Neurology, "Federico II" University Hospital;* [6]*Institute of Biostructure and Bioimaging, National Research Council (CNR) and Molecular Biotechnology Center, Turin, Italy*

Background and Aims: Hereditary Spastic Paraplegias (HSP) are classified as "pure", when spastic paraplegia is the only symptom or "complex" when other clinical features are present. SPG18 is due to ERLIN2 AD or AR gene mutations.
Methods: We describe clinical and molecular findings of a large Italian AD SPG18 family. Whole exome sequencing. Sanger sequencing was performed to verify the genetic variation in the proband and family members. Velocity gradient assay on proband's fibroblasts was performed to investigate propensity of the mutated ERLIN2 to form oligomers.



SPG18 pedigree

Results: Five affected family members showed progressive spastic paraplegia. Neuropsychological evaluation pointed out a slight mental retardation in two patients. One patient reported generalized epilepsy. The proband's father died at 58 years old with a diagnosis of amyotrophic lateral sclerosis (ALS). Some of his siblings also died around 60 years old with an anamnestic history ascribable to ALS. Genetic analysis revealed the heterozygous missense mutation, c.502G>A (p.V168M), in ERLIN2 gene, which cosegregated with the disease in the affected patients and was not present in healthy subjects. Velocity gradient assay indicated no differences in oligomerization between mutated and wild-type protein.



velocity gradient essay

Conclusion: We report a large Italian SPG18 kindred supporting AD transmission pattern with a broad phenotypic variability. Our data strength p.V168M more frequent association to ALS while biochemical assays unravelled that V168M does not affect the ability of erlin-2 to oligomerize, excluding a dominant negative effect.
Disclosure: Nothing to disclose.

EPO-092 | Findings from the ILLUMINATE prospective Natural History Study (NHS) in individuals with ALSP

D. Lynch[1]; J. Gelfand[2]; C. Wade[3]; N. Wolf[4]; W. Koehler[5]; C. Bergner[5]; L. Schols[6]; S. Hayer[6]; E. Finger[7]; J. Orthmann-Murphy[8]; B. Matys[9]; D. McLaren[9]; A. Meier[9]; R. Rajagovindan[9]; Z. Wszolek[10]
[1]*Department of Molecular Neuroscience, National Hospital for Neurology & Neurosurgery, Queen Square, and UCL Institute of Neurology, London, UK;* [2]*Department of Neurology, University of California San Francisco, San Francisco, CA, USA;* [3]*Department of Neurosurgery, University College London, London, UK;* [4]*Department of Child Neurology, Amsterdam Neuroscience, Amsterdam University Medical Centers, Amsterdam, The Netherlands;* [5]*Department of Neurology, University of Leipzig Medical Center, Leipzig, Germany;* [6]*Hertie-Institute for Clinical Brain Research & Department of Neurology, Tübingen University Hospital, Tübingen, Germany;* [7]*Department of Clinical Neurological Sciences, Western University, London, Ontario, Canada;* [8]*Department of Neurology, Hospital of the University of Pennsylvania, Philadelphia, PA, USA;* [9]*Clinical, Vigil Neuroscience, Inc., Watertown, MA, USA,* [10]*Department of Neurology, Mayo Clinic, Jacksonville, FL, USA*

Background and Aims: Adult-onset leukoencephalopathy with axonal spheroids and pigmented glia (ALSP) is a rare, autosomal-dominant, neurodegenerative microgliopathy caused by a CSF1R gene mutation characterised by brain white matter demyelination and atrophy, swollen axons, pigmented glial cells, and clinical symptoms of cognitive, neuropsychiatric, and motor dysfunction. ALSP symptoms typically develop around 40–50 years of age, leading to death within ≈6–8 years; no approved therapies exist.
Methods: ILLUMINATE, the first NHS in ALSP (NCT05020743), is a prospective, multicentre study of individuals with definitive (satisfying full radiological, genetic, clinical criteria) or prodromal (satisfying genetic, radiologic criteria only) ALSP. Participants ($N \approx 50$) are followed for 24 months, with clinical assessments and MRI collected at screening and every 6 months and blood and cerebrospinal fluid (CSF) disease biomarkers collected at specific visits.
Results: As of Sept-2023, 24/42 enrolled participants were symptomatic and 18/42 prodromal. Ventricular volumes were higher at baseline and expanded over time, and baseline grey matter volumes were lower and declined over time, in symptomatic vs prodromal patients (Fig-1). Baseline soluble CSF1R in CSF was substantially lower in all participants (reflecting reduced microglial activity) than healthy individuals, whereas neurofilament light chain (NfL) in CSF and serum was elevated in symptomatic (indicating neuroaxonal injury) vs prodromal and healthy individuals (Fig-2). Cognitive impairment was greater in symptomatic than prodromal patients and correlated with MRI volume changes (Fig-3).

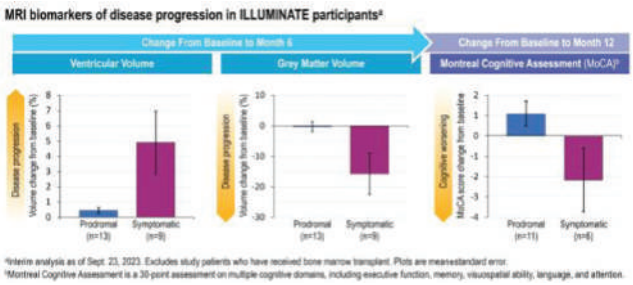


FIGURE 1

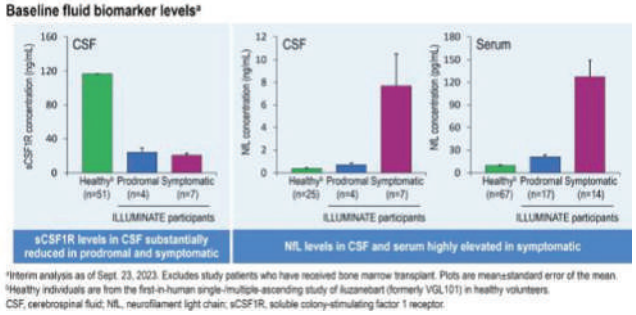

FIGURE 2

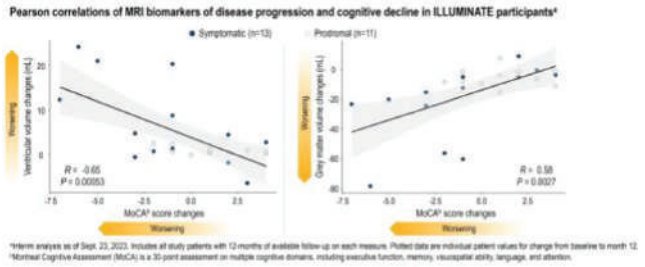

FIGURE 3

Conclusion: These findings demonstrate the sensitivity of MRI measures and NfL to ALSP pathophysiology, with potential to inform optimal clinical endpoints and interventional study design in ALSP and improve understanding of disease progression.

EPO-093 | A recurrent homozygous deletion in MED22 leads to a progressive neurodevelopmental disorder and neurodegeneration

E. Cali
UCL Institute of Neurology, University College London

Background and Aims: Proper neurodevelopment relies on gene expression programs influenced by signalling molecules, transcription factors (TFs), and epigenetic processes. In this study, we investigate an ultra-rare homozygous single amino acid deletion (p.Glu133del) in MED22, a component of Mediator, a key regulator of transcription, gene expression and posttranslational epigenetic modifications. Disruption of Mediator has been implicated in various neurodevelopmental and neurodegenerative disorders.

Methods: We analysed the variant's impact into the Mediator structure and function through cellular studies and computational simulations. We investigated MED22 protein function generating knock-out zebrafish model and knock-in Drosophila model. We performed scRNA-seq on zebrafish mutants.

Results: We identified eight affected individuals from six unrelated families with a severe progressive neurodevelopmental disorder, characterized by global developmental delay, microcephaly, dystonia, seizures, and microcephaly. In vivo models of Drosophila melanogaster and zebrafish demonstrate significant developmental disruption, mirroring major aspects of the human disorder. scRNA-sequencing data obtained from zebrafish mutants implicate MED22 in dopaminergic network dysfunction.

Conclusion: We establish the first association of MED22 with a human disorder, through integration of clinical, genetic and neuroradiological data. We provide insights in the molecular dynamics of Mediator dysfunction and in the neuronal pathways that might be affected by MED22 dysfunction.

Disclosure: Nothing to disclose.

EPO-094 | MicroRNA biomarkers of large vessel occlusion strokes in cross-sectional and longitudinal analysis

E. Sidorov[1]; M. Rout[2]; D. Sanghera[2]
[1]Department of Neurology/The University of Oklahoa Health Sciences Center, Oklahoma City, Oklahoma; [2]Department of Pediatrics/ The University of Oklahoa Health Sciences Center, Oklahoma City, Oklahoma

Background and Aims: Exosomal microRNAs play an important role in developing disease biomarkers. Many microRNAs were associated with stroke in case-control studies on heterogeneous populations, but none had solid evidence to become a biomarker. In this pilot investigation, we analyzed the microRNA of stroke patients with large vessel occlusion (LVO) using a combination of cross-sectional and longitudinal study designs.

Methods: We performed a cross-sectional analysis of 2,632 serum exosomal microRNAs on 55 stroke patients and 53 non-stroke controls; and a longitudinal analysis in 10 stroke patients, collecting blood samples at <24 h, 3, 5, and 30 days after stroke. MicroRNAs were isolated using the mir VANA RNA isolation kit (Ambion, USA). We ran miRNA expression assays using TaqMan probes (Applied Biosciences, USA) on 384-well microplates using QuantStudio 6 available in our lab. Each assay was run in duplicates using endogenous (U6) and blank controls.

Results: We identified 51 microRNAs associated with ischemic stroke, however, only microRNA 9-3p and microRNA 233-3p survived stringent Bonferroni correction ($p < 0.01$). MicroRNA 9-3p had 9-fold higher levels in LVO stroke patients compared to controls ($p < 0.01$), and a strong correlation with the infarction volume ($r = 0.393$; $p = 2.98 \times 10^{-3}$). Both microRNAs significantly increased during longitudinal analysis from presentation to days 3–5 and then slowly declined at 90 days after stroke ($p < 0.01$).

Table 1. Significantly altered serum exosomal miRNAs in large vessel occlusion stroke and the correlation with the infarction volume (N= 55 stroke cases and 53 controls)

miRNA	Fold Change	Log fold change	p-value	FDR p-value	Bonferroni corrected p-value	Correlation with stroke volume/p-value
hsa-miR-9-3p	9.39	3.23	2.0×10^{-7}	5.6×10^{-5}	1.3×10^{-4}	↑*
hsa-miR-223-3p	-1.83	-0.87	1.1×10^{-7}	1.5×10^{-4}	7.1×10^{-4}	↓

*p- value =0.003

Significant microRNAs

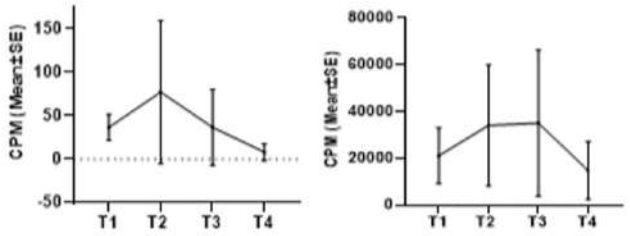

Figure 1. Longitudinal analysis of miRNA-9-3p (A), mi-RNA-223-3p (B) shows that they increase after presentation and decline at 90 days.

Longitudinal changes in microRNAS

Conclusion: Our study showed dysregulation of exosomal microRNAs 9-3p and 233-3p after ischemic stroke in cross-sectional and longitudinal analysis. If replicated in large-scale trials both microRNAs may be come ischemic stroke biomarkers

Disclosure: Nothing to disclose.

EPO-095 | Neurological symptoms in adults with Gaucher disease: A systematic review

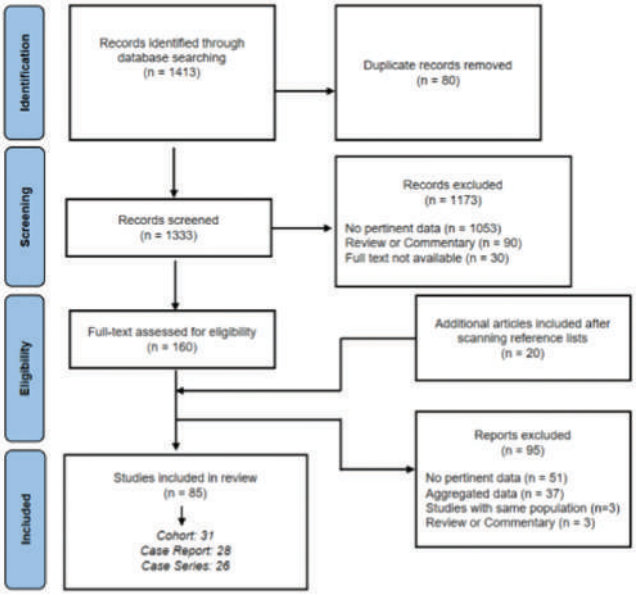
G. Imbalzano; C. Ledda; A. Covolo; A. Romagnolo; L. Lopiano; C. Artusi

Department of Neuroscience "Rita Levi Montalcini", University of Turin

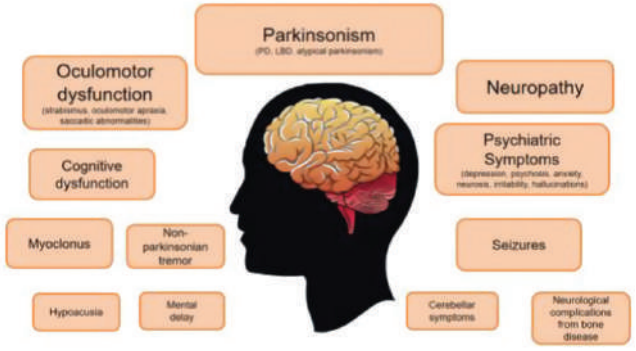
Background and Aims: Gaucher disease (GD) is traditionally classified into three types based on the presence or absence of neurological signs and symptoms, but their presentation can be highly variable in adulthood and they have not been adequately addressed in the literature so far. We performed a systematic literature review to analyze the entire spectrum of neurological manifestations in adult patients previously classified as GD type I, II or III, evaluating the role of variants in different neurological manifestations.

Methods: We searched databases for studies reporting clinical data of adult GD patients (age ≥18). Data extraction included GD types, GBA1 variants, age at disease onset and diagnosis, duration of GD and age at onset, and type of neurological symptoms reported.

Results: Among 4190 adult GD patients from 85 studies, 555 exhibited at least one neurological symptom. The median age at evaluation was 46.8 years (IQR 26.5), age at neurological symptoms onset was 44 years (IQR 35.1), and age at GD clinical onset was 23 years (IQR 23.4). Parkinsonism, including Parkinson's disease and Lewy Body dementia, was the most reported neurological manifestation. Other symptoms and signs encompassed oculomotor abnormalities, peripheral neuropathy, seizures, myoclonus, and cerebellar, cognitive and psychiatric symptoms. The genotype N370S/N370S mostly presented with Parkinsonism and the L444P variant with severe and earlier neurological symptoms.



The PRISMA flow diagram of the systematic review



Graphic summary of the principal neurological symptoms evaluated in adult patients with Gaucher Disease. The font size decreases based on the observed prevalence.

Conclusion: The findings of this systematic review highlight: (1) the relevance of a comprehensive neurological assessment in GD patients, and (2) the importance of considering possible undiagnosed GD in adult patients with mild systemic symptoms presenting unexplained neurological symptoms.

Disclosure: Nothing to disclose.

EPO-096 | **Description of a cohort of Primary Familial Calcification patients from a single centre in Italy: A systematic approach**

G. Bonato[1]; C. Bertolin[2]; F. Pistonesi[3]; R. Biundo[3]; P. Santurelli[1]; B. Savini[1]; L. Bresciani[1]; S. Andretta[1]; L. Salviati[2]; A. Antonini[1]; M. Carecchio[1]

[1]*Parkinson and Movement Disorders Unit, Centre for Rare Neurological Diseases (ERN-RND), Department of Neuroscience, University of Padova, Padova, Italy;* [2]*Clinical Genetics Unit, Department of Women's and Children's Health, University of Padova, Padova, Italy;* [3]*Department of General Psychology, University of Padova, Padova, Italy*

Background and Aims: PFBC is a rare neurodegenerative disorder characterized by calcium deposition in the brain. Clinical manifestations include movement disorders, cognitive or psychiatric features; 50% of cases recognize a genetic cause, with an autosomal dominant (SLC20A2, XPR1, PDGFB, PDGFRB) or recessive inheritance (MYORG, JAM2, CMPK2). Almost 500 cases have been described from different centres with different clinical workup. We systematically describe a cohort from a single centre in Italy (Padova).

Methods: Clinical-neuropsychological examination, NGS genetic panel, blood test, CT scan

Results: We examined 78 PFBC subjects, 33 males and 45 females; 46% had a positive family history; secondary causes of calcium deposition were excluded. 21% were asymptomatic; mean age at onset was 55 years (min 23, max 90). The most frequent symptoms were movement disorders (Fig. 1): parkinsonism (58%), followed by tremor (56%). Dystonia was documented in 27% (with 2 cases of paroxysmal dystonia); cerebellar signs (21%) and chorea (13%) were less frequent; pyramidal signs were also present in 45% of cases. Psychiatric features were associated in 51%, and cognitive deficits in 38% (22 MCI and 4 dementias, mainly affecting executive domains). Pathogenic mutations were found in 55% of subjects (Fig. 2), mostly in SLC20A2 (45%) and MYORG (21%). Dentate nuclei were frequently involved besides basal ganglia (Fig. 3). DAT-Scan was positive in 21/32 (65.6%) of patients with parkinsonism.

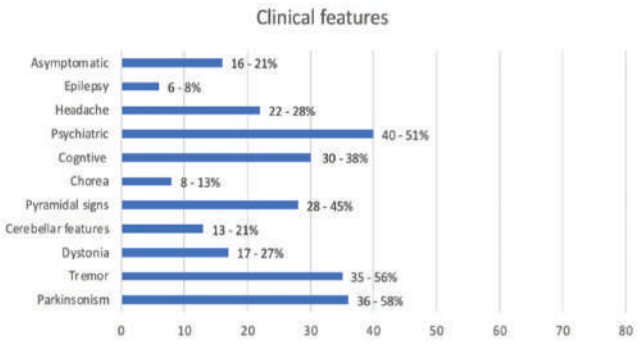


FIGURE 1 Clinical features of the cohort

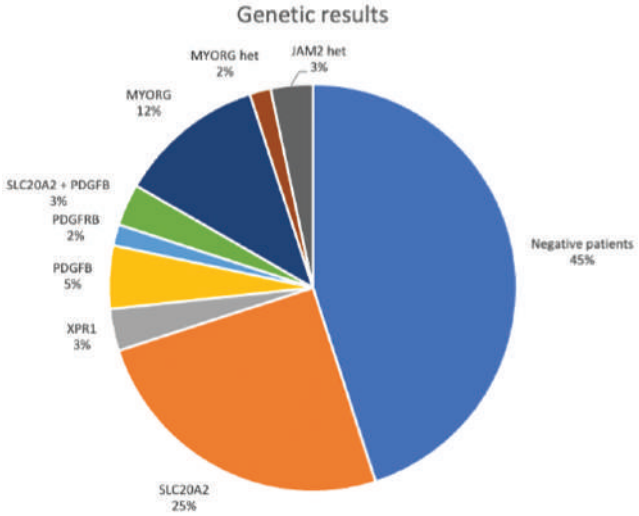

FIGURE 2 Genetic testing results in the cohort

CT brain site	%
Basal ganglia	100%
Dentate nuclei	65%
Thalami	45%
White matter	40%
Cortex	18%
Brainstem	8%

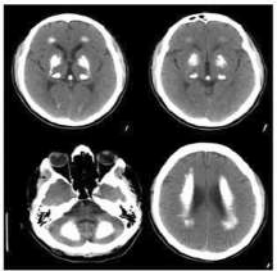

FIGURE 3 Radiologic features of the cohort and a CT example of a MYORG patient

Conclusion: Our work suggests a complete clinical, genetic and radiologic assessment to evaluate PFBC patients as a tool to obtain complete data to better understand this complex disease.

Disclosure: Nothing to disclose.

EPO-097 | Genetic study of SCA27B, CANVAS and other repeat expansion disorders in Greek patients with late-onset cerebellar ataxia

Macdonald Foundation Department of Human Genetics and John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, Florida, USA; [6]Parkinson's disease and Movement Disorders Department, HYGEIA Hospital, Athens, Greece, [7]1st Department of Neurology, National and Kapodistrian University of Athens, Eginitio Hospital, Athens, Greece

Background and Aims: Late-onset cerebellar ataxia (LOCA) encompasses heterogeneous neurodegenerative disorders with symptom onset after 30 years of age. A genetic diagnosis is established in fewer than 30% of LOCA patients. Intronic tandem repeat expansions (TREs) in RFC1 and FGF14 have recently emerged as common causes of LOCA. This study screened Greek LOCA patients for the commonest causative TREs.

Methods: Over a 28-year period, 206 consecutive LOCA patients were referred for genetic testing. Based on clinical data and inheritance pattern, patients were screened for FRDA, SCA1,2,3,6,7 and FXTAS, followed by testing for CANVAS and SCA27B. PCR, RP-PCR, agarose gel electrophoresis and fragment analysis were performed, as appropriate, to detect the pathogenic TREs.

Results: A genetic diagnosis was reached in 60 of 206 cases (29.1%). Mean age was 60.1 ± 11.2 (35–87) years and mean age at onset 52.5 ± 11.4 (30–80) years. SCA27B accounted for 9.7% of LOCA cases ($n = 20$), CANVAS for 6.8% ($n = 14$) and FRDA for 4.4% ($n = 9$). The overall frequency of SCA1 ($n = 5$), SCA2 ($n = 6$) and SCA7 ($n = 3$) was estimated at 6.8%. No cases of SCA3 and SCA6 were identified. FXTAS ($n = 3$) contributed another 1.5% of cases.

Conclusion: Our study provides comprehensive data on the genetic basis of LOCA in the Greek population. SCA27B, followed by CANVAS, represent the commonest known genetic causes of LOCA. FRDA is also a relatively common cause of LOCA. SCA1,2,7 and FXTAS are rare, whereas SCA3 and SCA6 are virtually absent. We recommend prioritizing testing for FGF14 and RFC1 expansions in the diagnostic algorithm of LOCA.

Disclosure: Nothing to disclose.

EPO-098 | Mutational screening of greek patients with Charcot-Marie-Tooth disease using whole exome sequencing

Background and Aims: Charcot-Marie-Tooth disease (CMT) is the most common cause of hereditary neuropathy, exhibiting extensive genetic heterogeneity, which can be addressed using whole exome sequencing (WES). This study screened previously undiagnosed Greek patients with CMT, using WES.

Methods: Over a 6-year period, 441 consecutive patients were referred for CMT molecular diagnosis. Following targeted testing for CMT1A and in selected cases for CMTX, 173 index-cases remained undiagnosed, of which 65 with a strong suspicion of hereditary neuropathy. To date, 32 of these, including 13 cases with demyelinating and 19 cases with axonal neuropathy, have been screened by WES using Ion Torrent technology and confirmed by Sanger sequencing.

Results: Causative variants were detected in 19 of 32 patients (59.4%) across 14 genes known to cause CMT, of which 3 were novel (in MPZ, SH3TC2 and KIF1A). In demyelinating forms the diagnostic yield was 76.9 % and in axonal forms 47.4%. Most causative variants were found in SH3TC2 (5 cases) and GJB1 (2 cases), all in demyelinating CMT. In patients with demyelinating CMT, single causative variants were found in EGR2, MPZ and NDGR1. In patients with axonal CMT, single causative variants were identified in HINT1, NEFH, BSCL2, NEFL, MORC2, GDAP1, KIF1A, SORD1 and MPV17.

Conclusion: The overall diagnostic yield of WES was comparable to other CMT populations. Our results contribute to the further mapping of gene variants associated with hereditary neuropathy and highlight the importance of WES in the diagnostic algorithm of disorders with high genetic heterogeneity, in the context of precision medicine.

EPO-099 | Phenotypical characterization of a cohort of SCA 27B patients

G. Falcone[1]; F. Santorelli[2]; O. Musumeci[1]

[1]Neurology and Neuromuscular Disorders Unit, Department of Clinical and Experimental Medicine, University of Messina, Italy; [2]Molecular Medicine for Neurodegenerative and Neuromuscular Diseases Unit, IRCCS Fondazione Stella Maris, Pisa, Italy

Background and Aims: FGF14 intronic heterozygous GAA expansions have recently been identified to be a frequent cause of late onset cerebellar ataxia (LOCA) (SCA27B). We evaluated the frequency and phenotype of SCA27B in a cohort of patients with unsolved hereditary cerebellar ataxia (HCA).

Methods: We recruited 25 patients affected with HCA with no age limit who had negative results on testing for repeat expansions and ataxia gene panels and screened them for the FGF14-GAA repeat expansion.

Results: 4 of the 25 patients (16%) carried an FGF14 (GAA) ≥250 expansion. Median age at onset was 51.75 years (range 16–79). Episodic symptoms at onset were present in two patients with episodes of vertigo, sweating, gait imbalance in one case and ataxia, dysarthria, rigidity, diplopia and dysphagia in the other. On examination abnormal smooth pursuit movements, downbeat nystagmus, dysarthria and gait ataxia were present in all patients; appendicular ataxia was mildly present only in one patient. Other signs were hyporeflexia at lower limbs (¾), tremor of chin and hands (2/4), postural instability (¼). Other symptoms reported were diplopia (¼), cramps (2/4), urgency (¼), dysphagia (3/4), depression (2/4), hearing loss (2/4), chronic cough (¼). Alterations in BAEPs (¼), VEPs (2/4) and SEPs (¾) were present. Brain MRI revealed cerebellar atrophy (4/4), frontoparietal atrophy (2/4), superior cerebellar peduncle hyperintensities (¼).

Conclusion: Our results show the highly heterogeneity of SCA27B and support FGF14-GAA repeat expansion screening in patients with LOCA and MSA look-alikes. However, we suggest screening younger cohorts as well.

EPO-100 | Parkinsonism in primary mitochondrial disorders: Clinical characteristics and follow up

I. Arena[1]; G. Falcone[1]; M. Porcino[1]; C. Terranova[1]; C. Rodolico[1]; O. Musumeci[1]

[1]Department of Clinical and Experimental Medicine, University of Messina Messina, Italy

Background and Aims: Primary mitochondrial disorders (PMDs) are a wide group of diseases characterized by a dysfunction of the mitochondrial respiratory chain, potentially involving the central and peripheral nervous system. Parkinsonism is described as a clinical feature of patients with PMDs. The objective of this study is to describe the clinical characteristics of parkinsonism in our cohort of patients affected by PMDs.

Methods: We revised the clinical records, including the extrapyramidal features, symptoms associated, the diagnostic investigations performed, genetic results, and response to therapy in all the patients presenting with parkinsonism in our PMDs cohort.

Results: 9/80 patients from our database presented characteristics of parkinsonism. Progressive external ophthalmoplegia (9/9), myopathy (9/9), ataxia (3/9), peripheral neuropathy (3/9), and optic atrophy (3/9) were the most frequent associated symptoms. Genetic analysis showed multiple mtDNA deletions with mutations in POLG1, TWNK and OPA1 nuclear genes. The most reported extrapyramidal symptom at onset was unilateral tremor. The age of onset was heterogeneous, ranging from 40 to 70 years old. Dopamine transporter imaging (DaTscan) showed a reduced or absent mostly asymmetrical striatal dopamine uptake. Overall, our cohort showed a good and sustained response to levodopa during follow up.

Conclusion: Our data confirm the role of mitochondrial nuclear genes in the pathogenesis of mitochondrial parkinsonism and the importance of screening these genes when suspecting a parkinsonism associated with "mitochondrial red flags". Extrapyramidal features in mitochondrial parkinsonism appear to be similar to those of idiopathic parkinsonism with an overall positive response to current therapies.

EPO-101 | Mortality in tuberous sclerosis complex after the introduction of everolimus in the UK

N. Loh[1]; C. Kidson[2]; Y. Syed[3]

[1]Paediatrics, KK Childrens Hospital, Singapore; [2]Medical School, University of Bristol, UK; [3]Neuroscience and Mental Health Research Institute, Hadyn Ellis Building, Cardiff, CF24 4HQ, UK

Background and Aims: Limited literature is available regarding causes of death of people with Tuberous Sclerosis Complex (TSC) since the introduction of everolimus therapy in 2016 in United Kingdom. The aim of this audit is to look for any change in the main causes of death of people with TSC

Methods: Patients who attended the Bath supra-regional TSC specialist clinic and died between 2016 and 2022 inclusive had their medical records reviewed to identify various disease-related factors and cause of death. Where cause of death was not available, information from the patient's general practitioner (GP) was used or their death certificate was sought from the General Registry Office. The cohort was then split into various subgroups to identify potential risk factors for earlier mortality.

Results: 369 patients attended this clinic from 2016 to 2022. Six deaths were definitely related to TSC, 5 possibly related and 8 unrelated. Primary causes of death included tumours in 7 (37%; one pancreatic neuroendocrine tumour), epilepsy in 3 (16%, including 1 probable SUDEP), aspiration pneumonia in 3 (11%), sepsis in 2 (11%), COVID in 1 (5%), hepatic AML in 1 (5%), SEGA in 1 (5%), and stroke in 1 (5%). Renal failure was a secondary cause in 2 (11%).
