Conclusion: Death at the Bath TSC clinic was associated with learning disabilities and possibly larger AML size. Mortality related to SUDEP causes has become less prominent, while cancers appear to be more prevalent in this cohort. Everolimus appears to positively impact renal and LAM risk.

Disclosure: Nothing to disclose.

EPO-102 | Whole exome sequencing-based testing of adult epilepsy in the Polish population

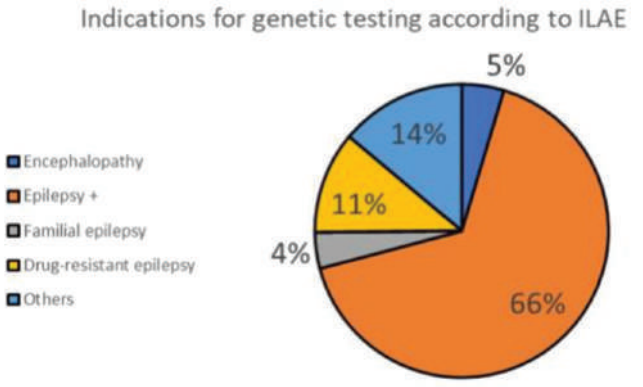
M. Mroczek[1]; D. Szczęśniak[2]; K. Ziora-Jakutowicz[2]; M. Kacprzak[2]; L. Kotuła[3]

[1]*Department of Neurology, University Hospital Basel, University of Basel, Basel, Switzerland;* [2]*Medgen Medical Centre, Warsaw, Poland,* [3]*Institute of Psychiatry and Neurology in Warsaw, Genetics Department, Warsaw, Poland*

Background and Aims: Genetic testing in pediatric populations demonstrated clinical utility and provided a diagnostic yield of 18–40%, depending on the cohort tested. However, the diagnostic yield and data on the potential classification of adult epilepsies are limited.

Methods: This study aims to investigate the diagnostic yield, analyze genetic diagnoses and apply International League Against Epilepsy (ILAE) classification for pediatric epilepsies to adult patients with epilepsies in Poland. We recruited 151 patients from 42 clinical centers across Poland. The patients had a diagnosis of epilepsy/seizures, were older than 18 years old at the time of the genetic testing and did not have a genetic diagnosis. The median age of the patient was 28 years.

Results: We reached a diagnostic yield, when considering pathogenic/likely pathogenic variants according to ClinVar of 8.6% ($n = 13$) and of 17% ($n = 26$) when applying American College of Medical Genetics (ACMG) criteria. According to the indications for genetic testing according to ILAE, most adult patients were tested for epilepsy + ($n = 100$, 66%), 21 patients were tested for drug-resistant epilepsy (14%), 17 for encephalopathy (5%), and 6 patients were tested for familial epilepsy (4%).



Indications for genetic testing according to ILAE

Nr	Indications according to ILAE	Additional features	Molecular results	Classification ClinVar/ACMG
1	epilepsy +	mental disability, no speech, obstructed breathing, generalized weakness	Rett syndrome	CV-P
2	epilepsy +	cerebellar atrophy	Rett syndrome	CV-P
3	familial epilepsy		Rett syndrome	CV-P

Summary of the molecular results and additional phenotypic features

Conclusion: There is a wide spectrum of diagnoses associated with epilepsy in adults. We applied the ILAE guidelines for childhood epilepsy to the adult population. Patients may have had a diagnosis related to childhood syndrome, but due to limited diagnostic possibilities it was not possible to diagnose them in childhood.

Disclosure: Nothing to disclose.

EPO-103 | Late-onset coats plus syndrome: Broadening the differential diagnosis of intracranial calcifications in adults

C. Serrão[1]; R. Rodrigues[1]; C. Guerreiro[2]; J. Oliveira[3]; J. Parente Freixo[3]; R. Barreto[1]

[1]*Department of Neurosciences and Mental Health, Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal;* [2]*Department of Neurological Imaging, Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal;* [3]*Center for Predictive and Preventive Genetics, Instituto de Biologia Molecular e Celular, i3S, Universidade do Porto, Porto, Portugal*

Background and Aims: Coats plus syndrome (CPS) is a multisystemic disorder, with intracranial calcifications, cysts and leukoencephalopathy as characteristic neurological features. CPS typically presents in infancy or childhood and is caused by bi-allelic defects in CTC1 gene, involved in telomere maintenance and DNA replication.

Methods: A 46-year-old woman presented a 2-year history of behavioral changes and cognitive decline. Her medical history was unremarkable until 33 years of age when diagnosed with infertility. At 38, she developed retinal vasculopathy and progressive restrictive lung disease under consideration for lung transplantation. Her family history was irrelevant. Clinical examination revealed greying of the hair, atrophic skin with violaceous and brownish macules and low body mass index. Neurological examination highlighted attention and executive function deficits, left homonymous hemianopsia, left central facial palsy and hyperreflexia.

Results: Head MRI revealed a frontal white matter lesion involving U fibers, with peripheral gadolinium enhancement and vasogenic oedema, as well as multifocal calcifications in the subcortical and deep white matter. MR angiography was normal. CSF analysis showed hyperproteinorrachia, mirrored oligoclonal bands and elevated neopterins, excluding infection or neoplasia. To further clarify the radiological findings, exome sequencing was ordered and identified a homozygous variant NM_025099.6:c.2954_2956del in CTC1 gene. The patient died 9 months after presentation due to pneumonia.

Conclusion: Adult-onset CPS is very rarely reported. We presented a case associated with a homozygous in-frame deletion (p.(Cys985del)), which presented in adulthood with a milder phenotype. Clinicians should consider CPS in the differential diagnosis of intracranial calcifications and leukoencephalopathy in adults.

Disclosure: Nothing to disclose.

EPO-104 | Optimized testing strategy for molecular diagnosis of GAA-FGF14 (SCA27B) ataxia: French SCA27B ataxia study group

C. Bonnet[1]; S. Puisieux[2]; V. Roth[1]; M. Wandzel[1]; D. Pellerin[3]; G. Clément[2]; B. Brais[4]; M. Renaud[5]

[1]Laboratory of Genetics, University Hospital of Nancy, France; [2]Department of Neurology, University Hospital of Nancy, France; [3]Department of Neuromuscular Diseases, UCL Queen Square Institute of Neurology and The National Hospital for Neurology and Neurosurgery, University College London, London, UK; [4]Department of Neurology and Neurosurgery, Montreal Neurological Hospital and Institute, McGill University, Montreal, Canada; [5]Department of Human Genetics, University Hospital of Nancy, France

Background and Aims: GAA expansions in FGF14 intron 1 are a common cause of autosomal dominant hereditary cerebellar ataxia (GAA-FGF14 ataxia; spinocerebellar ataxia 27B, SCA27B), particularly in Late Onset Cerebellar Ataxia (LOCA). SCA27B is classically characterized by a slowly progressive cerebellar syndrome with episodic onset in more than 2/3 of cases, over 40 years of age. Until now, molecular confirmation of FGF14 GAA expansions has mainly relied on long-read sequencing, a technology not yet routinely available in French genetics laboratories.

Methods: We developed and validated a three-step molecular diagnostic strategy: long-range fluorescent PCR (fLR-PCR) to determine allele sizes, bidirectional triplet-primed PCR (TP-PCR) to verify the presence and nature of the expansion and LR-PCR products gel electrophoresis and/or Sanger sequencing depending on the profile observed in TP-PCR. We compared this strategy to nanopore long-read sequencing on 22 Canadian SCA27B patients of French origin and then tested it on a national cohort of 560 patients with unresolved LOCA.

Results: We identified 107 patients (19.1%) carrying FGF14 expansions (GAA) ≥250 including 17/560 (3%) with expansions between 250 and 300 GAA (intermediate allele with incomplete penetrance). Further studies are needed to help in the interpretation of these intermediate alleles. We identified non-pathogenic non-GAA expansions and GAA-interruptions.

Conclusion: We confirm that SCA27B is a common cause of LOCA. Detailed phenotyping of patients appears essential particularly for the interpretation of intermediate alleles. This novel strategy reliably detected and sized FGF14 GAA expansions, and compared favorably to long-read sequencing.

Disclosure: None.

EPO-105 | Unveiling a stroke-like onset of Creutzfeldt-Jakob disease: A case report of V210I mutation

T. Giannelli; G. Ruta; D. Totaro; L. Parrulli; D. Paolicelli; G. Logroscino; A. Introna

Department of Translational Biomedicine and Neuroscience (DiBraiN), University of Bari "Aldo Moro", Bari, Italy

Background and Aims: Genetic prion diseases (PrD) account for 10–15% of prion diseases and are caused by mutations in the prion protein gene (PRNP).

Methods: A 75-year-old man suddenly developed nominum aphasia ten days before admission. His medical history included hypertensive heart disease and atrial fibrillation. His brain computed tomography (CT) and angiography-CT were unremarkable. At neurological evaluation the patient executed simple orders, however, comprehension and production of complex speech were compromised. A first brain magnetic resonance imaging (MRI) excluded ischemic lesions and inflammatory processes. Meanwhile, he progressively and rapidly developed ataxia, cerebellar signs, spontaneous myoclonus and mutism. Analysis of cerebrospinal fluid (CSF) revealed increased levels of total tau (>2000 pg/ml). His electroencephalogram showed pseudo-periodic triphasic waves over the left frontotemporal regions. PrD was suspected, therefore the patient underwent a new brain MRI. Diffusion-weighted imaging exhibited diffuse cortical ribbons in the left frontal, insular and parietal cerebral cortex. After discharge, the patient died shortly after due to ab ingestis pneumonia.

Results: CSF RT-QuIC for prion protein returned positive. Sanger sequencing of the PRNP gene showed the heterozygous V210I genotype (c.628 G>A – p.Val210Ile) and the homozygous Met/Met genotype at codon 129. These findings were suggestive of genetic Creutzfeldt-Jakob disease (CJD).

Conclusion: An acute onset of symptoms in CJD is rare (2% of all cases) and so far has been associated exclusively with the V203I mutation. The sudden appearance of focal symptoms without corresponding brain lesions requires a thorough investigation to rule out other rare causes including CJD, especially in rapidly progressive clinical scenarios.

Disclosure: Nothing to disclose.

Epilepsy 1

EPO-106 | Heart rate variability in patients with Epilepsy

S. Daoud[1]; S. Sellami[1]; R. Charfi[1]; A. Bahloul[2]; N. Bouattour[1]; N. Farhat[1]; S. Sakka[1]; K. Moalla[1]; L. Abid[2]; K. Masmoudi[3]; M. Damak[1]; C. Mhiri[1]

[1]Neurology Department and Research Laboratory LR12SP19, Habib Bourguiba University Hospital, Sfax, Tunisia; [2]Department of Cardiology, Hedi Chaker University Hospital, Sfax, Tunisia; [3]Department of Physiology and Functional Exploration, Habib Bourguiba University Hospital, Sfax, Tunisia

Background and Aims: Several studies have reported alterations of heart rate variability (HRV) and decreased cardiac rhythm abnormality in patients with epilepsy. The purpose of this study is to investigate epilepsy and its impact on HRV.

Methods: We obtained HRV data from an ambulatory 24-hour rhythm holter monitorization recordings in 73 patients with epilepsy. We calculated HRV parameters in both time and frequency domains including low frequency (LF) power, high frequency power (HF), LF/HF ratio, square root of the mean of the sum of the squares of differences between adjacent NN intervals (RMSSD), the standard deviation of all NN intervals (SDNN) and the standard deviation of the averages of NN intervals in all 5 min segments of the entire recording (SDANN). The HRV in epileptic patients was compared with 73 age- gender matched healthy controls.

Results: HRV analysis showed that epileptic patients presented lower values of HF than controls ($p=0.002$), also a lower values of LF (764.64 vs 801.3; $p=0.63$) with a significantly higher LF/HF ratio ($p<0.0001$). Time domain analyses also showed lower HRV and lower vagal activity in patients with epilepsy, as shown by lower SDNN (132.40 vs 136.24; $p=0.32$), lower SDANN (113.8 vs 123.11; $p=0.1$) and a significant lower RMSSD ($p=0.004$).

Conclusion: In conclusion, patients with epilepsy appear to have an altered autonomic control of the heart. The decrease in HRV parameters might be associated with the decrease in sympathetic tone. Further studies are warranted to explore these changes and their possible relevance for sudden death in epilepsy.

Disclosure: Nothing to disclose.

EPO-107 | Vagus Nerve Stimulation in paediatric drug-resistant epilepsy: Two decades experience in a Portuguese Tertiary Centre

A. Costa[1]; R. Lopes[1]; F. Sambayeta[1]; I. Laranjinha[1]; I. Carrilho[2]; S. Figueiroa[2]; T. Temudo[2]; C. Garrido[2]; M. Santos[2]; R. Chorão[3]; M. Tizziani[4]; R. Rangel[4]; J. Chaves[1]; R. Samões[1]

[1]Neurology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal; [2]Neuropediatrics Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal; [3]Neurophysiology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal; [4]Neurosurgery Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal

Background and Aims: Vagus Nerve Stimulation (VNS) is a therapeutic option in drug-resistant epilepsy. Real-world data on its application in children and long-term outcomes are crucial. We aimed to characterize an unicentric paediatric population undergoing VNS to evaluate its effectiveness/safety.

Methods: Clinical records of paediatric patients (<18 yo) implanted between 2000 and 2023 were reviewed. McHugh's classification (I-seizure frequency reduction 80–100%; II-50-79%; III-<50%; IV-magnet benefit only; V-no improvement) was applied at: a) first assessment after 1 year and stimulation >=1.5mA (T1) b) last assessment and stimulation >=1,5mA (T2).

Results: VNS was implanted in 56 paediatric patients; (51.8% were males. Median age and duration of epilepsy at implantation were 12 (IQR=6.8) and 9.2 (IQR=6.4) years. Ten patients had focal/multifocal, 20 generalized, and 26 combined focal/generalized epilepsies. Thirty were epileptic/developmental encephalopathies (16 with known mutations), 19 structural, 3 infectious, 2 immune, and 2 neurocutaneous syndromes. Median follow-up was 1.1 years (IQR=0.19) at T1 and 5.3 years (IQR=4.08) at T2. A reduction in seizure frequency was observed in 70.4% (T1) and 60% (T2) of patients, with 40.7% (T1) and 29.1% (T2) achieving ≥50% response. Among patients with falls, 48.5% had less events (T2). Cognitive-behavioural improvement was noticed in 50.9% of patients (T2). Mild complications occurred in 32.1%, most commonly dysphonia (61%) and cough (38.9%). VNS generator/battery was replaced in 15 patients, in 3 due to qualitative and/or cognitive-behavioural improvements. In 15 patients, lack of efficacy prevented its replacement.

Conclusion: Overall, VNS proved to be safe/effective, despite a less pronounced effect at T2. Notably, a significant qualitative and cognitive-behavioural benefit was observed.

Disclosure: Nothing to disclose.

EPO-108 | Time as a localizing sign: The challenge of identifying the origin of hyperkinetic seizures

İ. İlgezdi Kaya; G. Aliyeva; N. İşkan; A. Elmalı Yazıcı; N. Bebek
Department of Neurology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey

Background and Aims: Hyperkinetic seizures (HS), typically associated with the frontal lobe, are characterized by high amplitude, short duration, complex motor movements, although they may also originate from regions other than the frontal lobe. In our study, we aimed to differentiate HSs originating from the frontal and extra frontal lobes.

Methods: We retrospectively examined the data of 29 patients in whom HS was recorded with video-EEG. We reviewed the localization characteristics of HSs, onset time, duration of hyperkinetic movements, and ictal-postictal electrophysiological and semiological features. Two groups, early and late-onset HS, were created based on whether the onset of hyperkinetic semiology occurred in the first 10 seconds or later during the seizure.

Results: Seizure onset originated from the frontal region in 21 patients, and from the temporal and temporo-occipital region in 6 patients (Table 1). Clustering of hyperkinetic seizures (>3 seizures/day) was detected in 13 patients (44.8%), while >=1 seizure within 24 hours was observed in 22 patients. HS started in the early period in 21 patients and late period in 8. HSs originating from the frontal region started earlier than those originating from the temporal region (11.7 s, 23 s; $p=0.008$). Electrophysiological (12.0 s, 22.3 s; $p=0.013$) and clinical (11.9 s, 22. 7 s; $p=0.011$) seizure durations were shorter in frontal onset seizures (Table 2).

TABLE 1 Demographic and clinical data of the patients

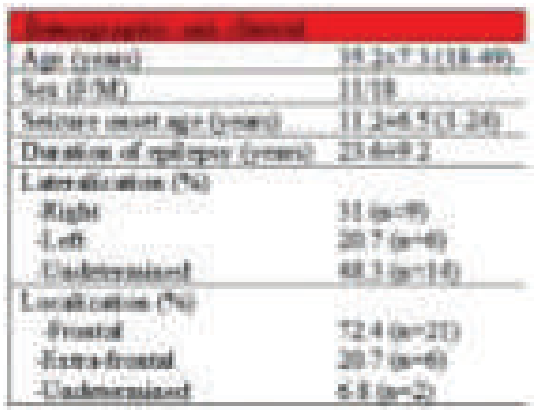

TABLE 2 Characteristics of seizures according to the region of onset

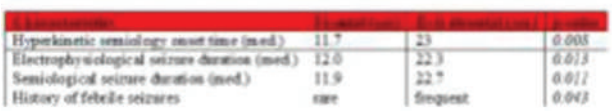


Conclusion: Our study indicates that the onset time and duration of hyperkinetic semiological findings are informative in terms of localization. Hyperkinetic semiology with earlier onset and shorter duration may suggest a frontal origin.

Disclosure: The authors declare no conflicts of interest. This study has been presented in the 39th National Clinical Neurophysiology EEG-EMG Congress, Turkey.

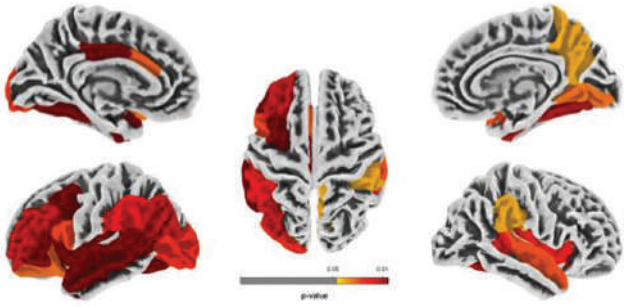
EPO-109 | The preliminary results of cortical thickness measurements in elderly patients with epilepsy and Alzheimer's dementia

B. Turk[1]; A. Oz[2]; B. Gulec[3]; D. Tezen[1]; M. Delil[1]; O. Kizilkilic[2]; M. Bozluolcay[1]; C. Ozkara[1]; S. Yeni[1]
[1]*Istanbul University-Cerrahpasa, Faculty of Medicine, Department of Neurology*; [2]*Istanbul University-Cerrahpasa, Faculty of Medicine, Department of Radiology*; [3]*Bilecik Training and Research Hospital, Neurology Department*

Background and Aims: Observational studies have suggested a bidirectional relationship between Alzheimer's dementia (AD) and epilepsy. However, whether a causal relationship exists and in which direction it operates is still a matter of debate. This study aims to assess the relationship between late-onset non-lesional epilepsy and AD by measuring cortical thickness in both patient groups.

Methods: Thirteen patients with epilepsy who experienced onset of seizures aged 50 and above, had a MOCA (Montreal Cognitive Assessment) score greater than 26, and exhibited normal findings in conventional neuroimaging, were included in the study. They were compared with 13 gender- and age-matched patients diagnosed with AD and 13 healthy controls. All subjects were scanned on 3T-MRI scanner. CAT12 software was employed to analyze T1-weighted images from each participant. Cortical thickness maps, smoothed with a 15 Gaussian kernel, were generated from the central surface classified according to anatomical cortical brain regions.

Results: No significant difference was detected in any brain region measured between the epilepsy and control groups. A significant decrease was detected in all brain regions in the dementia group compared to both groups (Figure).



Anatomical brain regions with cortical measurements between AD and Epilepsy

Conclusion: In the study conducted with the expectation of observing cortical changes in terms of the structural relationship between epilepsy and AD, the absence of any alterations may be attributed to the limited number of participants. It is aimed to continue the study by increasing the number of patients.
Disclosure: Nothing to disclose.

EPO-110 | Implementation of urgent eeg on-call in a tertiary hospital

A. Mas[1]; M. Olivera[1]; A. Muñoz-Lopetegui[2]; G. Maya[2]; P. Marrero[1]; A. Tercero[2]; M. Centeno[3]; C. Gaig[2]; E. Conde-Blanco[3]
[1]*Hospital Clínic de Barcelona;* [2]*Hospital Clínic de Barcelona, IDIBAPS;* [3]*Hospital Clínic de Barcelona. IDIBAPS, EPICARE*

Background and Aims: Urgent video-EEG (uvEEG) is crucial for early diagnosis and treatment of seizure and non-convulsive status epilepticus (NCSE) but is not always available. We aimed to evaluate its yield after implementation in our center.
Methods: We retrospectively identified patients who underwent an uvEEG at a tertiary hospital from September 2021 to January 2023. We categorized uvEEG findings and evaluated antiseizure medication (ASM) escalation.
Results: A total of 498 uvEEG were collected and 245 performed on-call (weekdays 5p-10p and weekends 9a-10p). Most studies were requested from the intensive care units (ICU) (47.2%) compared to neurology (21.4%) or the emergency room (ER) (17%), and other services (14.5%). UvEEG revealed non-convulsive seizures (NCS)/NCSE in 10.2% patients, epileptiform patterns (Lateralized and generalized periodic discharges, focal and generalized epileptiform activity) in 15.9%, attenuation/burst-suppression patterns in 8.98%, slowing/rhythmic patterns in 43.7%, normal activity in 18.8% and other patterns in 2.40%. We observed an association between hospital settings (ICU, ER or neurology) and uvEEG findings ($p=0.0003$). The proportion of normal uvEEG in the ER (44.6%) and neurology (39.4%) was similar but significantly different to the ICU (4.3%) and other departments (11.7%) ($p<0.000$). Most of the uvEEG were requested between 12 and 24h after clinical onset. Neurology, ICU and ER applications were significantly higher after-hours in contrast to other departments ($p<0.000$). Modifications of ASM were present in 84% ($n=95$) of patients.
Conclusion: uvEEG guides initiation and modifications of ASM in complex patients with neurological focal deficits at different hospital settings. uvEEG is mandatory in patients with NCS/NCSE for appropriate care.
Disclosure: No disclosures.

EPO-111 | Perampanel as only add-on treatment in post-stroke epilepsy: Real-world data from multicenter, observational study

A. Pascarella[1]; S. Gasparini[1]; O. Marsico[1]; L. Manzo[2]; D. Abelardo[1]; R. Cutellè[1]; A. Bulgari[1]; V. Cianci[2]; E. Ferlazzo[1]; U. Aguglia[1]; PEROC Study Group[3]
[1]*Department of Medical and Surgical Sciences, Magna Græcia University of Catanzaro, Italy;* [2]*Regional Epilepsy Centre, Great Metropolitan "Bianchi-Melacrino- Morelli Hospital", Reggio Calabria, Italy;* [3]*PEROC Study Group*

Background and Aims: Post-stroke epilepsy (PSE) is one of the most common causes of acquired epilepsy, with an estimated occurrence of 4–6% in the stroke population. Currently there is limited evidence regarding the clinical profile of antiseizure medications (ASMs) in PSE. This study aims to evaluate the 12-months effectiveness and tolerability of adjunctive perampanel (PER) as only add-on drug in patients with PSE in a real-world setting
Methods: We performed a subgroup analysis of PSE patients included in a previous 12-month retrospective, longitudinal, multicentre observational study investigating use of PER as only add-on treatment. Effectiveness outcomes included responders' rate (≥50% reduction of frequency), seizure-freedom and retention rate at 3, 6 and 12 months. Safety and tolerability outcomes included incidence of adverse events (AEs) and rate of treatment discontinuation due to AEs.
Results: The sample included 56 people with PSE (median age 49 years; IQR: 18.9–67.1). The mean daily dose of PER at 12 months was 5.3 ± 2 mg. We found a one-year retention rate of 66.7%. Responders' rate was 83.9% at the 12-month visit, with 51.6% of patients being seizure-free. Poor tolerability represented the main reason for drug withdrawal (11/13, 84.6%). AEs were registered in 25 out of 54 (46.3%) patients. Only 5 serious AEs (without deaths) were noticed. Behavioural problems resulted the most frequent AE, reported by 14 subjects.
Conclusion: Adjunctive PER was efficacious and generally well tolerated in patients with PSE in a real-world setting and could represent a suitable therapeutic option in this specific category.
Disclosure: All authors report no disclosure.

EPO-112 | Final analysis of perampanel as the only adjunctive anti-seizure medication from the observational PERPRISE study

B. Steinhoff[1]; T. Goldmann[2]; Y. Winter[3]
[1]*Kork Epilepsy Center, Kehl-Kork, Germany;* [2]*Eisai GmbH, Frankfurt am Main, Germany;* [3]*Mainz Comprehensive Epilepsy and Sleep Medicine Center, Department of Neurology, University Medical Center of the Johannes Gutenberg University, Mainz, Germany*

Background and Aims: In Germany, prior to perampanel reintroduction in 2017, only limited data of its use as late-line therapy were available. PERPRISE (PERampanel in patients with PRImary or

SEcondarily generalised seizures; NCT04202159) was a 12-month, prospective, observational, non-interventional study in a real-world setting in Germany evaluating the effectiveness and safety of perampanel as an only add-on anti-seizure medication (ASM) or a substitute for one ASM during dual therapy.

Methods: Patients (>=18 years) with focal or idiopathic generalised epilepsy who had >=1 focal to bilateral tonic-clonic seizure (FBTCS) or generalised tonic-clonic seizure (GTCS) <=3 months prior to inclusion were eligible. The Full Analysis Set included patients who received >=1 dose of perampanel. The primary endpoint was retention rate at 12 months; secondary endpoints were retention rate at 6 months, seizure-freedom rate at 12 months and safety.

Results: The Full Analysis Set included 183 patients (add-on: 86 patients; substitution: 96 patients). At 12 months, retention rates were 66.7% in the overall population and 67.4% and 66.7% in the add-on and substitution groups, respectively (Figure 1). Seizure-freedom rate in the overall population was 42.3% for FBTCS+GTCS at 12 months (Figure 2). Treatment-emergent adverse events (TEAEs) occurred in 44.0% (*n*=80/182 [Table 1]) of patients; 6.0% of patients reported serious TEAEs and 16.5% of patients withdrew from the study due to TEAEs.

Figure 1: Retention rates of perampanel in the overall population and add-on and substitution groups at 6 and 12 months (Full Analysis Set)

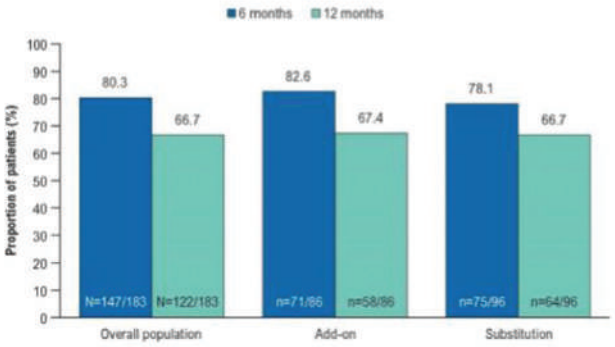


FIGURE 1

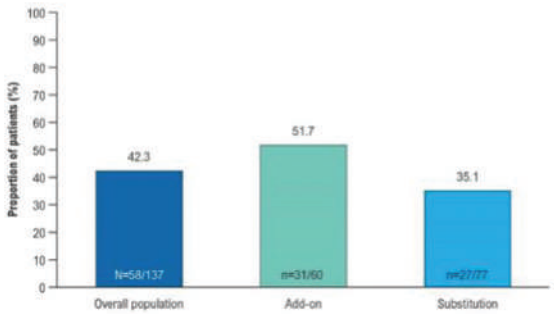
Figure 2: Seizure-freedom rates[a] of perampanel for patients with FBTCS and/or GTCS in the overall population and add-on and substitution groups at 12 months (Full Analysis Set)



[a]Percentages were calculated based on non-missing values. Seizure-freedom data were recorded for each month and patients who reported no generalised tonic-clonic seizures (FBTCS and GTCS) for all documented months were included in this analysis

FBTCS, focal to bilateral tonic-clonic seizure; GTCS, generalised tonic-clonic seizure

FIGURE 2

Table 1: Summary of TEAEs (Full Analysis Set)

	Overall population[a] (N=182)	Add-on (n=86)	Substitution (n=96)
Any TEAE, n (%)	80 (44.0)	43 (50.0)	37 (38.5)
Any serious TEAE, n (%)	11 (6.0)	4 (4.7)	7 (7.3)
Any severe TEAE, n (%)	7 (3.8)	3 (3.5)	4 (4.2)
Any TEAE with ADR, n (%)	59 (32.4)	29 (33.7)	30 (31.3)
Any TEAE leading to perampanel withdrawal, n (%)	30 (16.5)	14 (16.3)	16 (16.7)
Any serious TEAE leading to perampanel withdrawal, n (%)	4 (2.2)	1 (1.2)	3 (3.1)
Most common TEAEs (>=2% of patients overall), n (%)			
Dizziness	22 (12.1)	15 (17.4)	7 (7.3)
Fatigue	14 (7.7)	10 (11.6)	4 (4.2)
Nausea	10 (5.5)	7 (8.1)	3 (3.1)
Gait disturbance	8 (4.4)	4 (4.7)	4 (4.2)
Headache	8 (4.4)	6 (7.0)	2 (2.1)
Irritability	8 (4.4)	1 (1.2)	7 (7.3)
Aggression	5 (2.7)	3 (3.5)	2 (2.1)
Seizure	4 (2.2)	3 (3.5)	1 (1.0)

[a]Data were missing for one patient

ADR, adverse drug reaction; TEAE, treatment-emergent adverse event

Conclusion: This study showed that perampanel, as an only adjunctive therapy, had a favourable retention rate and was well tolerated in patients with FBTCS and/or GTCS during routine clinical care in Germany.

Disclosure: This study was funded by Eisai GmbH. EPO-113 | GATORopathies: An observational study of patients with familial focal epilepsy

C. Santos Martín; C. Amarante Cuadrado; J. Alcalá Torres; M. González Arbizu; R. Saiz Díaz; S. Bellido Cuéllar; J. González de la Aleja Tejera

Neurology, Hospital Universitario 12 de Octubre, Madrid, Spain

Background and Aims: In the last few decades, increasing interest in the genetics underlying familial focal epilepsy syndromes has emerged. Mutations in mTOR pathway regulatory genes, including the GATOR1 complex (DEPDC5, NPRL3, NPRL2), have been linked to malformations of cortical development and epilepsy.

Methods: A unicentric, retrospective observational study of adult patients with epilepsy and GATOR1 variants diagnosed between 2019 and 2023.

Results: We identified six patients (4 males) from three families. Two families had heterozygous pathogenic variants in DEPDC5 (2 patients with c.2760dupC and 2 with c.4098del) and the third family in NPRL3 (c.1374del). 4/6 patients had a known family history of epilepsy. The median age at onset of epilepsy was 10 years (3–22). One patient experienced focal impaired awareness seizures, 1/6 focal to bilateral tonic-clonic (FBTC), and 4/6 focal and FBTC seizures, mostly nocturnal in all cases. Brain MRI did not reveal any abnormalities. Interictal focal epileptiform abnormalities were detected by electroencephalogram in 2/6. Epilepsy was drug-resistant in three patients, 2/3 with three anti-seizure medications, whereas the other three were seizure-free with one drug. In family C, proband's relative III-13 presumably died of sudden unexpected death in epilepsy (SUDEP). None of them had cognitive impairments or psychiatric comorbidities.

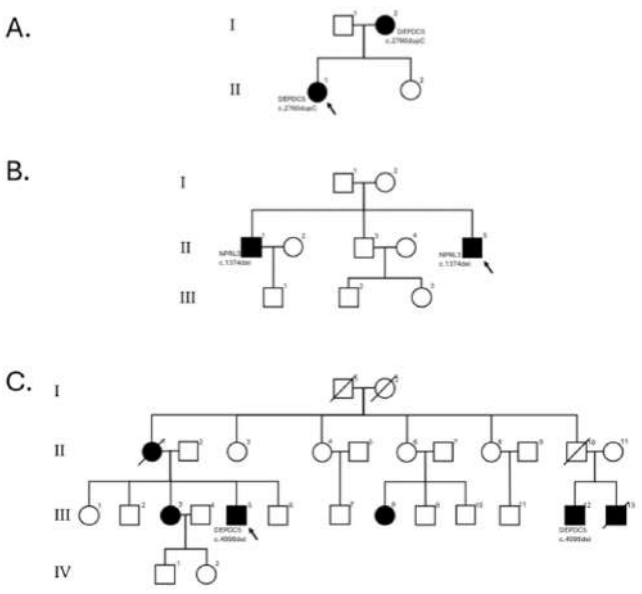

FIGURE 1 Pedigrees of the three families. Black squares/circles indicate male/female members with epilepsy in the family. Individuals with confirmed pathogenic variants in the GATOR complex are specify.

TABLE 1 Clinical and genetic characteristics of patients with GATOR1-related epilepsy included in the study. Abbreviations: F, female; M, male; N, normal

Table 1. Clinical and genetic features of the patients with GATOR1-related epilepsy

Patient	Variant	Age (onset)	Gender	Type of seizures	ASM (used)	Effective ASM	Drug resistant	EEG	MRI
Family A									
I-2	DEPDC5 c.2760dupC	9	F	Focal impaired awareness	VPA, CBZ, LTG	LTG	No	N	N
II-1	DEPDC5 c.2760dupC	11	F	Focal aware seizures Focal to bilateral tonic-clonic	LTG	LTG	No	Right parietal interictal epileptiform discharges	N
Family B									
II-1	NPRL3 c.1374del	22	M	Focal to bilateral tonic-clonic	CBZ	CBZ	No	N	N
II-5	NPRL3 c.1374del	13	M	Focal impaired awareness Focal to bilateral tonic-clonic	LEV, CBZ, ESL, CLB		Yes	Bifrontal (Right > Left) interictal epileptiform discharges	N
Family C									
III-5	DEPDC5 c.4098del	5	M	Focal impaired awareness Focal to bilateral tonic-clonic	LEV, CBZ, LCM		Yes	N	N
III-12	DEPDC5 c.4098del	3	M	Focal aware seizures Focal to bilateral tonic-clonic	LEV, CBZ, LCM		Yes	Generalized mild unspecific abnormalities	N

Conclusion: Pathogenic variants in the GATOR1 complex are associated with a broad spectrum of phenotypes, even in the same family, but typically cause familiar focal epilepsy with incomplete penetrance and nocturnal seizures. Drug-resistant epilepsy is frequent not only in our series but also in literature. Moreover, a higher risk of SUDEP has been reported.

Disclosure: Nothing to disclose.

EPO-114 | Abstract withdrawn

EPO-115 | The effect of epilepsy education on knowledge level, self-management, and stigma in individuals with epilepsy

İ. İlgezdi Kaya[1]; A. Çavuşoğlu[2]; A. Elmalı[1]; N. Bebek[1]
[1]*Department of Neurology, Clinical Neurophysiology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey;* [2]*Department of Neurology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey*

Background and Aims: This study aims to examine the impact of effective education for individuals with epilepsy on their knowledge level, self-management, and stigma.

Methods: A survey containing an 'Epilepsy Knowledge Form,' 'Epilepsy Self-Management Scale,' and 'Stigma Scale' was sent to all patients registered at our epilepsy outpatient clinic. Afterwards, patients were invited to an online live epilepsy lesson. Participants were re-tested after the training.

Results: Of the 265 patients who completed the pre-education survey, 69 (26%) attended the education. University graduates and individuals who use the internet as a source of information were more motivated to attend, while singles attended less. The average age of participants was 39.1 ± 9.2 (21–68) years; 42 (60.9%) were women, 65.2% were university graduates, and 60.9% were actively working. 44.9% had focal, 21.7% had generalized, and 33.3% had both focal and generalized seizures. 69.6% of the participants had seizure frequency of less than once a month. 50.7% were on monotherapy, and 94.2% regularly took their antiseizure medication. The most

common sources of information were doctors, the internet, other patients, television, and social media (100%, 65.2%, 27.5%, 20.3%, 17.4%, respectively). After the education, patients answered more knowledge questions correctly ($p=0.000$, before: 37.0 ± 6, after: 40.7 ± 6.1), awareness about the risks of swimming increased, and their motivation to carry health information cards, participate in support groups, and teach epilepsy to relatives increased. No change was observed in the stigma scale.

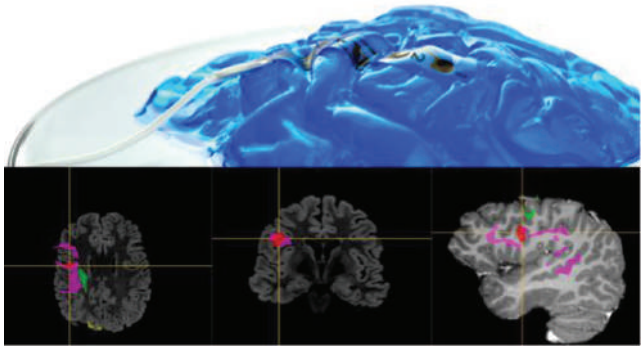
Conclusion: Education for individuals with epilepsy positively contributes to their awareness and self-management regarding their condition. Combating stigmatization requires broader societal involvement.

Disclosure: This study has been presented in 59th Turkish National Neurology Congress.

EPO-116 | Intraoperative recordings in bottom-of-the-sulcus focal cortical dysplasia with new highly flexible cortical strip

N. Biagioli[1]; S. Morandi[2]; E. Moriconi[3]; G. Giovannini[4]; V. Tramontano[2]; N. Orlandi[1]; M. Pugnaghi[4]; A. Vaudano[1]; S. Meletti[1]
[1]Department of Biomedical Metabolic Sciences and Neurosciences, University of Modena and Reggio Emilia; [2]SSD of Clinical Neurophysiology, AOU of Modena; [3]CS of Neurosurgery, Head and Neck Neuroscience Department, Modena AOU; [4]CS of Neurology, Head and Neck Neuroscience Department, Modena AOU

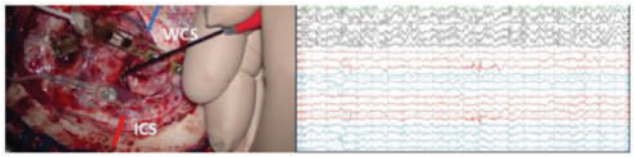
Background and Aims: the recording of epileptiform discharges from Bottom-Of-Sulcus focal cortical Dysplasia (BOSD) is often difficult during intraoperative electrocorticography (iECoG) due to the deep localization. We describe how the use of new generation electrodes with high flexibility easily adapting to cortical gyri and sulci can improve electrocortical recording.



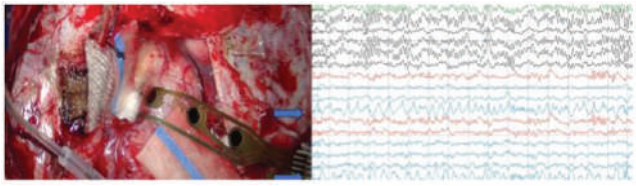
1) Example of the high flexibility of the strip 2) pre-surgical 3D reconstruction showing major tracts (BOSD in red)

Methods: a right-handed 20-years-old male with drug-resistant focal epilepsy due to a BOSD of the inferior frontal gyrus and daily focal aware seizures was evaluated for epilepsy surgery. Based on electroclinical and neuroimaging results a focal cortectomy guided by iECoG was proposed. iECoG recordings were performed with new generation cortical strips (Wise Cortical Strip; WCS®) and with standard cortical strips. Both bipolar and referential electrode montages were reviewed to identify epileptiform activity.

Results: iECoG, performed on the convexity of the frontal cortical surface recorded only sporadic spikes with both strip's types. Then, after a microsurgical trans-sulcal dissection, WCS was molded along the sulcal surface of the suspected BOSD based on 3D- imaging reconstruction, showing a continuous/subcontinuous 3–4 Hz rhythmic spikes activity from the deepest electrode. Registration after resection of the BOSD didn't show any epileptiform activity. Pathology showed dysmorphic neuron and gliosis. No surgical complications occurred. Patient is seizure free after 12 months.



Placement of the strip on the cortical convexity with related electocorticography (WCS in blue, ICS in red), No clear epileptic activities reordered



Placement of the strip at the bottom of the sulci, with electrocorticography showing continuous ictal activity from the deepest electrodes

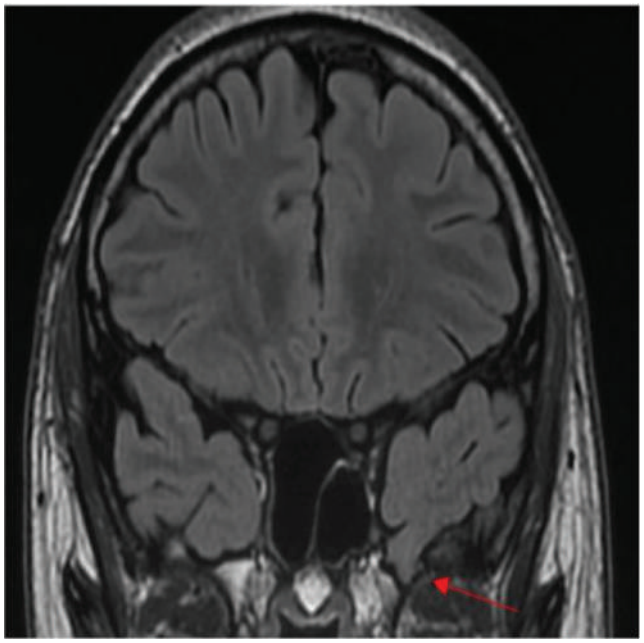
Conclusion: This case report showed that new generation cortical electrodes with high flexibility features allowed to perform high-quality recordings from the bottom of the sulcus, overcoming a limit of classical iECoG that typically doesn't allow registration from the deepest of the cortical sulci.

Disclosure: Nothing to disclose.

EPO-117 | Tailored surgery guided by intraoperative electrocorticography (iEcoG) in temporal lobe encephalocele (TE)

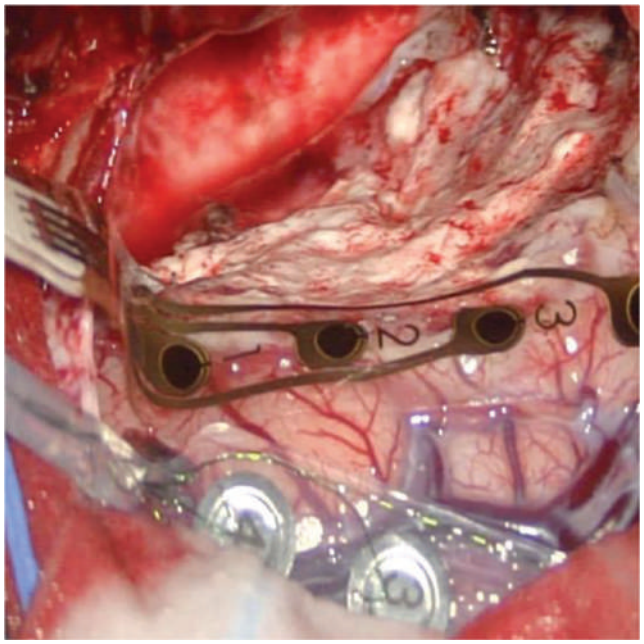
N. Blagioli[1]; S. Morandi[2]; E. Moriconi[3]; M. PPugnaghi[4]; N. Orlandi[1]; G. Giovannini[4]; V. Tramontano[2]; G. Pavesi[3]; A. Vaudano[1]; S. Meletti[1]
[1]Department of Biomedical Metabolic Sciences and Neurosciences, University of Modena and Reggio Emilia; [2]SSD of Clinical Neurophysiology, AOU of Modena; [3]CS of Neurosurgery, Head and Neck Neuroscience Department, Modena AOU; [4]CS of Neurology, Head and Neck Neuroscience Department, Modena AOU

Background and Aims: TE can lead to medically refractory epilepsy, warranting surgical intervention. However, there is a lack of consensus on the appropriate surgical approach. This case series illustrates the potential effectiveness of iEcoG in guiding personalized lobectomy procedures for TE.

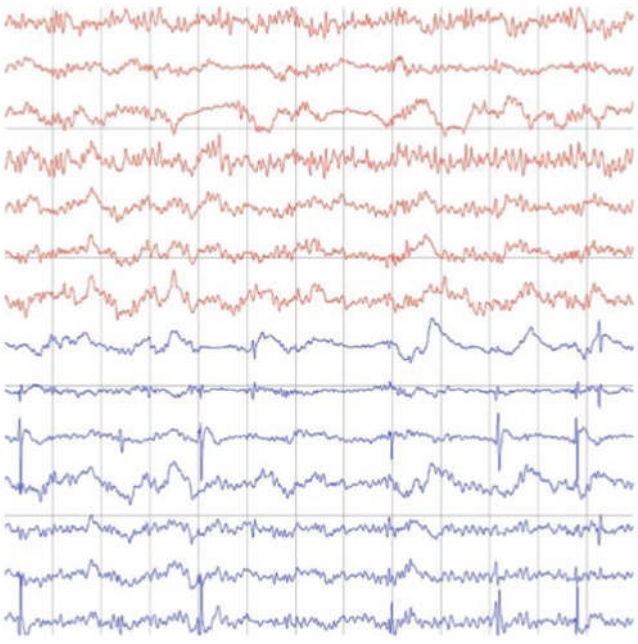


COR FLAIR brain MRI at the level of the temporal poles with finding of left temporal encephalocele (indicated by the red arrow)

Methods: patients underwent surgery following thorough anamnestic, neurophysiological, and neuroradiological assessments. iECoG were conducted on the cortical area pre- and post-resection, concluding with assessments on mesial temporal structures.
Results: Patient 1: 38-year-old male with left temporal pole encephalocele. iECoG show sporadic spikes on the neocortical temporal surface before surgical resection, while no epileptic activity was recorded on the amygdala and hippocampus. Therefore, the mesial structures were spared. Pathology: FCD-Ia. Patient 2: 20-year-old male with left mesial temporal pole encephalocele. iECoG revealed frequent irregular spiking on the neocortical temporal surface before surgical resection and persistent epileptic activity on the posterior temporal resection margin, so the surgical procedure was extended until the sylvian vein. No epileptic activity was seen on the hippocampus thus it was spared. Pathology: cortical dyslamination. Patient 3: 72-year-old female with extensive right temporopolar encephalocele. iECoG recorded sporadic epileptic activity in anterior section close to the borders of the encephalocele, sparing resection borders and temporomesial structures. Pathology: gliosis. All patients are in Engel class IA.



EcoG (patient 2) at the level of the encephalocele and neighboring cortex pre-resection



electrode strip placed on the posterior margin of the resection

Conclusion: These 3 cases show the usefulness of ECoG for a tailored surgical resection according to the irritative zone.
Disclosure: Nothing to disclose.

EPO-118 | Comparisons between traditional, brief, and ultra-brief anxiety and depression inventories in people with epilepsy

R. João; L. Scárdua-Silva; M. Alvim; F. Cendes; M. Nogueira; C. Yasuda
Neurology Department – University of Campinas (Unicamp), Campinas, Brazil

Background and Aims: While fast (and accurate) large scale detection of anxiety/depression symptoms is desirable for people with epilepsy (PWE), traditional inventories are time-consuming and less practical. Here, we compared traditional questionnaires (Beck Anxiety Inventory [BAI] and Beck Depression Inventory-II [BDI-II]) with brief inventories (Generalized Anxiety Disorders-7 [GAD-7] and Neurological Disorders Depression Inventory for Epilepsy [NDDIE]) and ultra-brief inventories (GAD-2, GAD Single-item [GAD-SI], and NDDIE-2) for symptom's detection.
Methods: We evaluated 548 consecutive PWE (60% women; median-age 41 years) with different questionnaires for anxiety/depression. We considered as symptomatic the individuals scoring ≥14 points in both BAI/BDI-II, ≥7 in GAD7, ≥3 in GAD-2, ≥2 in GAD-SI, ≥13 in NDDIE, and ≥ 4 in NDDIE-2. We used SPSS for the Receiver Operator Characteristic (ROC) curve analysis (with area under-curve values [AUC]) and cross-accuracy analysis (with Kappa-Index [KI] values).
Results: We compared the BAI's performance with GAD-7 (AUC=0.88; $p=0.017$), GAD-2 (AUC=0.84; $p=0.019$), and GAD-SI (AUC=0.80; $p=0.022$ – Figure 1A). We also compared the GAD-7's performance with GAD-2 (AUC=0.94; $p=0.01$) and GAD-SI (AUC=0.85; $p=0.019$ – Figure 1B). Moreover, we obtained similar values comparing BDI-II with both NDDIE (AUC=0.87; $p<0.001$) and NDDIE-2 (AUC=0.84; $p<0.001$ – Figure 1C) and comparing NDDIE with NDDIE-2 (AUC=0.93; $p<0.001$ – Figure 1D). There was an overall moderate-to-substantial agreement in the cross-accuracy analysis: KI=0.57 (BAI and GAD-7), KI=0.49 (BAI and GAD-2), KI=0.5 (BAI and GAD-SI), KI=0.62 (BDI-II and NDDIE), and KI=0.43 (BDI-II and NDDIE-2).

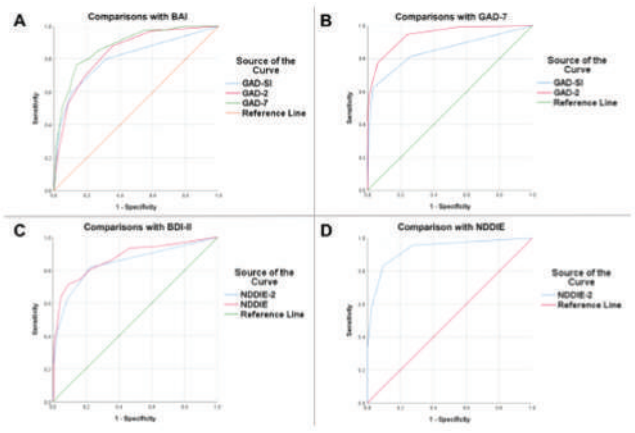


FIGURE 1 The ROC curve analysis showed high AUC in the comparisons between traditional, brief, and ultra-brief anxiety and depression inventories in people with epilepsy.

Conclusion: The shorter anxiety/depression inventories may be a fast and reliable alternative to traditional tests for PWE.
Disclosure: Nothing to disclose.

EPO-119 | A clinical case of targeted memantine treatment in a patient with GRIN2A mutation and epileptic encephalopathy

S. Shokhimardonov; N. Tuychibaeva; S. Kuzieva
Neurology Department, Tashkent Medical Academy, Tashkent, Uzbekistan

Background and Aims: Epileptic encephalopathy with continuous spike and wave during sleep (CSWS) is a syndrome marked by progressive cognitive decline, epileptic seizures, specific EEG patterns, and a complex/polygenic inheritance. Given the elevated incidence of drug resistance, the development of more effective and targeted treatment approaches for patients is relevant.
Methods: In our study, we intentionally selected 88 patients diagnosed with epileptic encephalopathy with continuous spike and wave during sleep. All participants were tested with: neuropsychological, clinical, neurophysiological, neuroimaging, and genetic assessments, including whole exome sequencing (WES). Among these individuals, we identified one with a GRIN2A mutation showing a gain of function variant (GoF), for further targeted treatment with memantine with daily dose 0.5 mg/kg per day."
Results: At a memantine dosage of 0.5 mg/kg, with no adjustments to antiepileptic drug doses, we observed a notable 65% reduction in average seizure frequency. This decline manifested within several weeks of reaching the full memantine dose and persisted throughout the 3-month follow-up period. We also observed an improvement in interictal EEG recordings, with no epileptiform discharges during both wakefulness and sleep, contrasting with the EEG prior to memantine initiation. While there were slight changes in cognitive skills, overall improvement was noted.
Conclusion: This clinical case exemplifies the significant potential of targeted treatment for epilepsy. Further clinical research and continuous follow-up are necessary to gather additional insights and information.
Disclosure: Nothing to disclose.

EPO-120 | Calponin-3 in astrocytes accelerate astrocytic activation and adenosine metabolism affects epileptogenesis

L. Chen; Y. Han
First Department of Neurology, First Affiliated Hospital, Kunming Medical University, Kunming, Yunnan, China

Background and Aims: Calponin-3—a member of the calponin family of actin-binding proteins, which is highly expressed in the mammalian brain—has been found increased in temporal lobe epilepsy (TLE)

patients and pilocarpine-induced epileptic rats. However, its role in the epileptogenesis is unclear.

Methods: Serum and brain tissues of epileptic patients and Kainic acid (KA) and pentattrazene (PTZ) induced epilepsy mouse model were used to detect the expression level and cellular localization of calponin-3. calponin-3 in the hippocampus of C57BL/6 mice was up-regulated, and calponin-3 in hippocampus of KA-induced epilepsy mice was down-regulated. The effect of calponin-3 expression change on the occurrence and development of epilepsy was observed in mice with specific knockout of calponin-3 in astrocytes.

Results: In epilepsy patients and KA-induced epilepsy models, calponin-3 was significantly up-regulated in serum and brain tissue. Meanwhile, the up-regulated calponin-3 expression was mainly in astrocytes. Behavioral and EEG findings showed that upregulation of calponin-3 increased the susceptibility to epilepsy, while down-regulation of calponin-3 in KA-induced mouse models had a protective effect on spontaneous seizures. Finally, it was found that the susceptibility to epilepsy was significantly reduced in transgenic GFAP-CNN3-KO mice. Mechanism, in vitro and in vivo confirmed that down-regulation of calponin-3 in astrocytes can suppress astrocyte activation and reduce adenosine metabolism.

Conclusion: Targeting calponin-3 in astrocytes, and reducing its expression will have a protective effect on epilepsy by regulating astrocyte activation and adenosine metabolism

Disclosure: Nothing to disclose.

EPO-121 | Plasma calcitonin gene-related peptide levels in idiopathic intracranial hypertension: An exploratory study

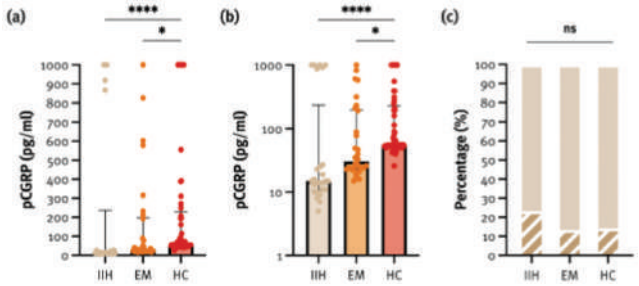
N. Krajnc; F. Frank[2]; S. Macher[1]; M. Michl[3]; N. Müller[1]; S. Maier[4]; S. Zaic[1]; C. Wöber[1]; B. Pemp[3]; G. Brössner[2]; G. Bsteh[1]

[1]Department of Neurology, Medical University of Vienna, Vienna, Austria; [2]Department of Neurology, Headache Outpatient Clinic, Medical University of Innsbruck, Innsbruck, Austria; [3]Department of Ophthalmology, Medical University of Vienna, Vienna, Austria; [4]Department of Medical Statistics, Informatics and Health Economics, Medical University of Innsbruck, Innsbruck, Austria

Background and Aims: Idiopathic intracranial hypertension (IIH) is a condition characterized by increased intracranial pressure often presenting with migraine-like headache. Calcitonin gene-related peptide (CGRP) plays an important pathophysiological role in primary headaches, whilst its role in IIH has not been established.

Methods: This longitudinal exploratory study included patients with definite IIH, episodic migraine (EM) in a headache-free interval and healthy controls (HC). Subjects were divided into those with: (1) log pCGRP Z scores ≤1.5 (termed as 'non-elevated'), and (2) log pCGRP Z scores >1.5 (termed as 'elevated').

Results: A total of 26 patients with IIH (mean age 33.2 years [SD 9.2], 88.5% female), 30 patients with EM (mean age 27.6 years [7.5], 66.7% female) and 57 HC (mean age 25.3 years [5.2], 56.1% female) were included. Median pCGRP levels in patients with IIH, EM and HC were 15 pg/ml (10.8–237), 30.5 pg/ml (23.2–197.4), and 56.3 pg/ml (53.4–228.2), respectively ($p < 0.001$). We found no differences between the prevalence of elevated pCGRP levels in patients with IIH, EM and HC (6 [23.1%], 4 [13.3%] and 8 [14.0%], respectively, $p = 0.523$). PwIIH with elevated pCGRP levels had more often a history of migraine (5/6 [83.3%] vs. 3/20 [15.0%], $p = 0.004$) and photo- and/or phonophobia as concomitant symptoms (6/6 [100.0%] vs. 7/20 [35.0%], $p = 0.015$). Elevated pCGRP levels were not associated with ophthalmological parameters.



pCGRP levels (pg/ml) in patients with IIH, EM in a headache-free interval, and HC; linear (a) and logarithmic (b) scale. Proportion of subjects with elevated pCGRP levels (log pCGRP Z score >1.5) in pwIIH, EM and HC (c).

Conclusion: PwIIH display similar prevalence of elevated pCGRP levels as pwEM. As elevated pCGRP levels are associated with headache presence and frequency, CGRP may play a role in the pathophysiology of headache in IIH.

Disclosure: Nothing to disclose.

EPO-122 | Brain resting state networks in episodic cluster headache: Cerebral connectivity analysis with HD-EEG

A. Antoniazzi[1]; R. De Icco[1]; G. Vaghi[1]; M. Corrado[1]; F. Cammarota[1]; F. Bighiani[1]; E. Mazzotta[1]; V. Grillo[1]; M. Semprini[2]; G. Sances[3]; M. Allena[3]; C. Tassorelli[1]

[1]Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; [2]Italian Institute of Technology, Genova, Italy; [3]Headache Science & Neurorehabiitation Center, IRCCS Mondino Foundation, Pavia, Italy

Background and Aims: A convincing explanation for the switch between the active and remission phases of episodic cluster headache (eCH) is lacking. In this study, we aim to shed some light on these mechanisms by analyzing internodal connectivity patterns in the brains of eCH patients by means of high-density electroencephalography (HD-EEG).

Methods: Twenty-four eCH patients underwent HD-EEG recordings in two conditions: active phase (T0) and remission period (T1).

Nineteen sex and age matched controls underwent a single HD-EEG evaluation. Through these data we reconstructed the inter-networks and intra-network connectivity of six resting state networks: default mode network (DMN), dorsal attention network (DAN), ventral attention network (VAN), language attention network (LAN), somatomotor network (SMN), visual network (VN).

Results: At T1 there was a significant difference in alpha band connectivity between eCH patients and HCs in the intra-network connectivity of the DMN (eCH = 0.089 ± 0.007; HC = 0.115 ± 0.009; mean difference 0.026 ± 0.012; $p = 0.034$) and of the VN (eCH = 0.085 ± 0.007; HC = 0.109 ± 0.008: mean difference 0.025 ± 0.011; $p = 0.034$). Moreover, eCH patients and HCs showed a significant difference at T1 in alpha band inter-network connectivity between the DMN and the VN (eCH = 0.089 ± 0.007; HC = 0.114 ± 0.008; mean difference 0.025 ± 0.012; $p = 0.038$).

Conclusion: Our findings show how eCH patients have a reduced alpha band connectivity during the remission period within and between the DMN and the VN networks. These alterations may be associated to the shift between the two states of the disease and support the relevance of electrophysiological studies in providing insights into cluster headache physiopathology.

Disclosure: None.

EPO-123 | Evaluation of premonitory symptoms among patients with cluster headache

A. Gonzalez-Martinez[1]; W. Diana[2]; N. Karsan[2]; H. Gosalia[2]; P. Goadsby[2]

[1]1NIHR King's Clinical Research Facility and Wolfson SPaRC, King's College London, UK 2Hospital Universitario de la Princesa & Instituto de Investigación Sanitaria Princesa (IIS-Princesa), Madrid, Spain, [2]1NIHR King's Clinical Research Facility and Wolfson SPaRC, King's College London, UK

Background and Aims: Cluster headache (CH) is a rare primary headache known for its unilateral very severe pain accompanied by cranial autonomic symptoms, which has a strong impact in patients' quality of life. Several studies have identified premonitory symptoms of migraine while few studies have evaluated the frequency and type of premonitory symptoms in patients with CH. This study aimed to assess the presence and type of premonitory symptoms in patients with CH.

Methods: A retrospective study was conducted to investigate the presence and type of premonitory symptoms in a cohort of patients with CH attended at a Headache Unit of a tertiary hospital specialized in CH treatment. Demographic data and premonitory symptoms in CH patients were evaluated as part of a service evaluation. The primary endpoint was the presence of premonitory symptoms in patients with CH. Secondary endpoints involved the description of the type of premonitory symptoms.

Results: A total of 164 patients, 121/165 (74%) males, 45.9 (SD: 13.8) years old, 66/164 (40%) chronic, from clinical CH cohort. Premonitory symptoms were present in 139/164 (85%) of CH patients. The most common general premonitory symptoms in CH patients were mood changes (44%), cognitive impairment (28%), neck stiffness (23%), fatigue (22%) and yawning (17%).

Conclusion: In summary, this study underscores the presence of recognisable spontaneous premonitory symptoms in CH that may have an impact in management of CH. Understanding the CH premonitory symptoms can aid in the development of more tailored treatment strategies for these patients.

EPO-124 | Neurophysiological and neuropsychological correlates of migraine with aura

A. Pjeci; M. Russo; S. Melchiorre; G. Polito; C. Ciprietti; L. Marzetti; S. Sensi

Department of Neuroscience, Imaging and Clinical Sciences, G. D'Annunzio University of Chieti-Pescara, Chieti, Italy

Background and Aims: Migraine with aura afflicts about 5% of the population and is frequently associated with psychological disturbances like depression and anxiety. Few studies in the literature have analyzed the functional connectivity of patients with this comparing it with that of healthy subjects. This study aims to fill this gap in the literature by comparing neurophysiological correlates of functional connectivity at resting state-EEG (rs-EEG) of subjects with migraine with aura and controls.

Methods: Migraine with aura subjects and controls were enrolled in a 1:1 ratio. The inclusion criteria were age between 18 and 50 and absence of other neurological, psychiatric, or system disorders in both groups of subjects. A 20-minute inter-ictal rsEEG was performed after subjecting them to a neuropsychological assessment including BAI and BDI II. Then EEG functional connectivity was evaluated by using coherence analysis.

Results: Comparisons in the beta frequency band showed hyperconnectivity in the right central-parietal regions in migraineurs. Furthermore, hyperconnectivity was found in the alpha band in the right occipital and parietal areas.

Conclusion: Migraineurs present a different resting state connectivity pattern in brain regions correlated with pain perception and elaboration (pain matrix), even in the inter-ictal phase. Our results

indicate that migraineurs share a neurophysiological "fingerprint" with other conditions associated with chronic or relapsing-remitting pain (e.g., fibromyalgia).

Disclosure: Nothing to disclose.

EPO-125 | Contemporary prospective understanding of migraine real-world evidence (CAPTURE): Baseline clinical characteristics

M. Ashina[1]; M. Peres[2]; R. Stark[3]; M. Lanteri-Minet[4]; E. Tucker[5]; Y. Liu[6]; J. Lam[5]; H. Ha[5]; L. Delahaye[7]; P. Pozo-Rosich[8]

Background and Aims: CAPTURE is a 2-year, international, prospective, longitudinal study that aims to enhance our understanding of disease burden and treatment patterns among people living with migraine, stratified by headache frequency.

Methods: Adults with >=1-year migraine diagnosis aged <50 years at onset who were taking >=1 medication indicated for migraine and had >=4 monthly headache days (MHDs) in the 3 months before screening were assigned to cohorts based on MHD frequency (cohort 1: 4-<8; cohort 2: 8-<15; cohort 3: >=15; Figure). Descriptive data for baseline demographics and clinical characteristics (migraine duration, MHDs, monthly migraine days [MMDs], monthly acute medication use days, migraine-related comorbidities) are presented. Changes from baseline in MHDs, MMDs, acute medication use days, and patient-reported outcomes across the study period and durations of current and subsequent migraine treatment use will be assessed.

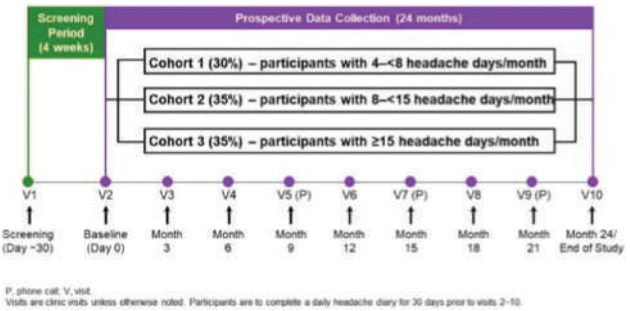

FIGURE CAPTURE Study Design

Results: As of December 2023, among the 239 participants (cohort 1: *n*=68; cohort 2: *n*=104; cohort 3: *n*=67), mean age was 40.8–42.6 years, >95% of participants were White, >78% were female, and >77% resided in Europe (Table 1). Mean duration of migraine since onset was similar among cohorts (23.0–23.8 years) (Table 2). Past use of preventive treatments was high (cohort 1, 81.8%; cohort 2, 81.4%; cohort 3, 92.3%). The most prevalent migraine-related comorbidity was hypertension (cohort 1: 4.4%; cohort 2: 7.7%; cohort 3: 9.0%).

TABLE 1 Baseline Demographic Characteristics

Characteristic	Cohort 1: 4 to <8 MHDs (n=68)	Cohort 2: 8 to <15 MHDs (n=104)	Cohort 3: ≥15 MHDs (n=67)
Age, mean (SD), y	42.3 (12.5)	42.6 (12.7)	40.8 (12.4)
Sex, n (%)[a]

EPO-126 | Female sexual dysfunction and distress in migraine: Results from a tertiary referral hospital

M. Bertão[1]; B. Martins[2]; A. Costa[2]
[1]*Faculty of Medicine, University of Porto, Portugal;* [2]*Neurology Department, Centro Hospitalar Universitário de São João, E.P.E., Porto, Portugal*

Background and Aims: Female sexual dysfunction (FSD) is a persistent, underdiagnosed, and undertreated problem, associated with psychological suffering. Only a few studies have addressed the sexual distress caused by migraine. We aimed to determine if migraine is associated with sexual dysfunction/distress and what their risk factors.
Methods: Retrospective, cross-sectional study, including 71 premenopausal female patients with migraine, followed in a tertiary hospital (05/2023–12/2023), and 34 healthy age-matched-controls. Female sexual function index-6 (FSFI-6), FS distress scale-revised (FSDS-R), Hospital depression and anxiety (HADS), Migraine disability assessment (MIDAS), and Satisfaction Alertness Timing Efficiency Duration of sleep (SATED) scales were applied.
Results: Of the 71 female patients [median age: 40.0 (AQR = 11.00) years; married/stable relationship: 78.9%], only 9 (12.7%) were not under migraine preventive treatment; most (33, 62.3%) reported severe disability (MIDAS-IV). Migraine patients showed lower FSFI-6 scores [19.0 (9.0) vs controls with 24.0 (6.0), $p = 0.003$), with significantly lower levels of desire ($p = 0.011$), lubrification ($p = 0.002$), and satisfaction ($p = 0.013$), and higher sexual distress [11.2 (25.6) vs 3.2 (9.6), $p = 0.001$). They had also higher anxiety [10.0 (6.0) vs 5.0 (6.0), $p \leq 0.001$] and depression [7.0 (7.0) vs. 2.0 (3.0), $p \leq 0.001$] levels, and lower sleep health scores [18.0 (12.0) vs 23.5 (9.0), $p = 0.005$] compared to healthy controls. Anxiety, depression, and dysfunctional sleep were found to be significantly related to sexual dysfunction.
Conclusion: This work showed that migraine is associated with sexual dysfunction and distress, reflecting the necessity of an evaluation of sexual health in these patients, mainly in the ones with higher levels of anxiety, depression, or poor quality of sleep.
Disclosure: Nothing to disclose.

EPO-127 | Role of venous sinus stenosis in intracranial hypertension: Pathophysiology and response to medical treatment

C. Gavancho[1]; R. Lindeza[2]; M. Pimenta[1]; M. Cazola[1]; J. Rosa[1]
[1]*Neurology Department, Hospital de São José, Unidade Local de Saúde São Jose, Lisbon, Portugal;* [2]*Neuroradiology Department, Hospital de São José, Unidade Local de Saúde São José, Lisbon, Portugal*

Background and Aims: Venous sinus stenosis (VSS) is described in intracranial hypertension (IH), but its role in its pathophysiology is not entirely established. We aimed to characterize VSS in intracranial hypertension and its possible influence in cerebrospinal fluid (CSF) opening pressure and clinical response to medical therapy.
Methods: We analyzed 21 patients admitted to the Neurology Ward of Hospital de São José in Lisbon, Portugal, between 2016 and 2023 with intracranial hypertension (19 with idiopathic IH). Using SPSS, we carried out a descriptive analysis of the variables and applied the Chi-squared, Shapiro-Wilk, Mann-Whitney, and Student's t tests.
Results: We identified VSS in 19% of the patients ($n = 4$), half in the transverse sinus and half in the transverse-sigmoid transition. The median CSF opening pressure was 32.67(9.5)cm H_2O and it was lower in the VSS group, suggesting a negative impact of the stenosis on this measure ($p = 0.017$). We found a correlation between the presence of VSS and poor clinical response to medical therapy ($p = 0.018$). There were no statistically significant differences in the CSF opening pressure or response to medical therapy between the group with transverse sinus stenosis and the group with transverse-sigmoid transition stenosis.
Conclusion: The presence of VSS seems to correlate with a less favorable clinical response to medical therapy in IH. We couldn't establish a correlation between VSS and the pathophysiology of IH. The role of VSS should be further explored to clarify its pathophysiology and the therapeutic potential of venous sinus stenting.
Disclosure: Nothing to disclose.

EPO-128 | Contemporary prospective understanding of migraine real-world evidence (CAPTURE): Baseline migraine treatment patterns

C. Tassorelli[1]; M. Matharu[2]; J. Ailani[3]; M. Lanteri-Minet[4]; E. Tucker[5]; J. Lam[5]; Y. Liu[6]; H. Ha[5]; L. Delahaye[7]; P. Pozo-Rosich[8]
[1]*University of Pavia and C. Mondino Foundation, Pavia, Italy;* [2]*Queen Square Institute of Neurology, London, England, UK;* [3]*MedStar, Georgetown University Hospital, Washington, DC, USA;* [4]*Pain Department and FHU InovPain, CHU Nice and Côte Azur University, Nice, France and INSERM U1107 Migraine and Trigeminal Pain, Auvergne University, Clermont-Ferrand, France;* [5]*AbbVie, Toronto, ON, Canada;* [6]*AbbVie, North Chicago, IL, USA;* [7]*AbbVie, Rungis, France;* [8]*Headache Unit, Neurology Department, Vall d'Hebron University Hospital and Headache and Neurological Pain Research Group, Vall d'Hebron Institute of Research, Universitat Autònoma de Barcelona, Barcelona, Spain*

Background and Aims: CAPTURE is a 2-year, international, prospective, longitudinal study that aims to elevate understanding of burden of illness, disease course, and treatment patterns among people living with migraine, stratified by headache frequency.
Methods: Adults with migraine diagnosed for >=1 year, aged <50 years at onset, and taking >=1 medication indicated for migraine with >=4 monthly headache days (MHDs) in the 3 months before screening were assigned to cohorts based on MHD frequency (cohort 1: 4-<8; cohort 2: 8-<15; cohort 3: >=15; Figure). Descriptive data for baseline characteristics, including current/prior migraine medications, are presented. Endpoints include change from baseline in MHDs, monthly migraine days, monthly acute medication

use days, and patient-reported outcomes across the study period. Durations of current and subsequent migraine treatment use and migraine-related healthcare resource utilisation will also be assessed.

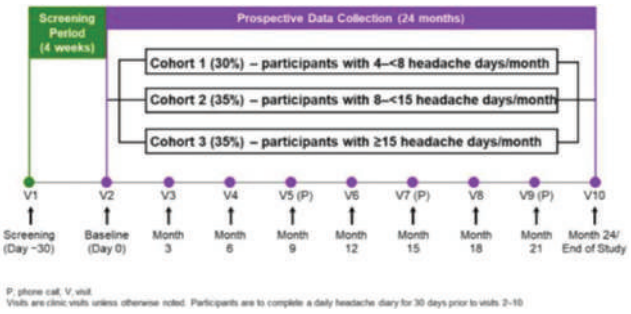

FIGURE CAPTURE Study Design

Results: This analysis set (December 2023) included 239 participants (cohort 1: $n = 68$; cohort 2: $n = 104$; cohort 3: $n = 67$; mean age 40.8–42.6 years); more than 78% were female (Table 1). In cohorts 1, 2, and 3, current use of acute migraine medication only was reported for 5.9%, 2.9%, and 0% of participants; preventive medication only for 19.1%, 27.9%, and 32.8%; and both acute and preventive medication for 27.9%, 20.2%, and 26.9%, respectively (Table 2). Most common current acute medications were triptans and propionic acid derivatives; most common current preventive medications were topiramate, amitriptyline and calcitonin gene–related peptide receptor monoclonal antibodies.

TABLE 1 Baseline Demographic Characteristics

Characteristic	Cohort 1: 4 to <8 MHDs (n=68)	Cohort 2: 8 to <15 MHDs (n=104)	Cohort 3: ≥15 MHDs (n=67)

EPO-129 | **Prophylactic polytherapy for chronic migraine: Evaluating the addition of atogepant to onabotulinumtoxinA**

J. Rothrock; A. Koutsandreas; L. Armstead
Inova Health/University of Virginia, Fairfax, VA, USA

Background and Aims: OnabotulinumA (BotoxA) may reduce migraine burden only partially in patients with chronic migraine (CM). We sought to determine whether adding atogepant 60 mg daily to ongoing treatment with BotoxA might be synergistic.

Methods: We prescribed atogepant 60 mg daily to a clinic population of CM patients who had been receiving BotoxA for at least one year and whose response had remained stable for the last 2

consecutive 12-week intervals between treatments. We assessed mean monthly migraine days (MMMDs), mean monthly headache days (MMHDs), mean monthly days of functionally incapacitating headache (FIHDs), mean monthly days of symptomatic medication use (MMDSMU), migraine burden index (MBI) and MIDAS scores for the 3 months preceding initiation of treatment with atogepant and again 12 weeks following initiation of treatment with atogepant. A patient was considered to be a positive responder to polytherapy if he/she reported a 50% or greater reduction in MMMDs relative to their pre-atogepant status (primary endpoint).

Results: Of 211 patients, 132 (63%) achieved the primary treatment endpoint of a 50% or greater reduction in MMMDs experienced over the 12 week treatment period relative to their pre-atogepant status. MMHDs declined by 6.6 days, mean FIHDs by 2.7 days, MMDSMU by 5.4 days, MIDAS by 21.6 and MBI score by 14.6.

Conclusion: Adding atogepant 60 mg to the prophylactic regimen of CM patients receiving BotoxA resulted in apparent synergism in almost two-thirds.

Disclosure: Dr. Rothrock has served as an consultant to/promotional speaker for AbbVie. His parent institution has received funding from AbbVie for research he has conducted.

EPO-130 | Management of migraine without aura in adolescents: The efficacy of flunarizine in a Turkish Cohort

F. İlik[1]; D. Ertem[2]; M. İlik[3]
[1]*Department of Neurology, KTO University, Medical Faculty, Konya, Turkey*; [2]*Department of Neurology, Silivri Anadolu Hospital, Istanbul, Turkey*; [3]*Department of Neurosurgery, Ozel Buyuksehir Hospital, Konya, Turkey*

Background and Aims: Flunarizine is a specific calcium antagonist and is frequently used in adults for the prophylactic treatment of migraine. The use of flunarizine may lead to somnolence and weight gain, depression, and rarely extrapyramidal symptoms in adults. However, studies detecting the efficacy and safety of flunarizine use in adolescents are limited. In the current study, the effectiveness of flunarizine for the management of chronic migraine without aura in Turkish adolescents was evaluated.

Methods: Forty-six patients with migraine without aura, aged 12–18 years, receiving flunarizine 5mg per day were included. In this retrospective study, the medical records of the cases were examined. Changes in the Numeric Pain Rating Scale (NPRS) and MIDAS scores were compared to assess the efficacy of the treatment in 3 months.

Results: The mean age was 14.37 ± 1.83 years. There was a significant improvement in the NPRS and MIDAS scores of the patients at the end of 3 months ($p < 0.05$). Side effects were detected in 23.9% of the patients, and these symptoms were sedation in 8.7% of the patients, mood swings in 4.3%, and vomiting %4.3 of them. None of the patients discontinued the treatment due to side effects.

Conclusion: Although the advancement of migraine research and treatment is inevitable, our findings support that flunarizine should still be considered in mind as an effective and tolerable treatment option in adolescent migraineurs

Disclosure: Nothing to disclose.

EPO-131 | Acute medication overuse in people with migraine from the 2022 European National Health & Wellness Survey

G. Coppola[1]; A. Gendolla[2]; M. Lewis[3]; A. Jenkins[4]; J. Cirillo[5]; K. Hygge Blakeman[6]; J. Yang[7]; L. Abraham[4]; J. Brown[3]
[1]*Department of Medico-Surgical Sciences and Biotechnologies, Sapienza University of Rome Polo Pontino, Latina, Italy*; [2]*Praxis Gendolla, Essen, Germany*; [3]*Real World Evidence, Pfizer, New York, NY, USA*; [4]*HTA, Value & Evidence, Pfizer, Tadworth, UK*; [5]*HTA, Value & Evidence, Pfizer, New York, NY, USA*; [6]*Global Medical Affairs, Pfizer, Stockholm, Sweden*; [7]*Global Medical Affairs, Pfizer, New York, NY, USA*

Background and Aims: Acute medication overuse (AMO) is a cycle of high-frequency analgesic use, such as triptans and non-steroidal anti-inflammatory drugs (NSAIDs) that may result in medication overuse headache (MOH). There is limited understanding of the frequency of analgesic use of both prescription and over-the-counter analgesics among people with migraine (PwM) in Europe.

Methods: Using the 2022 5-country European National Health and Wellness Survey (NHWS, Cerner Enviza), patients diagnosed with migraine receiving $>=1$ acute medication were described. AMO criteria were: 1) $>=10$ cumulative days per month with use of triptans, combination analgesics, ergotamines, or opioids; or 2) $>=15$ days of nonopioid analgesic, acetaminophen, or NSAID use. AMO was assessed separately among analgesics for migraine only and those used for migraine plus other pain conditions.

Results: Among over 16.7 million PwM represented by the survey, 21.2% reported AMO of migraine-specific medications, and 36.9% had AMO after including medications used for other conditions. Over half (51.4%) met the first AMO criterion with a cumulative mean [SD] of 21.0 [14.1] days, and 61.5% met the second criterion with 28.3 [15.9] cumulative days. PwM with AMO versus without AMO reported higher use of prescribed triptans (38.4% vs. 29.9%), NSAIDs (66.4% vs. 51.4%), and opioids (33.6% vs. 12.5%). Compared to individuals without AMO, those with AMO experienced worse quality of life, higher migraine disability scores, decreased productivity, and increased use of healthcare resources.

Characteristics	AMO 3,554 (21.2%)		w/o AMO 13,220 (78.8%)	
	N	%	N	%
AMO criterion 1: ≥ 10 days/month for ergot derivatives, triptans, opioids, combination analgesics	1828	51.4%	-	-
Total days of MO criterion 1 analgesic use (mean)	21.0	14.1	-	-
AMO criterion 2: ≥ 15 days/month for nonopioid analgesics, acetaminophen, and NSAIDs	2185	61.5%	-	-
Total days of MO criterion 2 analgesic use (mean)	28.3	15.9	-	-
Use of Rx acute agents	3114	98.9%	7400	81.0%

EPO-132 | Combining monoclonal antibodies and onabotulinumtoxina against highly resistant and invalidated migraine patients

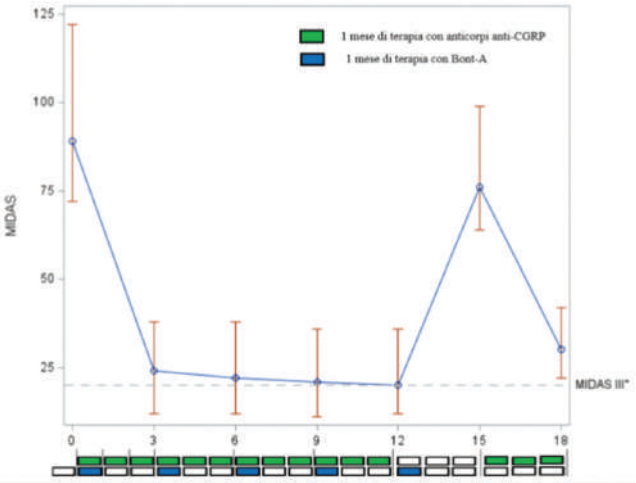
A. Doretti[1]; E. Colombo[1]; G. Demirtzidis[1]; S. Calzaferri[1]; M. Sodano[1]; U. Daniela[1]; L. Maderna[1]; V. Silani[1]; N. Ticozzi[2]; S. Messina[1]

[1]*Department of Neurology, Istituto Auxologico Italiano IRCCS, Milan;* [2]*Department of Pathophysiology and Transplantation, University of Milan, Milan*

Background and Aims: Onabotulinumtoxin A (BonTA) and monoclonal antibodies (mAbs) are approved migraine treatment targeting CGRP cascade. However, monotherapy does not always yield satisfactory benefits, which raises the question of whether dual therapy with BonTA and mAbs hold promise in patients with treatment-resistant chronic migraine (CM).

Methods: We retrospectively analyzed 75 subjects diagnosed with highly disabling (MIDAS >30) and resistant CM treated with BonTA that were considered responders, but had a decrease in effect or the effect was non-sufficient after one year. Therefore, they started a dual therapy with BonTA and mAbs for 1 year. CGRP-mAbs were stopped for 3 months continuing only BonTA, subsequently a monotherapy with CGRP-mAbs was performed for 3 months. We evaluated the MIDAS, HIT6, VAS, PGIC and drug intake for all patients in the different timepoints.

Results: 73/75 patients completed the treatment regimen, 2 dropped out for ineffectiveness. No adverse events were reported. Analysis showed a marked decrease in the MIDAS, HIT6, VAS, PGIC scores and analgesic drug intake from visit T0 to visit T3, while on dual therapy; subsequently the scores remained stable up to T12. When patients were on BonTA alone or mAbs alone, there was a worsening of evaluated scores.



MIDAS reduction during different times of therapies. In green antiCGRP mAbs, in blue BonTA injections

Conclusion: Our work suggests a possible synergistic effect of these two different therapies in modulating CGRP cascade, determining a greater control of migraine attacks in a population of patients suffering from highly resistant CM. This result without any increase of side effects.

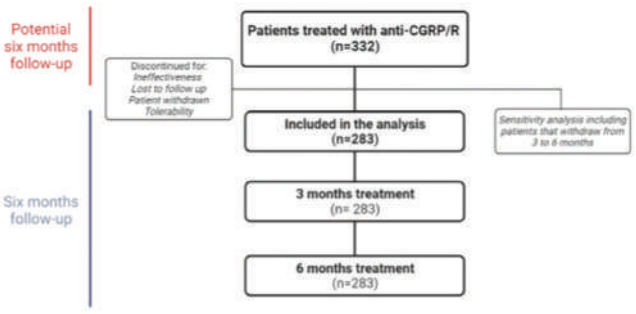
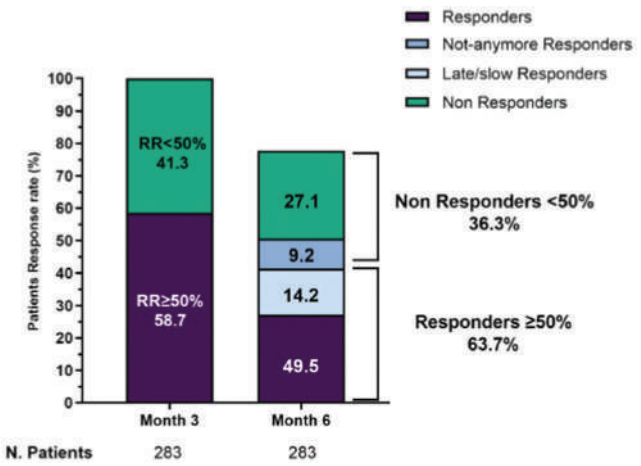
EPO-133 | Slow responders instead of late responders: Assessing the time to response to anti-CGRP/R monoclonal antibodies

L. Iannone[1]; A. Burgalassi[2]; A. Boccalini[2]; F. De Cesaris[2]; G. Vigani[1]; M. Romozzi[3]; C. Vollono[3]; P. Calabresi[3]; P. Geppetti[1]; A. Chiarugi[1]
[1]Section of Clinical Pharmacology and Oncology, Department of Health Sciences, University of Florence, Florence, Italy; [2]Headache Center and Clinical Pharmacology Unit, Careggi University Hospital, Florence, Italy; [3]Dipartimento Universitario di Neuroscienze, University Cattolica del Sacro Cuore, Rome, Italy

Background and Aims: To evaluated whether late responders to anti-CGRP mAbs (achieving response between 3 and 6 months) are actually slow responders, namely patients who already achieve a clinically meaningful response at 3 months and improve over time.
Methods: We performed a prospective analysis on outpatients that started treatment, with a potential 6-month follow-up. Based on studies on late responders, response was defined as a ≥50% reduction in MHDs at 3 and 6 months. The response rate was then evaluated using different intervals (0–9; 10–19; 20–29; 30–49; ≥50%) to assess responses at three months. The primary outcomes were the number of potential late responders and to evaluate how many patients defined as late responders have a response ≥30% at three months (slow responders).
Results: We include 332 patients and among them 283 (85.2%) continue treatment for six months. Responders were 63.6% (180/283) at six months. In particular, 40 (14.1%) patients not responders at three months achieve response status at six months, 140 (49.5%) persisted in response, 77 (27.2%) continued to be not responders and 26 (9.2%) lost the responder status. However, among the 40 patients defined as late responders, 21 (47.5%) already achieved a response ≥30% at three months with 14 (35.0%) of them with a 40–49% response.



Flowchart of patients' selection



Responder rate variation from 3 to 6 months of treatment

Fremanezumab, n (%)	44 (15.5)
Baseline features	
Monthly headache days, mean (SD)	23.8 (6.0)
Days with at least one analgesic use, mean (SD)	20.5 (8.5)
Analgesics number, median (IQR)	34.2 (28.5)
MIDAS score, mean ± SD	91.4±61.1
HIT-6 score, mean ± SD	68.0±6.2

IQR, interquartile range; SD, standard deviation. Percentages are expressed on column total.
[i]Only patients with chronic migraine.

Patients' demographic and clinical features at baseline

Conclusion: The majority of patients designed as late responders are instead slow responders, starting a meaningful response to anti-CGRP at three months and improving over time. Nevertheless, to maximize response, we recommend evaluating the treatment after a minimum of three to six months.

EPO-134 | POTS and autoimmune conditions as predictors of vestibular migraine

M. Villar-Martinez; S. Cheung; M. David; G. Peter J
Wolfson Sensory, Pain and Regeneration Centre, IoPPN, London, UK

Background and Aims: The vestibular migraine phenotype (VM) presents with vertigo/dizziness as a prominent non-headache symptom. Autoimmune conditions, such as rheumatoid arthritis or psoriasis, are potentially comorbid and may have a genotypic association with migraine. Cranial autonomic symptoms in migraine has been described and could be a protective mechanism in patients with severe symptoms. Dysautonomic symptoms could correlate with chronification of headache in patients with POTS. Our aim was to search for potential comorbidities that could predict a "dizzy" phenotype.

Methods: Cross-sectional study and clinical evaluation of migraine patients on the headache, neuro-otology and general neurology clinics at King's College Hospital and Charing Cross Hospital in London; February 2020 to July 2023. Predictors: sex, the presence of Postural Orthostatic Tachycardia syndrome (POTS), hypermobility, inflammatory/autoimmune and cutaneous conditions such as urticaria. Dependent variable: migraine type. SPSS 28 and generalised linear model with negative binomial-logit function were used.

Results: Age and biological sex were similar among migraine types. Of 525 cases; 185 had a diagnosis of vestibular migraine and 340 chronic migraine. Significant predictors of vestibular migraine: POTS ($B=1.08$, $p=0.045$) and autoimmune conditions ($B=0.53$, $p=0.01$). The rest of the predictors were not significant.

Conclusion: Dysautonomic conditions, such as POTS and the presence of autoimmune disorders, could predispose to a vestibular phenotype of migraine. Patients with the vestibular migraine phenotype may present a more dysfunctional autonomic nervous system with not only cranial, but also systemic symptoms.

Disclosure: Nothing to disclose.

EPO-135 | Is transcranial direct current stimulation effective as add-on therapy to monoclonal antibodies anti-CGRP in migraine?

F. De Santis[1]; C. Rosignoli[1]; R. Ornello[1]; A. D'Atri[1]; F. Salfi[1]; D. Corigliano[2]; R. De Icco[3]; V. Grillo[3]; M. Corrado[3]; F. Bighiani[3]; G. Vaghi[3]; G. Sances[3]; M. Ferrara[1]; C. Tassorelli[3]; S. Sacco[1]
[1]*Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy*; [2]*Department of Psychology, University of Rome Sapienza, Rome, Italy*; [3]*Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy*

Background and Aims: Transcranial direct current stimulation (tDCS) is a non-invasive central neuromodulation technique with potential effectiveness in migraine, while monoclonal antibodies acting on the calcitonin gene-related peptide pathway (CGRP-MAbs) act peripherally. We aimed to assess whether tDCS, as a synergic add-on, can enhance migraine prevention or affect cortical excitability.

Methods: TACTIC (NCT05161871) is a randomized, double-blind, multicenter, sham-controlled trial including patients with migraine on CGRP-MAbs treatment, with residual monthly migraine days (MMD) ≥8. After 5-day of tDCS bilateral occipital-cathodal and frontal-anodal stimulation (20-minutes sham/active sessions) we followed-up patients for 28 days. We recorded 64-channel EEG at day 1 (pre-stimulation) and day 5. We analyzed change in MMDs, clinical scales, and EEG spectral changes in the delta (2–4 Hz), theta (5–7 Hz), alpha (8–12 Hz) and beta-bands (13–30 Hz) through two-way mixed-design ANOVAs with Session (baseline vs. follow-up), as within-subjects factor, and Treatment (Sham vs. Active) as between-subject factor.

Results: We included 29 patients (median age = 48.0 [Interquartile-Range 38–56], 92.0% female), 15 active session and 14 sham. We found no significant interaction between Session and Treatment. However, explorative post-hoc t-test showed that only in the active group tDCS led to a decrease in MMDs (mean difference = 4.00, standard error (SE) = 1.52, $p = 0.014$). Moreover, a noteworthy enhancement was observed in the HIT6 scale for both active ($p = 0.005$) and sham ($p = 0.003$) groups. tDCS decreased the occipital alpha-power and the frontal delta-power only in the active stimulation group (both $p < 0.050$).

Conclusion: Centrally acting tDCS, as add-on therapy to peripherally acting CGRP-MAbs, has a significant preventive benefit on migraine associated with changed basal cortical activity on stimulated areas.

EPO-136 | Plasma pTAU levels can discriminate HC, PD, PDD, DLB and AD patients

A. Lupini[1]; A. Pilotto[1]; N. Ashton[2]; B. Battaglio[1]; E. Cottini[1]; C. Zatti[1]; C. Trasciatti[1]; I. Grossi[3]; A. Salvi[3]; G. De Petro[3]; M. Pizzi[4]; A. Canale[5]; K. Blennow[6]; H. Zetterberg[7]

[1]*Neurology Unit, Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy;* [2]*Department of Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden;* [3]*Division of Biology and Genetics, Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy;* [4]*Division of Pharmacology, Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy;* [5]*Department of Statistical Sciences, University of Padova, Padova, Italy;* [6]*Clinical Neurochemistry Laboratory Sahlgrenska University Hospital, Mölndal, Sweden,* [7]*10 Department of Neurodegenerative Disease, UCL Institute of Neurology, London, UK*

Background and Aims: plasma biomarkers are a promising field of research in neurodegenerative diseases, both oriented to diagnostic and therapeutic implications. Many patients with PD dementia or DLB have an AD-pathology overlap. In this study, we seek to explore the usefulness of plasma biomarkers in distinguishing between healthy controls, PD, DLB, PDD, and AD patients.

Methods: plasma PTau181, PTau231, Aβ1-40, Aβ1-42, GFAP and NfL concentrations were measured by Single molecule array (Simoa) technology in healthy controls (HC) and consecutive PD and AD patients who underwent an extensive motor and non-motor assessment. We established a cut-off in pTau181 and pTau231 levels based on their average values in patients with AD pathology. We compared clinical and demographic variables between normal and abnormal pTAU groups.

Results: One hundred fifty-three PD patients, thirty-two PDD, forty-two DLB, sixteen AD and ninety-five age matched HC entered the analyses. The percentage of patients with abnormal pTAU levels increases from HCs to PDs but especially in patients with DLB and PDD. When considering only alpha-synucleinopathies, the group with higher PTau231 showed lower MMSE scores at baseline.

Conclusion: The present findings confirm the potential utility of plasma AD biomarkers to differentiate healthy controls from PD patients and more importantly to separate PD cognitive unimpaired patients from patients with DLB or PDD.

EPO-137 | Longitudinal impact of vascular risk factors on progression and disability in Parkinson's disease

A. Lupini[1]; A. Pilotto[2]; M. Catania[1]; C. Zatti[1]; B. Battaglio[1]; F. Guarneri[3]; L. Bettoni[3]; S. Gipponi[4]; E. Cottini[4]; A. Padovani[1]
[1]Neurology Unit, Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy; [2]Laboratory of digital Neurology and biosensors, University of Brescia, Brescia, Italy; [3]Hospital Central Pharmacy Unit, ASST University Hospital Spedali Civili Brescia, Brescia, Italy; [4]Department of continuity of care and frailty, Neurology Unit, ASST Spedali Civili of Brescia, Brescia, Italy

Background and Aims: Vascular risk factors are common in the elder population in Western countries. Parkinson's disease incidence is increasing in the last years, along with population aging. Aim of the study was to address the impact of single and multiple vascular risk factors on cognitive and motor progression in patients with PD.
Methods: Consecutive Parkinson's disease patients underwent a comprehensive motor and non motor evaluation including baseline motor and non motor performances. A longitudinal motor and cognitive evaluation was performed with an average of 5 years of follow-up for each patient. The impact of vascular risk factors on motor and cognitive progression was implemented by linear, COX regression and repeated measures analyses adjusting for the effect of age, motor severity and disease duration.
Results: forty-hundred eighty six patient (62.1 % male) entered the study. 52–1% of patients had hypertension, while 21.2% had hypercholesterolemia, 17.3% had diabetes, and 27.2% had cardiac diseases. There was no correlation between vascular risk factors and neither cognitive nor motor impairment at baseline. Patients with diabetes and hypertension showed higher LEDD at follow up; patients with hypercholesterolemia had a higher incidence of falls, while patients with diabetes had a higher incidence of walking impairment at follow-up.
Conclusion: vascular risk factors impact on disease progression and disability in PD. More studies are warranted to evaluate the causality and best management strategies to reduce the impact of vascular risk factors on PD progression and disability.
Disclosure: Nothing to disclose.

EPO-138 | The midbrain-pons ratio as a marker for the vestibular stimulation effectiveness in the postural instability treatment

O. Alenikova; A. Chumak; G. Zobnina; S. Likhachev
Republican Research and Clinical Center of Neurology and Neurosurgery

Background and Aims: Axial symptoms associated with Parkinson's disease (PD), such as freezing of gait (FOG) and postural instability (PI) are frequently refractory to therapy. Due to the vestibular system deficiency participates in postural imbalance and gait disorders, vestibular galvanic stimulation (GVS) could become an effective neuromodulatory treatment for these symptoms. However, the effectiveness of GVS may vary depending on the neurodegeneration severity in brainstem locomotor centers, and midbrain-pons ratio (MPR) may provide valuable information about change in these regions. Objective: To assess the GVS effectiveness on cVEMP parameters, FOG and PI severity depending on the MPR.
Methods: Participants included 34 PD and 30 age-matched controls. Additionally to MRI-based measurements, we assessed the cVEMP, FOG-Q, TUG test and evaluated the PI severity before and after 12 GVS sessions.
Results: PD patients had longer of VEMP components latencies than controls, indicating slower vestibulospinal conduction. Nevertheless, there were no differences between groups in MRI measurements (table). GVS improved test scores and reduced N23 latency independent of MRI findings in PD patients. While the PI improvement depended on the MPR, and GVS was effective in PD patients with MPR >0.64 (figure).

TABLE Comparative assessment of the PD patients group and the control group

Parameters	PD patients group n = 34	Control group n = 30
	Median (IQR)	
Age, years	63 (57 – 68)	60 (55 – 70)
H & Y stage	2,5 (2–3)	-
Disease duration (years)	7 (6 – 13)	-
UPDRS (part III)	38 (28 - 49)	-
Midbrain (mm)	11,3 (10,9 – 11,5)	11,2 (10,7 – 11,6)
Pons (mm)	17,6 (17,1 – 18,5)	17,5 (16,9 – 18,4)
Midbrain to pons ratio	0,64 (0,61 – 0,66)	0,65 (0,64 – 0,66)
FOG-Q		
Before intervention	14 (7–19)	-
After intervention	9 (5 – 14) Δ	-
Changes	5 (2 – 7)	-
Timed Up and Go Test (TUG) (seconds)		
Before intervention	16 (14– 19)*	8 (7 – 9)
After intervention	13 (11 – 15) Δ	-
Changes	3 (2 – 4)	-
Postural instability (from 0 to 4, where 0 is the norm; 4 - cannot stand without help)		
Before intervention	2 (1 – 3)	-
After intervention	1 (0 – 2)	-
Changes	0 (0 – 1)	-
Cervical Vestibular Evoked Myogenic Potential (cVEMP) P13 latency / N23 latency (msec)		
Before intervention	13,25 (12,4 – 14,3)* / 24,8 (23,6 – 25,9)*	11,7 (10,8 – 22,1) / 22,5 (22,05 – 22,9)
After intervention	13,1 (12,1 -14) / 23,7 (23 – 24,2) Δ	-
Changes	0,15 (0,1 – 0,4) / 1,1 (0,6 – 1,7)	-

* - p ≤ 0,05 - Significant differences between PD patients and control group (Mann-Whitney test)
Δ - p < 0.05 - Significant difference when comparing results before and after GVS in the Wilcoxon Matched Pairs Test

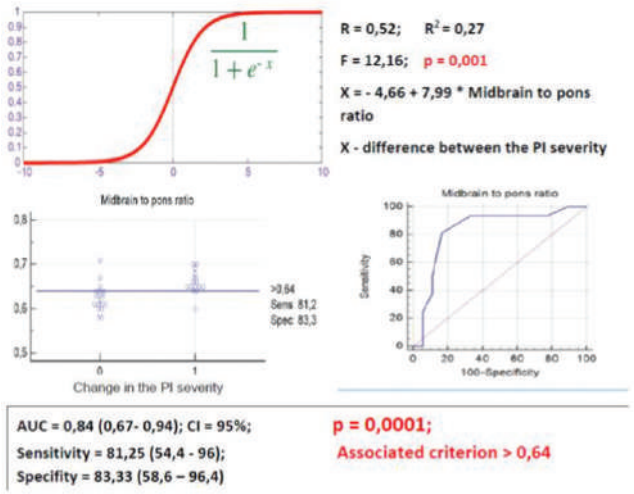

FIGURE Results of multiple regression and ROC analysis

Conclusion: GVS, acting on vestibular afferents, modifies the conflict between sensory systems and thereby reduces the severity of gait disorders. But the ability of GVS to reduce PI in PD probably depends more on morphometric features of the brainstem. Due to its high sensitivity and specificity, the MPR can be considered as a prognostic marker of the GVS effectiveness in the PI treatment.
Disclosure: Nothing to disclose.

EPO-139 | Amantadine improves executive and memory skills in patients with Parkinson's disease: A randomized controlled trial

A. Bougea[1]; E. Angelopoulou[1]; V. Georgakopoulou[2]; Y. Değirmenci[3]; P. Zikos[4]
[1]*1st Department of Neurology, Medical School, National and Kapodistrian University of Athens, Eginition Hospital, Athens, Greece;* [2]*COVID-19 Unit, Department of Infectious Diseases, Laiko General Hospital, Athens, Greece;* [3]*Head of Neurology Department, Istanbul Health and Technology University (ISTUN);* [4]*Galatsi Center for Parkinson's & Memory Disorders Galatsiou Avenue 127, Galatsi, Athens, Greece*

Background and Aims: Amantadine improves motor symptoms in patients with Parkinson disease (PD) as monotherapy or adjuvant therapy. However, data on cognitive functions are lacking. This Single blind randomized controlled study over 12 months investigated the effect of amantadine on PD cognition.
Methods: Mild cognitive impaired 35 PD patients (mean HY: 2), with amantadine 200 mg/day (100 mg twice a day) orally as monotherapy (Group A) and 30 PD patients without amantadine (only levodopa treatment Group B) were randomly enrolled. The data collected for each patient included: (1) verbal learning and memory (Hopkins Verbal Learning Test-Revised immediate total recall across trials and delayed recall trial), (2) auditory working memory (Letter-Number Sequencing subtest from the Wechsler Adult Intelligence Scale – III), (3) processing speed (Digit Symbol subtest from the Wechsler Adult Intelligence Scale-Revised), (4) visuospatial working memory/switching (Trail Making Test, Part B), (5) semantic verbal fluency (animals), (6) phonemic verbal fluency (letters F-A-S or C-F-L), (7) visuospatial functioning (Benton Judgment of Line Orientation), 8)Depression (Geriatric Depression scale).
Results: The cognitive function improved progressively in 3-, 6 and 12-month treatment interval as shown by significant improvement on verbal short term ($p < 0.001$) and auditory working memory ($p < 0.001$) and visual working memory ($p < 0.001$) in Group A compared to Group B. Even after controlling for depression, disease duration, there are persistent differences in the above cognitive tests between the two groups over the time
Conclusion: Amantadine alone significantly improved memory and visual-spatial skills in PD patients.
Disclosure: Nothing to disclose.

EPO-140 | Determination of clinical profile of patients with Parkinson's disease at 2-year follow up with deep brain stimulation

A. Bougea[1]; Y. Değirmenci[2]; E. Angelopoulou[1]; V. Georgakopoulou[3]; P. Zikos[4]
[1]*Department of Neurology, Eginition Hospital, National and Kapodistrian University of Athens, Greece;* [2]*Head of Neurology Department, Istanbul Health and Technology University (ISTUN);* [3]*COVID-19 Unit, Department of Infectious Diseases, Laiko General Hospital, Athens, Greece;* [4]*Galatsi Center for Parkinson's & Memory Disorders Galatsiou Avenue 127, Galatsi, Athens, Greece*

Background and Aims: Despite the beneficial effect of deep brain stimulation (DBS) on motor and non-motor symptoms, the selection of Parkinson's disease (PD) patients is challenging. This study aims to develop a random forest (RF)-based PD model to determine the postoperative clinical profile at 2 years follow-up with DBS using motor and non- motor symptoms.
Methods: 130 PD subjects (76 male, 54 female; age at baseline: 56.24 ± 4.23) were evaluated in years 0 and 2 by the Unified Parkinson's Disease Rating Scale part III (UPDRS- III). Hours of "Off" and dyskinesia time (UPDRS-IV), the Montreal Cognitive Assessment (MoCA), Geriatric Depression Scale (GDS), the Non-Motor Symptoms Scale (NMSS), Hoehn/Yahr(HY) and PD questionnaire- 39(PD39). RF analysis, with 10000 trees, was used to combine both non-motor and motor variables to determine motor outcome (UPDRS-III year 2: 22.55 ± 12.22).
Results: The proper combination of motor and non-motor measures significantly improved ($p < 0.001$) the prediction of outcome, reducing the RMSE (root-mean-square-error) of predicting UPDRS-III from 4.686567 to 4.04672 which signifies that the model was optimized quite well. Based on the "IncNodePurity", the factors of UPDRS-III (year 2) were, in descending order of magnitude, UPDRSIII (year 0), disease duration (year 2), GDS (year 0), NMSS (year 2), Time Dyskinesia (year 0), PDQ39 (year 2) after the implementation of DBS.

Conclusion: In the new era of neuromodulation, these results are promising for accurate patient selection for DBS by artificial intelligence models.
Disclosure: Nothing to disclose.

EPO-141 | Phenotype's evolution of cervical dystonia (CD) in patients treated with Botulinum toxin

A. Trinchillo[1]; N. Cuomo[1]; F. Habetswallner[2]; M. Esposito[2]
[1]Department of Neurosciences, Reproductive Sciences and Odontostomatology, "Federico II" University, Naples, Italy; [2]Clinical Neurophysiology Unit, Cardarelli Hospital, Naples, Italy

Background and Aims: Cervical dystonia (CD) phenotypes may change over the years. Objective of the study is to evaluate how such phenotypes change in CD treated with botulinum toxin (BoNT). Finally, we aim to identify the time within those changes may occur, the most predisposed CD phenotypes and predisposing factors.
Methods: We divided idiopathic CD patients into two groups – switch YES/NO, collecting general clinical and demographic variables. We added to general clinical variables the duration of BoNT treatment, Tsui total scores and subscores – assessed at T0 – before BoNT start – and at T1 – switch time in the YES group or last visit in the NO group. The risk of switch was assessed by Kaplan Meyer curves and Cox regression analysis. Finally, Multivariate linear regressions were employed to assess if Tsui severity correlated with the switch.
Results: Among 100 patients (60 women) aged 47.9 years (SD 15.3) at CD onset, 37 experienced a phenotype switch, mostly in the first five years of BoNT treatment, YES and NO groups were comparable. Multivariate Cox Regression revealed the presence of laterocollis or rotatocollis at T0 as predictors of switch (respectively $p=0.01$, HR = 3.5; $p=0.03$, HR = 1.5). Multivariate linear regressions revealed that high Tsui subscores for the tilt and low Tsui total scores were risk factors for the switch (respectively $p=0.002$, OR = 6; $p=0.03$, OR = 0.8).
Conclusion: Latero and Rotatocollis are the CD phenotypes most predisposed to switch. Dystonias with a low degree of severity improve after treatment with botulinum toxin, changing to a different and even simpler phenotype.
Disclosure: Nothing to disclose.

EPO-142 | The long-term response to botulinum toxin injections in patients with blepharospasm undergoing upper eyelid surgery

A. Trinchillo[1]; N. Cuomo[1]; F. Habetswallner[2]; M. Esposito[2]
[1]Department of Neurosciences, Reproductive Sciences and Odontostomatology, "Federico II" University, Naples, Italy; [2]Clinical Neurophysiology Unit, Cardarelli Hospital, Naples, Italy

Background and Aims: BACKGROUND Upper eyelid surgery (UES) is a therapeutical strategy used for those patients affected by blepharospasm (BSP) who either do not respond or experience a gradual decrease in responsiveness to botulinum toxin (BoNT) injections. Nevertheless, most of them need to restart with BoNT despite the intervention. AIM To evaluate the long-term post-surgical response to BoNT in patients with BSP and to identify predictive factors associated to treatment outcome.
Methods: We collected data of 60 BS patients, divided into two groups – blepharoplasty YES (8) and NO (52), collecting demographic – age, sex – and clinical data –disease duration, duration of the treatment with BoNT. Respective responses to injections – evaluated through the differences of both Jancovic Rating Scale and the Blepharospasm Disability Index pre and post BoNT (delta JRS and delta BSDI) just before their periodic three-month injection and after 1 month from it – were compared. Finally, clinical and demographics variables were included in multivariate regression and correlation analyses to assess their impact on the long-term response to injections.
Results: Patients who underwent UES had significantly lower delta at both scales, showing a poorer outcome after BoNT treatment. No variable was found to be associated with the response.
Conclusion: Our data seem to suggest that surgery does not improve response to BoNT injections on the long run. As such, UES could be considered as an efficacious treatment in BSP just if evaluated soon after its performing. Long-term BSP management seems still difficult to be performed adequately and new therapeutical approaches are still needed.
Disclosure: The authors have nothing to disclose.

EPO-143 | Assessment of the deep brain stimulation efficiency for the tremor correction in Parkinson's disease: STN vs Vim

A. Buniak; S. Likhachev; U. Alexeyevets; V. Bayarchyk; T. Paulouskaya
Neurological Department, Neurosurgical Department, Republican Research and Clinical Center of Neurology and Neurosurgery, Minsk, Belarus

Background and Aims: Correcting severe tremor, one of the disabling symptoms in Parkinson's disease (PD), is the most difficult tasks for neurologists. If there is no effect from drug correction of severe tremor, neurosurgical treatment is used, including deep brain stimulation (DBS) of the ventralis intermedius thalamic nucleus (Vim) or subthalamic nucleus (STN). To evaluate the efficiency of DBS Vim vs STN for the tremor correction in PD patients.
Methods: We examined 72 (59–II stage, 13–III stage of H&Y.) PD patients during DBS. The main characteristics of patients are presented in the table (Fig. 1). In patients with DBS Vim, the primary symptom was disabling tremor. The tremor index (TI) consists of

UPDRS scores 16, 20, 21. To assess the changes of drug therapy used LEDD.

Indicators	DBS STN	DBS Vim
Amount, patients	63	9
M/F	36/27	5/4
Age, years	57,0 (95% CI 54,0;59,0)	59,0 (95% CI 50,8;62,0)
PD duration, years	10,3 (95% CI 9,3;11,2)	8,4 (95% CI 5,8;11,1)
LEDD, before	1175,0 (95% CI 1000,0;1250,0)	750,0 (95% CI 656,2;987,5)
III part UPDRS, off med, before	41,0 (95% CI 34,0; 54,0)	46,0 (95% CI 33,5;58,0)
TI (16,20,21 UPDRS), off med, before	6,5 (95% CI 3,5; 12,5)	14,0 (95% CI 11,5;16,0)

FIGURE 1 Description PD patients before DBS

Results: The postoperative follow-up period was up to 2 years. The score by III UPDRS in the off-med decreased in patients with DBS STN ANOVA $\chi^2 = 12.44$, $p < .00001$ and DBS Vim ANOVA $\chi^2 = 11.58$, $p = .00011$(Fig 2). The TI in the off-med period decreased in patients with DBS STN ANOVA $\chi^2 = 14.68$, $p < .00001$ and DBS Vim ANOVA $\chi^2 = 4.51$, $p = .014$ (Fig 3). The LEDD score in DBS STN was decreased ANOVA $\chi^2 = 9.22$, $p < .000001$, but not under DBS Vim ANOVA $\chi^2 = 1.92$, $p = .15$.

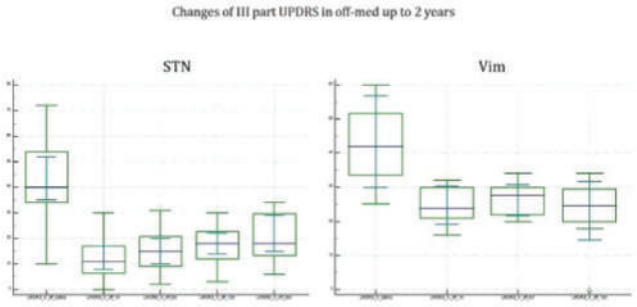

FIGURE 2 Changes of III part UPDRS in off-med DBS STN vs DBS Vim up to 2 years

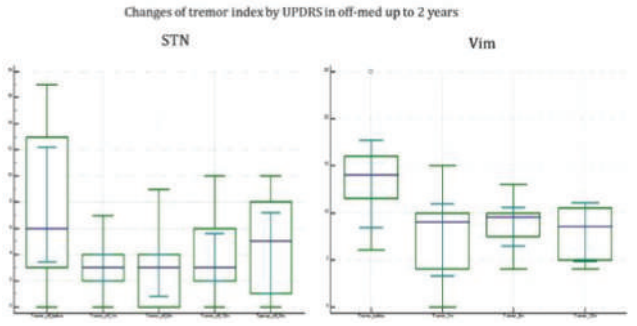

FIGURE 3 Changes of tremor index by UPDRS in off-med DBS STN vs DBS Vim up to 2 years

Conclusion: The results indicate an improvement of tremor both by DBS STN and DBS Vim. To correct hypokinesia and rigidity during DBS Vim, patients should take levodopa at the correct dose.
Disclosure: Nothing to disclose.

EPO-144 | Pain and related factors in patients with Parkinson's disease

C. Alis[1]; D. Selcuk Demirelli[1]; E. Ay[2]; G. Genc[1]
[1]*Department of Neurology, Sisli Hamidiye Etfal Training and Research Hospital, Istanbul, Turkey*; [2]*School of Medicine, Acibadem Mehmet Ali Aydinlar University, Istanbul, Turkey*

Background and Aims: Pain is a common non-motor symptom in Parkinson's disease (PD). We aimed to investigate pain frequency and pain-related factors in PD.
Methods: We interviewed PD patients from our movement disorders unit to assess pain presence, categorising it into four types: musculoskeletal pain (MP), radicular or neuropathic pain (RNP), dystonia-related pain (DRP), and central parkinsonian pain (CPP). We investigated demographic differences, General Anxiety Disorder-7 (GAD-7), Patient Health Questionnaire-9 (PHQ-9), EQ-5D-3L, MDS-Unified Parkinson's Disease Rating Scale (MDS-UPDRS) and Hoehn and Yahr scale (H&Y) scores, PD duration, PD drugs, and insomnia. Comparisons were made between patients with and without pain, and among those with different pain types.
Results: Ninety-three patients (34 female, 59 male; median age: 66 years, IQR: 17) were included. Seventy-five had pain (23 MP, 18 RNP, 12 DRP, 5 CPP, and 17 had a combination). No associations were found between pain and age, gender, GAD-7, PHQ-9, MDS-UPDRS, H&Y scores, PD duration, PD drugs, and insomnia. However, EQ-5D-3L scores were higher in patients with pain ($p = 0.019$). Among different pain types, no relationships were identified regarding age, PHQ-9, MDS-UPDRS and H&Y scores, PD drugs, and insomnia. RNP correlated with longer PD duration ($p = 0.01$), MP with shorter PD duration ($p = 0.04$). MP was less common in males ($p = 0.016$), and anxiety was more prevalent in CPP patients ($p = 0.008$).
Conclusion: Pain impairs PD patients' quality of life, and longer PD duration correlates with increased RNP. Anxiety correlates with CPP, suggesting a potential link between anxiety-control networks and CPP. Further studies are needed to support this hypothesis.
Disclosure: Nothing to disclose.

EPO-145 | Neurology survey on referral practices and perception of functional neurosurgery solutions in essential tremor in Europe

C. Ferrer[1]; C. Tengelin[1]; P. Crivelli[1]; K. Gant[2]; A. Grinspan[2]
[1]*Insightec Europe GmbH, Munich, Germany*; [2]*Insightec. Inc, Miami, USA*

Background and Aims: Functional neurosurgery for treatment of essential tremor (ET) has evolved in recent years. Magnetic resonance–guided focused ultrasound (MRgFUS) was introduced as an alternative neurosurgery modality. We investigated changes in referral patterns and familiarity with functional neurosurgery among European neurologists.

Methods: An anonymised web survey was conducted between 16-01-23 and 24-02-23. Relevant privacy legislation on personal data protection (GDPR 2016/679) and professional guidelines were followed. General neurologists (GN) and movement disorder neurologists (MDN) were interviewed about the ET pathway and their experience and perception of functional neurosurgery.

Results: The survey was answered by 224 neurologists (68 MDN, 156 GN). Patients came to the neurologist's attention mainly via their general practitioner (GP) and the patient's own initiative (up to 33% in Italy). Disease was mainly severe in those referred to the neurologist (approximately 55%) (Figure 1). Most were managed directly by the neurologist, without referral to another neurologist or centre (<18%); when the neurologist referred the patient to another centre, disease was generally severe (approximately 70%) (Figure 2). Most neurologists were familiar with deep brain stimulation (DBS [96.4%]), radiofrequency (RF [72.8%]), and gamma-knife thalamotomy (GKT [79.3%]). Fewer were familiar with MRgFUS (67.5%) (Figure 3).

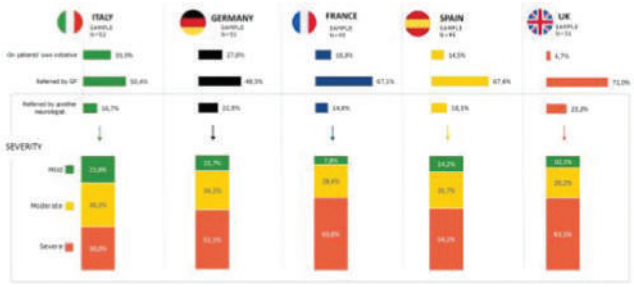

FIGURE 1 Origin and severity of essential tremor patients referred to general and movement disorder neurologists in Europe (Italy, Germany, France, Spain, and the UK). The sample number of neurologists per country is reported.

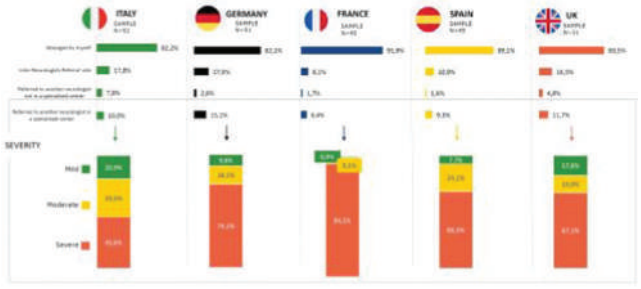

FIGURE 2 Distribution and management of essential tremor patients by and between neurologists in Europe (Italy, Germany, France, Spain, and the UK). The sample number of neurologists per country is reported.

FIGURE 3 Reported level of knowledge of non-pharmacological therapies among both general and movement disorder neurologists. The sample number of neurologists is reported. Familiarity is defined as the overlap between the 3 highest levels of knowledge.

Conclusion: Referral of ET patients remains variable and is mainly via the GP or the patient's own initiative. The most common profile is severe disease. Despite recent inclusion in national/international guidelines, MRgFUS remains the least familiar option for neurologists, followed by RF, GKT, and DBS. Further study is necessary to explain the low referral rate (<18%).

Disclosure: The authors are all employees of Insightec. To carry out the survey, support was provided by Stethos Srl, Italy, Milan. Writing assistance was provided by Content Ed Net, Madrid, Spain. The responses were used for market research purposes.

EPO-146 | General and movement disorder neurologists survey on prescription and perception of MRgFUS in Europe

C. Ferrer[1]; C. Tengelin[1]; P. Crivelli[1]; K. Gant[2]; A. Grinspan[2]
[1]*Insightec Europe GmbH, Munich, Germany;* [2]*Insightec. Inc, Miami, USA*

Background and Aims: Magnetic resonance–guided focused ultrasound (MRgFUS) emerged in the 2010s and is now a recommended neurosurgery alternative for essential tremor (ET). The increased presence of MRgFUS means that perception and potential application in ET may have changed. We investigated changes in perception of MRgFUS among European neurologists.

Methods: An anonymised web survey was conducted between 16-01-23 and 24-02-23. Relevant data privacy legislation and guidelines were followed. Both general neurologists (GN) and movement disorder neurologists (MDN) were asked about the positioning of MRgFUS, barriers to adoption, and medical education.

Results: The survey was completed by 68 MDN and 156 GN. Approximately two-thirds of patients had severe ET. Quality of life was poor, and many patients had not responded to previous therapy (Figure 1). Most neurologists (>70%) were satisfied with the effects of MRgFUS on patient management. The main conditions for extending referral were access to protocols and referral criteria. (Figure 2). Most felt that MRgFUS could be extended to a wider range of patients by enhancing communication with neurologists, creating access channels between MRgFUS centres and other centres, and offering staged-bilateral treatment. The recommended educational content to extend use of MRgFUS includes clinical efficacy data, safety-tolerability data, and side effects, as well as explanation of the technique/procedure (Figure 3).

FIGURE 1 Severity and main characteristics of essential tremor patients prescribed MRgFUS by neurologists in Europe (Italy, Germany, France, Spain, and the UK). The sample number of neurologists per country is reported.

FIGURE 2 A) Level of satisfaction for post-MRgFUS patient management among general and movement disorder neurologists. B) Conditions for extension of MRgFUS to more patients.

FIGURE 3 A) Channels of communication for extension of MRgFUS to more patients. B) Content to be included in communications on MRgFUS. The sample number of neurologists is reported. Outcomes are reported for general and movement disorder neurologists.

Conclusion: In Europe, MRgFUS is prescribed mainly in severe ET. Satisfaction was high. More widespread adoption depends on better access to centres, well-defined referral criteria, and the possibility of staged-bilateral treatment. Further education on MRgFUS is necessary.

Disclosure: The authors are all employees of Insightec. To carry out the survey, support was provided by Stethos Srl, Italy, Milan. Writing assistance was provided by Content Ed Net, Madrid, Spain. The responses were used for market research purposes.

EPO-147 | Use of the MNCD classification/staging in advanced Parkinson's disease patients treated with a device-aided therapy

Suárez-Muñoz[6]; J. Martínez Castrillo[7]; A. Perona[8]; J. Salom[9]; I. Legarda[10]; M. Valero-García[10]; E. Cubo[11]; N. López-Ariztegui[12]; D. Alonso-Modino[13]; R. Espinosa[14]; M. Mata[15]

[1]CHUAC (Complejo Hospitalario Universitario de A Coruña), A Coruña, Spain; [2]Hospital Universitario La Princesa, Madrid, Spain; [3]Hospital Clínico Universitario San Carlos, Madrid, Spain; [4]Hospital Universitario la Fe, Valencia, Spain; [5]Hospital General Universitario de Elche, Spain; [6]Hospital Dr. Negrín, Las Palmas de Gran Canaria, Spain; [7]Hospital Universitario Ramón y Cajal, Madrid, Spain; [8]Complejo Hospitalario Universitario de Albacete, Spain; [9]Hospital Clínico Universitario de Valencia, Spain, [10]Hospital Universitario Son Espases, Palma de Mallorca, Spain, [11]Hospital Universitario de Burgos, Spain, [12]Hospital Universitario de Toledo, Spain, [13]Hospital Universitario de la Candelaria, Santa Cruz de Tenerife, Spain, [14]Hospital Universitario de Jerez, Spain, [15]Hospital Infanta Sofía, Madrid, Spain

Background and Aims: Staging Parkinson´s disease (PD) with a novel simple classification called MNCD, based on 4 axes (Motor; Non-motor; Cognition; Dependency) and 5 stages, correlated with disease severity and patients´ quality of life and caregivers´ strain and burden (1,2). Our aim was to apply the MNCD classification in patients treated with levodopa-entacapone-carbidopa intestinal gel (LECIG) infusion.

Methods: A multicenter observational retrospective study of the first patients to start LECIG in Spain was performed (LECIPARK). The MNCD total score (from 0 to 12) and MNCD stages (from 1 to 5) were collected by the neurologist at V0 (before starting LECIG) and V2 (follow-up visit). Wilcoxon's signed rank and Marginal Homogeneity tests were applied to compare changes from V0 to V2.

Results: Forty-five PD patients (55.3% males; 69.6 ± 10 years old) with a mean disease duration of 13.9 ± 6.4 years were included. The mean treatment duration (V2) was 132.2 ± 81.3 days (range, 10–302). At V0, patients were classified as in stage 2 (31.9%), 3 (44.7%) or 4 (23.4%). The frequency of patients in stage 4 decreased to 10.6% at V2 ($p = 0.007$) (Figure 1A). The MNCD total score decreased from 6.6 ± 1.8 at V0 to 5.4 ± 2.1 at V2 ($p < 0.0001$). From V0 to V2, motor and non-motor symptoms burden decreased and autonomy for activities of daily-living improved (Figure 1B and 2).

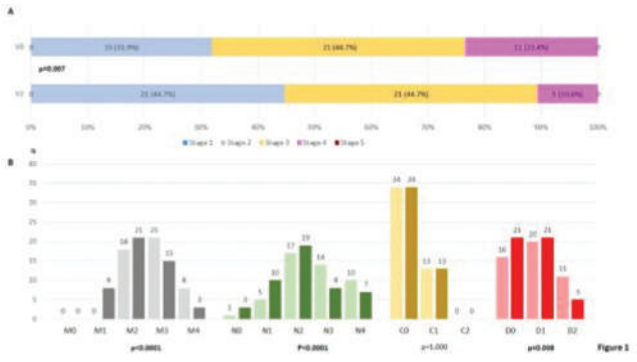

FIGURE 1 A. Frequency of different MNCD stages (from 1 to 5) at V0 (V0; pre-LECIG) compared to at V2 (follow-up visit; 132.2 ± 81.3 days after starting LECIG) ($p = 0.007$). B. Number of patients with each score of the MNCD classification (M, N, C and D) at

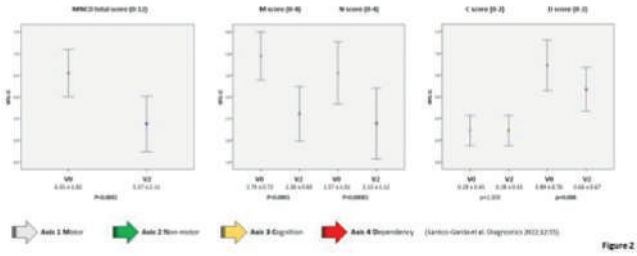

FIGURE 2 Change from the baseline (V0; pre-LECIG) to the follow-up visit (V2) in the MNCD total score (from 0 to 12), M and N scores (from 0 to 4), and C and D scores (from 0 to 2). Wilcoxon's signed rank tests was applied. The bars represent mean ± stan

Conclusion: The MNCD classification could be useful to classify advanced PD patients and to monitor the response to a device-aided therapy.

Disclosure: The authors report no conflict of interest.

EPO-148 | Exploring the distinct effect of onset age and caudate denervation on cognitive deficits in early PD

G. Palermo[1]; S. Giannoni[1]; L. Tommasini[1]; G. Bellini[1]; D. Frosini[1]; G. Aghakhanyan[2]; R. Morganti[3]; D. Volterrani[2]; N. Pavese[4]; R. Ceravolo[1]

[1]*Center for Neurodegenerative Diseases – Parkinson's Disease and Movement Disorders, Unit of Neurology, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy;* [2]*Regional Center of Nuclear Medicine, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy;* [3]*Section of Statistics, University of Pisa, Pisa, Italy;* [4]*Clinical Ageing Research Unit, Translational and Clinical Research Institute, Newcastle University, Newcastle upon Tyne, UK*

Background and Aims: Older age at onset and baseline caudate dopaminergic denervation are recognized risk factors for cognitive impairment in Parkinson's disease (PD), posing challenges in identifying their relative contribution to cognitive outcomes. The objective of this study was to assess the distinct contribution of age at onset and baseline caudate dopaminergic binding to the early cognitive deficits in PD patients.

Methods: We examined the relationship between baseline dopaminergic striatal dysfunction (measured using [123I]FP-CIT SPECT, age at disease onset and neuropsychological performance in 126 drug-naive PD patients, utilizing putaminal and caudate binding values of 77 healthy controls (HC) for a comparative exploration of age-dependent loss of DAT availability. Additionally, we investigated whether age at onset and caudate DAT binding could independently predict cognitive changes over a median of 7-year follow-up.

Results: [123I]FP-CIT-SPECT binding values had a significant negative correlation with age in both PD and HC, but in PD, aging was linked with a steeper slope for the caudate than the putamen. Older age at onset and lower caudate uptake were associated with worse global cognitive function and performance in specific neuropsychological tests at baseline and demonstrated to be significant independent predictors of cognitive dysfunction at follow-up.

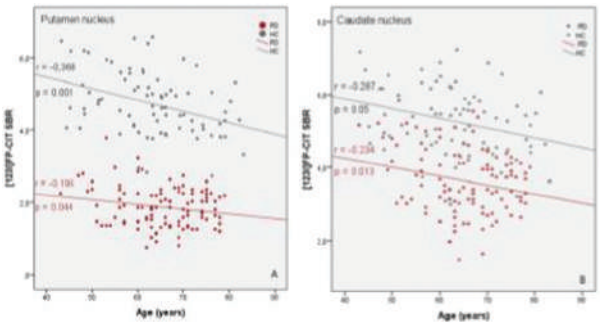

FIGURE 1 Effects of age: comparison of [123I]FP-CIT binding values between PD and HC in the putamen (A) and caudate (B)

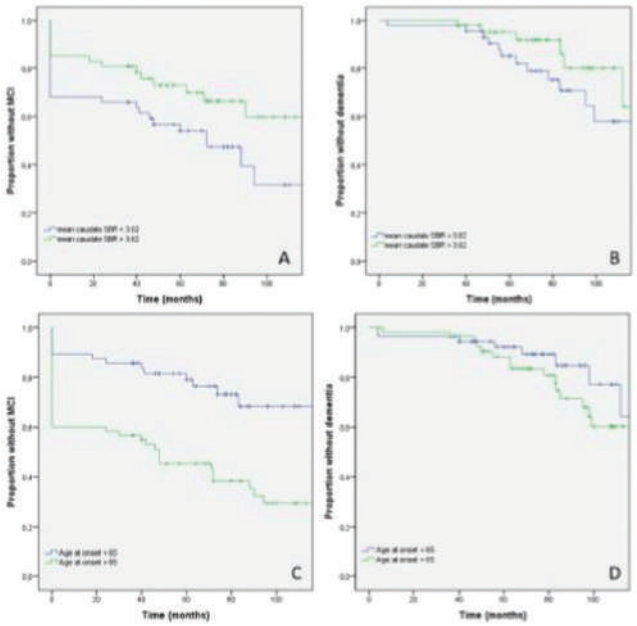

FIGURE 2 The survival curve determined using the Kaplan-Meier for cognitive decline in our patient cohort according to baseline [123I]FP-CIT SPECT binding values (A and B) and age at the onset of PD (C and D)

Conclusion: Our findings confirm a differential age effect on [123I] FP-CIT binding in the striatal subregions of denovo PD patients. Notably, we found less age-related attrition of dopaminergic binding in the putamen than in the caudate, reflecting likely the superimposition of putaminal compensatory mechanisms and an increased predisposition of old onset PD patients to develop cognitive disturbances.

Disclosure: The authors declare that there are no financial disclosures to report concerning the research related to this abstract.

EPO-149 | Vestibular and saccadic abnormalities in Parkinson's disease patients: Possible marker of neurodegenerative burdern?

G. Di Rauso[1]; A. Castellucci[2]; F. Cavallieri[3]; S. Grisanti[1]; V. Fioravanti[3]; E. Monfrini[4]; G. Toschi[3]; J. Rossi[1]; A. Tozzi[5]; G. Ferrulli[5]; R. Sabadini[3]; A. Scaglioni[6]; A. Di Fonzo[4]; A. Ghidini[2]; F. Valzania[3]

[1]Clinical and Experimental Medicine PhD Program, University of Modena and Reggio Emilia, Modena, Italy; [2]Otolaryngology Unit, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy; [3]Neurology Unit, Neuromotor & Rehabilitation Department, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy; [4]Neurology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [5]Otorhinolaryngology-Head and Neck Surgery Department, University Hospital of Modena, Modena, Italy; [6]Centro S. Maria ai Servi, Fondazione Don Gnocchi, Parma, Italy

Background and Aims: Vestibular dysfunction has been suggested as possible non-motor symptom in Parkinson's disease (PD), however so far data are still lacking in literature. Moreover, saccadic eye movements have been studied in PD with mixed results. The aim of our study is to assess vestibulo-ocular reflex gain and voluntary saccade eye movements in PD patients exploring possible correlation between vestibular and saccadic variables and demographic and clinical features. Secondary aim is to compare these variables in GBA1-PD and non-mutated PD (NM-PD) subgroups.

Methods: A consecutive cohort of GBA1-PD patients has been paired for age, sex, disease duration, Hoehn & Yahr stage, and Charlson Comorbidity Index with a cohort of consecutive NM-PD. Patients underwent clinical neurological assessment (MDS-UPDRS total scores and subscores, the Montreal Cognitive Assessment scale (MoCA)), the video head impulse test (vHIT) and saccadic instrumental assessment.

Results: 40 PD patients were included in this study: 20 GBA1-PD and 20 NM-PD. Bilateral saccadic latency directly correlated with age ($p < .05$), disease duration ($p < .001$) and PIGD subscore ($p < .001$), while it negatively correlated with MoCA score ($p < .05$). The bilateral vHIT gain of the lateral semicircular canal directly correlated with disease duration ($p < .05$), while the gain of the posterior semicircular canal negatively correlated with rigidity subscore ($p < .05$). No differences were found in vestibular and saccadic variables between GBA1-PD and NM-PD.

Conclusion: Our results highlight that vestibular and saccadic abnormalities may be associated with specific clinical features in PD. Particularly, saccadic latency could represent a marker of neurodegenerative burden, correlating with age, disease duration and axial and cognitive impairment.

Disclosure: The authors have no conflicts of interest to declare that are relevant to the content of this abstract.

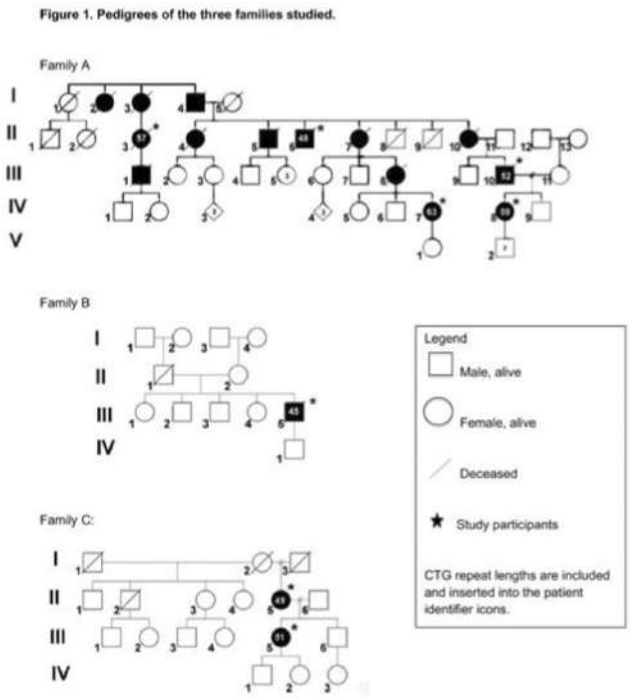
EPO-150 | Atypical presentations of Huntington disease-like 2 in South African individuals

H. Narotam Jeena[1]; M. Guttman[2]; L. van Hillegondsberg[1]; R. van Coller[3]; A. Krause[4]; J. Carr[1]

[1]Division of Neurology, Department of Medicine, University of Stellenbosch, Cape Town, South Africa; [2]Centre for Movement Disorders, Markham Ontario, Division of Neurology, University of Toronto, Canada; [3]Department of Neurology, University of Pretoria, South Africa; [4]Division of Human Genetics, National Health Laboratory Service and School of Pathology, Faculty of Health Sciences, University of Witwatersrand, Johannesburg, South Africa

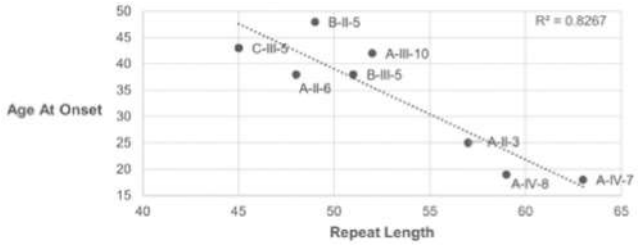
Background and Aims: Huntington's Disease Like 2 (HDL2) is a neurodegenerative disorder, described as being similar to HD with respect to phenotypic, radiologic and pathologic features. HDL2 only affects individuals of African ancestry. Affected individuals have 40–59 triplet repeats. We describe the phenotypic variability of HDL2 in a group of mixed ancestry individuals from South Africa.

Methods: Eight patients were assessed with the Unified HD Rating Scale (UHDRS), Montreal Cognitive Assessment (MoCA) tool, MR brain imaging, and analysis of repeat size.

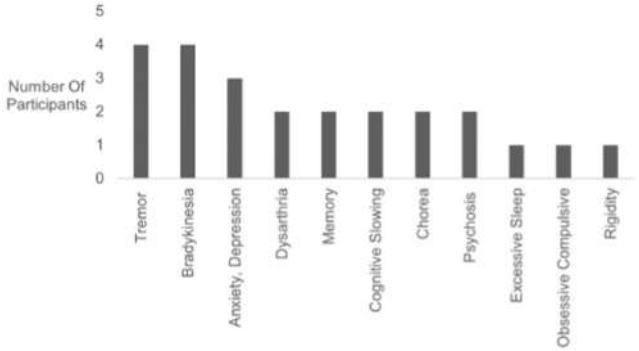


Pedigrees of the three families studied.

Results: Cognitive domains were more severely affected than motor domains. Neuropsychiatric symptoms were common in all, evident as behavioural change, memory impairment, depression, anxiety, and/or hallucinations. MoCA scores reflected impairments across all domains, although orientation and memory were less severely affected. UHDRS motor scores were notable for bradykinesia. Tremor and dystonia were also prominent motor symptoms; only one patient had marked chorea. Repeat lengths ranged from 45 to 63 and were inversely related to age at onset (AAO). We report two unique cases of juvenile onset HDL2, noting that an AAO younger than 20 years has not been previously documented.



Age at onset and corresponding repeat length



Symptoms at presentation

Conclusion: It is important for clinicians to be aware that individuals with HDL2 may present with severe and rapidly progressive cognitive and behavioural impairments, with variable degree of motor deficit and even absent chorea. The atypical HDL2 phenotype in this South African group of mixed ancestry is likely related to large repeat sizes and may represent a forme fruste of the Westphal variant seen in Huntington disease.

Disclosure: Nothing to disclose.

Movement disorders 2

EPO-151 | EEG microstate abnormalities in prodromal Lewy body diseases

D. Ondráček[1]; M. Lamoš[2]; L. Brabenec[2]; K. Mitterová[2]; I. Rektorová[3]

[1]*Brain and Mind Research Program, CEITEC, Masaryk University, Brno, Czechia + Faculty of Medicine, Masaryk University, Brno, Czechia;* [2]*Brain and Mind Research Program, CEITEC, Masaryk University, Brno, Czechia;* [3]*Brain and Mind Research Program, CEITEC, Masaryk University, Brno, Czechia + First Department of Neurology, Faculty of Medicine, Masaryk University and St. Anne's University Hospital, Brno, Czechia*

Background and Aims: Described EEG patterns may serve as diagnostic and prognostic biomarkers for prodromal dementia with Lewy bodies (DLB). While spectral frequency analysis is used to evaluate EEG patterns, EEG microstates (MS) provide temporal and spatial characteristics. We aimed at elucidating early changes in network dynamics across spectrum of healthy controls (HC), prodromal DLB and at-risk population using both EEG patterns and MS assessment.

Methods: 120 cognitive and dopaminergic medication-naïve subjects with or without core and supportive clinical features of prodromal DLB +- presence of mild cognitive impairment underwent a 5-minute recording of high-density resting state scalp EEG. Participants were sorted based on their EEG patterns into groups: pattern 1 (normal EEG), pattern 2 (early DLB) and pattern 5 (advanced DLB). EEG microstates were analyzed using k-means approach and temporal parameters were calculated.

Results: Results revealed higher mean duration ($p < 0.001$ and $p = 0.005$) and higher time coverage (TC) ($p = 0.004$ and $p = 0.004$) of the MS C, and lower TC ($p = 0.003$ and $p < 0.001$) and segment density ($p < 0.001$ and $p < 0.001$) of MS A in EEG pattern 1 compared to pattern 2 and 5, respectively. No significant differences between pattern 2 and 5.

Conclusion: MS A involves temporal cortices and represents sensory (auditory, visual) and arousal networks while MS C anterior cingulate and insular cortices representing salience network. Our results support early engagement of anterior insular cortices in prodromal DLB which reflects deficits in executive, autonomic, visual and affective/behavioral functions while abnormally enhanced involvement of the sensory/arousal network is related to cognitive fluctuations, and/or illusions/hallucinations in early DLB.

Disclosure: No disclosure.

EPO-152 | Functional Neurological Disorders (FND): Experience at a tertiary hospital in Madrid

A. Suárez Plaza; Á. Gutiérrez Viedma; C. García Campos; P. García Ruiz Espiga; J. Del Val Fernández; C. Feliz Feliz; R. Cutillas Ruiz; M. Machío Castelló; J. Serratosa Fernández; B. González Giraldez; A. Cascón Pinto; L. Salgado Calzada; M. Arias Villarán

Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

Background and Aims: Diagnosing functional neurological disorders (FND) might be daunting. Although the prevalence of overlapping structural neurological pathology in FNDs has been previously stated, the relationship between both is yet to be fully understood. Our aim was to describe all diagnoses reached at our FND-Unit and analyze its characteristics.

Methods: Prospective observational study of all patients referred to an FND-Unit, May-2022 to December-2023.

Results: 154 patients (72.7% female, median age 41 years) were included. 89.0% were diagnosed with FND, 11,0% received alternative diagnoses (non-FND). The most prevalent reason for referral were syncopes (22.1%) and gait abnormalities (20.1%). Amongst the alternative diagnoses, the most common clinical presentation was sensory disturbances (64.7%).The most prevalent alternative diagnosis was restless legs syndrome (RLS) (44.4%), followed by peripheral neuropathy (33.3%). 3.7% of FND confirmed cases presented an overlapping RLS (FND/RLS). The resulting prevalence of RLS was 8.4%. 46.2% of RLS patients presented exclusively sensory symptoms, and most of them (87.5%) were non-FND/RLS ($p = 0.047$). Within the FND/RLS group, median age was significantly lower (30.0 versus 49.5 years, $p = 0.021$) and median time to diagnosis after symptom onset was longer (60 versus 10 months, $p = 0.08$). No other differences were found.

Conclusion: The possibility of diagnostic errors at a FND-Unit is relevant. The most frequent misdiagnosis was RLS, which also commonly overlapped with FND. Age, solely sensory symptoms, and time to diagnosis might help distinguish FND/RLS from non-FND/RLS.

Disclosure: Nothing to disclose.

EPO-153 | Novel CACNA1A mutation associated with cerebellar ataxia and mild cognitive impairment in a Czech family; a case report

A. Afifi[1]; M. Nevrlý[1]; Z. Mušová[2]; P. Hedvičáková[2]; K. Menšíková[1]; P. Kaňovský[1]

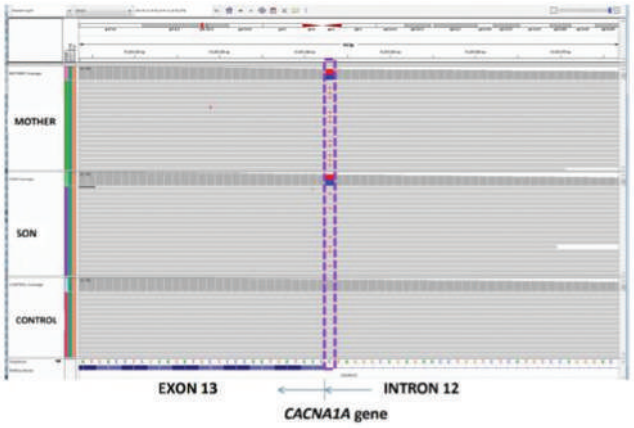
[1]*Department of Neurology, University Hospital Olomouc, Czechia;* [2]*Department of Biology and Medical Genetics, Second Faculty of Medicine, Charles University and University Hospital Motol, Prague, Czechia*

Background and Aims: Spinocerebellar ataxias (SCA) are a group of heterogenous neurodegenerative hereditary disorders characterized by progressive loss of balance and coordination, as well as other distinguishing symptoms that vary with the particular type and the involved genetic defect. Pathogenic variants in CACNA1A gene have been implicated in autosomal dominant hereditary spinocerebellar ataxia 6, episodic ataxia type 2, familiar hemiplegic migraine, and infantile epileptic encephalopathy 42.

Methods: Index case, 43-year-old patient, presented with progressive cerebellar ataxic gait clinically manifesting at age 41, horizontal nystagmus and mild cognitive impairment. Noteworthy from his history; he suffered epileptic seizures from ages 3–16, and his biological mother developed similar gait disorder since age 44. Her examination showed cerebellar ataxic gait, horizontal nystagmus with saccadic intrusions, ataxic dysarthria, intentional tremor and mild cognitive impairment. Both patients had global cerebellar atrophy on MRI. Patients initially tested negative for most common SCAs (SCA1-3 and SCA6-7). Subsequently, CACNA1A gene was analysed using new generation sequencing and bioinformatic analysis.

Results: In both patients, molecular genetic examination confirmed the presence of the heterozygous variant c.1672-1G>A in CACNA1A (NM 000068.3). In Sophia DDM, as well as Varsome and Franklin predictions, the variant is assessed as likely pathogenic (applied ACMG criteria PVS1, PM2). The mutation probably causes aberrant splicing by disrupting splicing acceptor site. To our knowledge, this variant is not yet recorded in literature and dbSNP, gnomAD and HGMD databases.

Conclusion: Based on our results, we propose that the above-mentioned variant in CACNA1A is likely to be associated with cerebellar ataxia, nystagmus and mild cognitive impairment.



Read alignments visualized with IGV (Integrative Genomics Viewer) shows the novel heterozygous germline variant c.1672-1G>A in the CACNA1A gene (NM 000068.3) (chr19-13308529 C>T) in the patient and her son and a comparison with a control sample.

Disclosure: Supported by MH CZ–DRO (FNOI, 00098892).

EPO-154 | Serum biomarkers of neurodegeneration in mitochondrial membrane protein-associated neurodegeneration (MPAN)

M. Skowrońska[1]; A. Cudna[1]; A. Antos[1]; M. Rydzewski[1]; J. Janikiewicz[2]; A. Dobosz[2]; A. Wydrych[2]; B. Pakuła[2]; P. Jakubek[2]; M. Lebiedzińska-Arciszewska[2]; M. Cwyl[3]; M. Popielarz[3]; A. Dobrzyń[2]; M. Więskowski[2]; I. Kurkowska-Jastrzębska[1]
[1]*2nd Department of Neurology, Institute of Psychiatry and Neurology*; [2]*Laboratory of Mitochondrial Biology and Metabolism, Nencki Institute of Experimental Biology Polish Academy of Sciences*; [3]*Association NBIA Polska*

Background and Aims: Neurodegeneration with iron accumulation (NBIA) associated with the mitochondrial protein C19orf12 – MPAN, is one of the hereditary diseases characterized by the accumulation of iron in the brain. There is currently no cure for MPAN, and the primary focus is on discovering the role of the C19orf12 protein, which may aid in the search for effective treatment. In this study, we aim to identify biomarkers that can serve as indicators of disease progression and treatment effectiveness.
Methods: Twenty-five patients with genetically confirmed MPAN had biomarkers of inflammation and neurodamage tested, and results were compared to those of an age- and sex-matched control group of healthy volunteers. Venous blood was collected in the fasting state in the morning, and serum was then frozen at −80°C for storage until testing. MMP-9, S100B, ICAM-1, E- and P-selectins, and total α-synuclein were measured using a sandwich-type ELISA following the manufacturer's instructions. Serum NfL, GFAP, Tau protein, and UHC-L1 were measured using SIMOA Quanterix methods.
Results: Our findings reveal that MPAN patients exhibited higher serum levels for all biomarkers, except BDNF. MMP-9, E- and P-selectins were increased 1.4–2 times above the control level. S100B was 10 times higher in MPAN patients, indicating potential blood-brain barrier damage. Alpha-synuclein was elevated 25 times, corresponding to an accumulation of this protein in the brain. NfL, GFAP, and UCH-L1 were higher by 8, 2, and 5 times, respectively.
Conclusion: Our results suggest that S100B, alpha-synuclein, NfL, and UHC-L1 might be useful as biomarkers in MPAN
Disclosure: Nothing to disclose.

EPO-155 | Gait and postural responsiveness to subthalamic stimulation and levodopa: A prospective clinical-instrumental study

I. Cani[1]; I. D'Ascanio[2]; L. Baldelli[1]; G. Lopane[1]; P. Mantovani[1]; A. Conti[1]; P. Cortelli[1]; G. Calandra-Buonaura[1]; L. Chiari[3]; G. Giannini[1]; L. Palmerini[3]
[1]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Via Altura, 3, Bologna, Italy*; [2]*Department of Electrical, Electronic, and Information Engineering, Alma Mater Studiorum – University of Bologna, Bologna, Italy*; [3]*Health Sciences and Technologies – Interdepartmental Center for Industrial Research (CIRI-SDV), Alma Mater Studiorum – University of Bologna, Bologna, Italy*

Background and Aims: This study delves into the dynamic interplay of balance and mobility, specifically probing their nuanced response to subthalamic stimulation.
Methods: We investigated alterations in the spatiotemporal dynamics of gait and posture in a prospective cohort of individuals with Parkinson's disease, examined both before and six months post subthalamic deep brain stimulation (STN-DBS) surgery. The standardized motor protocol included Timed-Up and Go, 18m walk test, quiet standing monitored by wearable inertial sensors.
Results: Twenty-eight patients were evaluated in 2 preoperative and 4 postoperative conditions comprising OFF/ON medication and stimulation states. Standardized response mean values were computed to assess the responsiveness of sensor-based motor parameters to treatments. Significant improvements in spatiotemporal gait parameters, including speed, cadence and stride length were observed following STN-DBS surgery. The effect of stimulation on postural parameters was less evident.
Conclusion: Our study revealed that stimulation and levodopa had similar effects on gait parameters, with stimulation proving more effective in enhancing gait speed and stride length.
Disclosure: Nothing to disclose.

EPO-156 | Mortality analysis in a Portuguese cohort of hereditary cerebellar ataxias

L. Silva[1]; S. Costa[1]; J. Moura[1]; F. Almeida[2]; C. Lemos[3]; M. Santos[3]; J. Oliveira[3]; J. Sequeiros[3]; J. Barros[1]; J. Damásio[1]
[1]Neurology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal; [2]Neuroradiology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal; [3]CGPP-IBMC, i3S – Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Portugal

Background and Aims: Hereditary cerebellar ataxias (HCA) are a heterogeneous group of diseases, associated with high morbidity and mortality. We aimed at analysing survival rate, causes, and place of death in a cohort of patients with HCA.
Methods: Prospective study of an HCA cohort, from the North of Portugal.
Results: Out of 252 patients with HCA, 38(15.1%) deceased, and 25(9.9%) lost to follow-up. Among those deceased, 20(52.6%) were male; 31(81.6%) had autosomal recessive (AR) HCA [16(42.1%) CANVAS; 4(10.5%) AOA4; 3(7.9%) HSP-MAG; 3(7.9%) FRDA; 1(2.6%) AOA1; 1(2.6%) HSP/ATX-PGN; 1(2.6%) ATX-PNPT1; 2(5.3%) undiagnosed]; and 7(18.4%) autosomal dominant (AD) HCA [5(13.2%) MJD/SCA3; 2(5.3%) undiagnosed]. Median age at death was 71.0 [IQR: 54.0–76.5] years. Overall survival was 35.6(±15.1) years after first symptoms, ranging from 19 (ATX-PNPT1) to 62 years (AOA1). AR-HCA patients lived with the disease for 39.4 (±13.8) years and AD-HCA patients for 20.0(±9.1) years ($p < 0.05$). Individuals with disease-causing variants survived for 42.5(±14.2) years, while those with disease causing repeats lived for 33.1(±11.8) years ($p < 0.05$). Causes of death were identified in 21 patients: 19(90.1%) infection, 1(4.8%) neoplasia, or 1(4.8%) stroke. Death occurred at the hospital in 13(34.2%), home in 8(21.1%), or nursing-home in 3(7.9%) [14(36.8%) unknown].
Conclusion: Life expectancy of HCA was lower than in general Portuguese population (71.0 vs. 81.5). Patients with AD-HCA or with disease-causing repeats had the lowest life expectancy. Survival rate, causes and places of death were similar to Huntington's disease. Knowledge on end-stage needs is crucial for patients and relatives advance-directive strategies and improving quality of life.
Disclosure: Nothing to disclose.

EPO-157 | The efficacy of Safinamide as an add-on treatment in improving the quality of life and the pain in Parkinson's disease

Background and Aims: Safinamide was found to improve on-time without troublesome dyskinesia and reduce wearing off. Furthermore, we aimed to investigate its efficacy in enhancing patients' quality of life and reducing pain.
Methods: This study is a prospective interventional study in Parkinson's disease patients who are receiving levodopa, and experience motor fluctuations with > = 1.5 hours of "off" time throughout the day. If there were no tolerability issues within 4 weeks, the initial dosage of 50 mg/day was increased to 100 mg/day, and the patients continued with the 100 mg/day dosage for 18 weeks. The efficacy outcome was measured by the change from baseline to week 18 in the questionnaire examination of the quality of life (PDQ-39) and the pain (KPPS).
Results: In this study, we evaluated 196 patients using PDQ-39 and KPPS. The mean disease duration of them is 6.6 years, and the mean daily levodopa dose is 502.4 mg/day at baseline. At week 18, a significant improvement in the total PDQ-39 score was observed compared to baseline ($p < 0.001$). Moreover, each domain (Mobility,

Activities of daily living and Stigma) in PDQ-39 demonstrated a significant improvement from baseline. The assessment of pain using KPPS also showed a significant decrease at week 18 compared to baseline ($p=0.013$). Particularly, Safinamide significantly reduced Fluctuation–related Pain ($p=0.002$).

TABLE 1 PDQ-39 change after 18 weeks compared to baseline

Category	Baseline score (mean±SD)	Change [Week 18 - Baseline] (mean±SD)	P value
	N= 196	N= 196	
Total score	24.9±15.9	-2.7±10.3	<0.001*(WS)
Mobility	30.5±25.4	-4.4±18.7	<0.001*(WS)
Activities of daily living	26.4±23.3	-5.4±18.2	<0.001*(WS)
Emotional well-being	28.4±24.5	1.1±21.0	0.932(WS)
Stigma	30.7±27.9	-6.3±23.2	<0.001*(WS)
Social support	15.9±16.0	-1.5±13.9	0.131(WS)
Cognitions	23.6±21.0	-1.9±17.1	0.322(WS)
Communication	17.3±21.3	-1.9±13.2	0.061(WS)
Bodily discomfort	26.6±22.5	-1.1±20.9	0.605(WS)

(WS) Wilcoxon signed rank test
*: p-value < 0.05

TABLE 2 KPPS change after 18 weeks compared to baseline

Category	Baseline score (mean±SD)	Change [Week 18 - Baseline] (mean±SD)	P value
	N= 196	N= 196	
Total score	10.6±14.4	-1.5±11.3	0.013*(WS)
Musculoskeletal Pain	2.2±2.7	0.3±3.0	0.432(WS)
Chronic Pain	1.3±2.9	-0.3±2.7	0.126(WS)
Fluctuation-related Pain	2.6±6.0	-1.1±5.4	0.002*(WS)
Nocturnal Pain	2.0±3.7	-0.1±3.2	0.356(WS)
Oro-facial Pain	0.4±1.7	-0.1±2.1	0.312(WS)
Discolouration; Edema/swelling	0.7±2.6	-0.2±2.5	0.394(WS)
Radicular Pain	1.2±2.4	0.1±2.5	0.516(WS)

(WS) Wilcoxon signed rank test
*: p-value < 0.05

Conclusion: Safinamide at a dosage of 100mg/day demonstrated significant improvements in PDQ-39 scores and significant reductions in KPPS. These findings indicate that Safinamide contributes to enhancing patients' quality of life and reducing the pain, particularly pain associated with motor fluctuations

Disclosure: This Study sponsored by Eisai Korea Inc., Seoul, Republic of Korea.

EPO-158 | The DashPD-Consortium: Importance of addressing bone health and anticholinergics to achieve holistic care in Parkinson's

M. Qamar[1]; L. Batzu[1]; K. Poplawska-Domaszewicz[2]; V. Metta[3]; I. Murasan[4]; D. Ziemele[5]; S. Khatchaturyan[6]; C. Falup-Pecurariu[4]; K. Ray Chaudhuri[1]

[1]Parkinson's Foundation Centre of Excellence, Institute of Psychiatry, Psychology & Neuroscience, Department of Basic and Clinical Neuroscience, King's College London and King's College Hospital, London, UK; [2]Department of Neurology, Poznan University of Medical Sciences, Poznan, Poland; [3]Kings College Hospital London, Dubai, UAE; [4]Department of Neurology, County Clinic Hospital and Transilvania University of Brasov, Brașov; [5]Department of General Neurology, Riga East Clinical University Hospital, Riga, Latvia; [6]Department of Neurology, Vagharshapat Polyclinic Hospital, Vagharshapat, Armenia

Background and Aims: A dashboard incorporating clinical "prompts" of the often ignored "five vitals" of Parkinson's disease (PD) (Chaudhuri et al., 2022, Qamar et al., 2023) has been published based on expert opinion and patient preferences. In an ongoing international multicentre observation survey (DashPD) we collected data on awareness and documentation of bone health and anticholinergic (ACh)-index (risk factor for dementia and cardiovascular events) in PD in clinics.

Methods: This initial analysis refers to data from the ongoing DashPD Consortium as well as the UK-arm of the 'Nonmotor International Longitudinal Study' (NILS, UKCRN.10084). A questionnaire asking "yes", "no", or "not applicable" format was used. Focus was on bone health, falls, and documentation of the Ach-index.

Results: Data were collected between July 2022 to December 2022 ($N=906$ PD). Results show bone health assessment in only 21%, while only 9% had bone density scans, and vitamin D and calcium levels were recorded in 25%. Despite frailty assessment performed in 61% there was no documentation of any fall prevention strategies. ACh-index was measured in only 6% and no specific advice on dangers of ACh use was documented.

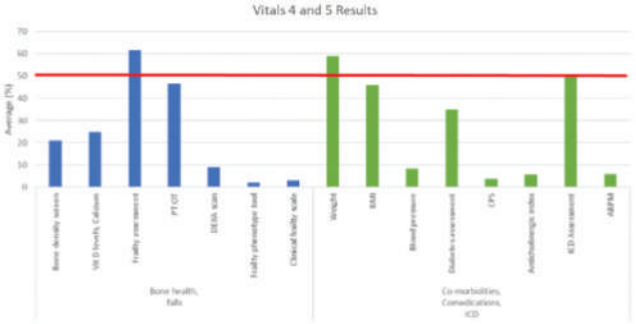

FIGURE 1 An extract of just vitals 4 and 5, from the multi-centre international observational survey analysis for the application of the Dashboard of Vitals in Neurology outpatient clinics.

Conclusion: This initial analysis of the DashPD-Consortium data, shows a glaring lack of awareness and documentation of bone health and Ach use related data which is likely to compromise patient health because of increased risk of fractures and negative effects of Ach use in PD.
Disclosure: Nothing to disclose.

EPO-159 | DysPKG project: Blinded clinical interrater reliability in assessing dyskinesia using the Parkinson's KinetiGraph (PKG)

M. Qamar[1]; L. Batzu[1]; C. Santoro[2]; A. Rekik[3]; S. Landolfo[2]; K. Ray Chaudhuri[1]
[1]Parkinson's Foundation Centre of Excellence, Institute of Psychiatry, Psychology & Neuroscience, Department of Basic and Clinical Neuroscience, King's College London and King's College Hospital, London, UK; [2]Department of Basic Medical Sciences, Neurosciences, and Sense Organs, University of Bari Aldo Moro, Bari, Italy; [3]Department of Neurology, Sahloul Hospital, Sousse, Tunisia

Background and Aims: In Parkinson's disease (PD), dyskinesia is levodopa-induced uncontrollable movements, which differ in phenomenology. We aim to visually recognise and characterise dyskinesia from reports using the validated Parkinson's KinetiGraph (PKG) and perform an interrater reliability analysis between independent clinicians to validate recognition of patterns of dyskinesia.
Methods: PKG reports with dyskinesia were identified from the UK-PKG database and two independent clinicians rated the dyskinesias (pattern and severity). Each clinician was given ninety-six patient PKG reports with the dyskinesia and bradykinesia graph. Raters were blinded to the patient's clinical assessment, medication, and history.
Results: PKG reports was assessed for daytime and night-time dyskinesia, with each further analysed for severity and characteristics of dyskinesia (figure 1). Cohen's K was performed to determine interrater reliability between two clinical raters in relation to presence of dyskinesia, severity of dyskinesia, and characteristic of dyskinesia. There was significant substantial agreement between the two clinicians' judgement for the presence, severity, and characterisation of dyskinesia at night-time (table 1). There was a significant substantial agreement for presence of daytime dyskinesia [k = 0.669 $p < 0.001$] and a significant moderate agreement for the severity of daytime dyskinesia [k = 0.555 $p < 0.001$]. However, there was only a fair agreement regarding the characterisation of daytime dyskinesia [k = 0.336 $p < 0.001$].

TABLE 1 Summary of Cohen Kappa (K) interrater agreement of PKG dyskinesia reports

	Cases (%)[1]	*K*[2]	95% CI[3]	p-value[4]	Strength of agreement[5]
Daytime Dyskinesia					
Presence	92.71	0.699	0.491 to 0.907	<.001	Good
Severity	70.83	0.555	0.416 to 0.694	<.001	Moderate
Characterisation	54.17	0.366	0.235 to 0.497	<.001	Fair
Night-time Dyskinesia					
Presence	94.79	0.753	0.547 to 0.959	<.001	Good
Severity	94.79	0.771	0.585 to 0.957	<.001	Good
Characterisation	92.71	0.66	0.446 to 0.874	<.001	Good

[1] Number of agreed cases between the raters from all reports analysed,
[2] Cohen's Kappa (*K*) measure of agreement,
[3] 95% confidence interval as calculated from the 65% CI of the Kappa standard error,
[4] Statistical significances, as defined as p<0.05,
[5] *K* interpretation of strength of agreement as suggested by Altman (1999) and adapted from Landis & Koch (1977).

TABLE 2 Level of agreement between raters about severity of dyskinesia

Daytime Dyskinesia severity	%	DKS range
Very mild	67.09	0.1-6.5
Mild	21.52	0.7-8
Moderate	6.33	6.2-12.5
Severe	5.06	6.5-123.3
Night-time Dyskinesia severity	**%**	**DKS range**
Very mild	66.67	1.7-8
Mild	0	0
Moderate	0	0
Severe	33.33	6.5-123.3

DKS: *dyskinesia score as defined by the PKG*

Conclusion: This is the first attempt to use visual interpretation of the PKG to grade dyskinesia. The results show there to be a role for the PKG, even if interpreted visually, in identifying and characterising dyskinesia. PKG analysis could therefore aid correct recognition and personalised therapies for dyskinesias in PD.
Disclosure: Nothing to disclose.

EPO-160 | Differences in prevalence of orthostatic hypotension between Parkinson's disease subtypes

P. Oikonomou; J. Koschel; C. Altmann; W. Jost
Parkinson-Klinik Ortneu, Wolfach, Germany

Background and Aims: Parkinson's disease (PD) is a clinically highly heterogeneous neurodegenerative disorder characterized by a wide range of motor and non-motor manifestations. The tremor-dominant (TD), mixed (M), and akinetic-rigid (AR) subtypes constitute one of the most commonly used classification systems. Orthostatic hypotension (OH), a common non-motor feature of PD, is linked to adverse outcomes and is evaluated with the modified Schellong test.
Methods: To investigate if patients with different motor subtypes also exhibit variations OH, we conducted a retrospective analysis

using data of inpatients admitted to our clinic, diagnosed with PD, based on the clinical diagnostic criteria of the Movement Disorders Society. The modified Schellong test was performed according to standard protocol.

Results: Of 1,809 patients included in the study, 1,121 were classified into AR-, 624 with M-, and 64 with TD-subtype. Interestingly, we found that patients with the AR-subtype exhibited significantly worse results in the modified Schellong test compared to patients with the M-subtype. Patients with the M-type were younger, had significantly worse motor function measured with the Unified PD Rating Scale part III but did not differ significantly in duration of disease or Hoehn and Yahr stage.

Conclusion: Our findings indicate differences in orthostatic regulation among PD motor subtypes (AR vs. M) and support the notion that PD patients with the AR motor phenotype may have distinct pathophysiological abnormalities, i.e., a prominent affection of noradrenergic pathways and a body-first pathogenesis. Further studies are needed to confirm these results, as they hold significant implications for personalized treatment and prognostic counseling in PD.

EPO-161 | Unmasking secondary parkinsonism: A case report of parkinsonism related to dural fistula

R. Ferrer Tarrés; M. Garcia Huguet; C. Vera Cáceres; C. Martínez Follana; I. Saurina Navarro; D. López Domínguez
Department of Neurology, Hospital Doctor Josep Trueta, Girona, Spain

Background and Aims: The most common cause for secondary parkinsonism is drug intake, but any disruption to the nigrostriatal dopaminergic pathway, such as a vascular insult or tumor, can prompt secondary parkinsonism. These secondary forms should always be considered in the differential diagnosis, as they often require specific therapeutic management, which may, in some cases, even lead to clinical reversal.

Methods: We present a case of a patient initially diagnosed with parkinsonism, later found to have a dural fistula, and experiencing clinical remission after undergoing fistula treatment.

Results: Presenting a 69-year-old woman who developed a progressive postural tremor, with a re-emerging and resting component. This tremor notably exhibited asymmetric predominance on the left side of the upper limbs, accompanied by bradykinesia, rigid-akinetic features, reduced arm swing, fragmented turning, and recurrent falls. The patient had no prodromal signs of synucleinopathy. DAT-SCAN revealed minimal asymmetry in the right putamen. Magnetic Resonance Imaging (MRI) revealed a dural fistula dependent on branches of the external carotids with drainage into the superficial and deep venous system. Angiography confirmed the diagnosis, and treatment led to a clear, progressive resolution of parkinsonian symptoms. We provide a comparative video of the neurological examination pre and post dural fistula embolization.

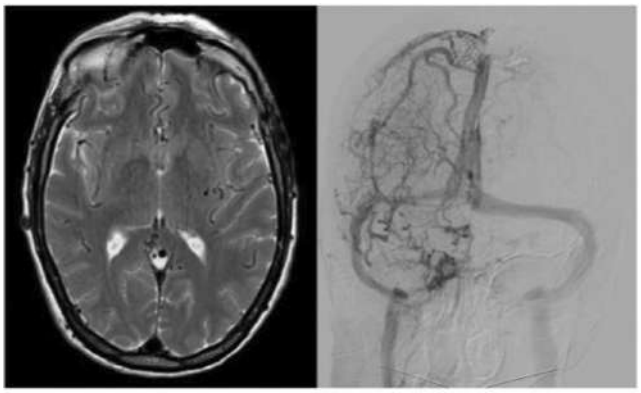

FIGURE 1 Cranial MRI with regurgitation of cerebral vessels and angiography revealing the dural fistula.

Conclusion: This case describes an uncommon cause of secondary parkinsonism- dural fistula, with limited instances reported in the literature. We suggest venous stasis as a potential trigger for dopaminergic pathway dysfunction, reflected in DAT-SCAN abnormalities. Emphasizing the need to rule out reversible conditions, as timely treatment offers symptom resolution.

Disclosure: No disclosure.

EPO-162 | Adult-onset PKAN with long disease duration: A case report and literature review

S. Othmani[1]; F. Pinna[1]; V. Floris[1]; C. Bagella[2]; C. Frau[2]; P. Solla[2]; A. Salis[3]
[1]*Department of Medical Sciences and Public Health, University of Cagliari;* [2]*Unit of Neurology, Department of Medical, Surgical and Experimental Sciences, University of Sassari;* [3]*Unit of Radiology, Department of Medical, Surgical and Experimental Sciences, University of Sassari*

Background and Aims: Pantothenate Kinase-Associated Neurodegeneration (PKAN), related to PANK2 gene mutation, is characterized by rapidly progressive movement disorders and cognitive impairment. While clinical presentation is typically in childhood, adult-onset forms have been described by milder clinical manifestations and slower disease progression[2], although data on the long-term outcome are scarce.

Methods: Case report and literature review.

Results: A 30 year-old man presented with slowly progressive speech disturbances and frequent falls. Over years, he had a gradual decline of intellectual functions, behavioral changes, orolingual dystonia with tongue protrusion, and spasticity leading to walking impairment. One brother and one sister had similar clinical manifestations with a slowly progressive course. At the age of 60, brain MRI revealed pathognomonic changes in the basal ganglia due to

iron accumulation. Genetic testing showed a homozygous c.965A>G mutation in the PANK2 gene. At 68 years of age, the patient's clinical and radiological manifestations remained stable, without further deterioration compared to the time of the diagnosis. Twenty-six additional cases of adult-onset PKAN with long-term follow-up available (all due to PANK2 gene mutation) were identified in the literature, for a total of 27 cases. The median age at symptoms onset was 30 (range, 20–67) and 9 (33.3%) were female. At last available follow-up, a median of 12 (range, 2–54) years from onset and 12 (44.4%) patients were alive.

Conclusion: The disease course in patients with adult-onset PKAN seems characterized by early development of symptoms followed by and a subsequent phase of clinical-MRI stability of years.

Disclosure: No disclosures.

EPO-163 | Phenotypic spectrum of GCH-1 pathogenic variants: A case series

S. Costa[1]; A. Sardoeira[1]; V. Oliveira[1]; R. Rodrigues[2]; E. Aires[1]; S. Morais[3]; J. Oliveira[3]; J. Barros[1]; J. Damásio[1]

[1]Neurology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal; [2]Clinical Pathology – Laboratory of Genetic Biochemistry/Endocrinology, Hospital D. Estefânia, Centro Hospitalar Universitário de Lisboa Central, Lisbon, Portugal; [3]CGPP-Centre for Predictive and Preventive Genetics, IBMC-Institute for Molecular and Cell Biology, i3S-Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Portugal

Background and Aims: Pathogenic variants in GCH1 are associated with dopa-responsive dystonia, and more rarely with Parkinsonism and spastic paraparesis (SP).

Methods: Analysis of clinical and genetic profile of patients with GCH1 pathogenic variants.

Results: Six female patients, from two families, were identified. Onset occurred in childhood, at 6.8 (±1.09) years. Presenting symptoms included foot dystonia ($n=5$, from the same family) and SP ($n=1$). Only dystonic patients had clinical deterioration throughout the day. There was progressive worsening over the years, into generalized dystonia, and marked SP. Clinical diagnosis, when observed at our center, was achieved 31.4 (±6.98) years after onset. Five, with dystonia, were treated with 200mg sustained-released levodopa/carbidopa and one, with SP, with 400mg immediate-release levodopa/carbidopa. All had major clinical improvement: dystonia resolution; improvement in spasticity and disappearance of Babinski and Trommer-Hoffman signs. With 24.0 (±16.4) years of follow-up, all retained clinical benefit. Dystonic patients were studied through single-gene testing of GCH1 [c.410T>A (p. (Met137Lys)], and SP with multigene panel for hereditary SP [c.541+1G>T (r.(spl))]. CSF analysis ($n=1$) disclosed reduced 5-HIAA level, increased HVA/5-HIAA ratio, 3-OMD, 5-OHTrp, reduced Pterins.

Conclusion: In our case-series the majority had a typical phenotype, of dopa-responsive dystonia, but an atypical presentation was also observed. Clinical diagnosis and treatment were only established three decades after onset, but still a dramatic response was observed. With this work we wish to contribute into the characterization of a treatable movement disorder.

Disclosure: All authors declare that they have no conflicts of interest related to the manuscript.

EPO-164 | A tablet based on artificial intelligence system to differentiate between Essential Tremor and Parkinson's disease

S. Sellami; N. Farhat; K. Moalla; N. Bouattour; S. Daoud; S. Sakka; M. Damak; C. Mhiri

Department of Neurology and Research Laboratory LR12SP19, Habib Bourguiba University Hospital, Sfax, Tunisia

Background and Aims: Patients with Essential Tremor were initially considered to have isolated tremor, but additional motor and non-motor features have been increasingly recognized. The term "Essential Tremor Plus" have started to be described in recent years with overlapping features that can make it difficult to differentiate between Essential Tremor (ET) and Parkinson's disease (PD). This study aims to evaluate on discriminatory features among ET and PD patients using handwriting analysis based on machine learning model.

Methods: We included a total of 90 participants: 30 ET, 30 PD and 30 age-gender matched controls. All participants were asked to perform five different handwriting tasks on a digitizer tablet recording various signals which are x-position, y-position and pressure. The tasks included drawing repetitive ellipses, spiral, repetitive digits and Latin character 'l' continuously eight times. Movement time, velocity and the size of writing were analyzed to characterise handwriting patterns and to compare between ET and PD patients.

Results: The results from this study showed that PD patients perform movements significantly slower than ET ($p=0.01$). Median time per repetition, median velocity and median acceleration of the 'l' task differed significantly between ET and PD ($p<0.05$). PD patients also produced smaller handwriting than ET as represented by smaller average width and height of the repetitive 'l' task compared to ET group ($p=0.035$).

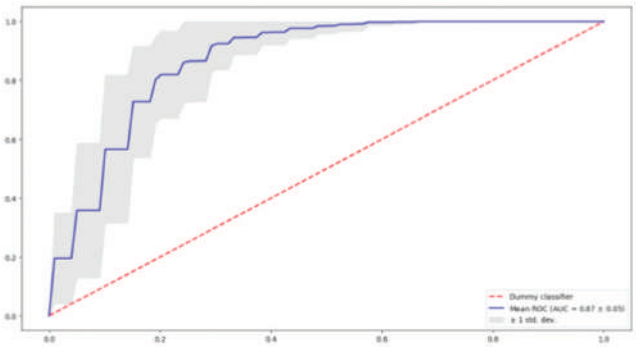
Conclusion: We present a novel machine learning model that can serve as a complementary and promising support tool for the clinical diagnosis of ET and to differentiate between PD and ET.

Disclosure: Nothing to disclose.

EPO-165 | Differential diagnosis model in parkinsonian syndromes from calibrated diffusion tensor imaging

M. Grange[1]; L. Chougar[2]; J. Martini[1]; D. Grabli[2]; F. Cormier[3]; M. Vidailhet[2]; J. Corvol[2]; B. Degos[4]; V. Perlbarg[1]; S. Lehéricy[2]
[1]*BrainTale SAS, Strasbourg, France;* [2]*Institut du Cerveau et de la Moelle épinière – ICM, INSERM U 1127, CNRS UMR 7225, Sorbonne Université, Team "Movement Investigations and Therapeutics" (MOV'IT), Paris, France;* [3]*Clinique des mouvements anormaux, Département de Neurologie, Assistance Publique Hôpitaux de Paris, Hôpital Pitié-Salpêtrière, Paris, France;* [4]*Dynamics and Pathophysiology of Neuronal Networks Team, Center for Interdisciplinary Research in Biology, Collège de France, CNRS UMR7241/INSERM U1050, Université PSL, Paris, France*

Background and Aims: Parkinson's disease (PD) poses a diagnostic challenge due to overlapping clinical features with other neurodegenerative disorders, such as multiple system atrophy (MSA) and progressive supranuclear palsy (PSP). This study aimed at evaluating the ability of diffusion tensor imaging (DTI) biomarkers provided by brainTale-care, a CE-marked solution, to differentiate PD from MSA and PSP and deriving reliable differential diagnosis tool.
Methods: A total of 189 subjects presenting with parkinsonian symptoms (92 patients with PD, 45 with MSA and 42 with PSP) collected from three different clinical studies were included in the study. DTI data were processed by brainTale-care v3.0 (www.braintale.eu) to provide calibrated regional fractional anisotropy, radial, axial and mean diffusivity parameters. A classification model was implemented by using a support vector classifier and cross-validation procedure. Classification performances were assessed through receiver operating characteristics (ROC) analysis.
Results: The classification model between PD patients and MSA and PSP patients, achieved a mean area under the ROC curve of 0.87 ± 0.05, a mean specificity of 0.74 ± 0.10, and a mean sensitivity of 0.90 ± 0.07 (Figure 1).



Cross-validated receiver operating characteristic curve for the classification model PD versus MSA/PSP

Conclusion: This study shows that calibrated DTI biomarkers can be used to develop a classification model that efficiently differentiates patients with idiopathic PD and patients with MSA and PSP, two frequent parkinsonian syndromes. The easy access of diffusion tensor markers in clinical settings with brainTale-care platform paves the way for the use of MRI-assisted differential diagnostics in clinical settings as well as for drug development.

MS and related disorders 1

EPO-166 | BeeWellwithMS Podcast: A pioneering platform for brain health advocacy in multiple sclerosis

A. Straukiene; F. Moxon; S. Hughes
Torbay and South Devon NHS Foundation Trust

Background and Aims: In response to the escalating need for comprehensive brain health education among people with Multiple Sclerosis (MS), this study examines the effectiveness of the "BeeWellwithMS" podcast www.beewellwithms.com, an innovative platform for disseminating brain health knowledge. As an EAN-certified brain health advocate, our objective was to leverage this medium to enhance understanding and self-management of MS.

Methods: We analyzed listener engagement and feedback from the podcast, which covers diverse MS-related topics, including brain health, emotional well-being, and lifestyle modifications. The podcast's evolution since its inception in 2020 was studied, with a focus on its expansion post-2024 following the integration of EAN-endorsed brain health advocacy strategies.
Results: Since incorporating EAN-certified brain health content, the podcast witnessed exponential growth in global listenership, with a significant increase in engagement from the MS community. Qualitative analysis of listener feedback highlighted an improved understanding of brain health issues and a more proactive approach to managing MS.

Downloads in the 25 countries, geolocation

Conclusion: The "BeeWellwithMS" podcast, underpinned by EAN's brain health initiatives, has proven to be a vital tool in educating and empowering the MS community. As an EAN brain health advocate, this platform signifies a novel approach to patient education, demonstrating significant potential in enhancing the quality of life for individuals living with MS.

Disclosure: No commercial support was received for this study. The podcast functions as an independent educational platform, with content driven by the latest research and patient needs in the MS community.

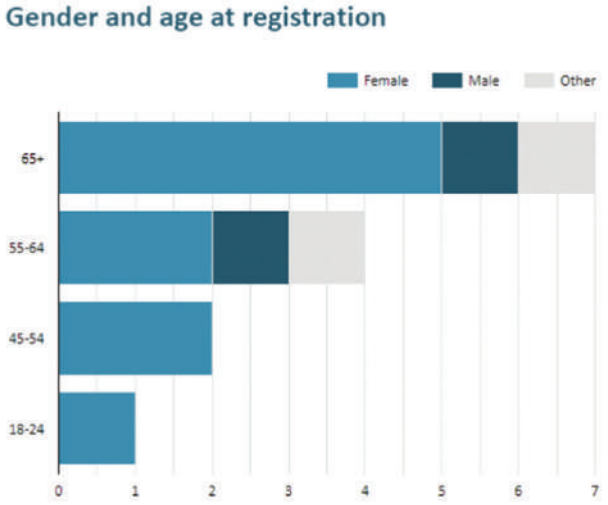
EPO-167 | Digital engagement in MS care: The impact of coordination on patient platform utilization

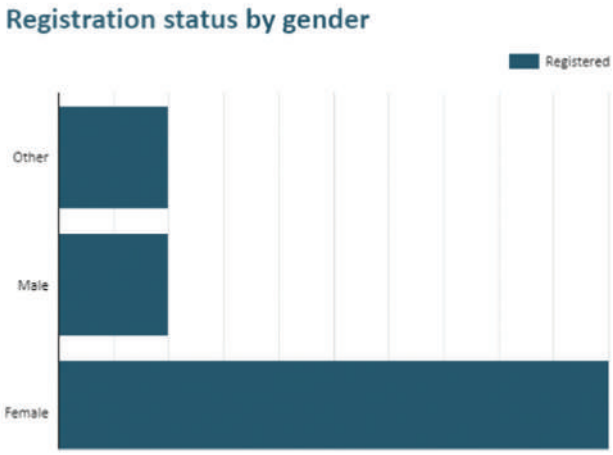
A. Straukiene; S. Hughes; F. Moxon
Torbay and South Devon NHS Foundation trust

Background and Aims: Innovative digital tools are reshaping MS care, aiming to enhance patient education and self-management. This study assesses the influence of dedicated coordination on user engagement with the MS Patients Know Best (MS PKB) platform.

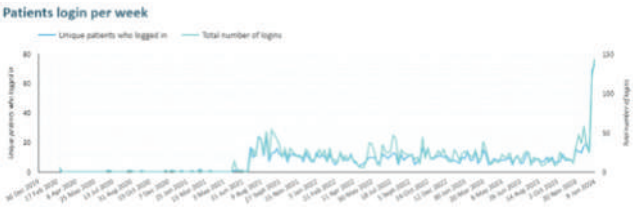
Methods: User engagement was analysed using the MS PKB dashboard, tracking weekly logins and registrations since its inception in 2016. In 2021, a dedicated coordinator role was introduced, providing personalized support and facilitating patient familiarity with the platform. Additionally, patient surveys and qualitative feedback assessments were conducted to measure user satisfaction and platform efficacy.

Results: Comparing 2016 to 2021, a substantial increase in engagement was observed. In 2016, user activity was minimal, with only 10 registered users. The appointment of a dedicated coordinator in July 2021 corresponded with an exponential increase in weekly logins to 130, a 225% rise from the preceding week, and total user registrations reached 100. A second peak in January 2024 demonstrated a further rise to 150 weekly logins. Qualitative feedback from patients showed high satisfaction, with the majority appreciating the platform's ease of use and the clarity of health information presented.

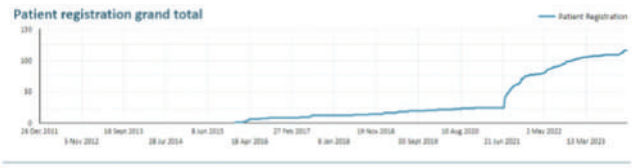




MS PKB demographics



MS PKB log in weekly



Total subscription of MS PKB

Conclusion: The implementation of a dedicated coordinator significantly boosted engagement with the MS PKB platform, as evidenced by increased logins and positive patient feedback. This suggests that

personalized guidance is crucial for maximizing the benefits of digital health tools in chronic disease management.

Disclosure: There are no financial conflicts of interest to declare. Data were sourced from hospital records within NHS guidelines.

EPO-168 | Thymic hyperplasia after autologous hematopoietic stem cell transplantation in multiple sclerosis: A case series

A. Mariottini[1]; R. Boncompagni[2]; D. Cozzi[3]; C. Nozzoli[2]; A. Repice[4]; V. Damato[1]; V. Miele[3]; R. Saccardi[2]; L. Massacesi[1]

[1]Department of Neurosciences, University of Florence, Florence, Italy; [2]Cell Therapy and Transfusion Medicine Unit, Careggi University Hosptial, Florence, Italy; [3]Department of Emergency Radiology, Careggi University Hospital, Florence, Italy; [4]Department of Neurology 2, Careggi University Hospital, Florence, Italy

Background and Aims: Reactivation of thymopoiesis in adult patients with autoimmune disorders treated with autologous haematopoietic stem cell transplantation (AHSCT) is supported by immunological studies. Thymic hyperplasia after AHSCT was previously reported in patients with systemic sclerosis, but, to our knowledge, it has not been described in multiple sclerosis (MS).

Methods: Monocentric case series of patients previously treated with AHSCT (BEAM/ATG regimen) for aggressive MS who performed a chest CT scan for clinical purposes. Chest CT exams before and after AHSCT were reviewed by a thoracic radiologist: thymic hyperplasia was defined as a rounded mass in the thymic loggia with density around 40HU and thickness >1.3cm.

Results: Fifteen MS patients were included (Table 1). The median time interval between AHSCT and CT scan was 2 (1–15) months. Thymic hyperplasia was detected in 3/15 (20%) patients in a scan taken 1 to 3 months after AHSCT; all these patients were females, and aged 30 to 40 years. Four further patients showed a thymic rebound, with increased thickness and soft-tissue lobulation. The time interval between AHSCT and CT was shorter in patients with thymic hyperplasia (median 1, range 1–2) vs those without (median 3; range 1–18); no differences in clinical-demographic characteristics were observed. All the patients were free from new focal inflammatory activity over median 36 months of follow-up (5–84).

TABLE 1 Clinical-demographic characteristics of the patients included.

	median	(range)
Age, years	40	(26 – 50)
Disease duration at AHSCT, years	16	(5 – 23)
Number of previous disease modifying treatments	3	(2 – 6)
EDSS at AHSCT	5.0	(1.5 – 6.5)
Time AHSCT – chest CT, months	2	(1 – 18)
	n	(%)
Sex, female	13	(87%)
MS form, relapsing-remitting	7	(47%)

Conclusion: Thymic hyperplasia was observed in 20% of MS patients recently treated with AHSCT. Our results suggest that AHSCT may promote thymic reactivation in MS patients, further supporting de-novo thymopoiesis as a cornerstone of immunoreconstitution after AHSCT.

Disclosure: Nothing to disclose.

EPO-169 | Treatment with anti-CD20 monoclonal antibodies after alemtuzumab in patients with relapsing-remitting multiple sclerosis

A. Llanes Ferrer[1]; D. Pérez Gil[1]; M. Espiño Martínez[2]; E. Rodríguez Martín[2]; A. Rodero Romero[2]; J. Fernández Velasco[2]; B. Martínez García[1]; P. Garay Albízuri[1]; R. Sainz Amo[1]; F. Rodríguez Jorge[1]; S. Sainz de la Maza[1]; E. Monreal Laguillo[1]; J. Masjuan[1]; M. Villar[2]; L. Costa Frossard[1]; J. Chico García[1]

[1]Neurology Department, Hospital Ramón y Cajal, Madrid, Spain; [2]Immunology Department, Hospital Ramón y Cajal, Madrid, Spain

Background and Aims: The aim of this study is to describe our experience using anti-CD20 monoclonal antibodies after alemtuzumab treatment failure in patients with relapsing-remitting multiple sclerosis (RRMS).

Methods: Retrospective study including patients with high activity RRMS that received anti-CD20 monoclonal antibodies after alemtuzumab. Clinical and paraclinical data were reviewed, including lipid-specific oligoclonal IgM bands (LS-OCMB), plasmablasts over total peripheral blood mononucleated cells (PB/PBMC) before alemtuzumab first administration, B-lymphocytes over total lymphocytes (BL) before anti-CD20 initiation, and light chain neurofilaments in serum (sNfL), at baseline, 6 month and 1 year follow-up with anti-CD20 treatment. BL threshold was stablished at 15%, PB/PBMC at 0.1%, and sNfL at 10pg/ml.

Results: Twelve patients were included [75% women, 35.78 (26.7–41.3) years-old]. Patients received a median of 2 (2–3) cycles of alemtuzumab. An anti-CD20 was initiated because of severe disease exacerbation (relapses and/or new lesions on MRI). Nine patients received ocrelizumab, 2 ofatumumab, and 1 rituximab. At baseline, 3/11 (27.3%) had a median of 7 (1–14) gadolinium-enhancing lesions. All patients who underwent lumbar puncture (10/12) had LS-OCMB, 6/7 had PB/PBMC >0.1%, and 6/12 had baseline BL>15% (data of high B-cell activity). sNfL were elevated in 4/10 and normalized after 6 months of anti-CD20 therapies. Eight completed 1 year follow-up. Of them, 3 patients had new non-enhancing lesions, one with a relapse. None experienced confirmed disability progression. Five (62.5%) achieved NEDA3. Three patients developed hypogammaglobulinemia with no serious infections.

Conclusion: In our series, anti-CD20 monoclonal antibodies were a safe and effective alternative for RRMS patients with uncontrolled disease after alemtuzumab.

Disclosure: The authors report no relevant conflict of interest regarding the current study. JLCG has received honorary for speaking

engagements or consulting services from Biogen, Bayer, Bial, Bristol-Myers, Johnson&Johnson and Sanofi-Genzyme. RSA has received honorary for speaking engagements from Johnson&Johnson. EM received research grants, travel support or honoraria for speaking engagements from Biogen, Merck, Novartis, Roche, Almirall, Janssen, Bristol-Myers Squibb, and Sanofi-Genzyme. EPO-170 | Neutropenia following ocrelizumab exposure in patients with multiple sclerosis: A single-center retrospective study

A. Favero[1]; L. Rossi[1]; A. Sartori[1]; A. Dinoto[2]; S. Baldini[1]; A. Bratina[1]; A. Bosco[1]; P. Manganotti[1]

[1]Clinical Unit of Neurology, School of Neurology, Department of Medicine, Surgery and Health Sciences, University Hospital and Health Services of Trieste, ASUGI, University of Trieste, Trieste, Italy; [2]Neurology Unit, Department of Neuroscience, Biomedicine and Movement Sciences, University of Verona, Verona, Italy

Background and Aims: Aim of this study is to describe the occurrence of neutropenia, defined as a reduction of the absolute neutrophil count below 1.5×10^3/uL, during treatment with ocrelizumab in patients with multiple sclerosis (pwMS), as a single-center experience.

Methods: We retrospectively analyzed blood test including white blood cells count in particular neutrophils, lymphocytes and their subpopulation in consecutive pwMS at 1st, 3rd and 6th month after ocrelizumab infusions. Clinical and paraclinical variables were collected.

Results: Seventy-four pwMS were enrolled. 88% was affected by a relapsing-remitting form; 20% was treatment-naïve and 40.5% switched from a first line therapy. Among our cohort, eight patients (10.8%) developed neutropenia. In three cases neutropenia was severe, down to $0.08\times10^3/\mu$L. In six patients, neutropenia was registered one month after the infusion, whereas in two cases after 5 and 6 months, respectively. None of them developed any infection during neutropenia. In two cases G-CSF were administered after hematological evaluation. No MS relapses were reported during the treatment period.

Conclusion: Neutropenia after ocrelizumab treatment occurred in more than 10% of cases and it was usually observed within the first month after administration. In our cohort, all patients were asymptomatic and did not report viral or bacterial infections. Despite the quite frequent occurrence of neutropenia, our data confirm the safety of the medication under study, confirming previous data from literature.

EPO-171 | Early on-treatment NfL levels are associated with MRI changes up to 4 years in dimethyl-fumarate treated RRMS patients

T. Sejbaek[1]; N. Pedrosa de Barros[2]; A. Ribbens[2]; J. B. Lewin[3]; J. P. Mendoza[3]; R. Antulov[4]; Z. Illes[5]

[1]Neurology, Esbjerg Hospital, University Hospital of Southern Denmark, Esbjerg, Denmark; [2]icometrix, Leuven, Belgium; [3]Biogen, Cambridge, MA, USA; [4]Department of Regional Health Research, University of Southern Denmark, Esbjerg, Denmark; [5]Neurology, Odense University Hospital, Odense, Denmark

Background and Aims: Dimethyl fumarate (DMF) is widely used in the treatment of relapsing MS and has shown a significant reduction in neurofilament light chain (NfL) levels in CSF and blood. Understanding the relationship between NfL and MRI biomarkers may help improve management of DMF-treated patients.

Methods: The study included 42 treatment naïve newly diagnosed RRMS patients from the TREMEND phase IV trial (EudraCT 2014-000254-11). Plasma NfL and GFAP levels were measured using Simoa at baseline, month 6, 12 and 24. MRI data from baseline and up to year 4 since DMF initiation were included in the analysis. Annualized percent brain volume change (aPBVC) and lesion volume changes were determined with icobrain. Association between biomarkers was assessed with a generalized-linear-model with age as a covariate.

Results: Associations between plasma biomarkers and atrophy and lesion changes are respectively shown in Figures 1 and 2. From these, a few results seem to indicate a predictive value of plasma biomarkers in terms of brain atrophy and lesion changes. More specifically, NfL at 12 months was associated with brain atrophy measured with MRI available between year 1 and 4. Additionally, NfL at 6 months was associated with new and enlarging lesion volume at 2 and 3 years.

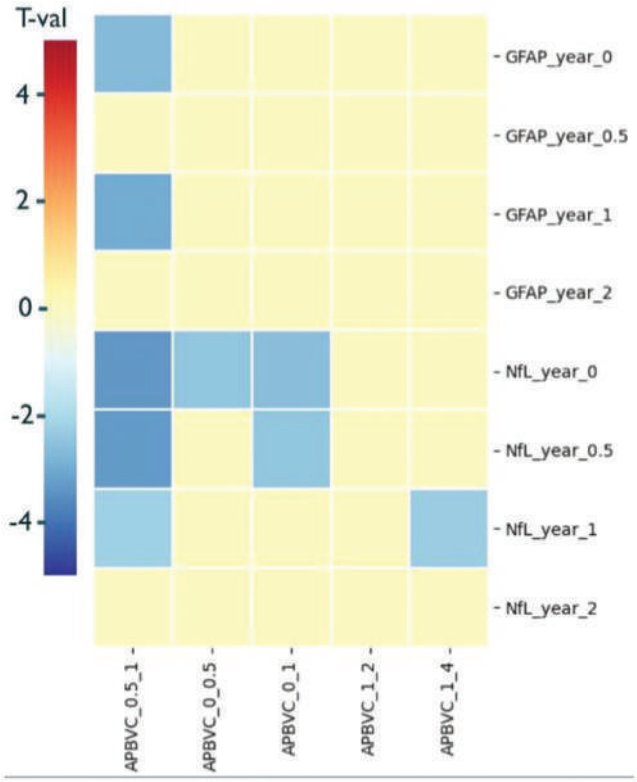

FIGURE 1 Associations between aPBVC measured in different intervals and plasma biomarkers collected at baseline, 6, 12 and 24 months. Only values with $p < 0.05$ shown.

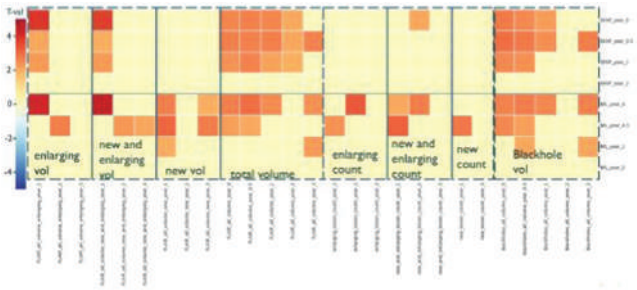

FIGURE 2 Associations between lesion volumes and plasma biomarkers collected at baseline, 6, 12 and 24 months. Only values with $p < 0.05$ shown.

Conclusion: In DMF-treated patients, higher plasma-NfL levels measured between 6 and 12 months are associated with subsequent lesion activity and brain atrophy, suggesting that NfL could be used additionally to MRI in the management of MS.

Disclosure: TS received travel grants from Biogen, Merck, Novartis and Roche, and research grants from Biogen, and served on advisory boards for Biogen, Merck and Novartis. NB and AR are employees of and hold stock/stock options in icometrix. JPM and JBL are employees of and hold stock/stock options in Biogen. EPO-172 | Lesion parenchymal fraction as empirical support for the topographical model in MS

T. Billiet[1]; N. de Barros[1]; C. Maes[1]; T. Phan[1]; W. Van Hecke[1]; A. Ribbens[1]; T. Wang[2]; K. Kyle[2]; L. Ly[2]; J. Garber[3]; M. Barnett[4]; S. Krieger[5]

[1]icometrix, Leuven, Belgium; [2]Brain and Mind Centre, University of Sydney, Sydney, NSW, Australia; Sydney Neuroimaging Analysis Centre. Sydney, NSW Australia; [3]Brain and Mind Centre, University of Sydney, Sydney, NSW, Australia; Department of Neurology, Westmead Hospital, Sydney, NSW, Australia; [4]Brain and Mind Centre, University of Sydney, Sydney, NSW, Australia; Department of Neurology, Royal Prince Alfred Hospital, Sydney, NSW, Australia; Sydney Neuroimaging Analysis Centre. Sydney, NSW Australia; [5]Department of Neurology, Icahn School of Medicine at Mount Sinai, New York, NY, USA

Background and Aims: The topographical model of MS postulates that a combination of parenchymal tissue atrophy and lesion topography contribute to a patient's disability trajectory. We previously showed that the lesion parenchymal fraction (LPF = lesion load/parenchymal volume ratio) is a useful MRI correlate of MS clinical symptoms (Fig.1). Here we validate the differential impact between cerebral, infratentorial and cervical LPF for explaining disability.

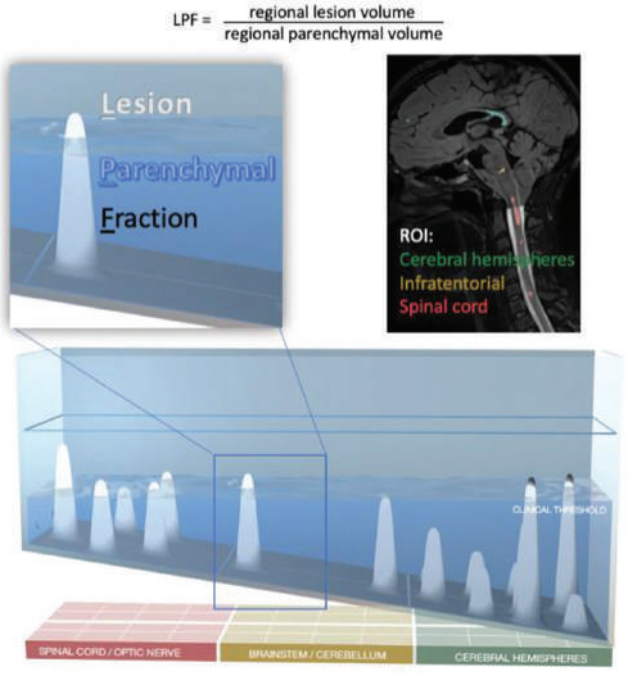

FIGURE 1 In the topographical model, the functional reserve is a water basin. Lesions (peaks) can cause clinical symptoms when crossing its surface. Lesion Parenchymal Fraction combines peaks (lesion volume) and water (parenchymal volume) in a single variable.

Methods: 78 MS patients with RRMS and SPMS were included (Table 1). Icobrain was used to measure T2-FLAIR lesions and parenchymal volumes on brain MRI, and adapted to measure T2 lesion volumes and mean upper cervical cord area. Per patient in the sample, the measurements were transformed into percentiles with respect to the remaining sample. A linear model for decoding EDSS with compartmental LPFs as factors was compared to models including lesion and/or parenchymal tissue measurements considered separately. Pearson correlation and root-mean-squared error (RMSE) between estimated and true EDSS were computed.

Results: Models with lesion or parenchymal measurements alone ranked last. In contrast, the LPF-model had the lowest error (RMSE = 1.638) and high correlation ($r = 0.275$). Setting the cerebral LPF coefficient to 1 in the LPF model, the ratio of the LPF coefficients was 2.5 for infratentorial and 3.8 for cervical. An individual case is depicted using LPF in Fig.2.

TABLE 1 Patient demographics

N	78
Gender - F	64
Age at onset (years, mean ± SD [min – max])	32.2±10.0 [15.0 - 59.0]
Clinical follow-up time (years, mean ± SD [min – max])	8.2±2.6 [3.6 - 17.1]
Number of brain MRI (mean ± SD [min – max])	5.1±3.1 [1.0 - 13.0]
brain MRI follow-up time (years, mean ± SD [min – max])	3.9±2.6 [0.0 - 8.8]
Number of spinal cord MRI (mean ± SD [min – max])	5.1±3.1 [1.0 - 13.0]
Spinal cord MRI follow-up time (years, mean ± SD [min – max])	3.9±2.6 [0.0 - 8.8]
Symptoms at Onset - Supratentorial - True N	11
Symptoms at Onset - Optic Pathways - True N	25
Symptoms at Onset - Brainstem-Cerebellum - True N	14
Symptoms at Onset - Spinal Cord - True N	32

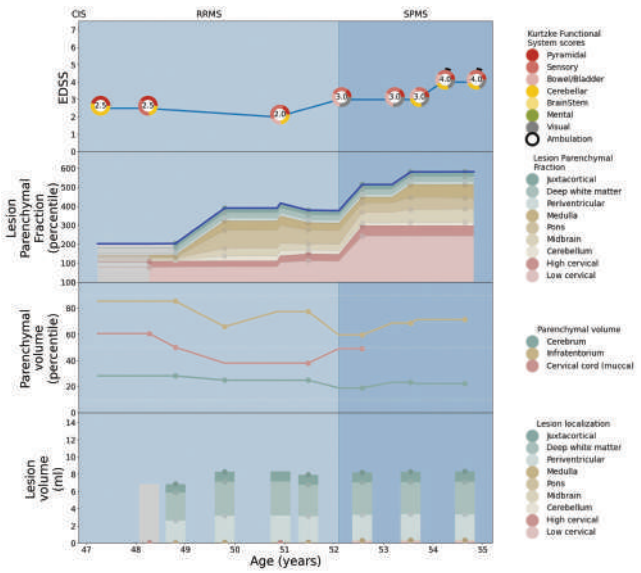

FIGURE 2 From bottom to top: Visualisation of lesion volume (bottom panel), parenchymal volume, the linear combination of local LPFs, resembling the longitudinal EDSS (top panel)

Conclusion: The results are in line with the topographical model describing proportional reserves for the spinal cord, infratentorium and cerebrum. LPF-based modelling helps explain disability by combining lesions and their topographical location with parenchymal reserve.

EPO-173 | Identifying neuropsychological multiple sclerosis phenotypes using latent profile analysis

A. Spiezia[1]; M. Petracca[2]; F. Falco[1]; F. Lamagna[3]; M. Eliano[1]; A. Esposito[1]; C. Di Monaco[1]; F. Novarella[1]; V. Nicolella[1]; M. Moccia[4]; R. Lanzillo[1]; V. Brescia Morra[1]; A. Carotenuto[1]

[1]*Multiple Sclerosis Clinical Care and Research Centre, Department of Neuroscience, Reproductive Science and Odontostomatology, Federico II University of Naples, Naples, Italy;* [2]*Department of Human Neurosciences, Sapienza University, Rome, Italy;* [3]*Department of Psychology, Università degli Studi della Campania L. Vanvitelli;* [4]*Laboratorio di Citometria Clinica e Sperimentale CEINGE-Biotecnologie Avanzate Franco Salvatore*

Background and Aims: Multiple sclerosis (MS) patients may present with a high variability in cognitive and psychological (i.e. depression and fatigue) impairment. However, clinic-demographic features underpinning such variability are still lacking. Hence, phenotypic classification base on clinic-demographic features could alert clinicians for a close monitoring on these disability aspects of the disorder.

Methods: In this mono-centric cross-sectional study, we collected clinico-demographic and neuropsychological data for each MS patients. Neuropsychological assessment included BICAMS battery, Beck Depression Inventory and Modified Fatigue Impact Scale. We employed a latent profile analysis (LPA) to unveil latent neuropsychological phenotype in MS patients clustering individuals in unobserved groups.

Results: We enrolled 600 MS patients. Using LPA, we unveiled five neuropsychological phenotype: 1) unaffected patients, with normal cognitive and psychological scores; 2) mild Cognition Impairment,

showing mild reduction in cognitive scores; 3) mild-to-severe psychological impairment, showing increased psychological scores with normal cognitive scores; 4) mild neuropsychological impairment, showing mildly reduced cognitive scores, and increased psychological scores; 5) severe neuropsychological impairment, showing severely reduced cognitive scores, and increased psychological scores vs unaffected patients. Overall, cognitive and psychological impairment increases with physical disability. Older age is a determinant for psychological impairment independent from cognitive impairment. Relapsing-remitting and paediatric-onset patients are more likely in the unaffected and mild cognition impairment class, whilst progressive patients were mostly allocated in neuropsychological impaired class.

Conclusion: We identified five neuropsychological phenotypes in patients with MS that showed distinct clinical features. Clinicians should closely monitor neuropsychological disability level in patients with that specific characteristic.

Disclosure: All authors have nothing to disclose.

EPO-174 | Effect of siponimod on lymphocyte subsets in active secondary progressive multiple sclerosis and clinical implications

A. Spiezia[1]; G. Scalia[2]; M. Petracca[3]; D. Caliendo[1]; M. Moccia[4]; A. Fiore[2]; V. Cerbone[2]; R. Lanzillo[1]; V. Brescia Morra[1]; A. Carotenuto[1]

[1]*Multiple Sclerosis Clinical Care and Research Centre, Department of Neuroscience, Reproductive Science and Odontostomatology, Federico II University of Naples, Naples, Italy*; [2]*Laboratorio di Citometria Clinica e Sperimentale CEINGE-Biotecnologie Avanzate Franco Salvatore*; [3]*Department of Human Neurosciences, Sapienza University, Rome, Italy*; [4]*Department of Molecular Medicine and Medical Biotechnology, Federico II University of Naples, Italy*

Background and Aims: Circulating immune cells play a pathogenic role in multiple sclerosis (MS). However, the role of specific lymphocyte subpopulations is not unveiled yet. We aimed to investigate lymphocyte changes during siponimod treatment in active secondary progressive MS (aSPMS) and their associations with clinical outcomes.

Methods: We enrolled 46 aSPMS patients with 2-year follow-up after the start of siponimod treatment and 14 healthy controls (HCs). Clinical and laboratory data were collected at baseline, 3rd, 6th, 12nd, and 24th month for MS patients, and at baseline for HCs.

Results: At baseline SPMS patients presented with increased naïve regulatory T lymphocytes vs HCs. Over time, SPMS patients showed decreased T CD4+ (coeff.range = −24/−17), B (coeff.range = −3.77/−2.54) and CD4/CD8 ratio (coeff.range = −4.44/−0.67) from month 3 thereafter vs baseline, and reduced CD3+CD20+ lymphocytes from month 12 thereafter (coeff.range = −0.32/−0.24). Patients not experiencing disability progression while on siponimod treatment showed B reduction from month 3 (coeff.range = −4.23/−2.32) and CD3+CD20+ lymphocyte reduction from month 12 (coeff.range = −0.32/−0.24) vs patients experiencing progression.

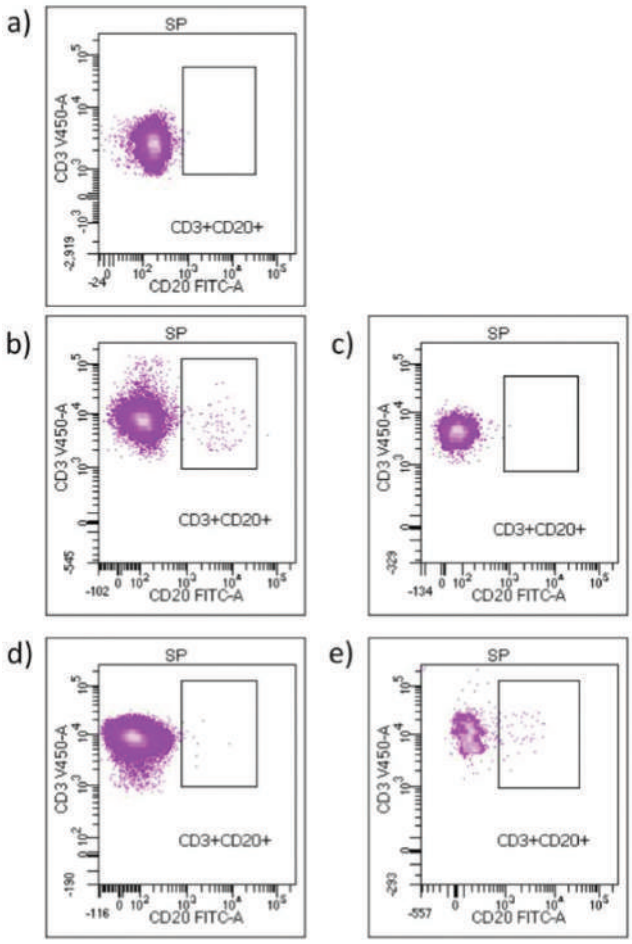

FIGURE 1 Flow cytometer dot plots. Plot of CD3+CD20+ cells in one male healthy control with no detectable cells (a), an aSPMS patient not progressing while on siponimod treatment at baseline with 0.9% CD3+CD20+ cells (b) and after 6 months from treatment

Conclusion: Patients treated with siponimod showed a T and B lymphocyte reduction, especially CD4+, CD3+CD20+, naïve regulatory T and memory regulatory B cells. Disability progression while on siponimod treatment was associated with a less pronounced effect on B and CD3+CD20+ lymphocytes.

Disclosure: MM has received research grants from the ECTRIMS-MAGNIMS, the UK MS Society, and Merck; honoraria from Biogen, BMS Celgene, Ipsen, Janssen, Merck, Novartis, Roche, and Sanofi-Genzyme. AC has received research grants from Almirall, research grants from ECTRIMS-MAGNIMS and honoraria from Almirall, Biogen, Roche, Sanofi-Genzyme, Merck, Ipsen and Novartis. EPO-175 | An atypical case of macular oedema in ozanimod

A. Bianco; T. Guerra; D. Intini; R. Vitobello; F. Oggiano; A. Manni
Department of Translational Biomedicines and Neurosciences, University of Bari Aldo Moro, Bari, Italy

Background and Aims: Macular edema (ME) is a well-established side effect of fingolimod (FTY), the first oral sphingosine 1 receptor S1PR modulator approved for MS. Ozanimod is a second-generation S1PR modulator, and it is thought to avoid some of the side effects associated with this class of drugs for its good bioavailability, high specificity and dose titration.

Methods: Our patient is a 48-year-old woman, diagnosed with RMS in 2009. She was treated with interferon beta 1a until 2013 when she switched to FTY for inefficacy. In 2016 FTY was discontinued for persistent and severe lymphopenia and interferon beta 1a was restarted. In August 2023, the patient began ozanimod after a new and symptomatic cervical lesion. However, in October, she reported a visual discomfort, therefore she underwent a complete ophthalmologic evaluation, including OCT, and was diagnosed as ME leading to ozanimod discontinuation.

Results: The incidence of FTY-associated ME in the population without pre-existing risk factors is approximately of 0.2%. ME was reported in 2882 (0.2%) participants during the ozanimod phase 3 trials, RADIACE and SUNBEAM, and in 0.4% participants during the long-term safety trial DAYBREAK. All cases of confirmed ME had pre-existing risk factors or confounding conditions. However, our patient did not present other risk factors and her pre-ozanimod ophthalmologic evaluation was normal.

Conclusion: This case highlights the risk of developing ME during ozanimod exposure. Further research is needed to better understand whether a long term exposition to different S1PR, with different drug sequencing, may be associated with higher risk of ME.

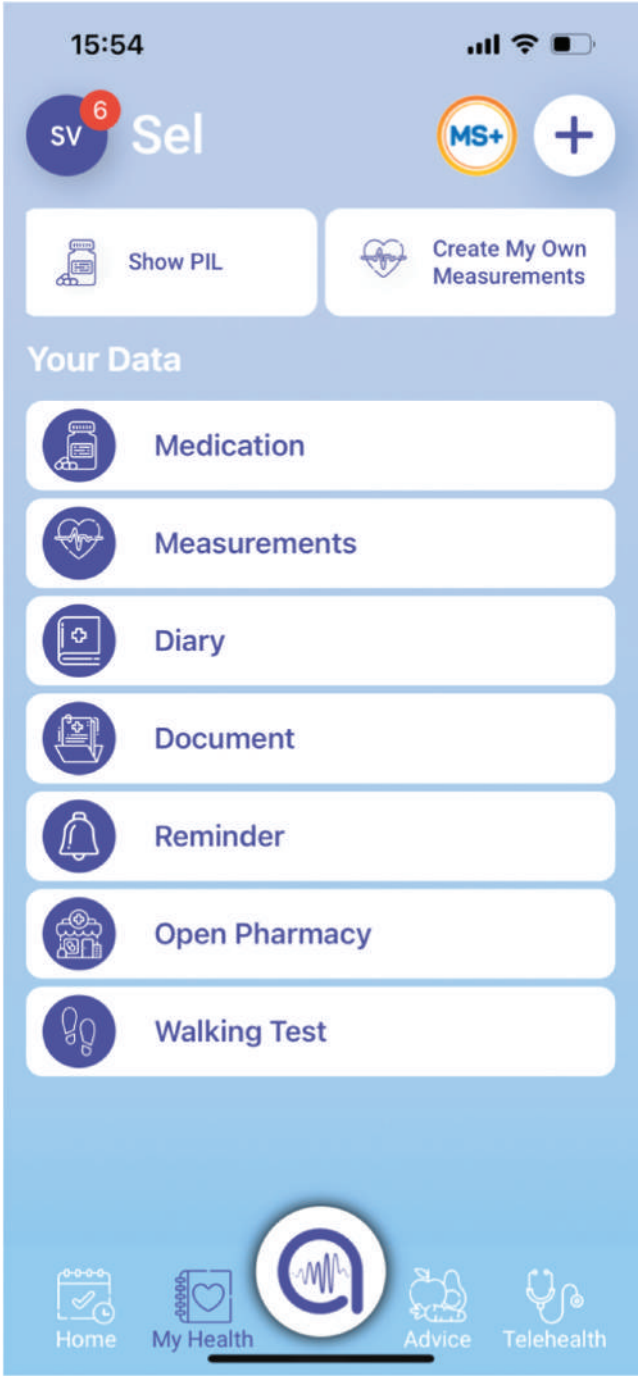
Disclosure: Dr Iaffaldano received personal fees from Merk, Novartis, Biogen, Roche, Alexion and Genzyme. Dr. Manni received compensation for travel grants, participation in advisory board and/or speakink activity from Biojen, Merck Serono, Sanofi, Novartis, Bristol MS, Janssen and Roche. Dr Paolicelli received personal fees from Sanofi, Merk, Biojen and Janssenn. Dr Bianco, Dr Guerra, Dr Intini, Dr Vitobello and Dr Oggiano have nothing to disclose.

EPO-176 | Validation study of a mobile app-based six-minute walking test compared to smartwatch measurements introduction

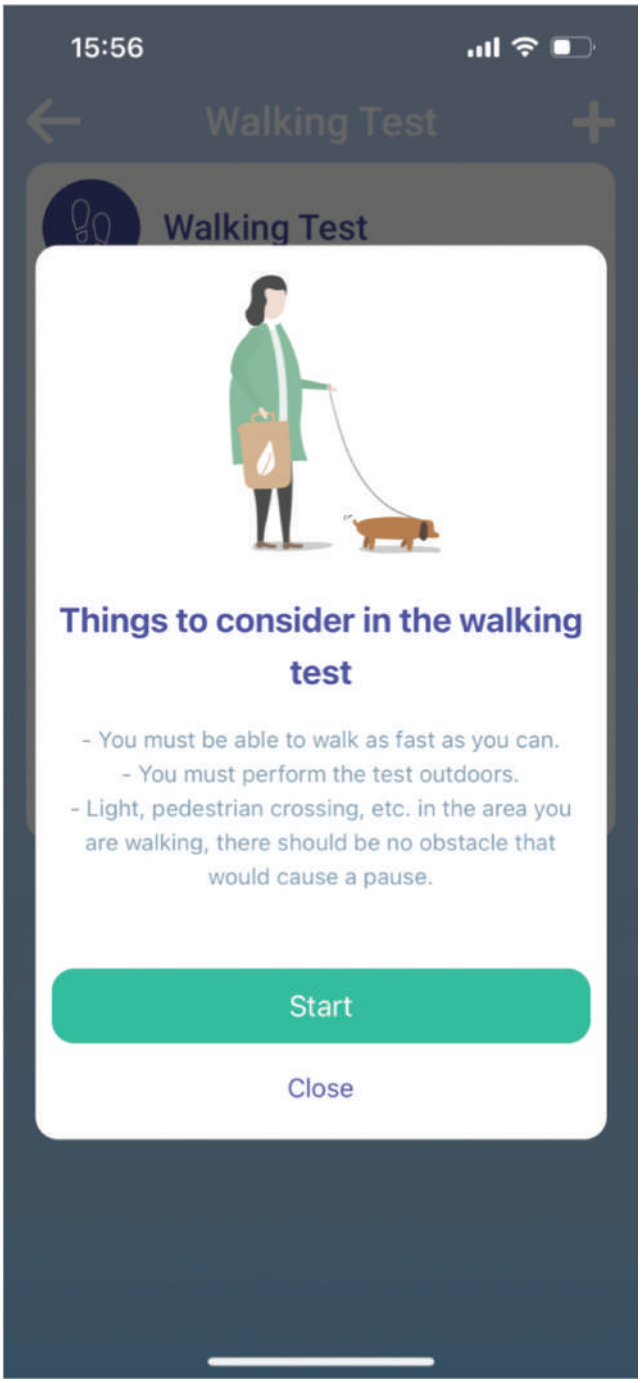
S. Demir[1]; E. Guven[2]; S. Colakoglu[2]; C. Benli[1]; Z. Polat[2]; M. Tutuncu[3]
[1]*University of Health Science, Sehit Prof.Dr.Ilhan Varank Sancaktepe Training and Research Hospital Department of Neurology;* [2]*Albert Heath Ltd, Clinical Development & Research;* [3]*Istanbul University – Cerrahpasa, Department of Neurology*

Background and Aims: The study focuses on validating a mobile app-based Six-Minute Walking Test (6MWT) by comparing its results with those obtained from a smartwatch in healthy adults. The aim is to measure the accuracy and reliability of the app-based 6MWT for potential clinical application in monitoring patients with chronic conditions like Multiple Sclerosis (MS)

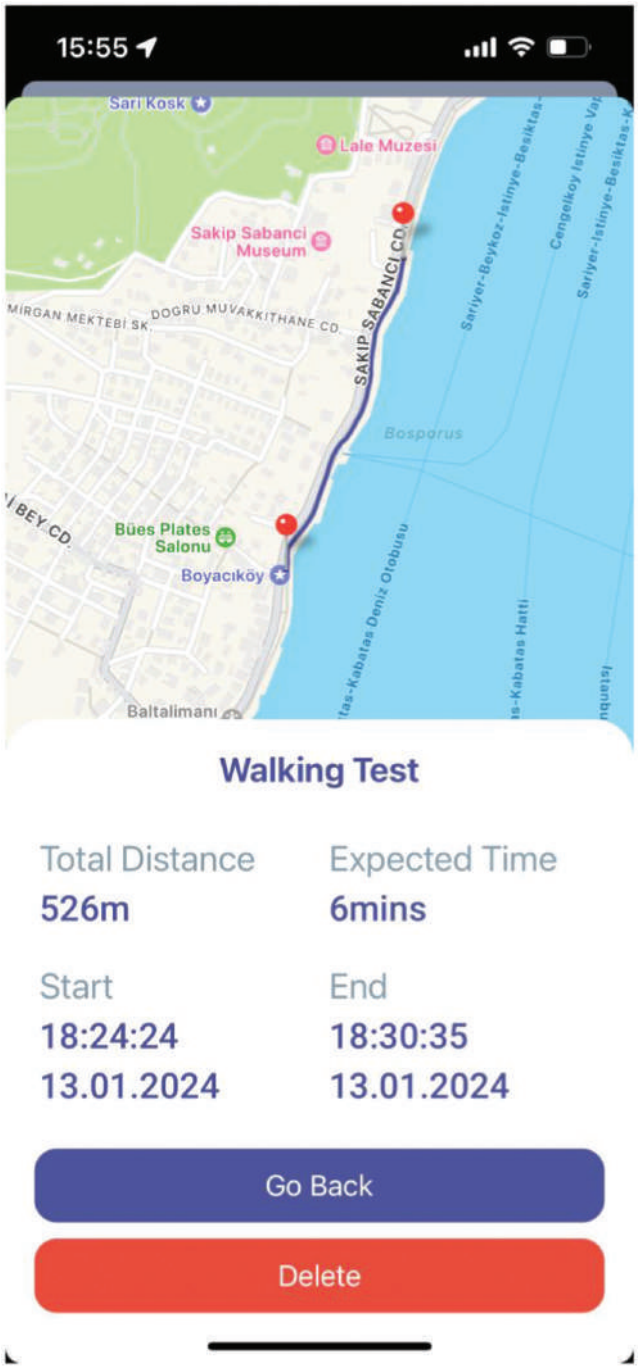
Methods: Twenty-one healthy adults with no comorbidities participated. E 6MWT performed using a mobile app (Albert Health / MS+) and a smartwatch (Apple Watch 7 or higher) two times. The smartwatch's accuracy was validated separately on a 150-meter course. Descriptive statistics and paired t-tests are used to compare the standard deviation and correlation between the app and smartwatch results.



Button of Test at App



Test guideline



Result of a patient

Results: The app-reported walking distance decreased by 13.62 meters on average (SD = 39.99 meters), whereas the smartwatch showed a smaller average decrease of 3.81 meters (SD = 13.22 meters) between the tests. Strong positive correlations were observed between the app and smartwatch in the 6MWT (Test 1: $r = 0.844$; Test 2: $r = 0.865$). Despite a slight decrease in mean walking distances over time, no statistically significant changes were noted (app p-value = 0.134, smartwatch p-value = 0.202).

Conclusion: The findings support that the app can be a reliable and accessible tool for assessing walking capacity, especially in clinical settings for managing chronic diseases like MS. Further research involving patients with MS is recommended to confirm the app's effectiveness in a clinical context.

Disclosure: Nothing to disclose.

EPO-177 | Calf muscles echo intensity in multiple sclerosis patients with lower limb spasticity treated with botulinum toxin

E. Bianchini[1]; A. Massimiani[1]; M. Nasello[1]; M. Buscarinu[2]; M. Salvetti[1]; M. Giovannelli[2]
[1]*Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Sapienza University of Rome, Rome, Italy*; [2]*Neurology Unit, Sant'Andrea University Hospital, Rome, Italy*

Background and Aims: Lower limb spasticity (LLS) is common in people with multiple sclerosis (PwMS). Previous studies suggested that muscle echo intensity could affect the efficacy of botulinum neurotoxin A (BoNTA) treatment and altered calf muscles echo-intensity was reported in children with cerebral palsy and post-stroke patients with LLS. However, this was not investigated in PwMS.
Methods: Muscle tone and echo intensity of gastrocnemius lateralis (GL), gastrocnemius medialis (GM) and soleus muscles were assessed in 19 PwMS through the modified Ashworth scale (MAS) and the modified Heckmatt scale (mHS), respectively. Patients were dichotomized into those who underwent BoNTA treatment for ≥ 3 sessions (longer group, median duration of treatment 78 months, $N = 11$) or < 3 sessions (shorter group, median duration of treatment 7 months, $N = 8$). The difference between each pair of muscles in terms of MAS and mHS in the overall population and in both subgroups was evaluated.
Results: A significantly higher mHS score in GM compared to soleus was found in the overall population and both subgroups. A significantly higher mHS score in GL than in soleus was found in the overall population and in the shorter group but not in the longer group. No difference was found between GM and GL in terms of mHS and between all pair of muscle in terms of MAS.
Conclusion: In PwMS with LLS, GL and GM showed a higher echo intensity than soleus irrespective of BoNTA treatment duration. This preliminary observation could stimulate research on muscle alterations in PwMS and its potential effect on BoNTA efficacy.
Disclosure: Nothing to disclose.

EPO-178 | Framingham risk score and patient determined disease steps in relapsing remitting multiple sclerosis

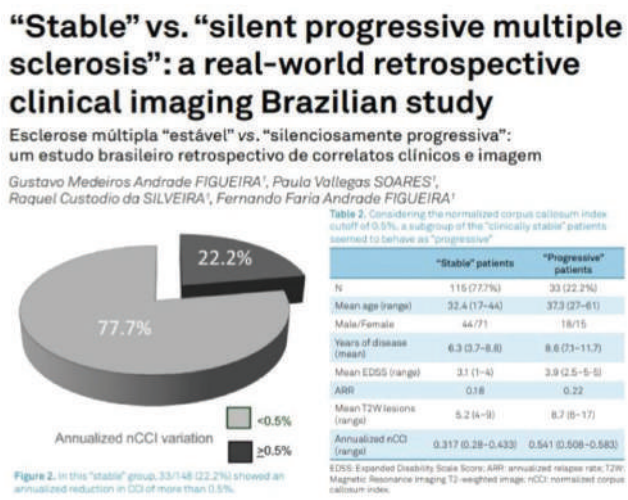
E. D'Amico; P. Di Filippo; C. Avolio; A. Zanghì
University of Foggia, Italy

Background and Aims: The associations between Multiple Sclerosis (MS) and cardiovascular diseases drawn from epidemiological studies have attracted much attention in the recent years.
Methods: The present study employed a monocentric, observational, retrospective cohort design. The primary study outcome was to describe in a cross-sectional fashion the FRS rate in our cohort of relapsing remitting MS patients regularly followed up and then, if any, to find association with patients. Patient Determined Disease Steps (PDDS). Cardiovascular risk was classified as follow: low if the FRS is less than 10%, moderate if it is 10% to 19%, and high if it is 20% or higher.
Results: s 229 were enrolled. The sample consists of 163 women (71.2%). FRS categories were distributed as follow: 97 (42.3%) patients had low FRS, 84 (36.7%) patients had moderate FRS and 48 (21%) patients had high FRS. In the univariable ordinal regression analysis, one point increase in the PDDS scale was associated with 24% risk of high FRS (vs low) (proportional OR = 2.426, 95% CI 1.660–3.545; $p < .0001$). The results were confirmed also by EDSS score, with one point increase in the EDSS score was associated with 19% risk of high FRS (vs low) (proportional OR = 1.953, 95% CI 1.429–2.669–1.04; $p < .0001$).
Conclusion: the FRS demonstrated an association with the patients 'perception of the disease as indicated by the PDDS. Careful attention should be given to addressing and treating cardiovascular risk factors, in addition to implementing lifestyle changes, when managing MS in the long term
Disclosure: Nothing to disclose.

EPO-179 | Silent progressive brain atrophy in clinically stable neuromyelitis optica a comparative proof-of-concept study

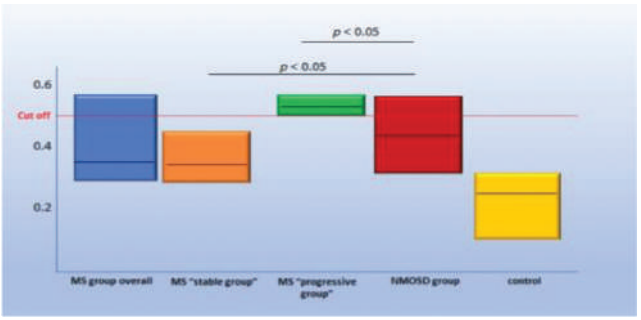
G. Medeiros Andrade Figueira; F. Faria Andrade Figueira; P. Vallegas Soares; R. Custodio Silveira; V. Tavares Carvalho Crelier; A. Seide Cardoso Vidal; M. Nunes Ferreirinha Leite de Castro
Hospital São Francisco

Background and Aims: Recently we demonstrated progressive corpus callosum atrophy occurring even in clinically stable multiple sclerosis (MS) patients, but literature data on brain atrophy in neuromyelitis optica spectrum disorder (NMOSD) patients are still scarce.
Methods: We compared longitudinal MRI data of 14 NMOSD (Wingerchuk, 2015), 148 relapsing remitting MS (McDonald 2001), and 23 control patients, followed regularly with clinical and imaging studies available on baseline and 5 years. All patients had at least 3 conventional MRI available studies with proper protocol leading to a reliable evaluation of activity and progression in at least 5 years. Clinical evaluation included annualized relapses rate and EDSS evolution at least annually, for at least 5 years. MRI data included gadolinium positive lesions or new/enlarging T2W lesion as well as the annualized evolution of corpus callosum index (CCI), measured as previously described.
Results: Patients with NMOSD were older and had EDSS scores higher than MS patients. Their mean CCI annual reduction was 0.477, ranging from 0.372 to 0.569, close to cut off and values situated between the stable and the progressive MS group.



Figueira G., et al. Arq Neuropsiquiatr 2022;80(4):405–409

Corpus callosum index (CCI): a two-dimensional measurement using an orthogonal semi-automated linear model, applied to a conventional mid-sagittal T1W MRI sequence. Figueira F., et al. Arq Neuropsiquiatr 2007;65(4-A):931–935



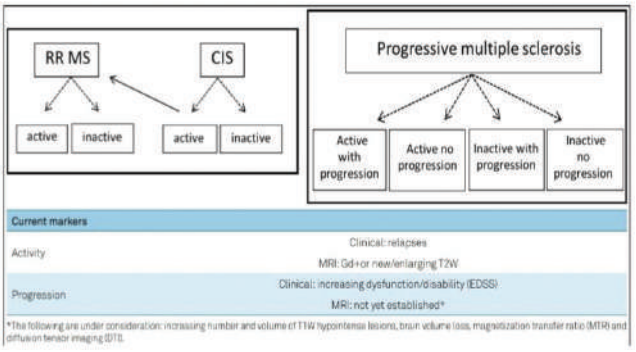
On NMOSD stable group mean CCI annualized reduction was 0.477 (range = 0.372 to 0.569), close to cut off and values were situated between the stable and the progressive MS group

Conclusion: In this small sample of 14 apparently "stable" NMOSD patients over 7 years follow up period, CCI was able to detect a reduction quite similar to that we see on relapsing remitting MS ones. More robust data are required, with a more significant sample, stratifying for clinical phenotypes and serologic status, but it seems reasonable to state that brain volumetry technique might be a useful tool for monitoring the real state of treatment response.
Disclosure: Nothing to disclose.

EPO-180 | "Stable" vs. "silent progressive multiple sclerosis": A real world retrospective clinical imaging Brazilian study

G. Medeiros Andrade Figueira; F. Faria Andrade Figueira; P. Vallegas Soares; R. Custodio Silveira; V. Tavares Carvalho Crelier; M. Nunes Ferreirinha Leite de Castro
Hospital São Francisco

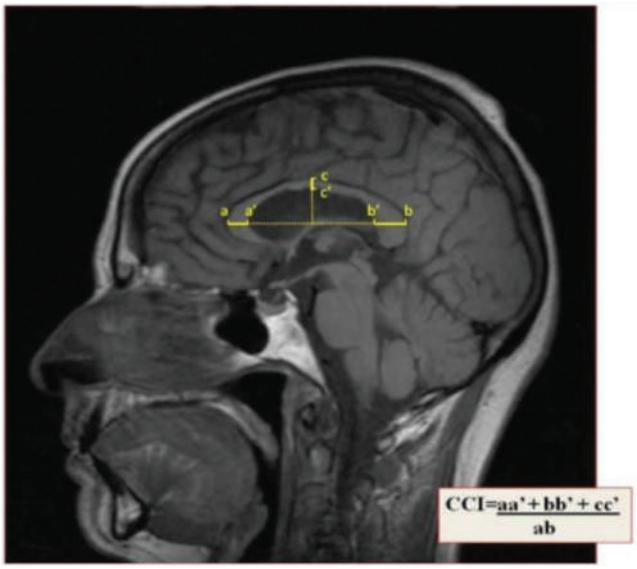
Background and Aims: Clinical and imaging are required to characterize activity and progression in MS. Parameters for activity are well defined but not progression ones. Ideal target for long term treatment includes neither clinical nor imaging signs of disease as well as no brain atrophy.



New MS phenotypes propose clinical and imaging requirements to characterize activity and progression in MS patients.

Methods: Comparative clinical-imaging study focusing on MRI brain volumetry. 174 consecutive relapsing remitting MS patients (McDonald 2001) were studied focusing on activity and progression. Annual clinical evaluation (relapse rate and EDSS) and MRI data as well as annualized evolution of corpus callosum index (CCI) were compared.

Results: From 174 patients 148 were considered clinically "stable" based on EDSS. However, 33 (22.2%) out of this group showed annualized reduction of more than 0.5% on CCI, cut-off to define significant brain atrophy.



Corpus callosum index (CCI): a two-dimensional measurement using an orthogonal semi-automated linear model, applied to a conventional mid-sagittal T1W MRI sequence.

N = 115 (77.7%)	N = 33 (22.2%)
32.4 (17 - 44)	37.3 (27 - 61)
44/71 *	18/15 *
6.3 (3.7-8.8) **	8.6 (7.1-11.7) **
3.1 (1-4)	3.9 (2.5-5.5)
0.18	0.22
5.2 (4-9)	8.7 (6-17)
0.317 (0.28-0.433) **	0.361 (0.308-0.583) **

Among 148 apparently "stable" MS patients over at least 7 years follow up period, 1/5 showed significant progressive brain atrophy.

Conclusion: Among apparently "stable" relapsing-remitting MS patients, 1/5 showed significant brain atrophy over at least 7 years follow up period. We consider reasonable to suggest that MRI volume sequences should be included in follow-up protocols, providing information on the real treatment response status.
Disclosure: Nothing to disclose.

MS and related disorders 2

EPO-181 | Echopraxia, an underrecognized clinical sign in multiple sclerosis: A biological and neuroimaging framework

G. Álvarez Bravo[11]; A. Quiroga Varela[2]; A. Gifreu[1]; C. Coll[2]; A. Boix Lago[1]; A. Miguela[2]; J. Huertas[2]
[1]University Hospital Dr. Josep Trueta of Girona; [2]Unit of Neuroimmunology and Multiple Sclerosis of Girona

Background and Aims: The study investigates echopraxia, an unrecognized clinical sign, in the context of multiple sclerosis (MS) and explores its potential association with cognitive decline. Echopraxia, a developmental element in social learning, typically disappears with central nervous system maturity. While observed in dementias, Gilles de la Tourette syndrome, and schizophrenia, its occurrence in MS has not been previously documented. The study hypothesizes that echopraxia may serve as a predictor of cognitive impairment in MS patients.
Methods: The research involved 21 patients with relapsing-remitting multiple sclerosis (RRMS) at the University Hospital Dr. Josep Trueta of Girona. Two cohorts, matched for age, gender, and clinical features, were established: one with 13 RRMS patients exhibiting echopraxia (RRMSwE) and another with 11 control RRMS patients. Tractography was used to identify morphological alterations in the cingulate gyrus, a region implicated in echopraxia pathogenesis. Circulating miRNAs in plasma from MS patients with and without echopraxia were also analyzed.
Results: Patients with echopraxia, particularly those with affective disorders had lower cingulate fiber numbers. Circulating miRNA analysis revealed that miR-143-3p and miR-181c-5p were twice less abundant in RRMSwE compared to RRMS patients. These miRNAs have been associated to cognitive impairment in patients with MS.
Conclusion: Atrophy of cingulum measured by tractography might be a radiological marker of echopraxia in patients with affective disorders such as depression. Some miRNAs (miR-143-3p and miR-181c-5p) involved in the cognitive impairment associated to MS could be related to echopraxia. Thus, echopraxia emerges a potential biomarker for predicting cognitive decline in patients with RRMS.
Disclosure: Nothing to disclose.

EPO-182 | Comparing adult-onset and late-onset multiple sclerosis: A real-world study

K. Ahtinen[1]; I. Korhonen[1]; I. Rauma[1,2]; H. Kuusisto[1,2,3]
[1]*Faculty of Medicine and Health Technology, Tampere University, Tampere, Finland;* [2]*Neural Medicine Responsibility Sector, Department of Sensory, Neural, and Musculoskeletal Medicine, Neurocenter Finland, Tampere Brain and Mind, Tampere University Hospital, Wellbeing Services County of Pirkanmaa, Tampere, Finland;* [3]*Department of Health and Social Management, Faculty of Social Sciences and Business Studies, University of Eastern Finland, Kuopio, Finland*

Background and Aims: The clinical presentation of multiple sclerosis (MS) may vary according to onset age. This Finnish retrospective registry study compares clinical characteristics of older adults (65+) with adult-onset MS (AOMS, onset at 18–49 years) and late-onset MS (LOMS, onset after 50 years).

Methods: Utilizing the Finnish MS registry, we analysed data of all older adults with MS in the catchment area of Tampere University Hospital (TUH, approximately 500,000 inhabitants) as of November 5th, 2023. Exclusions comprised patients with paediatric onset MS or unknown onset age.

Results: Altogether 248/1395 (17.8%) individuals from the catchment area of TUH were included, with 207/248 (83.5%) classified as having AOMS and 41/248 (16.5%) as having LOMS. Demographic details are presented in Table 1, age distribution in Figure 1 and MS diagnoses in Figure 2. At data acquisition, most patients had a progressive disease course (160/248, 64.5%), but primary progressive MS (PPMS) was more common in LOMS (15/41, 36.6%) compared to AOMS (26/207, 12.6%). No difference in disability outcomes emerged after 65 years. Among individuals with a current or previous relapsing-remitting disease course, those with LOMS exhibited more relapses after 65 years (6/15, 40.0% of RRMS patients) than those with AOMS (11/130, 8.5% of RRMS patients). Disease-modifying therapies had been used by 49/130 (37.7%) and 8/15 (53.3%) of relapsing remitting AOMS and LOMS patients, respectively.

TABLE 1 Demographic details. AOMS, adult-onset MS; LOMS, late-onset MS; CIS, clinically isolated syndrome; RRMS, relapsing-remitting MS; SPMS, secondary progressive MS; PPMS, primary progressive MS; EDSS, Expanded Disability Status Scale.

		Data available AOMS, LOMS	AOMS (n=207)	LOMS (n=41)
Age				
At disease onset	years, mean (SD)	207; 41	36.5 (8.4)	55.2 (5.4)
At diagnosis (excluding CIS)	years, mean (SD)	207; 41	43.7 (9.9)	56.8 (7.0)
At data acquisition	years, median (min-max)	207; 41	71.7 (65.0-91.9)	77.4 (65.1-90.1)
Disease duration from onset	years, mean (SD)	207; 41	35.9 (9.7)	21.1 (8.0)

EPO-183 | Clinical presentation of multiple sclerosis in older adults

I. Korhonen[1]; K. Ahtinen[1]; I. Rauma[1,2]; H. Kuusisto[1,2,3]
[1]*Faculty of Medicine and Health Technology, Tampere University, Tampere, Finland;* [2]*Neural Medicine Responsibility Sector, Department of Sensory, Neural, and Musculoskeletal Medicine, Neurocenter Finland, Tampere Brain and Mind, Tampere University Hospital, Wellbeing Services County of Pirkanmaa, Tampere, Finland;* [3]*Department of Health and Social Management, Faculty of Social Sciences and Business Studies, University of Eastern Finland, Kuopio, Finland*

Background and Aims: Older adults (65+) with multiple sclerosis (OAwMS) may carry substantial disease burden from prior activity or progression. However, limited data exists on their characteristics. We aimed to assess the clinical presentation of OAwMS in Finland.
Methods: OAwMS treated in Tampere University Hospital (TUH), Finland, were identified from the Finnish MS registry as of 5th December 2023. Clinical variables were analysed using summary statistics.
Results: At data acquisition, the Finnish MS registry included 13,037 subjects (26.8% aged 64 or older) of which 1395 were treated in TUH. Of these, 264/1395 (18.9%) were identified as OAwMS. Table 1 and Figure 1 present clinical characteristics and age distribution. Most patients exhibited a progressive disease course at data acquisition (170/264, 64.4%). Disease-modifying therapy (DMT) had been used by 60/150 (40.8%) patients with relapsing-remitting MS (RRMS), as well as 3/40 (7.7%) patients with secondary progressive MS who lacked a previous RRMS diagnosis and 1/46 (2.2%) patients with primary progressive MS. Only one patient with RRMS was currently on disease modifying therapy (DMT). After 65, relapses occurred in 18/150 (12.0%) patients with a current or previous RRMS. The median Expanded Disability Status Scale (EDSS) at the last available visit after the age of 65 years was 6.5 (range 0–9.0). Comorbidities were present in 205/264 (77.9%) patients.

TABLE 1 Demographic details of the study sample. SD, standard deviation; CIS, clinically isolated syndrome; RRMS, relapsing-remitting MS; SPMS, secondary progressive MS; PPMS, primary progressive MS; EDSS, Expanded Disability Status Scale.

		Data available		
Age				
At disease onset	years, mean (SD)	255	38.9	(11.2)
At diagnosis (excluding CIS)	years, mean (SD)	264	45.4	(10.8)
At data acquisition	years, median (min-max)	264	72.5	(65.0-91.2)
Disease duration from onset	years, mean (SD)	255	32.4	(11.8)
Sex category		264		
Female	n (%)		185	(70.1)
Male	n (%)			
Smoking		193		
No	n (%)		116	(60.1)
Yes	n (%)		32	(16.6)
Quit	n (%)		45	(23.3)
Diagnosis / phenotype				
Initial		264		
CIS	n (%)		51	(19.3)

EPO-184 | Follow-up of NMOSD course by using sensor-based gait analysis

K. Akar[1]; H. Youssef[1]; A. Vural[2]; A. Altıntaş[2]
[1]*Movement Analysis Laboratory, Koç University Research Center for Translational Medicine (KUTTAM), Koç University, Istanbul, Turkey;* [2]*Department of Neurology, School of Medicine, Koç University, Istanbul, Turkey*

Background and Aims: Neuromyelitis Optica Spectrum Disorder (NMOSD) is a rare autoimmune astrocytopathy affecting the central nervous system. Despite advancements in targeting pathogenic factors like AQP4-IgG, understanding the clinical course during relapse-free periods and the impact on gait and balance remains underexplored. This pilot study employs sensor-based gait analysis to assess NMOSD progression over one year.
Methods: Patients diagnosed with NMOSD underwent gait and balance assessments at initial, six-month and one-year visits using APDM OPAL sensors performing 2 MWT, T25FW, and various balance tasks. Paired Student t-tests compared the first visit to six months and one year, while mixed-effects analysis and Holm-Sidak's tests assessed changes across three visits.
Results: Thirteen NMOSD patients participated, with four completing six months and three completing one-year visits. Paired t-test

showed no change in gait and balance, but a trend emerged in mixed-effect analysis, suggesting decreased double support ($p=0.09$), increased midswing elevation ($p=0.09$), increased single limb support ($p=0.07$) and decreased terminal double support phase ($p=0.08$). Most parameters were successfully matched except toe-out angle, coronal ROM, and turn angle during gait analysis. Balance parameters when eyes were closed, feet apart on foam, and feet together did not change throughout a year of analysis in three visits conducted with mixed-effect analysis.

Conclusion: This ongoing study aims to reveal sensor-based gait analysis to monitor disability in NMOSD. Continuous tracking of the disease course is essential due to unpredictable prognosis. Highlighting parameters with matching success is crucial for effective disease follow-up, urging an increase in participant numbers for robust outcomes.

Disclosure: Nothing to disclose.

EPO-185 | Seizures in inflammatory demyelinating disorders of the central nervous system

Ö. Ertürk Çetin; İ. Güngör Doğan; Ü. Zanapalıoğlu; F. Yadi; D. Çetinkaya Tezer; S. Demir

Department of Neurology, University of Health Sciences, Sancaktepe Şehit Prof Dr İlhan Varank Training and Research Hospital

Background and Aims: Multiple sclerosis (MS), neuromyelitis optica spectrum disorder (NMOSD), and myelin oligodendrocyte glycoprotein antibody associated disease (MOGAD), may be associated with acute symptomatic seizures and chronic epilepsy as well. The clinical features of the seizures and/or accompanying epilepsy seen in each disease group may vary. We aimed to describe the clinical features of seizures and epilepsy in our demyelinating patient population.

Methods: We retrospectively analyzed patients who were followed up in our tertiary referral center between 2019 and 2024. Those with a definite diagnosis of MS, NMO and MOGAD were identified. Patients who had at least one seizure before, simultaneously or after the diagnosis of demyelinating disease were included in the study.

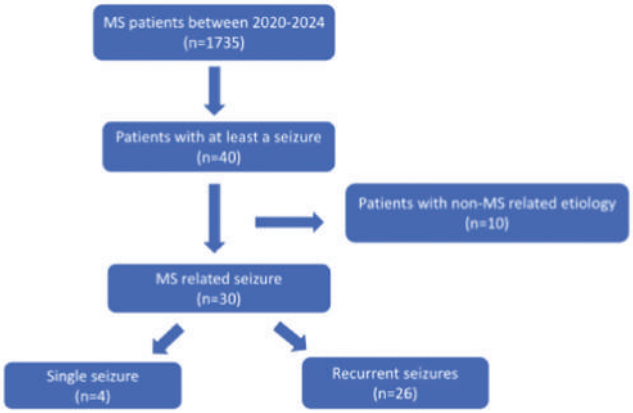

FIGURE 1

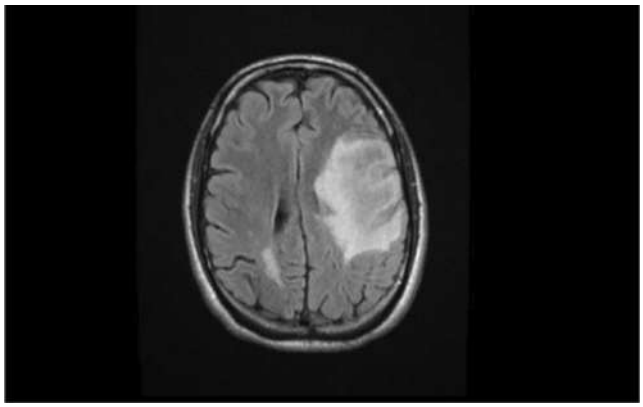
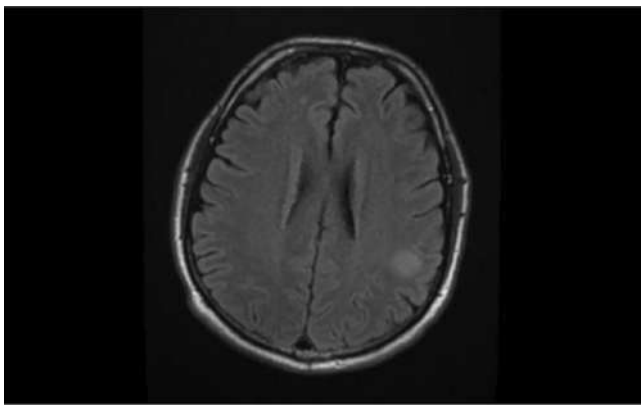
Results: Among 1735 patients with MS, 40 had experienced at least one epileptic seizure (2.3%). Thirty patients (1.7%) had seizures that could not be explained by other factor than MS. The interval between MS-epilepsy diagnosis was longer and seizure recurrence was more in SPMS compared to RRMS. However, the prognosis of epilepsy was good in both subtypes. Out of 21 patients with NMOSD, none had a seizure during follow-up. Out of 56 patients with MOGAD seizures were observed in three (5.4%). All of them had status epilepticus either at onset or during the course of the disease.



MRI of patient 1 with MOGAD



MRI of patient 3 with MOGAD

Conclusion: While the seizure seen during the relapses may be related to new cortical lesion formation and acute inflammation, it is more likely to be due to chronic atrophy, especially in SPMS. Prevalence of status epilepticus was common in MOGAD patients.

Disclosure: Nothing to disclose.

EPO-186 | Does natalizumab affect oligoclonal bands in the cerebrospinal fluid of patients with multiple sclerosis?

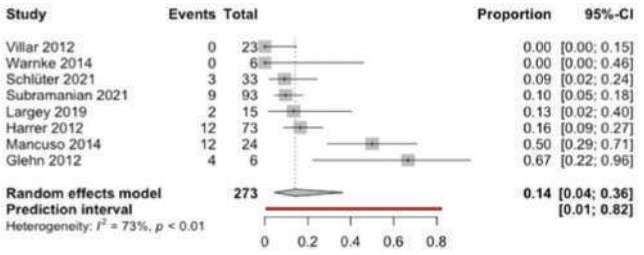
A. Liampas[1]; V. Tseriotis[2]; G. Vavougios[3]; P. Zis[3]; G. Hadjigeorgiou[3]; P. Bargiotas[3]; C. Pourzitaki[2]; A. Artemiadis[3]

[1]Department of Neurology, Nicosia General Hospital, Nicosia, Cyprus; [2]Laboratory of Clinical Pharmacology, Aristotle University of Thessaloniki, Thessaloniki, Greece; [3]Department of Neurology, Medical School, University of Cyprus, Nicosia, Cyprus

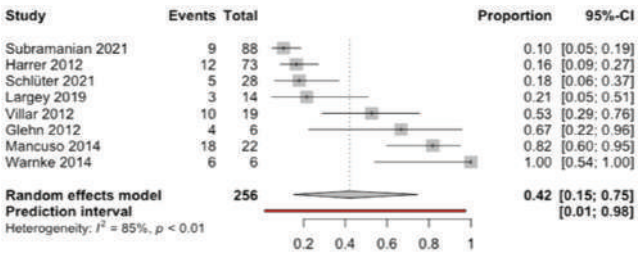
Background and Aims: The pathological role of cerebrospinal fluid (CSF) oligoclonal bands (OCBs) in multiple sclerosis (MS) has been demonstrated. Long-lived plasma cells are the main cells contributing to production of OCBs. Our aim was to demonstrate the quantitative effect of natalizumab (NTZ) on OCBs in the CSF of patients with MS.

Methods: A systematic search on MEDLINE, SCOPUS and Web of Science for English-written and peer-reviewed longitudinal studies on adults was performed. Meta-analysis of the data was also performed.

Results: Eight eligible studies of adequate quality with a total sample of 326 relapsing- remitting MS patients were included. A summary rate of 14.07% [95% CI, 4.48%–36.36%] was observed for complete loss of OCBs and 42.02% [95% CI, 15.23%–74.51%] for reduction in OCB number or intensity was observed, both with considerable heterogeneity. Pooled estimates dropped (11% [95% CI, 0.04%–0.29%] and 34% [95% CI, 0.11%–0.68%] respectively) after the identification of an influential study. Multivariable meta-regression identified IgG index as a factor contributing to heterogeneity (adj. $p = 0.0279$), regarding reduction of OCB number or intensity.



Forest plots of the meta-analysis on the proportion of patients with complete loss of OCBs after NTZ treatment.



Forest plots of the meta-analysis on the proportion of patients with reduction of OCB number or intensity after NTZ treatment.

Conclusion: In conclusion, our systematic review and meta-analysis showed that NTZ can lead to reduction of intrathecal OCBs in MS patients, indicating a possible effect of NTZ on memory plasma cells which are the main source of OCBs in MS.

Disclosure: Nothing to disclosure.

EPO-187 | Identifying definite patterns of unmet needs in patients with multiple sclerosis using unsupervised machine learning

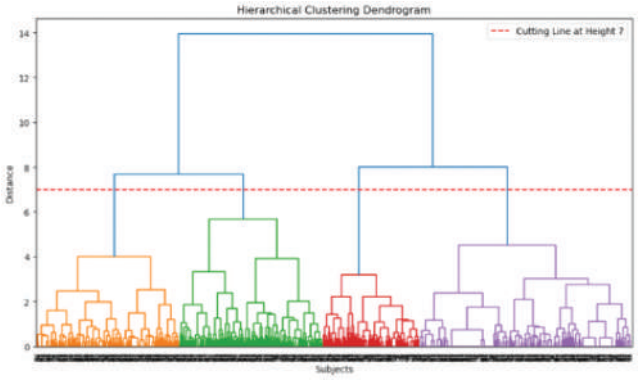
E. Maida[1]; G. Abbadessa[1]; E. Cocco[2]; P. Valentino[3]; A. Lerede[4]; J. Frau[2]; G. Miele[1]; F. Bile[1]; M. Vercellino[5]; F. Patti[6]; G. Borriello[7]; P. Cavalla[5]; M. Sparaco[1]; L. Lavorgna[1]; S. Bonavita[1]

[1]Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, Italy; [2]Department of Medical Science and Public health, Centro Sclerosi Multipla, University of Cagliari, Cagliari, Italy; [3]Institute of Neurology, University Magna Graecia, Catanzaro, Viale Europa, Catanzaro, Italy; [4]Department of Brain Sciences, Imperial College London, London W120BZ, UK; [5]MS Center, Department of Neuroscience, City of Health and Science University Hospital of Turin, Turin, Italy; [6]Department "GF Ingrassia", Section of Neurosciences, University of Catania, Catania, Italy; [7]MS Center, Hospital San Pietro Fatebenefratelli, Rome, Italy

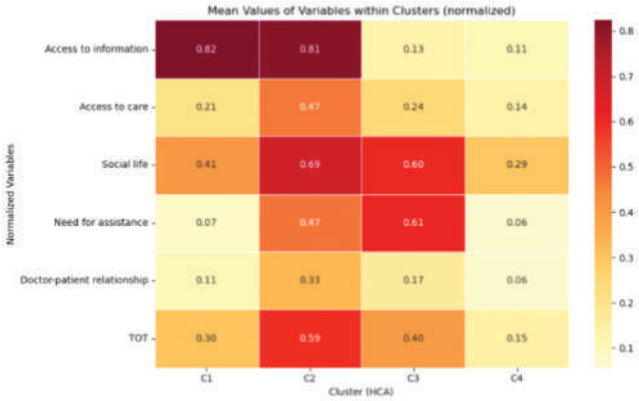
Background and Aims: People with Multiple Sclerosis (PwMS) exhibit a spectrum of needs that extend beyond solely disease-related determinants. Investigating unmet needs from the patient perspective may address daily difficulties and optimize care. Our aim was to identify patterns of unmet needs among PwMS and their determinants.

Methods: We conducted a cross-sectional multicentre study. Data were collected through an anonymous, self-administered online form. To cluster PwMS according to their main unmet needs, we performed agglomerative hierarchical clustering algorithm. Principal component analysis (PCA) was applied to visualize cluster distribution. Pairwise comparisons were used to evaluate demographics and clinical distribution among clusters.

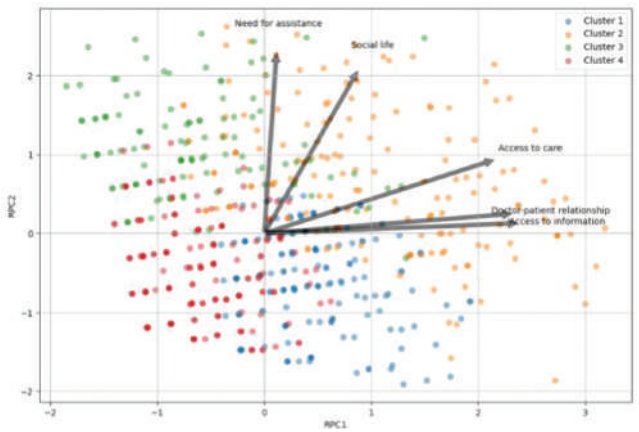
Results: Out of 1,764 mailed questionnaires, we received 690 responses. Access to primary care was the main contributor to the overall unmet need burden. Four patterns were identified: Cluster C1, "Information-Seekers with Few Unmet Needs"; Cluster C2, "High Unmet Needs"; Cluster C3, "Socially and Assistance-Dependent"; Cluster C4, "Self-Sufficient with Few Unmet Needs". PCA identified two main components in determining the patterns: the "public sphere" (access to information and care) and the "private sphere" (need for assistance and social life). Older age, lower education, longer disease duration, and higher disability characterized clusters with more unmet needs in the "private sphere". However, demographic, and clinical factors failed in explaining the four identified patterns.



Hierarchical clustering dendrogram. The figure displays the hierarchical clustering dendrogram generated using the Ward linkage method.



Mean values of normalized variables within clusters generated by hierarchical clustering algorithm (HCA). The heatmap presents the mean values of selected variables within distinct clusters, after the normalization process.



Biplots of principal component analysis (PCA) scores and component loadings with cluster assignments.

Conclusion: Our study identified four unmet need patterns among PwMS, emphasizing the importance of personalized care. While clinical and demographic factors provide some insight, additional variables warrant further investigation to fully understand unmet needs in PwMS.
Disclosure: Nothing to disclose.

EPO-188 | Systemic inflammation biomarkers in multiple sclerosis as potential indicators of underlying inflammatory process

E. Maida; G. Miele; D. Mele; G. Abbadessa; M. Sparaco; L. Lavorgna; G. Romano; E. Signoriello; G. Lus; S. Bonavita
Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, Italy

Background and Aims: The role of systemic inflammation biomarkers has been investigated in several autoimmune diseases. Our study aimed to assess whether inflammatory indices differ between healthy individuals and people with Multiple Sclerosis (PwMS), and explore whether they may correlate with demographic, clinical, and laboratory variables.
Methods: We conducted a retrospective study involving 100 PwMS admitted to our MS Center, and 83 age- and sex-matched healthy controls. Demographic, MS characteristic and laboratory data, including lymphocyte subsets, were collected. Neutrophil/lymphocyte ratio (NLR), platelet/lymphocyte ratio, monocyte/lymphocyte ratio, Systemic Inflammation Index and Systemic Immune-Inflammation Index (SIRI) were calculated.
Results: NLR and SIRI values were significantly higher in PwMS than in healthy control group ($p=0.03$, $p=0.02$, respectively). In the linear regression model, NLR was associated with primary-progressive forms (PPMS) ($p=0.03$), higher number of oligoclonal bands ($p=0.03$) and higher frequency of relapses before the diagnosis ($p=0.03$). SIRI was associated with PPMS ($p=0.03$) and higher frequency of relapses before the diagnosis ($p=0.04$). NLR and SIRI were associated with higher absolute CD20+ B cells count at disease onset ($p=0.02$, $p<0.01$, respectively).

	Patient Group (n=100)	Control Group (n=83)	*p*-value
Age, mean (SD), years	38.07 (13.09)	40.96 (15.06)	0.17
Female, No (%)	66 (66)	34 (55.42)	0.15
Duration of MS disease, mean (SD), years	1.4 (9.95)	-	
MS clinical descriptors, No (%)		-	
RRMS	84 (84)		
SPMS	8 (8)		
PPMS	8 (8)		
EDSS, mean (SD)	2.01 (1.47)	-	

Demographic and clinical characteristics of the two groups.

Conclusion: The results may highlight the role of NLR and SIRI as potential indicators of an underlying inflammatory process. The correlation with B cells at onset can further support the evidence in favour of their critical role in MS pathogenesis. Further studies are needed to validate such findings and assess the potential impact of disease-modifying therapies on systemic inflammation biomarkers.
Disclosure: Nothing to disclose.

EPO-189 | Natalizumab efficacy on radiological and clinical parameters in pediatric-and adult-onset multiple sclerosis

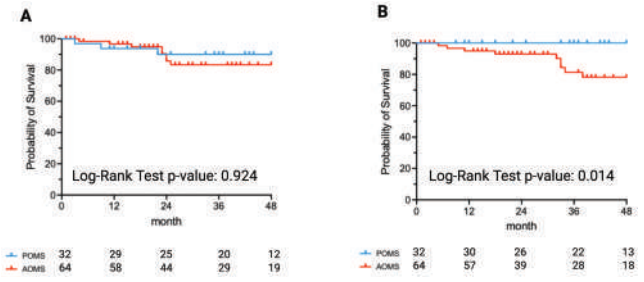
M. Puthenparampil[1]; M. Gaggiola[1]; M. Ponzano[2]; G. Scialpi[1]; G. Zanotell[1]; A. Miscioscia[1]; A. Berardi[1]; M. Nosadini[3]; S. Sartori[3]; P. Perini[1]; F. Rinaldi[1]; F. Bovis[2]; P. Gallo[1]

[1]Department of Neurosciences, University of Padua; [2]Department of Health Sciences, Section of Biostatistics, University of Genova, Genova, Italy; [3]Paediatric Neurology and Neurophysiology Unit, Department of Women's and Children's Health, University Hospital of Padova, Italy

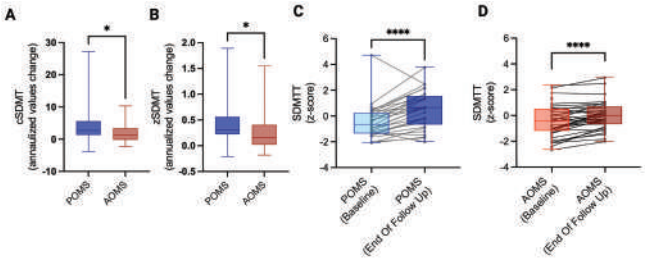
Background and Aims: Pediatric-onset Multiple Sclerosis patients (POMS) is characterized by a more rapid accumulation of CNS inflammation than Adult-Onset MS (AOMS). Therefore, the early use of HET has been highly recommended in POMS.

Methods: All patients who started natalizumab (NTZ) were enrolled in this retrospective single-centre study and were clinically evaluated at baseline and then every six months with EDSS score. The cohort was then divided based on age at onset in Pediatric-Onset (POMS) and Adult-Onset AOMS) MS and were propensity-matched. SDMT was assessed at baseline in all patients and in a sub-cohort of POMS (29) and AOMS (30) at least 2 years after baseline assessment.

Results: From 38 POMS and 122 AOMS, propensity-matching defined a cohort of 36 POMS and 72 AOMS. The effect on inflammatory MRI and clinical was evaluated by survival analysis did not differ between AOMS and POMS ($p=0.924$). PIRA was documented in 9 AOMS (12.5%, $p=0.0278$) during the follow-up (LogRank p-value 0.014). Corrected SDMT values did not differ between POMS and AOMS at baseline (49.43 ± 14.74 and 49.71 ± 10.75, $p=0.639$). While z-score improved in both AOMS and POMS ($p<0.001$), annualized z-score change was significantly higher in POMS than in AOMS (0.41 ± 0.40 vs 0.25 ± 0.34, $p=0.023$).



Survival analysis: NEDA and PIRA



SDMT score at baseline and during the follow up

Conclusion: Evaluation of inflammatory and clinical outcomes did not reveal any significant difference between POMS and AOMS, indicating an excellent response to NTZ in both groups. The favorable outcomes observed in clinical, radiological, and neuropsychological parameters support the use of NTZ as a viable treatment option in POMS.

EPO-190 | Retinal microglia changes in relapsing-remitting multiple sclerosis under natalizumab therapy

M. Puthenparampil[1]; E. Basili[1]; M. Ponzano[2]; V. Mauceri[1]; F. De Napoli[1]; A. Miscioscia[1]; E. Pilotto[3]; L. Rossi[4]; P. Perini[1]; F. Rinaldi[1]; F. Bovis[2]; P. Gallo[1]

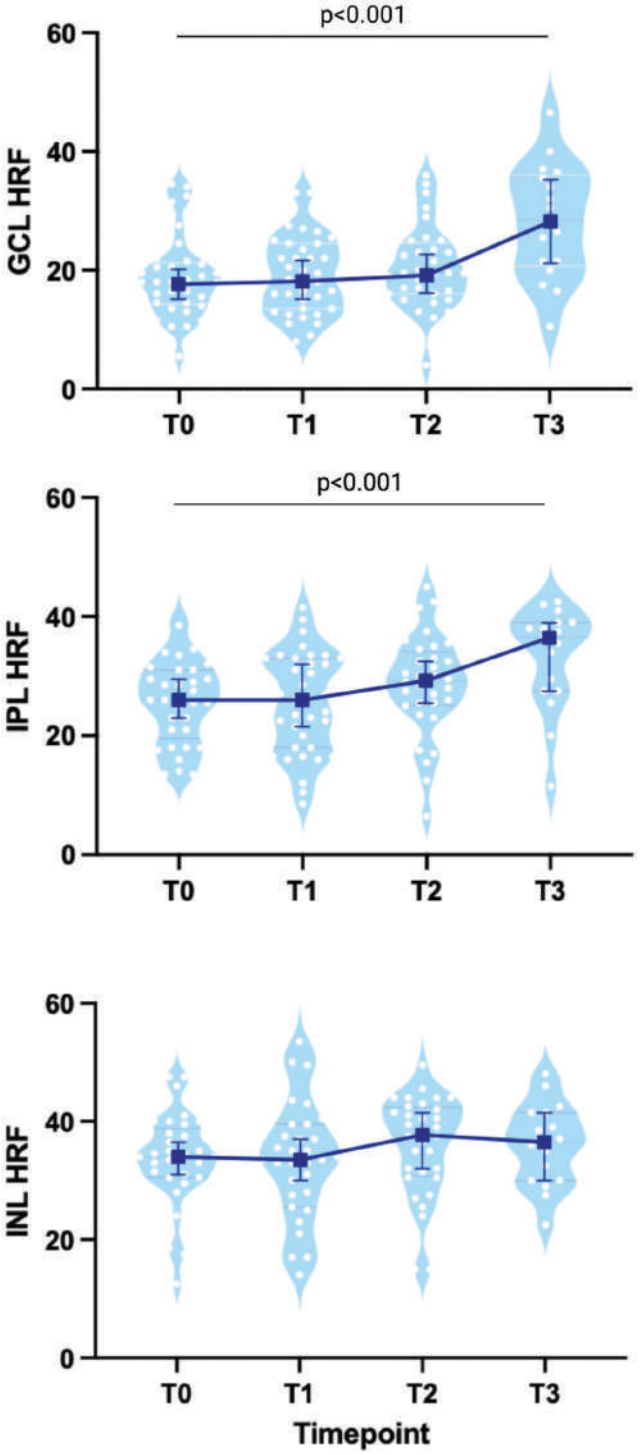
[1]Department of Neurosciences, University of Padua, Padua, Italy; [2]Department of Health Sciences, Section of Biostatistics, University of Genova, Genova; [3]Department of Neurosciences-Ophthalmology, University of Padua, Padua, Italy; [4]Department of Medicine, Surgery and Health Sciences, University of Trieste, Italy

Background and Aims: Microglia (MG) is suggested to play an immunopathological role of in Multiple Sclerosis (MS). In vivo analysis of retinal MG proliferation/activation, evaluating Retinal Hyperreflective Foci (HRF) by Optic Coherence Tomography (OCT), in MS patients under disease modifying therapies may help to clarify MS immunopathology as well as drug's mechanism of intrathecal action.

Methods: The effect of NTZ in retinal MG on 36 Relapsing-Remitting MS (RRMS) patients was investigated in a retrospective, single-centre study. OCT was performed immediately before the first infusion and then between infusion 3 and 4, infusion 6 and 7, infusion 11 and 13. Peripapillary and macular scans were acquired, evaluating peripapillary retinal nerve fiber layer (pRNFL) thickness, macular volumes (vertical scans), and HRF count (horizontal scan) in Ganglion Cell Layer (GCL), Inner Plexiform Layer (IPL) and Inner Nuclear Layer (INL). Clinical examination was performed every six months.

Results: HRF count significantly increased under NTZ therapy ($p<0.001$) in both GCL (18.85 ± 6.93 at baseline, 28.24 ± 9.55 after 12 months) and IPL (25.73 ± 7.03 at baseline, 33.21 ± 8.50 after

12 months) but remained stable in INL (33.65 ± 7.76 at baseline, 36.06 ± 6.86 after 12 months, $p = 0.868$), while no relevant modification of pRNFL and macular volumes were observed during the study.



HRF count in MS patients treated with Natalizumab

Conclusion: In RRMS NTZ affects retinal MG activation (HRF count) in GCL and IPL, but not in INL, suggesting that NTZ does not impact on all the aspects of MS immunopathology.

EPO-191 | PAI mutation 4G/5G-coagulopathy risk factor for multiple sclerosis?

M. Cholakova
Nikolay Mihnev

Background and Aims: Homozygous carrying of the PAI mutation, 4G/4G is clinical significant for thrombotic events. In multiple sclerosis (MS), malfunction of the plasminogen activation system and blood brain barrier disruption are pathological processes that might lead to an abnormal fibrin(ogen) extravasation into the parenchyma.
Methods: Healthy controls, patients with ischemic stroke, patients with MS, MRI, laboratory tests for thrombophilia, neurological examination, statistical analysis
Results: A prospective clinical trial of 54 patient with multiple sclerosis, 69 healthy controls and 101 patients with ischemic stroke. A total of number of 101 patients with ischemic stroke under 50 years were screened, 67 were examined for PAI mutation. The healthy control group consists of 44 women and 25 men. Homozygous carrier of the PAI mutation 4G/4G variant was found to increase the chance of stroke 3.00 times [OR = 3.00; CI: (0.70–12.93)]. Patients with multiple sclerosis were 54, with the majority of female – 39, and male – 15. We compared the groups of patients with stroke and multiple sclerosis to evaluate prevalence of PAI-1 mutation in both cohorts. According to our study, PAI-1 mutation could be a risk factor for the development of multiple sclerosis (p-value < 0.00001) and ischemic stroke at a young age ($p < 0.05$), and the difference between the two groups and healthy controls is statistically significant.

TABLE 1

Gender	n	%	Age		
			average	Standard deviation	Min
Female	32	31,7	41,66	7,196	19
Male	69	68,3	42,55	6,388	18
Total	101	100	42,27	6,632	18

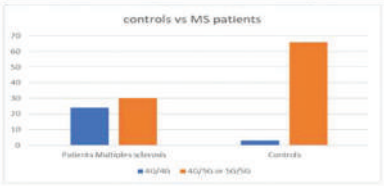
TABLE 2, 3

Group	N	Age				t	df
		Mean	Standard deviation	Min	Max		
Healthy controls	69	40,45	8,23	18,00	50,00	5,09	168
Patients with stroke	101	42,27	6,63	18,00	50,00		
Total	170	39,91	7,84	18,00	50,00		

iroup	count	Age		
		Mean	Standard deviation	Min
Control	69	40,45	8,23	18,00
MS	54	32,796296	10,51572	18,00

TABLE 4 Graphic 1

	Mutant 4G/4G	Normal 4G/5G or 5G/5G	Marginal Row Totals
MS	24	30	54
Control	3	66	69



Conclusion: PAI mutation could play a role as a risk factor for development of demyelinating disease like MS. In the future examination of patients with MS for PAI mutation could play role for the choice of treatment and prevention of invalidation.

Disclosure: No.

EPO-192 | Efficacy and safety profile of ocrelizumab in primary progressive multiple sclerosis patients from Montenegro

M. Roganovic; S. Perunicic; J. Erakovic; L. Radulovic; D. Milikic; B. Vujovic; Z. Idrizovic; S. Vujovic; M. Debeljevic; S. Gluscevic; M. Dajevic; S. Bojovic; A. Gucci; S. Martinovic

Clinic for Neurology, Clinical Center of Montenegro, Ljubljanska bb, 81000 Podgorica, Montenegro

Background and Aims: As only registered drug for patients with primary progressive multiple sclerosis (PPMS), ocrelizumab is in use in Montenegro since March 2019. Efficacy and safety of ocrelizumab in PPMS patients was confirmed in ORATORIO trial, as well as in several real-world studies. Our aim is to evaluate efficacy and safety of Ocrelizumab in PPMS patients in Montenegro.

Methods: We retrospectively examined data of PPMS patients treated with ocrelizumab in Montenegro from March 2019 to September 2023.

Results: During the abovementioned period, we treated 73 PPMS patients, mean aged 51.6 ± 10.6 years. In 61.6% of patients baseline Expanded Disability Status Scale (EDSS) was 5.5 or higher. During the follow-up period, no EDSS worsening was observed in 70.3% of treated-patients, while treatment was stopped in 16 patients: due to EDSS progression in 6 patients; due to death in 3 patients; due to adverse event (AE) in 1 patient; due to other reasons in 2 patients. Treatment discontinuation was choice of 4 patients. Regarding MRI activity during the follow-up period, presence of T1Gd+ lesions was detected in 1 patient, while 4 patients developed new/enlarging T2 lesions. Elevation of hepatic transaminases was observed in 10.6% of patients; lymphopenia grade 2 in 1.5%; one patient developed cervical malignancy. Urinary tract infection was detected in 3% of patients.

Conclusion: Our data, similar to other real-world studies, confirmed good efficacy as well as favorable safety profile of ocrelizumab in PPMS patients.

Disclosure: All authors have received speaker honoraria and/or travel grants.

EPO-193 | Executive dysfunction in multiple sclerosis patients

S. Sellami; N. Farhat; N. Bouattour; K. Moalla; H. Haj Kacem; S. Daoud; S. Sakka; M. Damak; C. Mhiri

Neurology Department and Research Laboratory LR12SP19, Habib Bourguiba University Hospital, Sfax, Tunisia

Background and Aims: Executive dysfunction occurs in 15%–28% of Multiple Sclerosis (MS) patients. The aim of this study is to identify characteristics of Executive Function Disorders (EFD) in a clinical cohort of Tunisian patients with MS.

Methods: A group of patients diagnosed with definite MS according to the 2017 McDonald criteria and followed up in the department of Neurology of Habib Bourguiba Hospital-Tunisia and a group of control subjects were assessed with a battery of classical executive tests which included semantic and phonemic verbal fluency test (SVFT/PVFT), Go/no-Go, digit-span-backwards and Delis Kaplan Executive Function System (D-Kefs).

Results: 70 MS patients with an average age of 34,6 years and 50 control subjects were included. As compared to controls, 74% of MS patients had executive disorders perceived by the D-Kefs ($p = 0.03$). The planning ability and the mental flexibility were disrupted as evidenced by impaired verbal fluency in all MS patients. The phonemic verbal fluency was clearly more affected ($p = 0.049$). There were no significant alterations regarding scores of Go/no-Go test ($p = 0.3$) and digit-span-backwards test ($p = 0.4$) in MS group compared to controls. Patients with SPMS (secondary progressive multiple sclerosis) showed significant EFD than those with RRMS (relapsing-remitting multiple sclerosis). Our study also showed a significant correlation between EFD and the EDSS (Expanded Disability Status Scale) ($p = 0.002$). No impact of DMT (disease modifying therapy) on EFD.

Conclusion: These results suggest that there are executive difficulties that are commonly found among patients with MS. The identification of these profiles in clinical practice could allow for more individualized rehabilitation.

Disclosure: Nothing to disclose.

EPO-194 | Assessment of visual function in multiple sclerosis patients over time

C. Oreja-Guevara[1]; E. Alba-Suárez[1]; I. Gómez-Estévez[1]; L. García-Vasco[1]; E. Santos-Bueso[2]; J. Rouco-Maseda[3]; J. Quezada-Sanchez[1]

[1]*Neurology, Hospital Clínico San Carlos, Idissc, Madrid, Spain;* [2]*Ophtalmology, Hospital Clínico San Carlos, Madric, Spain;* [3]*Ciencias de la Computación, Universidad de Coruña, Spain*

Background and Aims: Optic neuritis (ON) is often the first symptom at the onset of MS and can impair visual function. Objective: To longitudinally analyse the visual function in MS patients.

Methods: Stable MS patients over six months were included, with two assessments: baseline (V1) and one year later (V2). Visual acuity (VA), VA2.50% and VA1.25% were measured with ETDRS and low contrast test. Colour vision with Ishihara and Farnsworth-Munsell D28 (FM-D28) test. Contrast sensitivity with Pelli-Robson test. Comparisons were drawn between eyes affected by previous optic neuritis (ON) and those not.

Results: with Pelli-Robson test. Comparisons were drawn between eyes affected by previous optic neuritis (ON) and those not. Results Thirty-two patients, predominantly female (22), average age 43, were studied. Twenty eyes with previous ON. VA, VA2.50%, VA1.25% and contrast sensitivity showed significant differences between both groups (ON vs. no ON) in V1 and V2 ($p<0.05$). After one year a significant worsening in visual function ($p<0.05$) in the non-ON group were observed. The ON group showed significant reductions in VA1.25% ($p=0.005$) and contrast sensitivity ($p=0.000$). In the Ishihara test at V1 and V2, 95.5% of patients without optic neuritis had normal results. Meanwhile, 10% of the patients in the optic neuritis group displayed abnormalities. The non-ON group showed 43.2% altered FM-D28 values in V1 and 47.7% in V2. The ON group showed 80% of altered values in V1 and 85% in V2.

Conclusion: Visual acuity and contrast sensitivity decline as the disease progresses. The FM-D28 test offers a more precise evaluation of color vision.

Disclosure: Nothing to disclose in relation with the abstract.

EPO-195 | Hyperreflective foci in the inner retina in multiple sclerosis: Preliminary results of an external validation study

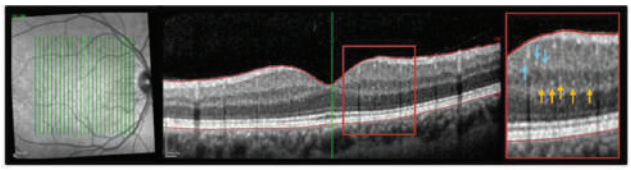
N. Krajnc[1]; T. Zrzavy[1]; F. Leutmezer[1]; B. Kornek[1]; P. Rommer[1]; T. Berger[1]; B. Pemp[2]; G. Bsteh[1]

[1]*Department of Neurology, Medical University of Vienna, Vienna, Austria;* [2]*Department of Ophthalmology, Medical University of Vienna, Vienna, Austria*

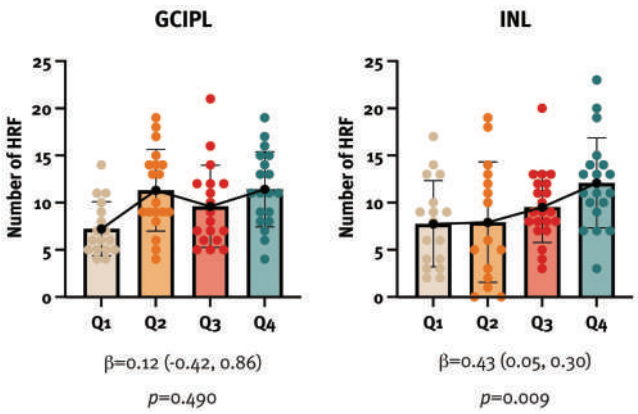
Background and Aims: Microglia, the resident immune cells of the central nervous system, are increasingly recognized to play an important role in the pathophysiology of multiple sclerosis (MS). Retinal microglia may be visualized as hyperreflective foci (HRF) by optical coherence tomography (OCT), but their origin and clinical relevance remain controversial.

Methods: In this cross-sectional retrospective study, we included patients with MS (pwMS) who had undergone an OCT scan. HRF counting was performed separately in the ganglion cell-inner plexiform layer (GCIPL) and the inner nuclear layer (INL). Eyes with a clinical history of ON or asymptomatic ON (interocular asymmetry with cut-off values of ≥5μm for pRNFL and ≥4μm for GCIPL) were excluded from the analysis.

Results: In total, we included 38 eyes of 36 pwMS (47.2% female, median age 31.5 years (24.9–43.8), median disease duration 1.8 years (0.1–10.2), median EDSS 1.0 (0–2.5)). Mean GCIPL and INL thicknesses were 67.3 μm (7.2) and 34.7 μm (2.2), respectively. The mean GCIPL HRF count was 10.8 (3.9), and the mean INL HRF count was 9.5 (5.5). The INL HRF count was associated with the INL thickness (β = 0.43; 95% CI 0.05, 0.30; $p=0.009$), whereas the GCIPL HRF count was not associated with the GCIPL thickness (β = 0.12; 95% CI −0.42, 0.86; $p=0.490$).



HRF Protocol. Macular scan and HRF visualization in a patient with MS. HRF were defined as isolated, small sized (<30 μm), punctiform elements with moderate reflectivity but without any back shadowing.



The INL HRF count was associated with the INL thickness, whereas the GCIPL HRF count was not associated with the GCIPL thickness.

Conclusion: This study demonstrated that HRF can be assessed by OCT and confirmed that the INL HRF count is associated with the INL thickness, providing indirect evidence that HRF may indeed represent activated microglia. Further studies are needed to confirm their clinical relevance.

Disclosure: Nothing to disclose.

Muscle and neuromuscular junction disorder 1

EPO-196 | Advancing clinical practice: Impact of online education on implementation of novel therapies for myasthenia gravis

A. Stan[1]; M. Calle[1]; F. David[1]; F. Saccà[2]
[1]*Medscape LLC, New York, New York, USA;* [2]*University of Naples Federico II, Napoli, Italy*

Background and Aims: We developed an online CME activity titled: "Navigating the Changing Landscape in Myasthenia Gravis: An Expert Case-Based Discussion". We hypothesized that participation in this education would lead to improved knowledge of implementing targeted MG treatments.
Methods: Neurologists participated in a 30-min expert discussion educational activity (www.medscape.org/viewarticle/993422). Educational effect was assessed using a repeated-pair design with pre-/post-assessment. Three multiple choice questions assessed knowledge and 1 question (Likert-type scale) assessed confidence. A paired samples t-test was conducted for significance testing on overall average number of correct responses and for confidence rating, and a McNemar's test was conducted at the learning objective level (5% significance level, $p < .05$). Cohen's d with correction for paired samples estimated the effect size of the education on number of correct responses (<.20 modest, .20–.49 small, .59–.79 moderate, ≥.80 large). Data were collected from 7/14/2023 to 10/25/2023.
Results: A total of 789 neurologists participated of which 104 completed all the pre- and post-activity questions during the study period. Overall 64% neurologists improved their knowledge and competence related to implementing novel targeted therapies in the management of MG (average knowledge/competence pre: 33% vs post: 68%) $p < .001$, Cohen's d = 1.02) (see Table). 56% had increased confidence in appropriately integrating novel targeted therapies for MG.

TABLE Impact of education on neurologists' knowledge and competence

Learning Objective	Aggregated data		Linked Learning Results[a]	
Knowledge	Average % of correct responses Pre- vs. Post-education	P-value	% Improved[b] learners Pre- vs. Post-education	% Reinforced[c] learners Pre- vs. Post-education
Regarding novel targeted therapies for the management of MG	23% vs 56%	<.001	35%	21%
Competence				
Related to individualizing therapy for patients with MG	38% vs 74%	<.001	56%	33%
Confidence	Mean Pre- vs. Post-education (1 – not confident; 5 – very confident)		% Increased learners Pre- vs. Post-education	% Maintained learners Pre- vs. Post-education
In appropriately integrating novel targeted therapies for MG such as FcRn inhibitors in clinical practice	2.00 vs 2.87	<.001	56%	44%

[a]Each individual learner tracked pre and post-education
[b]Incorrect answer pre-education, Correct answer post-education
[c]Correct answer pre-education, Correct answer post-education

Conclusion: This online CME activity significantly improved neurologists' knowledge and competence related to implementing novel targeted therapies in the management of MG; however, substantial gaps remain which should be addressed in future medical education.
Disclosure: Nothing to disclose.

EPO-197 | Impact of myasthenia gravis on patients' daily life: Findings from the ME&MGopen decentralised study

C. Barnett-Tapia[1]; S. Lehnerer[2]; C. Gorin[3]; D. Ravindra[3]; N. Sellami[3]; M. Keller[4]; E. Aras[5]; E. Touré Cuq[3]; J. Howard Jr[6]
[1]*Department of Medicine, Division of Neurology. University of Toronto and University Health Network;* [2]*Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin,Department of Neurology with Experimental Neurology, Berlin, Germany;* [3]*Ad Scientiam, Paris, France;* [4]*Alexion GmbH;* [5]*Alexion Pharmaceuticals Inc.;* [6]*The University of North Carolina, Dept of Neurology, CB 7025*

Background and Aims: Generalised myasthenia gravis (gMG) is an autoimmune disease causing fluctuating and debilitating muscle weakness, profoundly affecting patients' quality of life. Capturing its daily impacts objectively remains a challenge. The ME&MGopen study aims to address this gap. This study describes gMG impact using electronic patient-reported outcomes (ePROs) and potential influencing factors.
Methods: 199 gMG patients were enrolled in ME&MGopen, a multicountry (USA, Canada), decentralised research study. Sociodemographic, clinical and treatment data were collected during baseline remote visit. Participants used the ME&MGopenTM digital tool for up to 8 months and completed questionnaires on a monthly basis (MG-QOL-15r, MG-ADL, ISI, Chronic Pain, PHQ-8).
Results: Of the 199 participants, 65% were female, with a mean age 57 ± 16 years. 60 self-reported their MGFA Disease Class, with the following distribution: 55% Class III, 28% Class II, 17% Class IV. Across all participants, PHQ-8, ISI, Chronic Pain, MG-ADL, MG-QOL-15r baseline scores indicated a meaningful gMG impact on their lives [6.5 ± 5.1, 9.0 ± 6.0, 2.5 ± 2.4, 5.2 ± 3.7, 12.0 ± 8.0 respectively]. PHQ-8, MG-ADL, MG-QoL-15r scores were significantly higher when disease control was considered inadequate [9.8 ± 4.0 ($p < 0.05$), 10.6 ± 3.2 ($p < 0.0001$), 21.0 ± 6.0 ($p < 0.01$)] versus controlled patients. PHQ-8 and MG-QoL-15r scores were significantly increased in patients unable to work [10.0 ± 5.0 ($p < 0.05$), 20.0 ± 5.7($p < 0.001$)] versus working or unemployed patients.
Conclusion: These findings show the impact of gMG on quality of life, consistent with literature of gMG. The reliability of ME&MGopenTM to collect ePROs will be confirmed during upcoming longitudinal analyses.

EPO-198 | The ME&MGopen study: Analysis of 8-month adherence trends to a smartphone application in generalized Myasthenia Gravis

C. Barnett-Tapia[1]; S. Lehnerer[2]; M. Boyer[3]; N. Sellami[3]; D. Ravindra[3]; M. Keller[4]; E. Aras[5]; E. Touré Cuq[3]; J. Howard Jr[6]
[1]Department of Medicine, Division of Neurology, University of Toronto and University Health Network; [2]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Neurology with Experimental Neurology, Berlin, Germany; [3]Ad Scientiam, Paris, France; [4]Alexion GmbH; [5]Alexion Pharmaceuticals Inc.; [6]The University of North Carolina, Dept of Neurology, CB 7025

Background and Aims: Generalised Myasthenia Gravis (gMG) is a debilitating, chronic, autoimmune disease characterized by fluctuating fatigable muscle weakness. The ME&MGTM smartphone application is a research tool enabling the unsupervised data collection of gMG symptoms as well as quality of life and mental health measures. Improving users' long term adherence will optimize data quality for research. We evaluated patient adherence to ME&MGTM digital tests and e-questionnaires in this fully decentralized ME&MGopen study.

Methods: Patients diagnosed with anti-AChR autoantibody positive gMG were enrolled in the USA and Canada. Five active digital tests and five e-questionnaires were completed at baseline and on a monthly basis for one year. App adherence was assessed until Day-240.

Results: After their remote baseline inclusion visit, 176 participants complied to the ME&MGTM tasks (adherence rate = 91%). Adherence rate dropped at Day 30 for both digital tests (78%) and e-questionnaires (79%) and remained above 60% until Day-240. Once a digital test or e-questionnaires was initiated, it was generally brought to completion. The most demanding task (sit-to-stand test) was interrupted in less than 4% of evaluations.

Conclusion: These results show promising immediate and lasting adherence to ME&MGTM, persisting beyond 6 months, a critical turning point in digital studies. Additional subgroup analyses will inform on specific adherence profiles and offer avenues to maintain patients' long-term engagement.

Disclosure: Carolina Barnett Tapia: Research funding (paid to her institution) (Ad Scientiam, Alexion AstraZeneca (AZ) Rare Disease, Cartesian Therapeutics, US Department of Defence, Muscular Dystrophy Canada, MGNet, Grifols and Octapharma); Honoraria (consulting and/or Advisory board) fees (AcademicCME, Alexion AZ Rare Disease, argenx, Sanofi, UCB Pharma and Janssen). Hoffmann-LaRoche Ltd, Horizon Therapeutics plc, Medscape CME, Merck EMD Serono, NMD Pharma, Novartis Pharma, PeerView CME, Physicians' Education Resource (PER) CME, PlatformQ CME, Regeneron Pharmaceuticals, Sanofi US, UCB Pharma, Zai Labs); non-financial support (Alexion AZ Rare Disease, argenx, Cartesian Therapeutics, Toleranzia AB, UCB Pharma and Zai Labs).

EPO-199 | Efficacy and safety of nusinersen and risdiplam for adult spinal muscular atrophy: A systematic review and meta-analysis

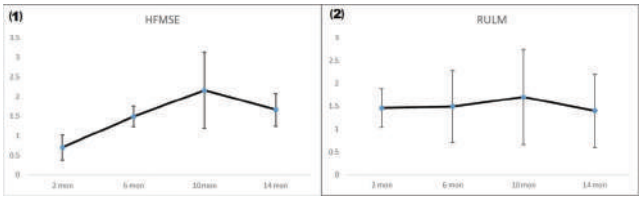
M. Mostafa Asla[1]; A. Abdelsalam[1]; A. Ahmed Nawar[1]; A. Saad Isa[2]; M. Abdelazim Rizk[1]; W. A. Kamel[3]
[1]Faculty of Medicine-University of Zagazig, Egypt; [2]Al-Azhar University, Faculty of Medicine, Damietta, Egypt; [3]Neurology department, Faculty of Medicine, Beni-Suef University, Egypt

Background and Aims: Nusinersen and risdiplam were approved by the US food and drug administration (FDA) for adult SMA patients. However, clinical evidence for their efficacy in adults are still inconclusive. We conducted this meta-analysis to establish the clinical efficacy and safety of them on the adult patients.

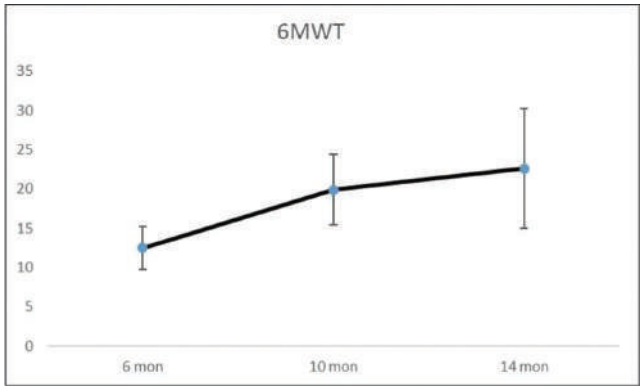
Methods: A literature search was conducted using the Web of Science Library, Scopus, PubMed, Wiley, and Cochrane up to August

2023. Data were pooled for analysis using OpenMeta Analyst software for Windows.

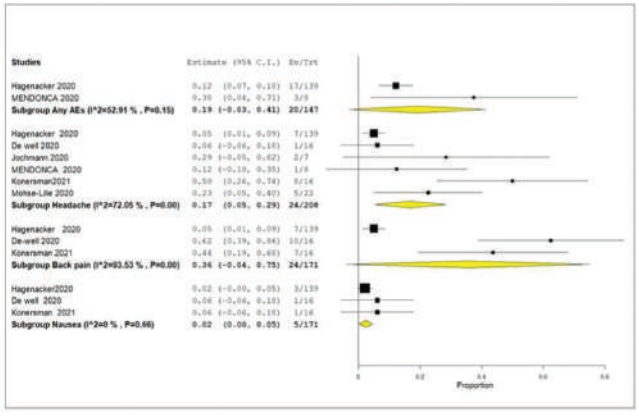
Results: 29 studies met the eligibility criteria, including 25 studies related to nusinersen and only 4 studies related to risdiplam. After 6 months of follow-up, nusinersen showed a statistically significant improvement of the HFMSE and the 6MWT. However, its effect on the RULM was not statistically significant. Regarding risdiplam, the findings of RULM showed a significant improvement during a year of follow-up. Frequent adverse events included headache, back pain, nausea, infections, and vomiting, which were more likely related to the disease progression or the lumbar puncture procedure as in nusinersen treatment rather than the drugs themselves. No significant serious adverse effects were reported for either.



Linear graphs of the changes in the mean during the follow-up periods of nusinersen on HFMSE and RULM.



Linear graphs of the mean change during the follow-up periods of nusinersen on 6MWT



Reported Adverse effects at 6 months

Conclusion: Nusinersen can improve motor and respiratory functions in adult patients with SMA, and its effects become more pronounced with extended follow-up periods. Risdiplam has shown promising results, but more clinical trials on adults with more sample size are needed. Both of nusinersen and risdiplam are generally tolerated and have an acceptable safety profile.

Disclosure: Nothing to disclose.

EPO-200 | Efficacy and safety of anti FcRN treatment in refractory MG: The UK experience of the Efgartigimod EAMS

J. Moniz Dionísio[1]; N. Thambirajah[2]; P. Ambrose[3]; G. Burke[4]; M. Farrugia[5]; P. Garcia-Reitboeck[6]; C. Hewamadduma[7]; T. Riswick[7]; S. Jacob[8]; D. Kullmann[2]; M. Hill[9]; M. [1]Department of Neurology, Kings College Hospital London, UK; [2]Department for Neuromuscular Disease, National Hospital for Neurology and Neurosurgery, Queen Square, UCLH, London, UK; [3]Department of Clinical Neurology, University of Nottingham, Queen's Medical Centre, Nottingham, UK; [4]Wessex Neurological Centre, Southampton General Hospital, Hampshire, UK; [5]Institute of Neurological Sciences, Queen Elizabeth University Hospital, Glasgow, UK; [6]St George's University Hospitals NHS Foundation Trust, London, UK; [7]Department of Neuroscience, Sheffield Institute for Translational Neurosciences (SITRAN), University of Sheffield and Sheffield Teaching Hospitals Foundation NHS Trust, Sheffield, UK; [8]Department of Neurology, University Hospitals Birmingham, Birmingham, UK; [9]Department of Neurology, Morriston Hospital, Swansea, Wales, UK, [10]Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, UK, [11]Department of Neurology, Royal Victoria Infirmary, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle, UK, [12]Division of Neurology, Imperial College London, UK, [13]Department of Neurology, The Walton Centre, UK

Background and Aims: We report our experience of patients with generalised MG (gMG) treated with Efgartigimod an FCRN antagonist, under the early access to medicine scheme (EAMS) in the UK.

Methods: Data from all UK patients treated with Efgartigimod under the EAMS June 22-July 23 were collected retrospectively. Efgartigimod was administered as per the ADAPT protocol (treatment cycle of 4 infusions at weekly intervals with further cycles given according to clinical need).

Results: 49 patients with AchR antibody positive gMG were treated in 12 centres. Most (76%) were female and most had a disease duration of over 10 years. The average MG-ADL score at baseline was 11.2 (SD 3.2). Most (73%) patients had undergone thymectomy. 71.4% were taking prednisolone at baseline. All patients had utilized non-steroidal immunosuppressant treatments, the average number tried was 4.3 (range 1–7) and 51% had received Rituximab. 57% of patients required regular IVIg/PLEX and 38% had required rescue IVIg/PLEX in the year before starting Efgartigimod. 77% of patients

had a mean reduction in the MG-ADL of ≥2 points in the first cycle and this remained stable throughout the study. The mean reduction in the MG-ADL score in the 1st, 2nd, 3rd and 4th cycles were −4.5, −6.3, −6.9 and −7.8 respectively. Side effects were generally mild though one patient stopped treatment due to severe hypokalemia. No rescue treatments were required. At the end of the study 96% of patients remained on Efgartigimod.

Conclusion: Efgartigimod is a safe and effective treatment for patients with refractory, treatment resistant gMG.

EPO-201 | Navigating the triggers of fear and anxiety after diagnosis of Myasthenia Gravis

R. Govindarajan[1]; R. Rodriguez[2]; Z. Choudhry[3]; C. Brethenoux[4]; J. Pesa[3]; S. Ramchandren[5]; K. Gandhi[6]; K. Heerlein[7]; N. Souayah[8]
[1]HSHS Medical Group Multispecialty Care – St. Elizabeth's, O'Fallon, IL, USA; [2]Janssen Global Services, Commercial Data Science, Titusville, NJ, USA; [3]Janssen Scientific Affairs, LLC, Titusville, NJ, USA; [4]Human Dot Plus, TX, USA; [5]Janssen R&D, LLC, Titusville, NJ, USA; [6]Janssen Global, Commercial Strategy Organization, Titusville, NJ, USA; [7]Janssen Global Services, Medical Affairs, Titusville, NJ, USA; [8]Rutgers NJMS – Department of Neurology, Newark, NJ, USA

Background and Aims: As individuals living with Myasthenia Gravis (MG) have high rates of anxiety, we aimed to understand the experience of anxiety and its triggers among individuals discussing a recent diagnosis of MG online.

Methods: A research study was conducted using a proprietary AI-powered methodology to examine English-language public domain online conversations about MG from August 2022–August 2023.

Results: Of 9901 online conversations about MG, 33% ($n=3268$) were immediately after diagnosis. Self-described anxiety was expressed in 36% of posts ($n=1177$) at diagnosis, which was 25% lower than at pre-diagnosis (48%). Fear was discussed by 43% ($n=1405$), an increase of ~13% from pre-diagnosis (38%). Unknowns surrounding their future were discussed. Uncertainty (18%) was the most common anxiety trigger ($n=1177$) and could be sub-categorized into anxiety about diagnosis severity, not knowing the prognosis, and if symptoms will worsen. Symptom discomfort (13%) and fatigue (5%) were also important anxiety triggers. Fear ($n=1405$) was primarily triggered by catastrophizing thoughts (21%), including fear of loss of function, limitations in lifestyle, and death. The fear about physical impact (14%) was driven by physical symptoms, discomfort, and fatigue. Other fears included financial impact (3%) and impact on relationships (5%).

Conclusion: Anxiety and fear are frequently experienced by individuals recently diagnosed with MG, primarily due to physical symptoms, uncertainty about the future, lifestyle impacts, and catastrophizing thoughts. These observations provide important insight that healthcare practitioners can consider when treating newly-diagnosed MG, particularly the need for early symptom alleviation and mental health support.

EPO-202 | The impact of depression on quality of life for individuals with Myasthenia Gravis

N. Goyal[1]; R. Rodriguez[2]; Z. Choudhry[3]; C. Brethenoux[4]; J. Pesa[3]; S. Ramchandren[5]; K. Gandhi[6]; K. Heerlein[7]; A. Anderson[8]
[1]Stanford Neuroscience Health Center, Palo Alto, CA, USA; [2]Janssen Global Services, Commercial Data Science, Titusville, NJ, USA; [3]Janssen Scientific Affairs, LLC, Titusville, NJ, USA; [4]Human Dot Plus, TX, USA; [5]Janssen R&D, LLC, Titusville, NJ, USA; [6]Janssen Global, Commercial Strategy Organization, Titusville, NJ, USA; [7]Janssen Global Services, Medical Affairs, Titusville, NJ, USA; [8]Houston Methodist Hospital, Houston, TX, USA

Background and Aims: Individuals with myasthenia gravis (MG) have a higher prevalence of depression than the general population (1–4). Therefore, we aimed to evaluate the occurrence of online discussions related to MG, depression, and depression triggers.

Methods: A research study was conducted using a proprietary AI-powered methodology to examine English-language public domain online conversations about MG from August 2022–August 2023.

Results: Nearly 10,000 online conversations about MG were identified. One-third of posts (33%; $n=3268$) discussed experiences immediately following diagnosis. Self-described depression was indicated in 21% ($n=686$) of posts regarding recent diagnosis, representing a 50% increase from the period prior to diagnosis (14%). Out of all conversations ($n=3268$), the progressive worsening of MG symptoms was the most common depression trigger (9%), and the impact of MG on quality of life (QoL) was the second most frequent depression trigger (6%). One individual shared a sentiment, "I long for my life as it used to be". A lower portion (4% of 3268) stated their depression was related to lack of control over various aspects of their life as a result of MG. Depression related to ineffective treatment experiences was also discussed (2%).

Conclusion: An increase in reported depression was observed at diagnosis compared to the pre-diagnosis stage of MG in this social listening study. Depression was attributed to progressive worsening of symptoms and QoL, loss of control, and ineffective treatments. Healthcare practitioners can use this information to guide treatment decisions to improve symptom control and provide emotional support resources.

EPO-203 | Interactive application for the study of neuromuscular jitter

A. Malanda[1]; C. Valle[1]; D. Stashuk[2]; O. Garnés[3]; J. Rodríguez[1]; J. Navallas[1]
[1]*Electrical, electronics and Communication Engineering Dept., Public University of Navarra. Spain;* [2]*System Design Engineering Dept., University of Waterloo. Canada;* [3]*Neurophysiology Service, Jiménez-Díaz Foundation University Hospital*

Background and Aims: This work presents a software application that incorporates the necessary features to perform jitter studies off-line in a precise and efficient manner, so that comparative studies using manual jitter extraction procedures or new automatic methods can be conducted.
Methods: JitterAnalizer is a Matlab-based application for manual jitter analysis (Fig. 1). Time alignment and jitter estimation (MCD, MSD, etc.) of motor unit potential trains (MUPTs) can be performed either by the peak method or by the flank method. Other functionalities include: selection of sampling frequency, elimination of non-valid potentials, visualization of MUPTs in shimmer and raster modes, and results exportation.

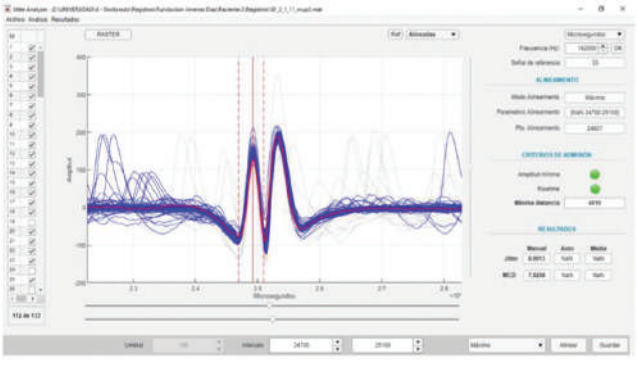

FIGURE 1 Interface of JitterAnalizer

Results: As a test example, EMG signals were recorded from 7 patients with pathologies of the neuromuscular junction or neuropathies. These signals were acquired using concentric facial needles and a Keypoint system. Jitter (MCD) measurements were then obtained from the Keypoint and from JitterAnalizer, using the peak method. Table 1 shows the statistical values of the jitter measurements obtained by each method from the 71 MUPTs that were taken as valid for the comparative study.

TABLE 1 Statistical results of the jitter measurements

EMG System	Mean (µs)	Standard deviation (µs)
Keypoint	32,92	23,65
JitterAnalyzer	36,91	35,05

Conclusion: JitterAnalizer has proved easy-to-use and fast. The statistical values of the jitter measurements obtained with the Keypoint and with JitterAnalizer are comparable. Their differences can be explained considering that the MUPTs presented to the two systems were not composed by exactly the same potentials.
Disclosure: This work has been funded by the Department of Health of the Government of Navarra (project GN2022/29) and by the Spanish Ministry of Science and Innovation (project PID2022-136620OB-I00).

EPO-204 | Comparison of manual methods in the measurement of neurophysiological jitter

A. Malanda[1]; C. Valle[1]; D. Stashuk[2]; O. Garnés[3]; J. Navallas[1]; J. Rodríguez[1]
[1]*Electrical, Electronics and Communication Engineering Department, Public University of Navarra, Spain;* [2]*System Design Engineering Department, University of Waterloo, Waterloo, Canada;* [3]*Neurophysiology Service, Jiménez-Díaz Foundation University Hospital, Madrid, Spain*

Background and Aims: The goal of this work is to compare the jitter measurements obtained by the peak method and the flank method in both small and large muscle recordings, in order to evaluate the equivalence of the two methods.
Methods: 238 EMG recordings taken from 22 patients were used for the study, following two different protocols: 1) single fiber EMG protocol, small muscles (frontalis), facial-concentric electrodes; and 2) a similar protocol, large muscles (biceps, tibialis anterior, etc.), conventional concentric electrodes.
Results: Table 1 and Fig. 1 show statistical results of the jitter measurements obtained with both protocols, using the two methods. The Wilcoxon test was applied (0.05 significance level) and *p*-values of

0.0002 and 0.0001 were obtained for protocol 1 and protocol 2, respectively, suggesting significant differences between the measurements obtained with the two methods. Linear regression models were also obtained, yielding high coefficients of determination (0.994 for protocol 1. and 0.991 for protocol 2), slope values close to 1 (0.989 and 0.992), and small intercept values (1.35 and 2.35 μs, respectively) (Fig. 2).

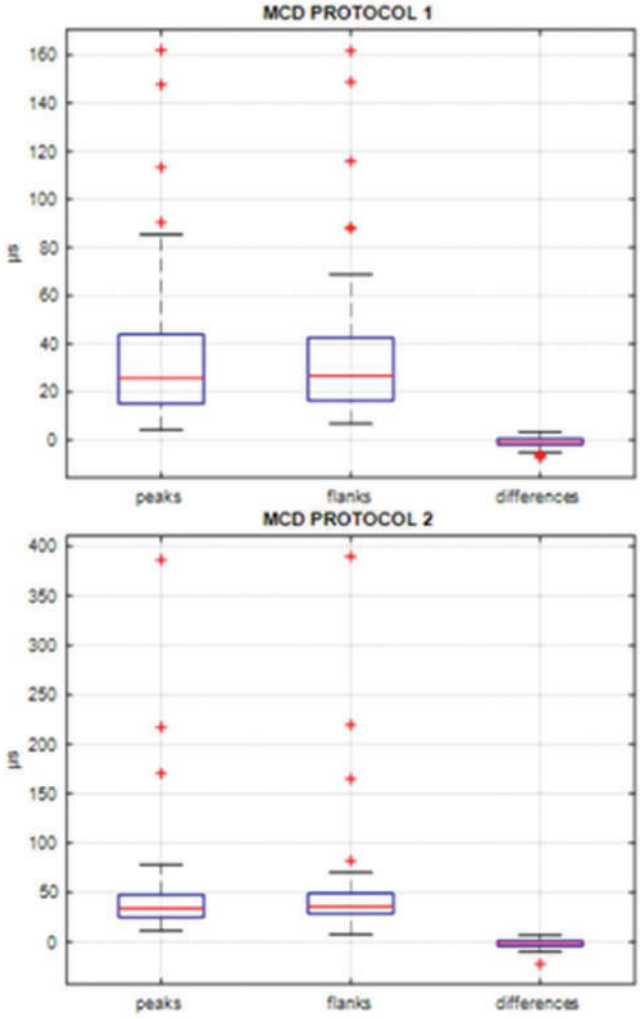

FIGURE 1 Boxplots of the jitter measurements obtained with the peak and the flank methods and the differences between them, for EMG recordings obtained from protocols 1 and 2.

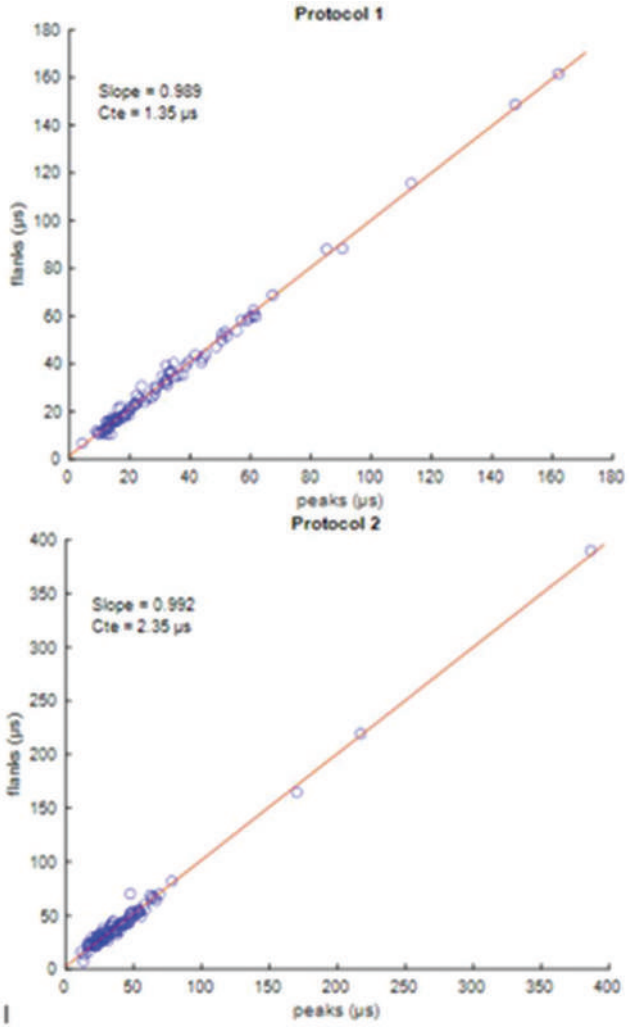

FIGURE 2 Regression models of the jitter measurements obtained with both methods in the two protocols.

TABLE 1 Statistical parameters of jitter measurements obtained by the peak and the flank methods and their differences, for EMG recordings obtained from protocols 1 and 2.

PROTOCOL 1				
	Median (μs)	[25th, 75th] percentiles (μs)	[5th, 95th] percentiles (μs)	Range (μs)
Peaks	25.78	[15.1, 43.9]	[10.5, 87.6]	[4.3, 161.9]
Flanks	26.76	[16.4, 42.6]	[10.9, 88.1]	[6.8, 161.7]
Differences	-0.92	[-1.9, 0.0.5]	[-5.1, 2.1]	[-7.3, 3.2]
PROTOCOL 2				
	Median (μs)	[25th, 75th] percentiles (μs)	[5th, 95th] percentiles (μs)	Range (μs)
Peaks	35,08	[24.8, 47.7]	[16.3, 71.7]	[11.4, 386.4]
Flanks	35.73	[28,2, 49.6]	[19.5 ,73.7]	[7.4, 389.9]
Differences	-1,47	[-4.5, 0.9]	[-9.0, 4.9]	[6.3, -22.6]

Conclusion: Although the jitter measurements obtained with the two methods were statistically different for both protocols, this difference seems to be small and not too relevant from a clinical viewpoint. However, in some isolated cases, the difference in their measurements may be high, which could affect the diagnosis.

EPO-205 | Myocarditis/myositis/myasthenia gravis overlap syndrome: Description of three patients

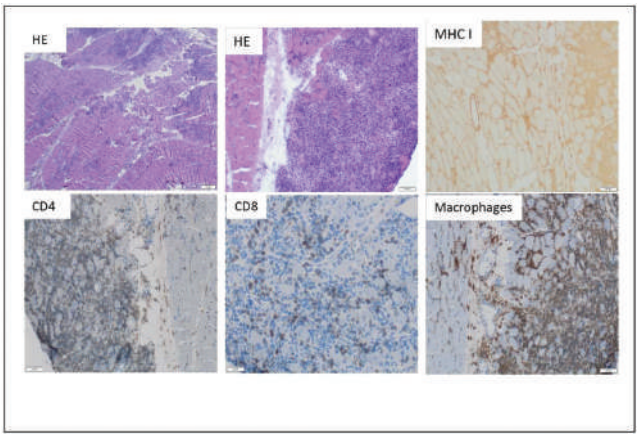
M. Domine; M. Olivé Plana; B. Albertí Vall; N. Blanco Sanroman; M. Coronel Coronel; R. Sainz Torres; M. Borrell Pichot; T. Mederer Fernández

Neurology Department, Hospital de la Santa Creu I Sant Pau, Barcelona, Spain

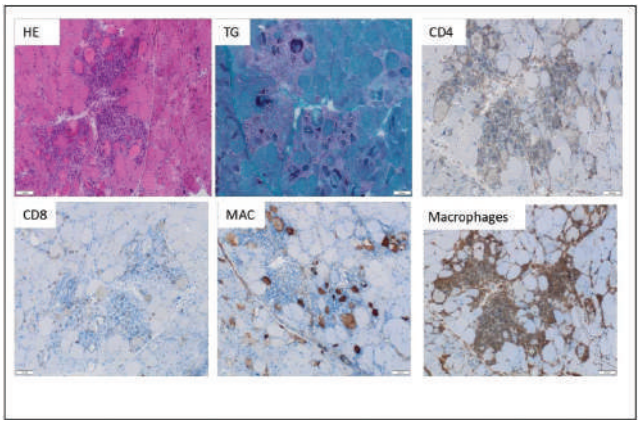
Background and Aims: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of tumors with a poor prognosis. Despite their high effectiveness, these therapies are associated with a broad spectrum of adverse effects, including the overlap syndrome of myocarditis/myositis/myasthenia gravis (IM3OS Syndrome).

Methods: We report on three patients undergoing treatment with ICIs (pembrolizumab and nivolumab). The first patient presented with binocular diplopia and ptosis. The second patient complained of muscle weakness, diplopia, chest pain, and recurrent syncope. The third patient was asymptomatic but was referred due to elevated CK levels.

Results: In all three patients, serum CK levels (>1000 IU/L) and troponins (>200 ng/L) were elevated. Whole-body muscle MRI was normal. EMG showed spontaneous activity at rest and myopathic patterns suggestive of inflammatory myopathy. The repetitive nerve stimulation test was normal. AntiRACh and anti-MUSK (anti-receptor tyrosine kinase) antibodies were positive only in one of the patients. Muscle biopsy revealed inflammatory myopathy. Two patients received corticosteroid therapy, intravenous immunoglobulins, and pyridostigmine. The second patient also required a pacemaker implantation due to complete atrioventricular block and ultimately succumbed to respiratory failure. The third patient only required corticosteroid treatment.



Patient 1. Biopsy of the right quadriceps



Patient 2. Biopsy of the brachial biceps muscle.

Conclusion: An increased incidence of IM3OS Syndrome has been observed in patients treated with ICIs, associated with high mortality. The presence of any of the symptoms should alert to the possibility of coexistence of others. Early diagnosis is essential for the management and prevention of potentially fatal complications.

Disclosure: Nothing to disclose.

EPO-206 | **Efgartigimod consistently improved health-related quality of life in AChR-Ab+ participants with gMG in IV and SC trials**

F. Saccà[1]; J. L. De Bleecker[2]; K. Utsugisawa[3]; D. Korobko[4]; S. Steeland[5]; B. Van Hoorick[5]; R. Kerstens[5]; J. Podhorna[5]; A. Meisel[6]; R. Mantegazza[7]

[1]NRSO Department, Genesis Center, Federico II University of Naples, Naples, Italy; [2]Department of Neurology, Ghent University Hospital, Ghent, Belgium; [3]Department of Neurology, Hanamaki General Hospital, Hanamaki, Japan; [4]State Budgetary Healthcare Institution of Novosibirsk Region "State Novosibirsk Regional Clinical Hospital," Novosibirsk, Russian Federation, [5]argenx, Ghent, Belgium; [6]Department of Neurology and Neuroscience Clinical Research Center, Charité – Universitätsmedizin Berlin, Berlin, Germany; [7]Department of Neuroimmunology and Neuromuscular Diseases, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy

Background and Aims: Myasthenia gravis (MG) causes substantial burdens on patient health-related quality of life (HRQoL). Recent MG guidelines indicate that therapeutic goals should aim for the best possible disease control, with the best possible preservation/restoration of QoL. Here we report HRQoL outcomes from efgartigimod-treated, AChR-Ab+ generalised MG (gMG) participants in the completed, placebo-controlled, Phase 3 ADAPT (IV) and ongoing, open-label extension ADAPT-SC+ (SC) trials.

Methods: Efgartigimod was administered via IV infusion (10mg/kg) or SC injection (coformulated with recombinant human hyaluronidase PH20; 1000mg), in cycles of 4 once-weekly administrations. Subsequent cycles were initiated >=5 weeks (ADAPT) or >=4 weeks (ADAPT-SC+) from last dose based on clinical evaluation. HRQoL was assessed by validated MG-specific (MG-QoL15r) and general (EQ-5D-5L VAS) scales.

Results: Demographics/baseline characteristics for AChR-Ab+ participants are in Table 1. In ADAPT, efgartigimod-treated AChR-Ab+ participants ($n=63$) showed statistically significant improvements in HRQoL versus placebo ($n=60$). Mean (SE) MG-QoL15r score decreased from baseline to week 4, cycle 1: efgartigimod, –7.3 (0.79); placebo, –2.3 (0.51). Mean (SE) EQ-5D-5L VAS score increased from baseline to week 4, cycle 1: efgartigimod, 15.8 (2.20); placebo, 4.1 (1.64)(Fig.1). Improvements in QoL were consistent in ADAPT-SC+, with peak mean (SE) changes from baseline in MG-QoL15r and EQ-5D-5L VAS scores of –5.1 (0.44) and 13.8 (1.54), respectively, at week 4, cycle 1 (Fig. 1). In ADAPT-SC+, MG-QoL15r and EQ-5D-5L VAS cycle baseline scores improved with subsequent cycles, indicating durable QoL improvements.

Conclusion: Efgartigimod IV/SC demonstrated consistent and meaningful improvements in QoL across clinical trials in AChR-Ab+ gMG, achieving an important treatment goal for these participants.

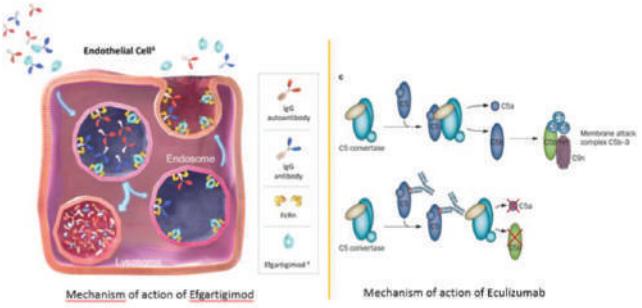
EPO-207 | Eculizumab as rescue therapy in two gMG patients with worsening symptoms while on Efgartigimod

N. Cuomo; A. Sarnataro; A. Marsili; G. Puorro;
M. Campanile; C. Pane; F. Saccà
Department of Neurosciences, Reproductive and Odontostomatological Sciences – Federico II University – Naples

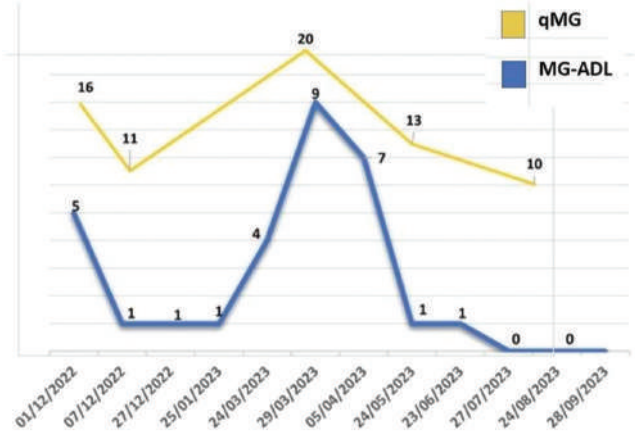
Background and Aims: Eculizumab and Efgartigimod are available for refractory anti-AChR+ gMG. We describe two cases who suffered a relapse while on Efgartigimod, rescued with Eculizumab.



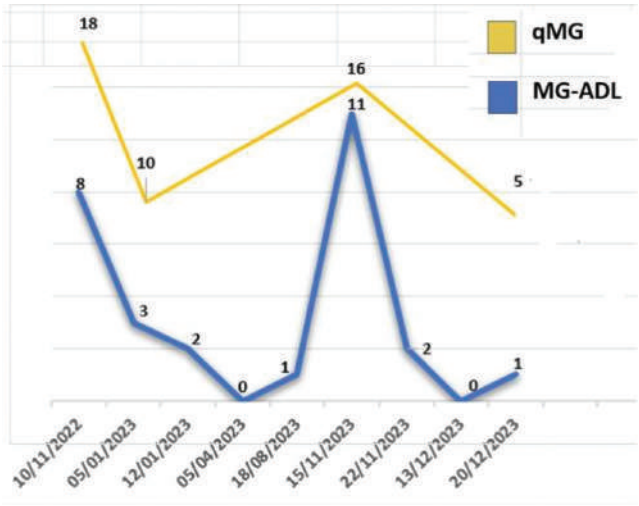
Efgartigimod and Eculizumab mechanisms of action

Methods: Case 1: A 46 yo woman treated with thymectomy, pyridostigmine, prednisone, azathioprine, IVIg. In December 2022 she started Efgartigimod IV (10 mg/kg weekly for four weeks, every two months). Her MG-ADL and qMG were 5 and 16. Case 2: A 47 yo woman treated with thymectomy, pyridostigmine, prednisone and azathioprine. In November 2022 she started Efgartigimod. Her MG-ADL and qMG were 8 and 17.

Results: Case 1: After the first cycle her MG-ADL and qMG dropped to 1 and 11 and remained stable, until, during the third cycle (18th week) she worsened (MG-ADL 9, qMG 20). We discontinued Efgartigimod and started Eculizumab (900 mg iv weekly for 4 weeks, followed by 1200 mg from the fifth week and every two weeks). Her MG-ADL dropped to 5 and at the fifth week her MG-ADL and qMG were 1 and 14. Case 2: After the first Efgartigimod cycle her MG-ADL and qMG were 2 and 10. 48 weeks later her symptoms worsened (MG-ADL 11 and qMG 16). We stopped Efgartigimod and started Eculizumab: after the first infusion her MG-ADL was 2 and at the beginning of the maintenance phase her MG-ADL and qMG were 0 and 5.



Case 1 – MG-ADL and qMG scores



Case 2 – MG-ADL and qMG scores

Conclusion: As far as we know, these are two of the first reports of Eculizumab as rescue therapy in patients not responding to Efgartigimod.

Disclosure: Nothing to disclose.

EPO-208 | Dysferlinopathies: Insights from two Portuguese tertiary centers

R. Lopes[1]; A. Ferreira[2]; D. Barros[3]; E. Vieira[4]; A. Gonçalves[5]; M. Oliveira[5]; R. Santos[6]; R. Maré[2]; A. Sousa[7]; M. Pinto[8]; M. Cardoso[7]; T. Coelho[7]

[1]Neurology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal; [2]Neurology Department, Hospital de Braga, Braga, Portugal; [3]Radiology Department, Hospital de Braga, Braga, Portugal; [4]Medical genetics Department, Centro de Genética Médica Jacinto Magalhães, Centro Hospitalar Universitário de Santo António (CHUdSA), Porto, Portugal; [5]Unidade Multidisciplinar de Investigação Biomédica (UMIB), Instituto de Ciências Biomédicas Abel Salazar (ICBAS), University of Porto, Porto, Portugal; [6]European Reference Center of Neuromuscular Diseases (EURO-NMD), Centro Hospitalar Universitário de Santo António (CHUdSA), Porto, Portugal; [7]Neurophisiology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal; [8]Neuropathology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal

Background and Aims: Dysferlinopathies constitute a subgroup of rare autosomal recessive muscular dystrophies characterized by high phenotypic and genetic heterogeneity. We aimed to characterize the adult patient population with dysferlinopathy from two Portuguese centers.

Methods: Retrospective analysis of patients with a molecular diagnosis of dysferlinopathy followed in an outpatient setting. Recording of demographic, clinical, laboratory, imaging and molecular data were used.

Results: Twenty-one patients from 19 families were identified (male-to-female ratio 1.65:1) with an average age of 48.3 years and symptom onset at 23 ± 9 years. Fifteen different pathogenic variants were identified in the DYSF gene (2 homozygous, 9 compound heterozygous). Most patients reported symptoms in the 20 years preceding molecular diagnosis. Eleven (52%) underwent muscle biopsy, with most showing absence of dysferlin staining. Fourteen patients presented with limb-girdle muscular dystrophy type R2 (LGMDR2) phenotype, two with Miyoshi myopathy, two with distal anterior compartment myopathy, two with hyperCKemia, and one with proximodistal. Fifteen patients progressed to generalized weakness. At an average of 26 years of disease progression, 11 patients (52%) were unable to walk, and 14% required walking aids. Four patients reported dyspnea, 8 with abnormal respiratory function tests, and 3 with cardiomyopathy. Initial CK levels were globally elevated (average 4,953 U/L). Muscle MRI, performed in 4 patients, revealed a similar pattern of adipose infiltration.

Conclusion: Our findings are consistent with the existing literature, demonstrating a diverse spectrum of phenotypes, onset patterns, and progression rates. Given the described clinical and molecular heterogeneity, the ongoing progress in molecular genetic techniques have facilitated a more rapid and definitive diagnosis.

Disclosure: Nothing to disclose.

EPO-209 | Efficacy and safety of Efgartigimod IV and PH20 SC in gMG: analysis of AChR-Ab− participants in ADAPT+/ADAPT-SC+

S. Hoffmann[1]; J. F. Howard; Jr[2]; T. Vu[3]; J. L. De Bleecker[4]; K. Utsugisawa[5]; H. Murai[6]; F. Saccà[7]; D. Korobko[8]; C. T'joen[9]; S. Steeland[9]; B. Van Hoorick[9]; J. Podhorna[9]; A. Meisel[10]; R. Mantegazza[11]

Background and Aims: Efgartigimod, a human IgG1 antibody Fc fragment, reduces IgG autoantibody levels by blocking the neonatal Fc receptor. AChR-Ab− patients comprise 15–20% of the generalised myasthenia gravis (gMG) population but have limited treatment options. Efficacy (AChR-Ab− participants) and safety (overall population) from the completed, Phase 3 ADAPT+ (IV) and ongoing, open-label extension ADAPT-SC+ (SC) trials are reported.

Methods: Efgartigimod was administered via IV infusion (10mg/kg [ADAPT+]) or SC injection (coformulated with recombinant human hyaluronidase PH20; 1000mg [ADAPT-SC+]) in cycles of 4 once-weekly administrations. Subsequent cycles were initiated based on clinical evaluation. Efficacy was assessed using MG-ADL scores from final (ADAPT+) and interim (ADAPT-SC+; cut-off December 2022) analyses.

Results: Demographics/baseline characteristics were similar between AChR-Ab− and AChR-Ab+ populations (Table 1). Efgartigimod improved total mean (SE) MG-ADL scores in AChR-Ab− participants (week 3, cycle 1): ADAPT+, −5.3 (0.74); ADAPT-SC+, −3.5 (0.51), with most achieving clinically meaningful improvements (ADAPT+: 79.4%; ADAPT-SC+: 67.6%). MG-ADL score improvements were consistent across multiple cycles (Fig.1). A subset of AChR-Ab− participants achieved minimal symptom expression (MSE) at any time during cycle 1 (ADAPT+: 26.5%; ADAPT-SC+: 13.2%). Proportions achieving MSE were consistent across multiple cycles in both trials. Efgartigimod was well tolerated, and most adverse events (AEs)

were mild/moderate in severity. The most frequent AEs were headache (24.8%, 20.1%), nasopharyngitis (13.8%, 15.6%) and COVID-19 (12.4%, 22.3%) in ADAPT+ and ADAPT-SC+, respectively (Table 2). Reported deaths (ADAPT+: $n = 5$; ADAPT-SC+: $n = 4$) were unrelated to treatment.

TABLE 1

Table 1 Demographics and baseline disease characteristics (AChR-Ab− and AChR-Ab+ participants)

	ADAPT+*		ADAPT-SC+	
	AChR-Ab− (n=34)	AChR-Ab+ (n=111)	AChR-Ab− (n=38)	AChR-Ab+ (n=141)

EPO-210 | Achievement of minimal symptom expression in participants treated with Efgartigimod in ADAPT+ and ADAPT-SC+

S. Hoffman[1]; S. Muppidi[2]; J. Howard Jr.[3]; H. Murai[4]; G. Phillips[5]; C. Qi[5]; D. Gelinas[5]; E. Brauer[5]; S. Zhao[5]; V. Bril[6]; J. Vissing[7]; J. Verschuuren[8]; R. Mantegazza[9]; ADAPT and ADAPT-SC Study Groups[10]

[1]Department of Neurology and NeuroCure Clinical Research Center, Charité – Universitätsmedizin Berlin, Berlin, Germany; [2]Stanford Healthcare, Palo Alto, California, USA; [3]Department of Neurology, The University of North Carolina, Chapel Hill, North Carolina, USA; [4]Department of Neurology, School of Medicine, International University of Health and Welfare, Tokyo, Japan, [5]argenx, Ghent, Belgium; [6]Ellen & Martin Prosserman Centre for Neuromuscular Diseases, University Health Network, Toronto, Ontario, Canada; University of Toronto, Toronto, Ontario, Canada; [7]Copenhagen Neuromuscular Center, Rigshospitalet, University of Copenhagen, Denmark; [8]Department of Neuroimmunology and Neuromuscular Diseases, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy; [9]Department of Neuroimmunology and Neuromuscular Diseases, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy

Background and Aims: Efgartigimod, a human IgG1 antibody Fc-fragment, reduces IgG levels through neonatal Fc receptor blockade. Efgartigimod has been investigated in the treatment of generalised myasthenia gravis (gMG) through intravenous (IV) and subcutaneous (SC, coformulated with recombinant human hyaluronidase PH20) administration in the ADAPT/ADAPT+ and ADAPT-SC/ADAPT-SC+ studies, respectively. A key efficacy indicator in gMG treatment is MG-ADL score improvement. Minimal symptom expression (MSE, MG-ADL total score of 0 or 1) is explored as a novel proposed treatment target in gMG.

Methods: The proportion of acetylcholine receptor antibody positive (AChR-Ab+) participants in ADAPT+ ($n=111$) and ADAPT-SC+ ($n=141$) to achieve MSE was assessed.

Results: In ADAPT, MSE was achieved in 44.6% of efgartigimod-treated participants vs 10.9% of placebo-treated participants at any time point up to 3 cycles. In ADAPT+, the number of participants achieving MSE at any time in up to 19 cycles was 40.5%. Eighty-one percent of efgartigimod-treated participants who achieved MSE in ADAPT also achieved MSE during ADAPT+; 23% who had not achieved MSE in ADAPT did so in ADAPT+. In ADAPT-SC, 45.5% and 41.3% of participants receiving efgartigimod PH20 SC or efgartigimod IV achieved MSE at any time in cycle 1, respectively. In ADAPT-SC+, the number of participants achieving MSE at any time in up to 9 cycles was 54.6%. Clinical improvements may not have been fully captured in OLEs (ADAPT+/ADAPT-SC+) due to the limited number of assessment timepoints.

Conclusion: Achievement of MSE was consistently seen across cycles in AChR-Ab+ participants of both ADAPT+ and ADAPT-SC+, similar to results demonstrated in ADAPT and ADAPT-SC.

Ageing and dementia 2

EPO-211 | Knockdown of hippocampal calponin-3 alleviates memory impairment and Aβ deposition in APP/PS1 mice

W. Yang; Y. Han; L. Chen; K. Wang

First Department of Neurology, First Affiliated Hospital, Kunming, Yunnan, China

Background and Aims: Alzheimer's disease (AD) is characterized by progressive cognitive decline, with senile plaques of beta-amyloid (Aβ). Calponin-3, encoded by CNN3, is highly expressed in the brain and regulates cytoskeletal reorganization and dynamics as well as actin interactions through efficient binding to F-actin, thereby controlling dendritic spine morphology, density and plasticity.

Methods: Adenovirus with calponin-3 knockdown or control virus were injected into the hippocampi of APP/PS1 mice to construct APP/PS1-CNN3-KD or APP/ PS1-CNN3-Ctrl mice. The expression of calponin-3 in the hippocampi of experimental mice were confirmed by western blot and Immunofluorescence (IF). Cognitive function of mice were tested by novel object recognition testing(NOR)for working memory, and object location recognition testing(OLR)and morris water maze (MWM) for spatial memory.

Results: The level of hippocampal calponin-3 of 4-, 6- and 9-month old APP/PS1 mice were significantly higher than those of wide type (WT) mice at the same age. IF revealed that calponin-3 distributed in clusters and colocalized with Aβ in the hippocampi of APP/PS1 mice. 7-month old APP/PS1-CNN3-KD mice showed significantly better the working memory and spatial memory, and reduced Aβ deposition and β secretase enzyme 1 (BACE1) levels than APP/ PS1-CNN3-Ctrl mice.

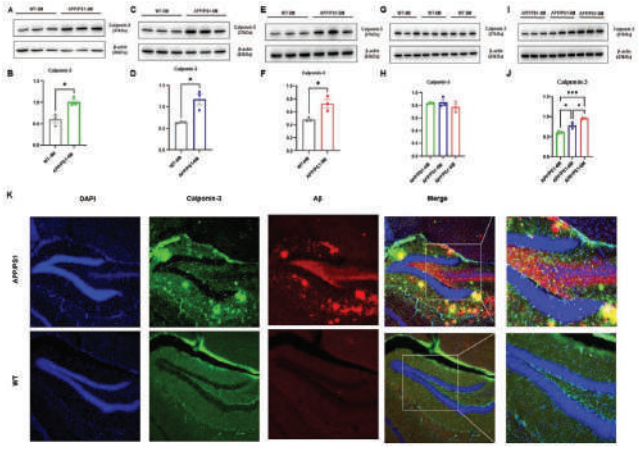

FIGURE 1

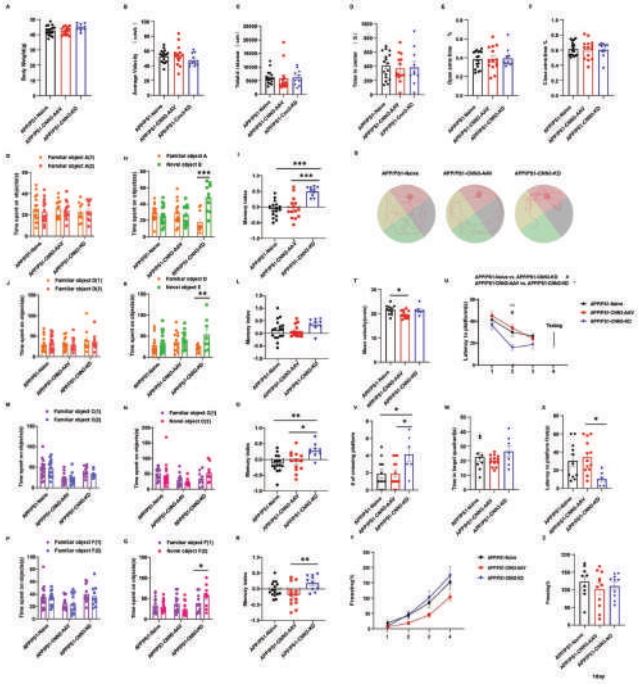

FIGURE 2

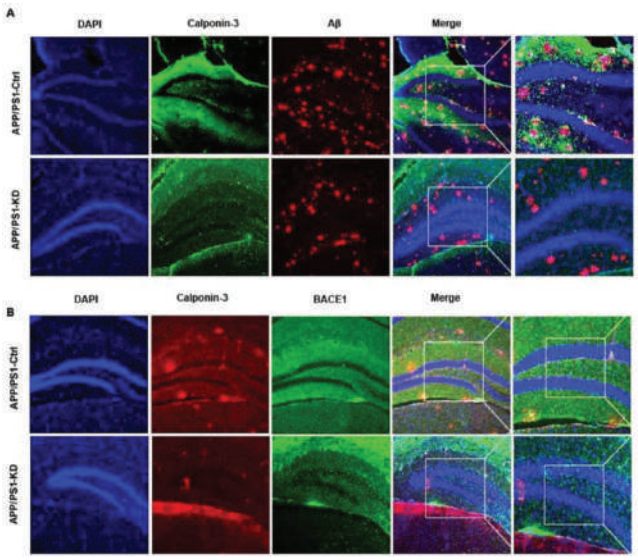

FIGURE 3

Conclusion: Knockdown of hippocampal calponin-3 can improve working and spatial memory and alleviate deposition of Aβ in APP/PS1 mice. Abnormally up-regulation of hippocampal calponin-3 may involve in pathogenesis of AD.

Disclosure: Nothing to disclose.

EPO-212 | Randomized, placebo-controlled, multiple ascending dose study of NX210c safety/tolerability and PK/PD in the elderly

D. Dumas[1]; J. Le Douce[2]; S. Marie[2]; P. Kremer[1]; F. Sips[3]; P. Bambury[4]; G. Pasculli[4]; R. Bursi[3]; Y. Godfrin[2]; S. Lemarchant[2]; A. Janus[2]

[1]*Centre for Human Drug Research, Leiden, The Netherlands;* [2]*Axoltis Pharma, Lyon, France;* [3]*InSilicoTrials Technologies B.V., s' Hertogenbosch, The Netherlands;* [4]*InSilicoTrials Technologies S.p.A, Trieste, Italy*

Background and Aims: Blood-brain barrier (BBB) dysfunction underlies various neurodegenerative diseases (NDD). NX210c is an oligopeptide that reduces blood-brain barrier (BBB) permeability via claudin-5, supports neuroprotection and promotes synaptic transmission in preclinical models. multiple A multiple ascending dose (MAD) study assessed safety and tolerability of intravenously (IV) administered NX210c (at 5 and 10 mg/kg) in healthy elderly volunteers (HEV) with secondary and exploratory objectives to assess blood pharmacokinetics (PK) and pharmacodynamic (PD) parameters, respectively, including blood biomarkers relevant to NDD.

Methods: We report results of a randomized, double-blind, placebo-controlled, MAD study of two doses of NX201c in HEVs run in a single centre with two cohorts of 15 HEVs randomized (4:1 ratio) to NX210c dose or placebo 3x/week (w) for 4w with a follow-up visit 2w after last dosing.

Results: Of 29 HEV randomized, 20 registered 73 treatment-emergent adverse events with all possibly related adverse events mild and no serious adverse events or evidence of NX210c accumulation. According to modelling data, NX210c treatment demonstrated a robust PK/PD relationship, characterized by inhibition of claudin-5, NfL, and SPARCL-1 production, as well as degradation of homocysteine.

Conclusion: NX210c demonstrated a good safety profile following multiple doses in HEV and showed a PD relationship for biomarkers relevant to the BBB, including a reduction of plasma claudin-5. As BBB disruption is a driving feature of NDD, NX210c effect on target biomarkers may represent an important disease-modifying treatment for several neurological disorders and warrants further study in patients with NDD.

Disclosure: DD and PK are employed by CHDR. JLD, SM, SL and AJ are employed by Axoltis Pharma. YG is a shareholder of Axoltis Pharma.

EPO-213 | Neuropathological, clinical and genetic comparison of four peculiar FTLD cases from the Abbiategrasso Brain Bank

A. Gatti[1]; G. Negro[2]; C. Calatozzolo[3]; V. Medici[4]; X. Profka[3]; A. Costa[1]; E. Poloni[3]

[1]*IRCCS "C. Mondino" Foundation, National Neurological Institute, Department of Behavioral Sciences, University of Pavia, Italy;* [2]*Department of Neurology and School of Medicine and Surgery, University of Milano Bicocca, Monza; Italy Department of Neuropathology, Golgi-Cenci Foundation, Abbiategrasso, Italy;* [3]*Department of Neurology and Neuropathology, Golgi-Cenci Foundation, Abbiategrasso, Milan, Italy;* [4]*Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy*

Background and Aims: The spectrum of fronto-temporal lobar degeneration (FTLD) encompasses several proteinopathies and clinicopathological features: (1) heterogeneous clinical presentations; (2) heterogeneous neuropathology; (3) involvement of many genes; (4) atrophy of the frontal and/or temporal cortex. The aim of the study is to present four emblematic cases in order to emphasize the clinical and pathological heterogeneity of FTLD.

Methods: We followed four subjects with major-neurocognitive disorder (major-NCD), belonging to the Abbiategrasso Brain Bank, and analyzed the neuropathology of their brains.

Results: Case 1 – Major-NCD: nfv-PPA/CBS: progressive non-fluent aphasia (nfPPA), apraxia, disinhibition, apathy, hyperorality, severe right hemiparkinsonism and dystonia; neuroimaging: asymmetrical left frontal atrophy; neuropathology: prevalent type A TDP-43 histopathology, limbic co-localization of synuclein pathology and low AD pathology. Case 2 – Major-NCD: behavioral variant FTD (bvFTD): spatial disorientation, wandering, disinhibition, delusions, apathy, hyperorality, postural instability and bilateral parkinsonism; neuroimaging: asymmetrical right temporo-parieto-occipital atrophy; neuropathology: pure type A TDP-43 histopathology. Case

3 – Major-NCD: frontal variant AD (fvAD): logopenic language impairment, progressive memory loss, social withdrawal, apathy, aggressivity, wandering, sleep disturbances, delusions, hallucinations, bilateral rigid-hypokinetic parkinsonism in the advanced stages; neuroimaging: symmetrical fronto-temporal atrophy; neuropathology: predominant AD pathology, limbic co-localization of synuclein pathology and mild TDP-43 pathology. Case 4 – Major-NCD: semantic variant FTD (svFTD): spatial disorientation, fluent aphasia with comprehension and naming deficits, delusions, wandering, aggressivity, postural instability and rigid-hypokinetic parkinsonism; neuroimaging: symmetrical temporal atrophy; neuropathology: predominant AD pathology.

Conclusion: The clinical-pathological comparison of these four cases demonstrates the heterogeneity of FTLD and the essential role of neuropathology in determination of definitive diagnosis of neurodegenerative diseases.

Disclosure: Nothing to disclose.

EPO-214 | CSF biomarkers of Alzheimer's disease, neuropsychological tests and UPDRS-III in patients with Parkinson's disease

A. Scalese; G. Giuffrè; T. Morganti; F. Musso; A. Cimmino; G. Di Lazzaro; D. Quaranta; C. Marra; P. Calabresi
Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy; Institute of Neurology, Catholic University of the Sacred Heart, Rome, Italy

Background and Aims: CSF biomarkers of amyloidopathy (Aβ42 and Aβ42/40), tauopathy (p-tau) and neurodegeneration (t-tau) have been widely used as a measure of Alzheimer's disease (AD) pathology in vivo and as a predictor of cognitive impairment in AD. These biomarkers have been proven to predict cognitive decline in PD as well. We aimed to assess the associations between CSF biomarkers of AD pathology and cognitive/motor impairment in a cohort of PD patients.

Methods: We recruited 45 subjects with diagnosis of PD. A lumbar puncture (LP) was performed and CSF biomarkers of AD were quantified. At the time of LP, a complete neuropsychological battery and UPDRS-III motor scale were used to assess cognitive and motor domains respectively. A 12–24 months follow-up UPDRS-III was available for every patient. Correlations between CSF biomarkers, neuropsychological tests and UPDRS-III at the time of LP and after 12–24 months were carried out.

Results: Our results revealed a significant correlation between biomarkers of amyloidopathy and poorer performances in MMSE, RAVLT delayed recall, Spatial Span, Raven matrices, MFTC, semantic verbal fluency, ROCF delayed. Aβ42/40 was found to predict the change between the UPDRS-III score at the baseline and follow-up.

Conclusion: Amyloidopathy is a frequent PD co-pathology. This study highlighted the role of CSF biomarkers of amyloidopathy as a tool to predict worse performances in some common neuropsychological tests. Furthermore, Aβ42/40 showed potential in identifying PD patients at risk of accelerated motor decline, suggesting a possible synergistic role of Aβ42 with alpha-synuclein in the clinical progression of Parkinson disease.

Disclosure: Nothing to disclose.

EPO-215 | Genetically proxied PDE5 inhibition and risk of dementia: A drug target Mendelian randomisation study

S. Brennan; A. Tinworth
The Mater Misericordiae University Hospital

Background and Aims: Phosphodiesterase-5 (PDE5) inhibitors have gained interest as a potential treatment for dementia. However, current evidence is limited to observational and pre-clinical studies. This drug-target Mendelian Randomisation (MR) study aims to elucidate the on-target effects of pharmacological PDE5 inhibition on dementia subtypes, cognitive traits, and neuro-imaging phenotypes.

Methods: Two independent ($r^2 < 0.001$) blood pressure lowering variants from around the PDE5A locus were used in two-sample MR to assess the effect of genetically proxied PDE5 inhibition on risk of dementia subtypes, cognitive performance, and neuroimaging traits (cortical thickness, surface area and volume of white matter hyperintensities) in large-scale genomic consortia. The instrument's predictive validity was assessed against erectile dysfunction and pulmonary arterial hypertension (PAH) as positive controls.

Results: Following correction for multiple comparisons, genetically proxied PDE5 inhibition was associated with lower odds of erectile dysfunction (OR 0.85, 95% CI 0.83–0.87) and PAH (OR 0.58, 95% CI 0.55–0.61), and higher odds of Alzheimer's disease (OR 1.07, 95% CI 1.04–1.10), Lewy body dementia (OR 1.20, 95% CI 1.17–1.23) and vascular dementia (OR 1.04, CI 1.02–1.07). Furthermore, genetically proxied PDE5 inhibition was associated with reduced cortical thickness (SD change −0.003, 95% CI −0.004, −0.002) and cognitive performance (SD change −0.010, 95% CI −0.013, −0.007), but not cortical surface area or volume of white matter hyperintensities.

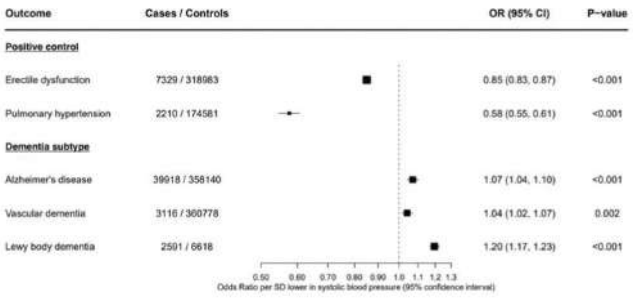

FIGURE 1 Forest plot depicting Mendelian randomisation estimates for genetically proxied PDE5 inhibition and associations with positive controls and dementia subtypes (Bonferroni correction: $p < 0.0036$ for statistical significance)

TABLE 1 Mendelian randomisation estimates for genetically proxied PDE5 inhibition and associations with cognitive traits and neuro-imaging phenotypes (Bonferroni correction: $p < 0.0036$ for statistical significance)

Outcome	Mean (SD)	SD difference (95% CI)	P-value
Cognitive performance	Score 0 ± 1	-0.010 (-0.013, -0.007)	<0.001
Average cortical thickness	2.45 ± 0.11mm	-0.003 (-0.004, -0.002)	<0.001
Average cortical surface area	169,647.43 ± 16,501.45mm²	320.172 (25.464, 614.881)	0.033
White matter hyperintensities	-0.027	-0.027 (-0.050, -0.005)	0.016

Conclusion: In contrast to evidence from observational studies, our findings indicate that inhibition of PDE5 is associated with higher risk of dementia, and an unfavourable neurocognitive profile. This risk should be further investigated prior to clinical trials of pharmacological PDE5 inhibition in the treatment and prevention of dementia.

Disclosure: The author Alexander Tinworth may receive support from the Nuffield Department of Population Health at the University of Oxford or his scholarship benefactor, the British Heart Foundation to attend conferences but has not received financial or academic support in the conducting or writing of the study.

EPO-216 | Identification of novel dysregulated proteins in Alzheimer's disease patients with therapeutic and diagnostic potential

A. Montero-Calle[1]; R. Coronel[2]; V. de los Ríos[3]; A. Peláez-García[4]; M. Fernández-Aceñero[5]; J. Martínez-Useros[6]; M. Mendes[7]; I. Liste[2]; R. Barderas[1]

[1]*Chronic Disease Programme (UFIEC), Instituto de Salud Carlos III, Majadahonda, Madrid, Spain;* [2]*Unidad de Regeneración Neural, Unidad Funcional de Investigación de Enfermedades Crónicas, Instituto de Salud Carlos III (ISCIII), Majadahonda, Madrid, Spain;* [3]*Centro de Investigaciones Biológicas, CSIC, Madrid, Spain;* [4]*Hospital Universitario La Paz, Madrid, Spain;* [5]*Hospital Universitario Clínico San Carlos, Madrid, Spain;* [6]*Translational Oncology Division, OncoHealth Institute, Fundación Jimenez Diaz University Hospital, Madrid, Spain;* [7]*Department of Infection and Immunity, Luxembourg Institute of Health, Strassen, Luxembourg*

Background and Aims: Alzheimer's disease (AD) is the most common cause of dementia worldwide. Its pathogenesis has not been well elucidated yet and effective treatments are needed. We aimed to analyze protein dysregulation in AD to identify dysregulated proteins that could be key for the study of AD by two proteomics strategies, TMT (Tandem Mass Tags) 10-plex quantitative proteomics and LFQ (Label Free Quantification).

Methods: For TMT, brain protein extracts from AD patients (Braak IV-VI) were analyzed by tandem mass spectrometry coupled to liquid chromatography (LC-MS/MS) using a Q-Exactive. Protein extracts from VD (vascular dementia) and FTD (frontotemporal dementia) patients, and healthy individuals were used as controls. For LFQ, a pull-down with in vitro synthesized Abeta (Amyloid-beta) fibers was performed, and interacting proteins analyzed by LC-MS/MS. Subsequent analysis of proteomics data was performed with MaxQuant and the R program.

Results: 169 out of 3281 proteins identified by TMT were found statistically significant ≥1.5-fold dysregulated in AD in comparison to controls, with the dysregulation of 10 of them confirmed using a different cohort of tissue and plasma samples. Two of these proteins were found associated to Abeta fibers, and two as blood-based biomarkers of AD. Regarding the pull-down, 332 proteins were identified as potential interactors of Abeta fibers, with 18 of them validated in vitro and ex vivo.

Conclusion: Novel proteins associated to AD pathogenesis, with a potential role in AD development and as biomarkers of the disease were described here. In addition, these proteins possess a high potential as therapeutic targets.

Disclosure: This work was supported by the PI17CIII/00045 grant from the AES-ISCIII program to R.B. The A.M-C. FPU predoctoral contract was supported by the Spanish Ministerio de Educación, Cultura y Deporte. The authors declare no competing interests.

EPO-217 | Structure-based discovery of choline acetyltransferase ligands as potential theranostic agents for Alzheimer's disease

A. TK Baidya[1]; B. Das[1]; T. Darreh-Shori[2]; R. Kumar[1]

[1]*Department of Pharmaceutical Engineering & Technology, Indian Institute of Technology (Banaras Hindu University), Varanasi, Uttar Pradesh, India;* [2]*Division of Clinical Geriatrics, Centre for Alzheimer Research, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden*

Background and Aims: Choline acetyltransferase (ChAT), is a key cholinergic enzyme that biosynthesizes neurotransmitter acetylcholine, which plays a pivotal role in fundamental brain processes. Gradual loss of cholinergic neurons is observed in the brain with Alzheimer's disease which correlates well with the progressive decline of ChAT levels. This makes ChAT a key biomarker to estimate AD progression. The absence of specific, potent, blood-brain-barrier permeable small molecule ligands motivated us to discover novel ChAT ligands.

Methods: In this study, we have screened a VITAS-M small molecule library containing ~1.4 million compounds by using a structure-based virtual screen protocol based on VinaMPI. The top scoring compounds were manually inspected for their interaction with the active site amino acid residues and fifty compounds were selected.

Results: The fifty structurally diverse hits were identified. All showed potentially good interaction with the hotspot residues in the binding pocket of ChAT. They also showed prominent interaction with the catalytic residue His324 which is necessary for inhibitory activity of ligands. These hits will be validated in an in-house developed fluorimetric assay to evaluate their enzyme inhibition kinetics

and molecular dynamic simulation to understand their dynamic interaction in the process of ChAT inhibition.

Conclusion: The potential ChAT hits identified in this study can be further developed into ChAT PET tracers for the diagnosis of cholinergic dysfunction and to initiate timely therapeutic interventions to prevent or delay the progression of AD.

Disclosure: Nothing to disclose.

EPO-218 | Clinical correlations with diffusion-weighted MRI in probable Creutzfeldt-Jakob Disease

H. Rhee

Department of Neurology, Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea

Background and Aims: Diffusion-weighted imaging (DWI) of the brain is important in diagnosing CJD. Also, elevated CSF total tau (t-tau) is considered a useful CJD biomarker revealing neuro-axonal damage although it is not specific for CJD. In this study, we attempted to find out the association between DWI abnormality and CSF t-tau in CJD patients.

Methods: The patients who had been diagnosed and reported as human prion disease to the Korea Disease Control and Prevention Agency (KDCA) by medical institutions in South Korea from January 1, 2019, to December 31, 2019, were included in the clinical review. A total of 186 patients had been reported as suspected human prion disease during the one year and 53 patients who satisfied the criteria for human prion disease were included in the analysis.

Results: Hyperintense lesions on DWI were observed in 52 patients (98%). The involvement of the neocortex was observed in almost all patients (98%) and asymmetrical and bilateral hyperintensities on DWI were common. Among the neocortex, the most commonly involved region was the parietal lobe, followed by the frontal lobe, temporal lobe, and occipital lobe. DWI abnormality in the striatum and/or thalamus was observed in 65.3% of patients. There was no significant association between the extent of the lesions on DWI and CSF t-tau.

Conclusion: In this study, most of the patients with probable CJD showed DWI abnormality mainly on the neocortex (parietal > frontal > temporal > occipital). The association between the pattern of DWI abnormality and the level of CSF t-tau was not observed.

Disclosure: Nothing to disclose.

EPO-219 | Linking mitochondrial dysfunction with glial and neuroaxonal degeneration in Creutzfeldt-Jakob disease

C. Manco; D. Plantone; D. Righi; S. Locci; N. De Stefano

Department of Medicine, Surgery and Neuroscience, University of Siena, Siena, Italy

Background and Aims: Creutzfeldt-Jakob Disease (CJD) is a rare human prion disease characterized by the aberrant accumulation of a misfolded prion protein in neurons, causing spongiform changes, and neuronal loss. The exact neuropathogenic mechanisms associated with the rapid neuronal death partly remain unclear, with mitochondrial dysfunction possibly giving a contribution. This study explores the serum concentrations of biomarkers of neurodegeneration, glial activation, and mitochondrial dysfunction in CJD and their associations.

Methods: We assessed the serum material of 16 CJD patients [median age 66 years (25th-75th percentile 59.8–77.3)] and 72 healthy controls [HC median age 64 years (25th-75th percentile 56–72)]. Serum neurofilament light chain (sNfL) and serum glial fibrillary acidic protein (sGFAP) levels were assessed with single molecule assay (SIMOA), and serum Growth Differentiation Factor-15 (sGDF-15) with ELISA. Spearman correlation and analysis of covariance, considering age as covariate, were performed.

Results: Significant differences were found in sNfL [median CJD sNfL: 129 pg/ml (25th–75th percentile 102–252), median HC sNfL: 12.1 pg/ml (25th–75th percentile 7.96–16.2); $p < 0.001$] and sGFAP [median CJD sGFAP 586 pg/ml (25th-75th percentile 394–1300), HC 101 pg/ml (25th-75th percentile 50.8–169); $p < 0.001$] between CJD and HC. No difference was shown when sGDF-15 was considered [median CJD sGDF-15: 780 ng/ml (25th-75th percentile 402–2151); median HC sGDF-15 704 ng/ml (25th-75th percentile 444–992)]. In CJD patients, however, we found a significant positive correlation of sNfL with sGDF-15 levels ($p = 0.001$, $r = 0.748$).

Conclusion: Our study suggests a role of mitochondrial dysfunction in the complex process of neurodegeneration in CJD.

Disclosure: Nothing to disclose.

EPO-220 | Unilateral magnetic resonance-guided focused ultrasound thalamotomy for essential tremor and Parkinson's disease

C. Sempere Navarro[1]; G. Fernández Pajarín[1]; J. García de Soto[1]; J. Casillas Clot[2]; P. Román[3]; M. Blanco[4]; E. Ares[3]; B. Ares[3]; J. Prieto[1]; Á. Sesar[1]

[1]*Department of Neurology, Hospital Clínico Universitario, Santiago de Compostela, Spain;* [2]*Department of Community nursing, preventive medicine and healthcare, University of Alicante, Alicante, Spain;* [3]*Department of Neurosurgery, Hospital Clínico Universitario, Santiago de Compostela, Spain;* [4]*Department of Radiology, Hospital Clínico Universitario, Santiago de Compostela, Spain*

Background and Aims: Magnetic Resonance-guided focused ultrasound (MRgFUS) thalamotomy is a minimally invasive procedure with proven efficacy in the management of refractory tremor. The objective of this study is to analyse differences of effectiveness in tremor reduction between Essential Tremor (ET) and Parkinson's disease (PD).

Methods: A total of 22 patients, 11 with refractory essential tremor (ET) and 11 with PD, who underwent MRgFUS thalamotomy in our center were included. The Clinical Rating Scale for Tremor of the

treated hemibody (CRST A+B) and functional disability (CRST C) were compared before and 6 months after MRgFUS thalamotomy, as well as adverse effects at 1 and 6 months.

Results: At baseline, mean (±SD) age was 71.1 1±8.53 for ET patients and 70.1±12.89 years for PD patients ($p=0.832$). Before treatment, CRST A+B scores were 21.45±5.94 and 19.64±5.89 ($p=0.438$) and CRST C were 17.18±5.4 and 14.09±6.46 ($p=0.365$), respectively. After 6 months of MRgFUS thalamotomy, a significant improvement in tremor severity and disability was observed (CRST A+B: 1.82±2.44 and 3.45±3.53 ($p=0.003$); CRST C: 1.82±2.18 and 4.09±4.23 ($p=0.003$)), although there were not significant differences between both groups ($p=0.193$ and $p=0.065$, respectively). Dysarthria and unsteadiness were the most common adverse effects reported, which were mild and transient.

Conclusion: Unilateral MRgFUS thalamotomy is safe and effective for refractory tremor in ET and PD. Further studies with larger sample sizes are needed to address possible differences in efficacy.

Disclosure: Nothing to disclose.

EPO-221 | Obstructive sleep apnoea and cognitive decline: Quest for new biomarkers

C. da Silva[1]; J. Neiva Machado[2]; J. Moita[3]; C. Loureiro[3]; T. Almeida[3]; M. Lima[1]; J. Durães[1]; M. Leitão[1]; P. Faustino[1]; C. Bernardes[1]; I. Baldeiras[1]; A. Silva-Spínola[1]; I. Santana[1]; M. Tábuas-Pereira[1]

[1]Neurology Department, Unidade Local de Saúde Coimbra, Coimbra, Portugal; [2]Pulmonology Department, Unidade Local de Saúde Região de Leiria, Leiria, Portugal; [3]Pulmonology Department, Unidade Local de Saúde Coimbra, Coimbra, Portugal

Background and Aims: Obstructive sleep apnea (OSA) is the most common type of sleep-related breathing disorder. The underlying chronic intermittent hypoxia and sleep fragmentation are pointed out as the main mechanisms leading to cognitive decline. Apnea-hypopnea index has been used to evaluate severity of OSA, but oxygen desaturation index (ODI) is a relevant parameter, reflecting hypoxia. We aim to explore the link between different OSA markers and CSF biomarkers related to Alzheimer's disease (AD).

Methods: Transversal and retrospective study. We selected patients with cognitive complaints followed in a neurology appointment from a tertiary health center that met criteria for OSA through polysomnography (PSG). We gathered demographic and clinical data, including PSG parameters and CSF biomarkers of dementia. Statistical analysis comprised univariate and multivariate analysis adjusted for potential confounding variables. Statistical significance was set at $p<0.05$.

Results: A total of 81 patients were included (mild OSA 29.6%, moderate OSA 35.8%, severe OSA 21.0%). Forty-six (56.8%) were women, mean age of 69.2 years, 7.3 years of education, mean MMSE of 23.6, mean AHI of 22.0 events/h and mean ODI of 20.6 events/h. The univariate analysis showed a positive correlation between ODI and pTau ($r=0.29$; $p=0.033$). In stepwise multivariate regression analysis, the best predictors of pTau were Tau ($\beta=0.161$, 95% CI=[0.143, 0.178], $p<0.001$), Aβ42 ($\beta=-0.023$, 95% CI=[−0.036, −0.011], $p=0.001$) and ODI ($\beta=0.446$, 95% CI=[−0.011, 0.903], $p=0.055$).

Conclusion: We found an association between ODI and CSF pTau levels, suggesting that severe nocturnal hypoxemia might contribute to neurodegeneration. These findings further emphasize the possible role of OSA treatment in preventing further neuronal damage.

Disclosure: Nothing to disclosure.

EPO-222 | Repetitive transcranial magnetic stimulation and mild cognitive impairment

F. D'Ammora[1]; M. De Stefano[1]; D. Buonanno[1]; R. Pepe[1]; D. Atripaldi[1]; M. Siciliano[2]; A. Iavarone[3]; D. Ippolito[3]; G. Tedeschi[1]; F. Trojsi[1]; S. Esposito[1]

[1]First Division of Neurology, University of Campania "Luigi Vanvitelli", Naples, Italy; [2]Department of psychology, University of Campania Luigi Vanvitelli, Caserta, Italy; [3]Neurologic Unit, CTO Hospital, AORN "Ospedale dei Colli", Naples, Italy

Background and Aims: Repetitive transcranial magnetic stimulation (rTMS) can be used to improve cognition in mild cognitive impairment (MCI) and Alzheimer's disease (AD). Possible neurobiological mechanisms underlying the rTMS therapeutic effects are maladaptive plasticity, glial activation and neuroinflammation, including metalloproteases (MMP) activation. Our aim was to evaluate the effects of bilateral rTMS over the dorsolateral prefrontal cortex (DLPFC) on plasmatic levels or MMP1, -2, -9 and -10, MMPs-related tissue inhibitors TIMP1 and TIMP2, and cognitive performances in MCI patients.

Methods: MCI patients ($n=18$) were randomly assigned to two groups: one group received high frequency rTMS daily four weeks and the other received sham stimulation. Cognitive and psychobehavioural scores were measured at baseline (T0), after five weeks (T1), and six months after rTMS stimulation (T2). To determine the concentration of MMP1, -2, -9 and -10 and the respective inhibitors, TIMP1 and TIMP2, we used commercially available ELISA kits.

Results: We observed reduction in plasmatic levels of MMP-1, -9, and -10 in the MCI-TMS group and an increased in plasmatic levels of TIMP1 and TIMP2. We also detected an improvement in visuospatial performances.

Conclusion: Our study showed a possible long-term impact of bilateral rTMS, a non-invasive neuromodulation technique, on plasmatic levels of selected MMPs and TIMPs in MCI patients. These biological effects, after a 4-week course of rTMS, associated with improvement of visuospatial perceptive abilities, prompt us to hypothesize a neuroprotective effect of rTMS.

Disclosure: I have no disclosure.

EPO-223 | Internetworks functional connectivity in Alzheimer's disease and Mild Cognitive impairment patients with Anosognosia

D. Ballotta[1]; M. Tondelli[1]; C. Carbone[1]; R. Maramotti[1]; A. Chiari[2]; G. Pagnoni[1]; G. Zamboni[1]

[1]*Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy;* [2]*Neurology Unit, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy*

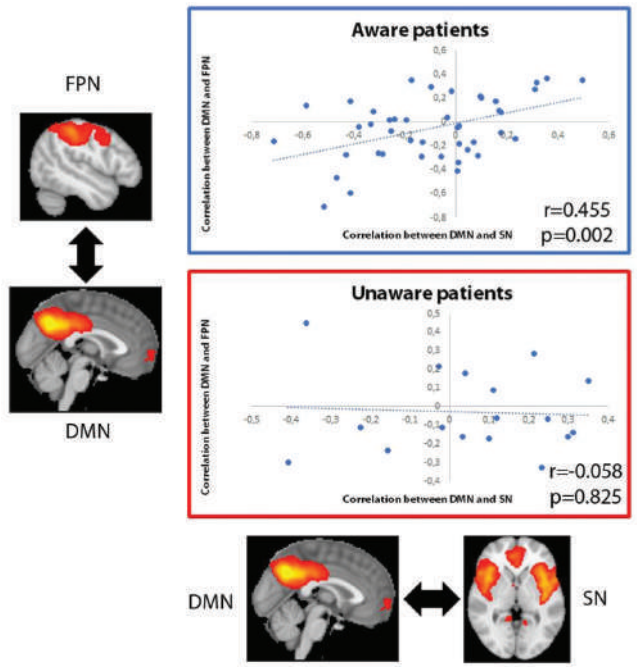
Background and Aims: Unawareness in the Alzheimer's disease (AD) continuum has been hypothesized to arise from an impaired communication between brain regions. Reduced functional connectivity in the default-mode network (DMN) has been demonstrated in AD patients with anosognosia; altered interaction between DMN and Frontoparietal Network (FPN) has been reported in Mild Cognitive Impairment (MCI); stronger connectivity within the salience network (SN) has been linked to anosognosia in prodromal AD. We hypothesized that anosognosia in AD could be associated with an imbalance between the activity of the DMN, the SN and the FPN, detectable using resting state functional magnetic resonance imaging (fMRI).

Methods: Sixty patients with MCI and AD underwent fMRI and neuropsychological assessment. Patients were categorized as aware or unaware of their condition, according to the Anosognosia Questionnaire Dementia. Independent component analysis (ICA) of the fMRI data was used to identify DMN, SN and FPN. Partial correlations were performed on the individual ICA time-courses associated with each network to assess inter-network functional connectivity. Finally, we examined whether the strength of functional connectivity between DMN and SN was a significant predictor of the connectivity strength between DMN and FPN, separately for aware and unaware patients.

Results: Functional connectivity between DMN and SN was positively correlated with functional connectivity between DMN and FPN only in aware patients (Figure 1).

Conclusion: Functional connectivity between DMN, SN and FPN is altered in MCI and AD patients with anosognosia, suggesting that a possible imbalance in these large-scale networks might be associated to anosognosia expression in AD continuum.

Disclosure: Nothing to disclose.



Correlation between internetwork functional connectivity in aware and unaware patients. Images represent average group maps of both aware and unaware patients obtained using independent component analysis.

EPO-224 | Mitigating Alzheimer's: Neurosteroids' effect against mitochondrial dysfunction

D. Divya[1]; M. Faruq[2]; D. Vohora[1]

[1]*Department of Pharmacology, School of Pharmaceutical Education & Research (SPER), Jamia Hamdard, New Delhi, India;* [2]*Division of Genomics and Molecular Medicine, CSIR-Institute of Genomics and Integrative Biology (IGIB), New Delhi, India*

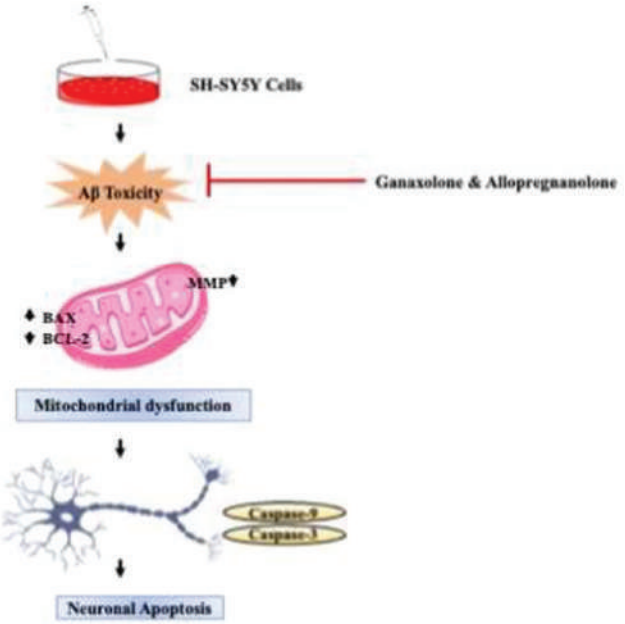
Background and Aims: Introduction: Alzheimer's disease (AD) is a neurological disorder characterized by pathological features such as synaptic and neuronal loss, the accumulation of amyloid-beta (Aβ) deposits, and the formation of neurofibrillary tangles. The disease is closely linked to oxidative stress, stemming from increased reactive oxygen species (ROS), altered mitochondrial biogenesis, and changes in mitochondrial membrane potential (MMP), ultimately leading to disrupted mitochondrial function and cellular apoptosis. Ganaxolone and allopregnanolone have displayed neuroprotective effects; however, their impact on Aβ deposits and mitochondrial dysfunction in AD remains unclear. This study delves into the influence of Ganaxolone and allopregnanolone on Aβ toxicity-induced mitochondrial dysfunction and explores the subsequent cellular processes.

Methods: The SH-SY5Y neuroblastoma cell line was transfected with an amyloid precursor protein (APP) plasmid construct to establish an AD cell model. Cells underwent a 24-hour treatment with Ganaxolone and allopregnanolone, followed by a ThT binding assay and immunoblotting to assess the effects on in vitro amyloid formation. Mitochondrial alterations were monitored using mitosox, and changes in MMP were analyzed through flow cytometry using TMRE. Additionally, apoptotic protein were investigated via Western blotting.

Results: Ganaxolone and allopregnanolone treatment significantly decreased mitochondrial ROS associated with Aβ toxicity and restored altered MMP mitigated apoptosis and amyloid-beta toxicity. We also showed that Ganaxolone decreased the rate of apoptosis in cells by modulating important evolutionarily conserved proteins of apoptosis.

Conclusion: These findings suggest that Ganaxolone and allopregnanolone provide protection against mitochondria to APP-transfected SH-SY5Y cells, proposing Ganaxolone and allopregnanolone as a potential therapeutic agent for AD.

Disclosure: This work was supported by the Indian Council of Medical Research (ICMR) New Delhi, India, for SRF to DG (Ref. No. 45/05/2020-PHA/BMS) and ICMR grant proposal no. IIRP/2023/1050 for financial support.



EPO-225 | Associations between PM2.5 exposure and Alzheimer's disease prevalence among elderly in eastern China

L. Yang
Zhejiang Hospital

Background and Aims: Studies showed that PM2.5 might be associated with various neurogenic diseases such as Alzheimer's disease (AD). However, this topic had been little studied in Zhejiang province of China.

Methods: We established a cohort of AD high-risk population with 1,742 elderly aged 60 and above. The average residential exposure to PM2.5 for each participant that in a 5-years period prior to the first survey, was estimated using a satellite-based spatial statistical model. We determined the association between PM2.5 and AD prevalence by cox proportional hazards regression model.

Results: This study showed that an increase in the PM2.5 level was an important associated risk factor that contributed to AD. The average PM2.5 exposure levels among the study population ranged from 32.69μg/m3 to 39.67μg/m3 from 2013 to 2017, which were much higher than 5μg/m3 that specified in the WHO air quality guidelines. There was an association between PM2.5 exposure and AD, and the correlations between PM2.5 and Mini-Mental State Examination, Montreal cognitive assessment scale scores were statistically significant. An increase in the PM2.5 level by 10μg/m3 elevated the risk of AD among residents by 2%-5% (HR model 2-model 4 = 1.02 to 1.05, CI model 2-model 4 = 1.01–1.10). The subgroups of male, with old age, with low education levels, used to work as farmers or blue-collar workers before retirement, overweight and obese were associated with a higher effect of PM2.5.

Conclusion: Reducing PM2.5 exposure might be a good way to prevent AD.

Disclosure: Nothing to disclose.

Table 1. Association between $PM_{2.5}$ exposure (per 10 μg/m³ increment) and incidence of AD

Model	HR	95% CI	*P* values
Model 1	0.85	0.76-1.05	0.06
Model 2	1.02	1.01-1.09	0.04

Autonomic nervous system diseases 2

EPO-226 | Heart rate variability fluctuations within 48 hours following a stroke and their association with symptom severity

E. Olbert[1]; W. Struhal[2]
[1]*Karl Landsteiner University of Health Sciences, Krems, Austria;*
[2]*Department of Neurology, University Hospital Tulln, Tulln, Austria*

Background and Aims: The impact of cerebrovascular events such as stroke, transient ischemic attack (TIA), and intracranial hemorrhage (ICH) has been the subject of prior publications. However, comprehensive data pertaining to the initial stages of acute cerebral events

is lacking. In this study, we conducted an examination of the fluctuation of heart rate variability, specifically analyzing standard deviation of NN intervals (SDNN), at different intervals after an acute cerebral event.

Methods: Monitoring data from 714 patients treated at the Stroke Unit of University Hospital Tulln were analyzed. For each patient, a 10-minute ECG signal was examined hourly, and heart rate variability and baroreceptor sensitivity were calculated. Heart rate variability fluctuation was quantified as the difference between maximum and minimum values within the specified time frame for each patient.

Results: Stroke patients exhibited the lowest SDNN fluctuation (mean: 16.6, 6 h post-onset), maintaining consistently lower levels over the initial 48 hours compared to individuals with ICH and stroke mimics (ICH: 29.8, stroke mimic: 27.3). Stroke severity influenced SDNN fluctuation, with milder strokes exhibiting increased fluctuation (mean: 26.7) at 6 hours post-onset compared to moderate (mean: 19.8) and severe strokes (mean: 14.9). This effect diminished within 24 h post-onset; however, distinctions between stroke, ICB, and stroke mimic persisted even after 48 h.

Conclusion: Fluctuations in autonomic parameters may suggest autonomic nervous system instability or rigidity during the acute phase following an acute cerebral event. These findings may explain discrepancies in previous analyses, dependent on variances in analyzed datasets and the specific time points considered after symptom onset.

Disclosure: Nothing to disclose.

EPO-227 | Quality indices: A pre-requisite for using automatically monitored electrocardiograms in autonomic dysfunction research

E. Olbert[1]; Y. Teuschl[2]; W. Struhal[1]

[1]*Department of Neurology, University Hospital Tulln, Tulln, Austria. Karl Landsteiner University of Health Sciences, Krems, Austria;* [2]*Department for Clinical Neurosciences and Preventive Medicine, University for Continuing Education Krems, Krems, Austria*

Background and Aims: While providing indirect assessment of the autonomic nervous system, electrocardiograms (ECG) are often corrupted by noise or irregularities. Gold standard is human expert assessment, which is challenged in large databases. In this study, the performance of two automated, modulation spectrum-based quality indicators were assessed for the detection of corrupted ECG signals in real-life monitoring data.

Methods: Datasets included 1000 ECG-recordings, each 600 seconds, collected at a stroke-unit. ECG quality was evaluated by an expert, including the duration of artefacts and the number of extrasystoles. The modulation spectral based quality index (MSQI) and the Peak Distance Quality Index (PDQI) were calculated, as well as their sensitivity, specificity, accuracy and the area under the curve (AUC) for the detection of high quality ECGs compared to expert rating.

Results: The percentage of ECG signals in the recordings based on the modulation spectrum approach correlates with expert rating ($r = 0.99$, $p < 0.001$). According to expert rating, of 861 recordings, 85 (9.8%) showed more than 15% of extrasystoles and 60 (6.9%) more than 100s of artefacts and were rated as "reduced quality". The AUC for PDQI ranges from 0.758 to 0.916 and for MSQI from 0.728 to 0.834. PDQI is superior in identifying extrasystoles, while the MSQI is better in identifying artefacts.

Conclusion: The large number of artefacts and irregularities makes automated quality indicators indispensable for the use of real-life EGC monitoring data in science. We propose a combination of the MSQI and PDQI to select signals before analyzing data for the evaluation of the autonomic nervous system.

Disclosure: Nothing to disclose.

EPO-228 | Sex-related differences in multiple system atrophy

F. Leys[1]; S. Eschlböck[2]; N. Campese[1]; P. Mahlknecht[1]; M. Peball[1]; G. Goebel[3]; V. Sidoroff[1]; F. Krismer[1]; R. Granata[1]; S. Kiechl[1]; W. Poewe[1]; K. Seppi[4]; G. Wenning[1]; A. Fanciulli[1]

[1]*Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria;* [2]*Department of Neurology, Hochzirl-Natters Hospital, Zirl, Austria;* [3]*Institute of Medical Statistics and Informatics, Medical University of Innsbruck, Innsbruck, Austria;* [4]*Department of Neurology, Provincial Hospital of Kufstein, Kufstein, Austria*

Background and Aims: Here we aimed at investigating sex-related differences in the clinical presentation of multiple system atrophy (MSA) by means of a literature review and analysis of a retrospective Innsbruck cohort.

Methods: We searched the PubMed database for articles entailing sex-related information in MSA. The baseline to last follow-up clinical demographic differences between female and male individuals of the Innsbruck MSA cohort were investigated with a univariate followed by a multivariable binary regression analysis.

Results: The literature search identified 46 publications. Earlier studies showed comparable survival rates between female and male MSA individuals, while recent ones indicated that a more frequent motor-symptomatic onset and generally less severe autonomic failure may confer female MSA individuals a survival benefit. Fifty-six women and 60 men with a comparable median follow-up of 27 months were included in the retrospective analysis. At baseline, female sex was associated with depression (OR = 4.7; $p = 0.007$), male sex with severe orthostatic hypotension (OR = 5.5; $p = 0.016$). At follow-up, female sex was additionally associated with the intake of CNS-active drugs (OR = 4.1; $p = 0.029$), while male sex also showed an association with the presence of supine hypertension (OR = 3.0; $p = 0.020$) and antihypertensive treatment (OR = 8.7; $p = 0.001$). We also observed an association between male sex and the initiation of antihypertensive regimes over the observational period (OR = 12.4; $p = 0.004$).

Conclusion: Our results indicate dynamic sex-related differences in the clinical presentation of MSA, which need to be taken into account both for therapeutic and research purposes.

Disclosure: Academic study without external funding. Dr Leys and Dr Campese are/were supported by the US MSA Coalition and the Dr. Johannes & Hertha Tuba Foundation throughout conducting this study.

EPO-229 | DA-9701 treatment for gastrointestinal symptoms and quality of life in postural orthostatic tachycardia syndrome

H. Jung[1]; D. Seo[1]; J. Kim[1]; J. So[1]; H. Kim[1]; Y. Lim[1]; Y. Koo[1]; J. Lee[2]; E. Lee[1]

[1]Department of Neurology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea; [2]Clinical Research Center, Asan Institute for Life Sciences, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea

Background and Aims: Gastrointestinal (GI) symptoms commonly affect patients with postural tachycardia syndrome (POTS), detrimentally impacting their quality of life (QoL). DA-9701, acting on 5-HT1A, 5-HT4, and D2 receptors, may improve GI symptoms and enhance the QoL in patients with POTS.

Methods: This randomized, double-blind, placebo-controlled, pilot trial was conducted at a single center. Patients with POTS were randomized in a 1:1 ratio following a crossover design. Participants received either oral DA-9701 (30 mg) or a placebo thrice daily for eight weeks. This was followed by a four-week washout period and an additional eight-week treatment with the alternate therapy. The primary endpoint was the change from baseline in GI symptoms (total Nepean Dyspepsia Index-Korean version (NDI-K) symptom score) and related QoL (total NDI-K QoL score) over the 8 week-treatment period (cris.nih.go.kr, number KCT0006932).

Results: A total of 24 patients were randomized to initially receive either DA-9701 ($n=12$) or placebo ($n=12$). DA-9701 did not significantly improve the primary endpoints in total NDI-K symptom (Least-squares means, −13.9 vs. −9.5, $p=0.326$) and QoL scores (4.2 vs. 2.4, $p=0.596$). However, there was a tendency for improvement in specific GI symptoms, such as upper abdominal pain (−0.6 vs. 0.7, $p=0.066$) and pressure (−1.4 vs. −0.1, $p=0.061$). A carryover effect was observed in total NDI-K QoL ($p=0.036$), and analysis for the period 1 showed marginally significant treatment difference (-1.3 vs. 9.2, $p=0.067$).

Conclusion: Although DA-9701 was not successful to improve GI symptom and related QoL in this crossover trial, its potential merits warrant further investigation.

Disclosure: Funded by Dong-A Pharmaceutical.

EPO-230 | Painful small fiber neuropathy: A novel mutation in the SCN10A gene

F. Masciarelli[1]; D. Dell'Aversana[1]; S. Tozza[1]; V. Provitera[2]; G. Caporaso[2]; F. Vitale[1]; R. Iodice[1]; L. Ruggiero[1]; R. Dubbioso[1]; F. Manganelli[1]; M. Nolano[2]

[1]Department of Neurosciences, Reproductive Sciences, and Odontostomatology, University of Naples Federico II, Naples, Italy; [2]Neurology Department – Skin Biopsy, Lab Istituti Clinici Scientifici Maugeri, Spa SB Institute of Telese Terme – IRCCS

Background and Aims: We describe the case of a 35-year-old patient with severe painful small fiber neuropathy, early onset of symptoms and a long history of clinical and instrumental examinations who underwent overtime several aggressive and ineffective treatments for a putative rheumatological disease.

Methods: Symptoms started at the age of 21 with paraesthesia and burning pain in pectoral and periscapular area and at the hands. Shortly thereafter pain gradually spread to involve both feet and pelvic area. Twelve years after onset of symptoms, the patient reported generalized burning pain affecting also face and tongue. The pain was so severe he could only walk with the help of crutches. He also complained of gastroesophageal reflux, early satiety, bloating and severe constipation. Neurological examination was normal except from mechanical allodynia at both feet. He underwent functional and morphological assessment of small fibers.

Results: Spine and brain MRI, nerve conduction study, blood examination for dysmetabolic and dysimmune disorders were not relevant. Quantitative sensory testing showed abnormal thermal thresholds. Sympathetic skin response was abnormal and dynamic sweat test showed a non-length-dependent hypohidrosis. Cardiovascular reflexes were normal. Skin biopsy revealed a moderate non-length dependent loss of sensory and autonomic nerves. Exome sequencing revealed a heterozygous VUS mutation (c.4852A>C; p.Met1618Leu) in the SCN10A gene. The same clinical and instrumental features were present in a sister and in the father of our patient who carried the same mutation.

Conclusion: Awareness of the genetic causes of SFN is crucial for providing correct diagnosis and treatment for patients and their family.

Disclosure: Nothing to disclose.

EPO-231 | Cardiac 123I-MIBG Scintigraphy in the differential diagnosis of parkinsonian syndromes – monocentric cohort

J. Alves[1]; R. Melo[2]; A. Moreira[3]; J. Lemos[1]; D. Reis Carneiro[1]
[1]*Department of Neurology, Unidade Local de Saúde de Coimbra, Portugal;* [2]*Faculty of Medicine, University of Coimbra, Portugal;* [3]*Department of Nuclear Medicine, Unidade Local de Saúde de Coimbra, Portugal*

Background and Aims: Cardiac [123I]metaiodobenzylguanidine scintigraphy (123I-MIBG) reflects postganglionic cardiac sympathetic denervation (CSD). It is used for the differential diagnosis of parkinsonian syndromes, particularly between Parkinson's Disease (PD) and Multiple System Atrophy (MSA). We aimed at knowing whether there were clinical features that predict a 123I-MIBG without CSD.

Methods: Retrospective study of a cohort of patients followed in the Neurology department of a tertiary university hospital, who performed 123I-MIBG. Clinical data were retrieved from individual clinical registries. Patients with and without postganglionic cardiac autonomic denervation were compared to find factors associated to absence of CSD. A significant *p*-value was considered below 0.05.

Results: From the thirty patients who performed 123I-MIBG between 2018 and 2023 in our center, twenty-seven did so for differential diagnosis between parkinsonian syndromes (22.2% presumed PD, 51.9% presumed MSA, 25.9% others). Only 44.4% of patients performed a Schellong test. The median time from the onset of the disease to the 123I-MIBG was 3.0 (2.0–6.0) years. 44.4% exhibited cardiac denervation, while 55.6% did not. Univariate analysis revealed statistically significant differences between groups in terms of MDS-UPDRS-III, cardiovascular symptoms, isolated urinary symptoms (without cardiovascular symptoms), cardiovascular plus urinary symptoms, constipation, and presumed MSA diagnosis (Table 1). According to the logistic regression (Table 2), predictors of absence of CSD were isolated urinary symptoms (OR 8.1), constipation (OR 11.7), and a presumed MSA diagnosis (OR 21.2).

TABLE 1 Statistically Significant Differences Between Groups: Univariate Analysis Results

	^{123}I-MIBG with cardiac denervation n=12 (44.4%)	^{123}I-MIBG without cardiac denervation n=15 (55.6%)	p-value
MDS-UPDRS-III (mean +/- SD)	43.2 +/- 20.8	24.3 +/- 13.4	0.029
Cardiovascular symptoms	10 (83.3%)	6 (40.0%)	0.023
Isolated urinary symptoms	1 (8.3%)	9 (60.0%)	0.006
Cardiovascular plus urinary symptoms	8 (66.7%)	4 (26.7%)	0.038
Constipation	2 (16.7%)	10 (66.7%)	0.009
MSA Diagnosis	2 (16.7%)	12 (80.0%)	0.001

TABLE 2 Predictors of Absence of Cardiac Sympathetic Denervation: Logistic Regression Analysis

Logistic regression (p=0.0002)	
MDS-UPDRS-III	OR 8.1 (CI 95% 0.4 – 162.1), p = 0.170
Constipation	OR 11.7 (CI 95% 0.8 – 181.3), p = 0.079
Isolated urinary symptoms	OR 21.2 (CI 95% 1.5 – 299.2), p = 0.024

Conclusion: In our cohort, individuals presenting with isolated urinary symptoms, constipation, and a presumed MSA diagnosis are more likely to exhibit an absence of CSD.

Disclosure: Nothing to disclose.

EPO-232 | Cardiovascular autonomic disorders following COVID-19 infection or vaccination

A. Fanciulli[1]; M. Verginer[1]; F. Leys[1]; E. Kirchler[1]; L. Marino[1]; G. Göbel[2]; N. Campese[1]; S. Eschlböck[1]; S. Dürr[1]; G. Broessner[1]; A. Djamshidian[1]; A. Heidbreder[1]; B. Högl[1]; K. Hüfner[3]; S. Iglseder[1]; W. Löscher[1]; A. Stefani[1]; J. Wanschitz[1]; G. Weiss[4]; L. Zamarian[1]; J. Löffler-Ragg[4]; R. Helbok[5]; S. Kiechl[1]; R. Granata[1]; G. Wenning[1]
[1]*Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria;* [2]*Department of Medical Statistics, Informatics and Health Economics (MSIG), Medical University of Innsbruck, Innsbruck, Austria;* [3]*Department of Psychiatry, Psychotherapy, Psychosomatics and Medical Psychology, Medical University of Innsbruck, Innsbruck, Austria;* [4]*Department of Internal Medicine II, Medical University of Innsbruck, Innsbruck, Austria;* [5]*Department of Neurology, Kepler Universitätsklinikum, Linz, Austria*

Background and Aims: Cardiovascular autonomic disorders have been reported both after coronavirus-disease-2019 (COVID-19) infection and COVID-19 vaccination, but are not well characterized to date. Here we studied the type, frequency and clinical outcome of newly-diagnosed cardiovascular autonomic disorders following COVID-19 infection or vaccination in a retrospective series from the Innsbruck Dysautonomia Center.

Methods: We reviewed the medical records of all individuals referred between March 2020 and March 2023 for new-onset of orthostatic intolerance (OI) within 6 weeks after COVID-19 infection or vaccination.

Results: 102 individuals were studied ($n=76$ with new-onset OI after COVID-19, $n=26$ post-vaccination). In post-COVID-19-infection cases, postural orthostatic tachycardia syndrome (POTS) was the most common cardiovascular autonomic diagnosis ($n=21$, 86% female, 33 ± 9 years of age). POTS was also the most frequent cardiovascular autonomic disorder in post-COVID-19-vaccination cases ($n=11$, 73% female, 32 ± 10 years of age). In 51 (50%) of all cases with post-infectious or post-vaccination OI, no cardiovascular autonomic cause was found. All newly diagnosed POTS cases were recommended non-pharmacological measures, 33% of post-infectious and 55% of post-vaccination cases received additional pharmacological treatment. At follow-up, 68% of post-COVID-19-infection POTS

($n = 13/19$, 7 ± 4 months follow-up) and 78% of post-COVID-19 vaccination cases ($n = 7/9$, 8 ± 6 months follow-up) reported improvement.
Conclusion: A specialized diagnostic work-up is pivotal to diagnose or exclude autonomic disorders in individuals with newly-developed OI following COVID-19 infection or vaccination. POTS is the most frequent autonomic disorder developing after both COVID-19-infection and COVID-19-vaccination, mainly affecting female individuals in their fourth decade of life. Improvement is observed under multimodal treatment at follow-up.
Disclosure: Nothing to disclose.

EPO-233 | Indices of cardiovascular autonomic failure in multiple system atrophy

M. Kermorgant[1]; M. Fabbri[1]; C. Leung[1]; A. Foubert-Samier[2]; O. Rascol[1]; W. Meissner[3]; A. Pavy-Le Traon[1]
[1]*Centre de référence de l'AMS, Département de Neurologie, Toulouse, France;* [2]*Univ. Bordeaux, Bordeaux Population Health Research Center, Inserm U1219, Bordeaux, France;* [3]*CHU Bordeaux, Service de Neurologie des Maladies Neurodégénératives, IMNc, CRMRAMS, NS-Park/FCRIN Network, Bordeaux, France*

Background and Aims: Multiple system atrophy (MSA) is a rare and progressive neurodegenerative disorder. Severe cardiovascular autonomic failure (CAF) is one of the main clinical features with prognostic implications. Moreover, little is known about gender differences in CAF. In this study, we sought 1) to compare heart rate variability (HRV) and baroreflex sensitivity (BRS) as CAF indices between MSA and control patients, and 2) to determine the gender differences in these markers.
Methods: 193 MSA patients (88 men and 105 women) and 88 control patients (32 men and 56 women) were included in the study. HRV was assessed in time (pNN50, SDNN, RMSSD), frequential (LF, HF, LF/HF) and non-linear (SD1, SD2) domains. BRS was estimated by the sequence method. Mann-Whitney test was performed to analyze data between MSA and control patients. To compare men and women, we used two-way ANOVA (condition × gender) with Tukey's method post-hoc.
Results: Mean disease duration from symptom onset was 4.5 ± 2.3 years. Reduced overall variability (SDNN, LF, LF/HF, SD2), parasympathetic activity (pNN50, RMSSD, HF, SD1) and BRS were observed in MSA patients. No gender differences were observed.
Conclusion: Our results indicate a severe impairment in HRV and BRS in MSA patients. These additional markers may be considered as an index of CAF. However, there is no gender difference in the manifest of CAF. Further studies are needed to assess the prognosis value of these markers.
Disclosure: Nothing to disclose.

EPO-234 | Sudomotor function in multiple system atrophy, Parkinson's disease and four-repeat tauopathies: A cross-sectional report

M. Andréasson[1]; P. Karlsson[2]; K. Samuelsson[3]; A. Terkelsen[4]; P. Svenningsson[1]
[1]*Department of Clinical Neuroscience, Karolinska Institutet; Center for Neurology, Academic Specialist Center and Department of Neurology, Karolinska University Hospital, Stockholm, Sweden;* [2]*Danish Pain Research Center, Department of Clinical Medicine, Aarhus University, Aarhus, Denmark;* [3]*Department of Clinical Neuroscience, Karolinska Institutet and Department of Neurology, Karolinska University Hospital, Stockholm, Sweden;* [4]*Department of Neurology, Aarhus University Hospital and Danish Pain Research Center, Department of Clinical Medicine, Aarhus University, Aarhus, Denmark*

Background and Aims: Autonomic dysfunction is a well-established feature of Parkinson's disease (PD) and multiple system atrophy (MSA). Sudomotor dysfunction may occur in both diseases and underlying pre- and postganglionic pathology have been suggested. We aimed to non-invasively assess sudomotor function in PD and atypical parkinsonism and explore possible discriminative features.
Methods: In an ongoing longitudinal study, controls and patients with PD, MSA and four-repeat tauopathies were prospectively included. Assessments included clinical rating scales, questionnaires, orthostatic blood pressure and quantification of electrochemical skin conductance in feet and hands using Sudoscan®. Non-parametric testing was performed to explore group differences, and associations with measures of disease burden.
Results: An overview of the study population ($n = 63$) is shown in Table 1. No significant group differences were seen with regard to sex and age. Significant differences in skin conductance were evident between groups ($p = 0.012$ (hands); $p = 0.0068$ (feet)), reflecting reduced conductance in MSA (Figure 1). In a subgroup analysis, significant strong associations between skin conductance in feet and clinical rating scales were demonstrated in MSA (rho = −0.72, $p = 0.0087$; rho = −0.61, $p = 0.034$) (Table 2). No significant associations were evident in other groups (data not shown).

TABLE 1 Clinical and demographic characteristics of the study cohort ($n=63$). Significant group differences with regard to skin conductance are shown. Group comparisons were performed with Fisher's exact test and Kruskal-Wallis H-test.

	PD (n=20)	MSA (n=12)	4R (n=11)	HC (n=20)	p
Age at examination (y), median (IQR)	63.2 (14.2)	59.3 (12.7)	68.6 (10.5)	62.9 (6.3)	0.08

Mean conductance hands* (μS), median (IQR)	69.5 (29)	55.5 (28)	75.8 (19.9)	67.5 (13)	**0.012**
Mean conductance feet** (μS), median (IQR)	81.8 (14)	57.5 (39.9)	82.3 (15.8)	76.5 (15.9)	**0.0068**
UENS (p), median (IQR)	5.0 (5)	3.0 (3)	3.0 (4)	2.0 (2)	**0.0036**

Abbreviations: PD – Parkinson's disease; MSA – Multiple system atrophy; 4R – four-repeat tauopathy defined as possible corticobasal degeneration or probable progressive supranuclear palsy; HC – healthy control; IQR – interquartile range; LEDD – L-dopa equivalent daily dose; mHY – modified Hoehn and Yahr; MDS-UPDRS – Movement Disorders Society Unified Parkinson's Disease Rating Scale; UMSARS – Unified Multiple System Atrophy Rating Scale; PSP-CDS – Progressive Supranuclear Palsy Clinical Deficits Scale; SCOPA-AUT - Scales for Outcomes in Parkinson's Disease-Autonomic questionnaire; BP – blood pressure; UENS – Utah Early Neuropathy Scale. **3 missing values; **1 missing value*

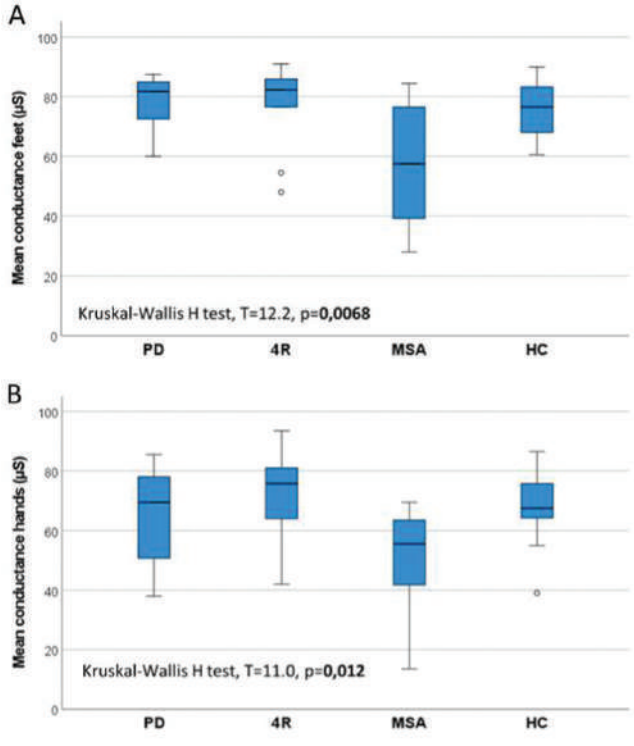

FIGURE 1 Mean skin conductance measured from feet (A) and hands (B). Post-hoc comparisons with Bonferroni correction demonstrate: (A): MSA vs PD, $p=0.010$; MSA vs 4R, $p=0.019$; MSA vs HC, $p=0.12$ (B): MSA vs PD, $p=0.054$; MSA vs 4R, $p=0.018$; MSA vs HC, $p=0.033$

TABLE 2 Associations between skin conductance and measures of disease burden in MSA. Negative associations were demonstrated between skin conductance in feet and UMSARS part II, and mHY stage (rho = −0.72, $p=0.0087$; rho = −0.61, $p=0.034$ respectively).

	Mean conductance hands* (μS)	Mean conductance feet (μS)
UMSARS part II (p)	ns	**-0.72**
UMSARS part IV (p)	ns	ns
mHY (stage)	ns	**-0.61**
SCOPA-AUT (p)	ns	ns

Abbreviations: ns – not significant; UMSARS – Unified Multiple System Atrophy Rating Scale; mHY – modified Hoehn and Yahr; SCOPA-AUT - Scales for Outcomes in Parkinson's Disease-Autonomic questionnaire. **1 missing value*

Conclusion: Reduced electrochemical skin conductance, as measured with Sudoscan®, may be a prevalent finding in MSA relative to PD and four-repeat tauopathies, and possible associations with clinical measures of disease burden may indicate prognostic properties. Further studies are needed to determine whether these findings are detectable in early disease or rather reflect an advanced disease stage with more widespread disease pathology.

EPO-235 | Autonomic testing in children with inflammatory bowel disease and irritable bowel syndrome: In search of dysautonomia

P. Ruška[1]; A. Jerković[1]; S. Sila[1]; A. Močić Pavić[1]; M. Krbot Skorić[2]; M. Habek[2]; I. Hojsak[1]

[1]*Referral Center for Pediatric Gastroenterology and Nutrition, Children's Hospital Zagreb, Zagreb, Croatia;* [2]*Referral Center for Autonomic Nervous System, Department of Neurology, University Hospital Center Zagreb, Zagreb, Croatia*

Background and Aims: The autonomic nervous system (ANS) is an important pathway connecting the brain and the gut. The aim of this study was to investigate the subjective and objective ANS abnormalities in children with irritable bowel syndrome (IBS) and inflammatory bowel disease (IBD) compared to healthy controls (HC).

Methods: A total of 58 children were enrolled: 23 in IBS group (mean age 15 years, male $n=7$), 18 in IBD (mean age 14.25 years, male $n=7$) and 17 HC (mean age 14.83 years, male $n=8$). ANS symptoms were evaluated with the Composite Autonomic Symptom Score (COMPASS-31). Heart rate (HR) and blood pressure (BP) responses were monitored with the Task Force Monitor (CNSystems, Austria) and quantitative sudomotor axon reflex test (QSART) were performed. The severity and distribution of ANS function was quantitated using the Composite Autonomic Severity Scale (CASS).

Results: Children with IBS scored highest on the COMPASS 31, followed by patients with IBD and HC (median scores were 10.9, 5 and 1.6, respectively; $p=0.001$). Moreover, children with IBS scored the highest on questions that involved various gastrointestinal symptoms. There was no significant difference between groups in CASS ($p>0.05$). However, there was a significant difference in symptomatic dysautonomia (defined as COMPASS-31 >7.913 and CASS >0) between children with IBS (56.5%) compared to children with IBD (38.9%) and HC (11.8%), $p=0.015$.

Conclusion: Symptomatic dysautonomia is most frequently observed in children with IBS, indicating important contribution of ANS abnormalities to pathophysiology of IBS.

Disclosure: Founding: Croatian science foundation (IP-2019-04-3028).

EPO-236 | Parasympathetic and cerebral hemodynamic impairment in adults with sickle cell disease and cerebral microangiopathy

C. Ferreira de Matos[1]; P. Cougoul[1]; O. Zaharie[2]; M. Kermorgant[3]; A. Pavy Le Traon[4]; C. Gales[3]; J. Sénard[3]; M. Strumia[5]; F. Bonneville[2]; N. Nasr[3]

[1]Internal Medicine Department—IUCT Oncopole, Toulouse, France; [2]Neuroradiology Department of Toulouse University Hospital, Toulouse, France; [3]UMR 1297 Team 10 Institute of Metabolic and Cardiovascular Disease (I2MC), Toulouse, France; [4]Neurology Department of Toulouse University Hospital, Toulouse, Franc; [5]Maintain Aging Research Team, CERPOP, INSERM, 1295, Toulouse University, Toulouse, France

Background and Aims: White matter lesions (WML) on brain imaging are common both in patients with sickle cell disease (SCD). The autonomic nervous system (ANS) is involved in the homeostasis of cerebral hemodynamics. The aim of this study was to evaluate the association between ANS parameters and cerebral microangiopathy in adult patients with SCD.

Methods: We prospectively assessed adult patients with SCD from our cohort for heart rate variability in the frequency domain, baroreflex sensitivity (BRS), cerebral autoregulation using Mx, cerebral arterial compliance (Ca) and cerebral time constant (tau) based on TCD and ABP monitoring. These patients also had cerebral MRI. Patients with history of stroke were excluded.

Results: Forty-one patients (F/M:25/16) were included. Median age was 37.5 years (range 19–65). Twenty-nine (70.7%) patients had SS genotype. Eleven patients had cerebral microangiopathy (26.8%). These patients were older (44.5 vs 30.6 years; $p<0.001$), had a lower HF (HF 157 ms2 vs HF 467.6 ms2; $p<0.005$) and impaired Ca (15.4 vs. 37.3 cm3/mmHg $p<0.014$). AUC for the model with age as single predictor was of 0.876. For age and HF model, AUC was of 0.946.

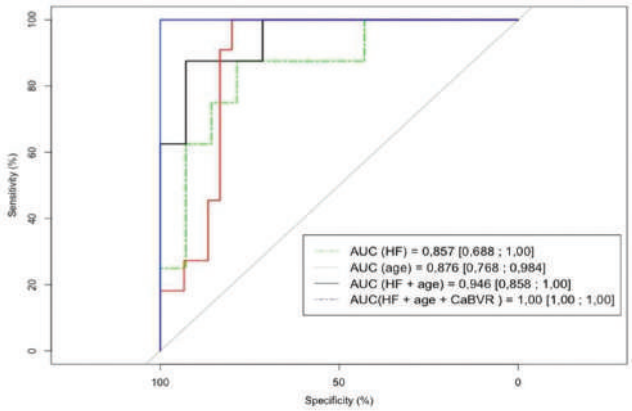

Figure AUC for the model with age as single predictor was of 0.876. For age and HF model, AUC was of 0.946. For age, HF and cerebral compliance model, AUC was of 1.

Conclusion: Lower parasympathetic activity was associated with cerebral microangiopathy in adults in SCD. Cardiovascular prevention including non-drug treatment and physical activity could improve cerebrovascular function and parasympathetic activity. HF monitoring can help assess the cardiovascular impact of such interventions. Including novel hemodynamic parameters such as Ca could yield better understanding of integrative cardiovascular and cerebrovascular hemodynamic regulation in SCD.

Disclosure: Nothing to disclose.

EPO-237 | Pain in multiple system atrophy: A community-based survey

N. Campese[1]; B. Caliò[1]; F. Leys[1]; L. Kaltenbach[2]; G. Göbel[2]; J. Wanschitz[1]; A. Schlager[3]; P. Bower[4]; L. Kellermann[4]; L. Zamarian[1]; K. Bannister[5]; K. Chaudhuri[6]; A. Schrag[7]; R. Freeman[8]; H. Kaufmann[9]; R. Granata[1]; S. Kiechl[1]; W. Poewe[1]; K. Seppi[1]; G. Wenning[1]; A. Fanciulli[1]

[1]Department of Neurology, Medical University of Innsbruck, Innsbruck (Austria); [2]Institute for Medical Statistics and Informatics, Medical University of Innsbruck, Innsbruck (Austria); [3]Department of Anesthesiology and Intensive Care Medicine, Medical University of Innsbruck, Innsbruck (Austria); [4]The Multiple System Atrophy Coalition, Inc., McLean, VA, USA; [5]Institute of Psychiatry, Psychology and Neuroscience, King's College London, London (UK), [6]Parkinson Foundation International Centre of Excellence, Kings College Hospital, London, UK; [7]Department of Clinical and Movement Neurosciences, University College London, London (UK); [8]Department of Neurology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, Massachusetts, USA; [9]Department of Neurology, Dysautonomia Center, New York University Grossman School of Medicine, New York, New York, USA

Background and Aims: According to a meta-analysis pain affects approximately 60% of individuals with multiple system atrophy (MSA), but its prevalence and characteristics remain poorly characterized. Here we assess prevalence, features, risk factors and treatment options for pain in MSA.

Methods: We performed a community-based cross-sectional study. Following a whole population sampling approach, MSA individuals and their informal caregivers were invited via patient advocacies, to complete a survey, available online between February and May 2023. The survey was accessed by 264 MSA individuals and 178 caregivers. After checking for data completeness and plausibility, questionnaires from 194 MSA individuals and 114 caregivers were retained for final analysis.

Results: Pain was reported by 87% of MSA individuals, more frequently by women [OR: 6.38 (95% C.I. 1.27–32.08), $p=0.025$] and subjects with a self-reported annual income below the average of the country [OR: 5.02 (95% C.I. 1.32–19.08), $p=0.018$]. Pain was mostly located in the neck and shoulders (58%), back (45%) and legs (45%). Among individuals with pain, 69% received any kind of treatment, mostly non-steroidal anti-inflammatory drugs (30%), acetaminophen (25%) and opioids (17%) but only 52% of them was at least partially satisfied with pain management. Pain mostly affected patients' work, household activities, and hobbies and caregivers' social activities.

Conclusion: Pain is more common than previously reported in MSA, is mostly located in the neck, shoulders, back and legs, and especially affects women and individuals with lower income. Despite the frequent occurrence, pain remains undertreated or not satisfactorily managed, pinpointing an important unmet need in MSA.

Disclosure: Academic study supported by a grant of the MSA Coalition.

EPO-238 | Autonomic dysfunction in fibromyalgia: A skin biopsy and tilt testing study

P. Falco[1]; E. Galosi[1]; C. Leone[1]; G. Di Pietro[1]; G. De Stefano[1]; N. Esposito[1]; D. Litewczuk[1]; G. Di Stefano[1]; S. Strano[2]; A. Truini[1]

[1]*Department of Human Neuroscience, Sapienza University, Rome, Italy;* [2]*Department of Cardiovascular, Respiratory, Nephrology, Anaesthesiology and Geriatric Science, Sapienza University, Rome, Italy*

Background and Aims: Fibromyalgia patients frequently report autonomic symptoms, with previous studies suggesting sympathetic nervous system dysfunction, the pathophysiological mechanisms of which remains unknown [1]. Recent findings indicate sympathetic denervation in a subgroup of fibromyalgia patients with small fiber pathology (SFP) [2]. Our study aims to confirm the existence of cardiovascular autonomic dysfunction in fibromyalgia patients, examining its connection with peripheral autonomic denervation and the manifestation of autonomic symptoms.

References

1. Sympathetic nervous system dysfunction in fibromyalgia, chronic fatigue syndrome, irritable bowel syndrome, and interstitial cystitis: a review of case-control studies. Martínez-Martínez L-A, Mora T, Vargas A, Fuentes-Iniestra M, Martínez-Lavín M. J Clin Rheumatol. 2014 Apr;20(3):146-50. doi: 10.1097/RHU.0000000000000089.
2. Autonomic Small-Fiber Pathology in Patients With Fibromyalgia. Falco P, Galosi E, Di Stefano G, Leone C, Di Pietro G, Tramontana L, De Stefano G, Litewczuk D, Esposito N, Truini A. J Pain. 2024 Jan;25(1):64-72. doi: 10.1016/j.jpain.2023.07.020. Epub 2023 Jul 29.

Methods: We enrolled 35 fibromyalgia patients and assessed them using autonomic symptom scale (COMPASS-31), skin biopsy, analyzing intraepidermal (IENFD) and dermal autonomic nerve fibers densities, and a battery of cardiovascular autonomic function tests: tilt test, Valsalva maneuver (VM), deep breathing (DB), heart rate (HR) power spectral analysis, blood pressure (BP) short-term variability with baroreflex sensitivity (BRS) calculation. Based on distal IENFD, patients were divided into two subgroups: with and without SFP (Figure 1). Autonomic test results were compared with 35 sex and age- matched healthy controls and between the two patient subgroups. Correlations to skin biopsy data and autonomic symptoms were studied.

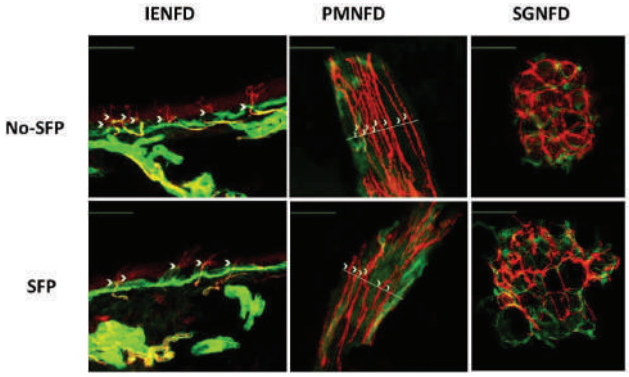

Figure 1: Representative skin biopsy images from fibromyalgia patients with and without SFP, showing nerve fibre counting examples for intraepidermal nerve fibre density (IENFD), piloerector muscle (PMNFD), and sweat gland (SGNFD) nerve fibre density evaluation. Red staining represents PGP9.5 marking nerve fibres, while green staining corresponds to collagen IV. All morphometric variables were reduced in patients with SFP respect to patient without SFP. Intraepidermal nerve fibre density calibration bars: 200 µm; PMNFD and SGNFD: 100 µm.

Representative skin biopsy images from fibromyalgia patients with and without SFP, showing nerve fibre counting examples for intraepidermal nerve fibre density (IENFD), piloerector muscle (PMNFD), and sweat gland (SGNFD) nerve fibre density evaluation.

Results: Fibromyalgia patients exhibit a reduced BP difference between phase IIb and IIa of VM ($p<0.001$), a decreased HR difference in DB ($p<0.001$) and a greater reduction of BRS during tilt ($p<0.004$) compared to healthy subjects, without differences between the two patient subgroups. There isn't correlation between functional and morphometric variables with clinical scales.

Conclusion: Fibromyalgia patients display cardiovascular autonomic dysfunction, which doesn't correlate with peripheral autonomic denervation. This suggests that multiple mechanisms (central and peripheral) contribute to autonomic symptoms complaint by patients.

Disclosure: Nothing to disclose.

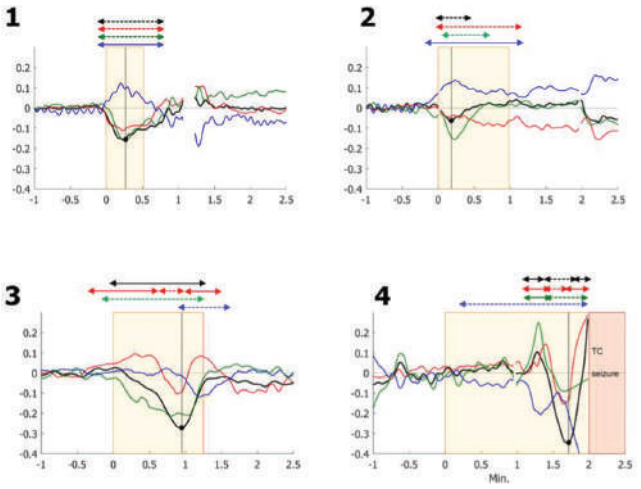
EPO-239 | The spectrum of autonomic responses to focal seizures

B. Gagaouzova[1]; I. van Rossum[2]; J. Hoey Smith – van de Wetering[1]; F. de Lange[3]; R. Thijs[1]; J. van Dijk[2]
[1]*Stichting Epilepsie Instellingen Nederland, The Netherlands;* [2]*Leiden University Medical Centre, The Netherlands;* [3]*Amsterdam University Medical Centre, The Netherlands*

Background and Aims: The cardiovascular response to focal seizures is rarely examined in full due to lack of ictal simultaneous heart rate (HR) and blood pressure (BP) recordings. We explored the temporal patterns in three cases using the log ratio method to dissect the main hemodynamic components.

Methods: We identified three subjects who experienced a seizure during a tilt test: one had two focal with impaired awareness seizures (FIAS #1&2), one had one FIAS (#3) one had a focal to bilateral tonic-clonic seizure (fbTCS, #4). All cases were monitored with video, HR and continuous BP (Finapres) recordings. We used the 'log-ratio method' to determine the relative contributions of HR, stroke volume (SV), and total peripheral resistance (TPR) to mean arterial pressure (MAP). A 'phase' was defined as a temporary departure form baseline.

Results: During seizure 1&2 there was one phase, in which HR and TPR decreased and SV increased simultaneously. During seizure #3 we observed one negative phase for MAP and TPR, three phases for HR (positive-negative-positive), and only one late negative phase for SV; hence, HR changed out of phase with TPR and MAP. In seizure #4 there was no autonomic involvement during the first minute, after which MAP and HR showed an asynchronous three phasic course.



Log-ratio results of the four focal seizures (seizure 1,2,3: focal impaired awareness seizure; seizure 4: focal to bilateral tonic-clonic seizure).

Conclusion: This chance sample illustrates that hemodynamic variables may change during focal seizures in different directions, sometimes in phase, sometimes independently. We speculate that these complex autonomic patterns represent different ictal propagation pathways and may include ictal as well as corrective changes.

Disclosure: None.

EPO-240 | Multimodal assessment of neurogenic lower urinary tract symptoms in people with multiple sclerosis

S. Grlić[1]; K. Tešija[1]; I. Šućur[1]; K. Budimir[1]; M. Habek[2]; I. Adamec[2]; B. Barun[2]; I. Jurjević[2]; M. Krbot Skorić[3]; T. Gabelic[2]
[1]*School of Medicine, University of Zagreb, Zagreb, Croatia;* [2]*University Hospital Center Zagreb, Department of Neurology, Referral Center for Autonomic Nervous System Disorders, Zagreb, Croatia;* [3]*Faculty of Electrical Engineering, University of Zagreb, Zagreb, Croatia*

Background and Aims: During the disease course symptoms of lower urinary tract (LUTS) are present in more than 80% of people with multiple sclerosis (pwMS), significantly impairing the quality of life (QoL). Objectives: to define the association between subjective LUTS symptoms, assessed by International Consultation on Incontinence Questionnaire (ICIQ) modules, with the results of neurological and neurophysiological evaluation.

Methods: 102 consecutive pwMS (90 females, age 37.7 ± 9.4 years), were included and Expanded Disability Status Scale (EDSS) with Bowel/Bladder Function System (BFS) was calculated. All participants answered the Croatian version of the ICIQ comprised of three parts (ICIQ – overactive bladder (OAB), ICIQ-OAB QOL, and ICIQ – urinary incontinence (UI)). Somatosensory evoked potentials (SSEP) of median (latency N20, amplitude P15-N20) and tibial (latency P40, amplitude P40-N50) nerve were performed.

Results: Positive correlation was found between the EDSS and BFS with ICIQ-OAB ($r = 0.424$ and $r = 0.741$), ICIQ OAB QOL ($r = 0.462$ and $r = 0.785$), and ICIQ-UI ($r = 0.484$ and $r = 0.705$), all p values < 0.001. Latencies of the right P40 wave on the tibial SSEP positively correlated with OAB (ICIQ-OAB: $r = 0.242$, $p = 0.016$; ICIQ-OABqol: $r = 283$, $p = 0.005$) and latencies of both P40 waves with UI symptoms ($r = 0.350$, $p = <.001$ and $r = 0.291$, $p = 0.004$). Amplitudes of the right P40-N50 wave on the tibial SSEP negatively correlated with OAB (ICIQ-OAB: $r = -0.214$, $p = 0.034$; ICIQ-OABqol: $r = -0.211$, $p = 0.036$) and amplitudes of both P40-N50 waves with UI symptoms ($r = -0.371$, $p = <.001$ and $r = -0.340$, $p = 0.001$).

Conclusion: Subjective affection of the LUTS evaluated with ICIQ Questionnaire modules demonstrated significant association with clinical as well as neurophysiological findings.

EPO-241 | Can clinical risk scores predict atrial fibrillation in patient with cryptogenic stroke? A retrospective analysis

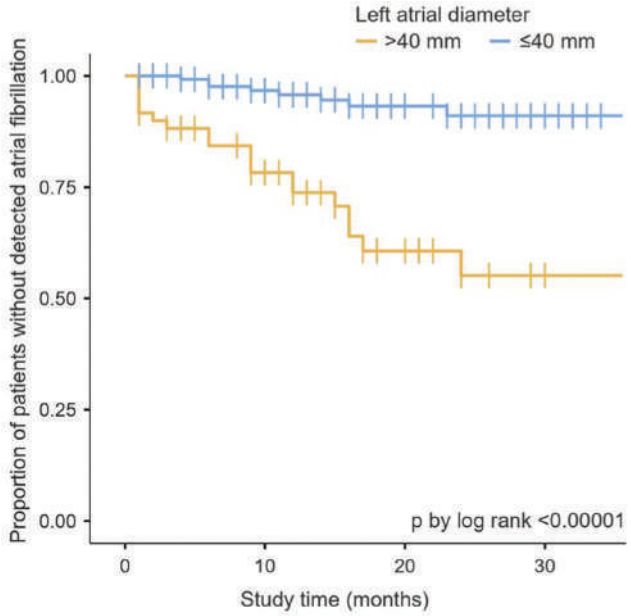
D. Galotto[1]; M. Caccamo[1]; N. Marrone[1]; S. Grimaldi[1]; V. Velucci[1]; A. Manni[1]; G. Falcicchio[2]; G. Milella[2]; D. Mezzapesa[2]; M. Petruzzellis[2]; G. Defazio[1]

[1]*Neurology Unit, Department of Translational Biomedicine and Neurosciences, Bari, Italy;* [2]*Stroke Unit, Policlinic Hospital, Bari, Italy*

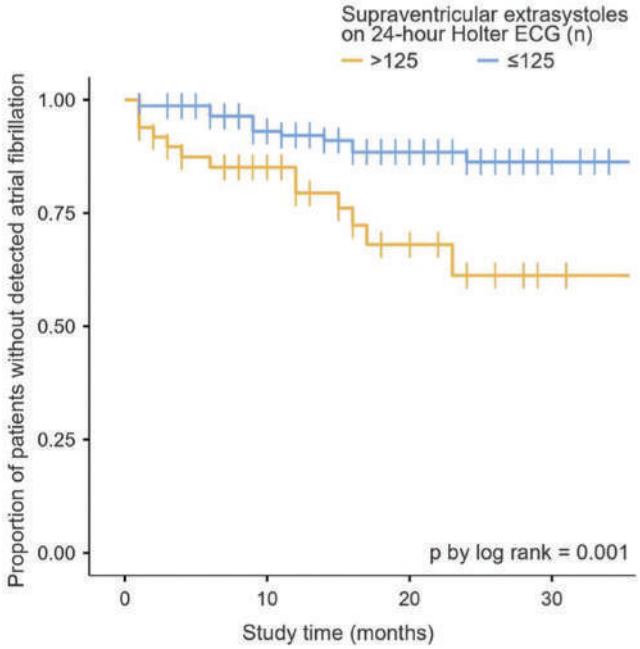
Background and Aims: Atrial fibrillation (AF) is the most common arrhythmia and cause of acute ischemic stroke, often underdiagnosed in cryptogenic stroke (CS), mostly due to inadequate cardiac monitoring. The identification of a clinical risk score to predict AF in CS, could improve patients selection for prolonged monitoring.

Methods: We retrospectively collected data of CS patients discharged from our Stroke Unit from February 2018 to November 2023. A time-to-event analysis was performed to investigate variables associated to AF.

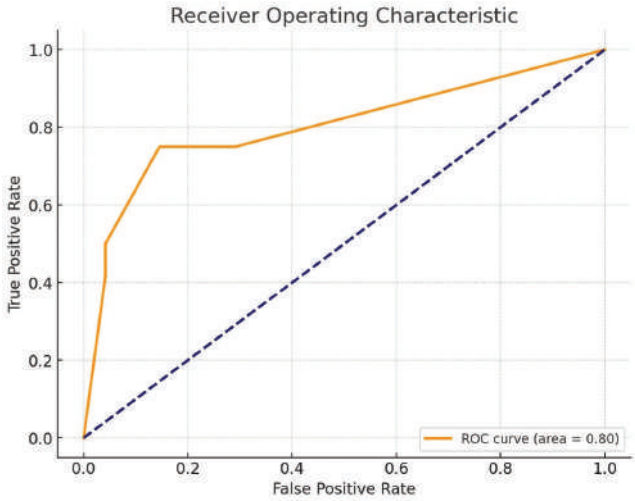
Results: We collected clinical data of 199 CS patients with median age of 70.5 years old. Median follow-up from discharge was 16 months. 52 patients underwent loop recorder implantation of whom, 16 revealed AF after a mean time of 7 months. 14 patients without implantable device discovered AF after a mean time of 15 months. Overall 30 patients (15%) experienced AF. Univariate analysis identified left atrial (LA) dilation with diameter >40 mm ($p<0.001$), supraventricular premature beats (SPB) >125 on 24-hs electrocardiogram ($p=0.03$) and multi-territorial lesions on head TC scan ($p=0.001$) as significant AF predictors. Logistic regression model integrated these three variables and showed: an area under the ROC curve of 0.80, sensitivity of 75.0 % and specificity of 85.4 %.



Left atrial diameter



Supraventricular extrasystoles on 24h ECG



ROC curve (AUC = 0.80)

Conclusion: Our data confirmed studies reporting a significant association between AF and LA dilation, SPB and multi-territorial lesions. For the need to select CS patients for expensive cardiac long-term monitoring, we suggest to integrate these three variables with specificity and reasonable sensitivity in a new clinical risk score.

Disclosure: Nothing to Disclose.

EPO-242 | Does amyloid cerebral deposits influence delayed cognitive impairment after stroke?

O. Godefroy[1]; N. Trinchard[1]; T. Shields[2]; C. Lamy[1]; A. Courselle-Arnoux[1]; S. Canaple[1]; C. Leclercq[1]; M. Roussel[1]; M. Meyer[2]; E. Marchal[2]; F. Wollenweber[3]
[1]*Neurology depart. Amiens University Hospital. F;* [2]*Nuclear Med. Amiens University Hospital. F;* [3]*Neurology Depart. Horst Schmidt Kliniken, Wiesbaden, G*

Background and Aims: Amyloid deposits in has been shown to be associated with post-stroke cognitive impairment (PSCI) at baseline. Long-term outcomes have only been examined in a single study and remain to be documented.
Methods: We included 91 stroke patients (age: 63.3 ± 10.7; NIHSS: 5.6 ± 5.8; infarct: *n* = 81): 40 (44%) had subjective cognitive decline (SCD), 44 (47.2%) mild CI and 7 (8.8%) major CI) at 6 months PS. After the amyloid PET performed at baseline, they were followed up annually for 5 years using a clinical and neuropsychological battery.
Results: Amyloid PET was positive in 14 patients (15.4%). At this last visit (mean duration: 80.6 ± 27.9 months), SCT was observed in 59 patients, mild CI in 14 patients and major CI in 18 patients. Focusing on the 84 patients without major CI at baseline, Kaplan Meier survival analysis showed that amyloid PET status was associated with cognitive outcome ($p = 0.03$) due to a faster and higher rate of CI in PET-positive patients (PET+: 60%; PET-: 25.7%). The effect was significant for both mild ($p = 0.03$) and major CI ($p = 0.003$). It was independent ($p = 0.5$) from the stroke subtype. Cox regression analysis showed that the effect of amyloid status ($p = 0.004$) survived the 2 significant covariates (age at stroke: [$p = 0.013$] and pre-stroke ADL impairment score [$p = 0.016$]).
Conclusion: In addition to the higher risk of PS CI at baseline, amyloid deposits are associated with a higher risk of developing incident CI during follow-up, particularly dementia, with major consequences for patient outcome.

EPO-243 | Early cognitive trajectories after stroke: Still prevalent cognitive impairment despite neurological recovery

L. Gallucci[1]; C. Sperber[1]; D. Seiffge[1]; U. Fischer[2]; A. Hakim[3]; M. Arnold[1]; R. Umarova[1]
[1]*Department of Neurology, University Hospital, Inselspital, University of Bern, Bern, Switzerland;* [2]*Department of Neurology, University Hospital and University of Basel, Basel, Switzerland;* [3]*University Institute of Diagnostic and Interventional Neuroradiology, Bern University Hospital, Inselspital, University of Bern, Bern, Switzerland*

Background and Aims: Early cognitive trajectories after stroke are barely investigated, despite their crucial significance for tailored early intervention in patients at risk for persistent post-stroke cognitive impairment (PSCI).
Methods: We prospectively evaluated non-aphasic patients with a first-ever ischemic stroke without premorbid cognitive decline. Patients underwent a detailed neuropsychological testing in the acute phase and 3 months post-stroke. PSCI was defined as performance < −1.5 SD in ≥ 2 cognitive domains. Cognitive trajectories across 3 months were evaluated using generalized linear models.
Results: Of 257 patients (66 ± 14 years old, 37% female, median NIHSS 24h = 1.00 [0.00, 4.00]) 68% had PSCI 2.8 ± 2.0 days post-stroke. At 3 months post-stroke, despite only minor neurological residual symptoms (NIHSS = 0.00 [0.00, 1.00]), 37% of patients had persistent PSCI and 4% newly developed PSCI. The most often affected domains were verbal episodic memory (43% of patients), constructive abilities (32%), learning (26%), and working memory (24%; Figure 1). The prevalence of PSCI at 3 months post-stroke was comparable between young (<55 years old) and older (>55 years old) stroke adults ($\chi^2 = 0.3$, $p = 0.579$), meaning that this phenomenon could not be explained by covered pre-stroke neurodegenerative processes. Higher stroke severity (NIHSS 24h, OR = 1.14, 95% CI 1.05–1.23) and lower years of education (OR = 0.81, 95% CI 0.73–0.91), but not age (OR = 1.01 95% CI 0.99–1.03), were identified as risk factors of persisting PSCI.

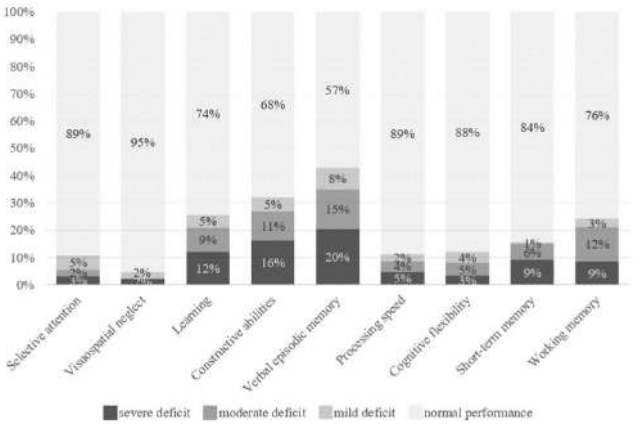

FIGURE 1 Prevalence of cognitive deficits at 3 months post-stroke.

Conclusion: Despite favorable neurological outcome, PSCI still affects every third patient at 3 months post-stroke, even in young adults. New early therapeutic interventions are needed to improve cognitive outcomes.
Disclosure: Nothing to disclose.

EPO-244 | Mechanical thrombectomy vs medical treatment in >85yo patients with acute ischemic stroke from large vessel occlusion

L. Vidal; C. Hervás; E. Mariño; B. Fuentes; M. Alonso de Leciñana Cases; G. Ruiz; R. Rigual; E. de Celis; L. Casado; E. Alonso; J. Rodríguez Pardo de Donlebún
Neurology, Hospital Universitario La Paz, Madrid, Spain

Background and Aims: The evidence on the benefits of mechanical thrombectomy (MT) in patients older than 85 years is scarce. Our

aim was to compare the functional outcomes of patients treated with MT versus best medical treatment (BMT) exploring potentially related factors.

Methods: Retrospective observational study of consecutive stroke code patients >85 years old with large vessel occlusion attended within 24 hours of stroke onset and NIHSS>5 in a comprehensive stroke center from 1/1/2021 to 1/8/2022. We analyzed baseline characteristics, radiological findings and reperfusion treatments and their association with favorable outcomes (mRS <= 3 at 3 months) univariate analysis and binary logistic regression.

Results: We included 78 patients, 68% women, mean age 88 ± 3 years. 39 (50%) had terminal ICA occlusion-M1, 28 (36%) M2, 3 (4%) BA, 8 (10%) ACA/PCA. Median (IQR) NIHSS was 17 (13–20) and ASPECTS 9 (6–10). Intravenous thrombolysis was administered to 30 (38.5%) patients and 52 received (66.7%) MT. We found no significant differences in the proportion of patients with favorable outcomes between the MT group and the BMT group (30% vs 42.3%; $p=0.283$). Univariate analysis showed that higher NIHSS, longer onset-to-door time, higher glycemia and lower ASPECTS were related to worse outcomes. Logistic regression showed that only baseline NIHSS and ASPECTS were independently related to functional outcomes.

Conclusion: In patients older than 85 years with large vessel occlusion, we failed to demonstrate a benefit of MT over BMT. NIHSS and ASPECTS remain the most determinant prognostic factors.

Disclosure: Nothing to disclose.

EPO-245 | Survival and functional outcomes of patients aged ≥ 85 years treated with mechanical thrombectomy after ischemic stroke

C. Moreno López[1]; R. López Rebolledo[1]; G. García Alcántara[1]; A. Llanes Ferrer[1]; A. Cruz Culebras[1]; A. De Felipe Mimbrera[1]; M. Matute Lozano[1]; S. García Madrona[1]; I. Bermúdez Coronel[2]; J. Méndez Cendón[2]; E. Fandiño Benito[2]; J. Masjuan Vallejo[1]; R. Vera Lechuga[1]

[1]Department of Neurology, Ramón y Cajal University Hospital, Madrid, Spain; [2]Department of Neuroradiology, Ramón y Cajal University Hospital, Madrid, Spain

Background and Aims: Age is no longer an exclusion criterion for endovascular treatment of ischemic stroke. However, the progressive aging of the population raises questions about the efficacy and safety of mechanical thrombectomy (MT) in the older population.

Methods: Retrospective study of a prospective database of patients treated with MT at our center between 2017- 2023. We compared our experience using MT in patients aged ≥85 years to those aged < 85 years.

Results: Among the 647 patients treated with MT, 94 (14.5%) were ≥ 85 years old (median age, 87.4 ± 2.4). Both groups had similar stroke severity evaluated by the NIHSS scale (16.5 in ≥85 years old vs 16 in the younger group, $p=0.116$) and had a similar proportion of fibrinolysis treatment (50% vs 53.7%, $p=0.526$). We found no significant differences in the complete recanalization rate (87.7% vs 87.7%, $p=0.903$) or symptomatic hemorrhagic transformation (4.3% vs 4.9%, $p=0.792$) between both groups. However, there were significant differences in the functional outcome at 3 months with a smaller proportion of independence (38% vs 53.9%, $p=0.014$) and higher mortality (21% vs 13.3%, $p=0.029$) in older patients. In this group, we also found higher hospital mortality differences close to significant (17% vs 10.7%, $p=0.07$).

Conclusion: In our experience, treatment with MT in the older population has a high rate of recanalization with no increment in the risk of hemorrhagic transformation but with higher mortality and worse functional outcome at 3 months comparing it with the younger population.

Disclosure: Nothing to disclosure.

EPO-246 | MicroRNAs as biomarkers of carotid atherosclerotic disease in ischaemic stroke patients

P. Jansky[1]; T. Sramkova[1]; K. Benesova[1]; A. Olserova[1]; H. Magerova[1]; V. Matoska[2]; A. Tomek[1]

[1]Department of Neurology, Second Faculty of Medicine, Charles University and University Hospital Motol, Prague, Czechia; [2]Department of Clinical Biochemistry, Hematology and Immunology, Na Homolce Hospital, Prague, Czechia

Background and Aims: MicroRNAs are small non-coding RNA molecules regulating gene expression at the posttranscriptional level. The carotid atherosclerotic disease (CAD) is an important cause of ischaemic stroke. MicroRNAs play a complex role at different stages of atherosclerotic plaque development. Both upregulation and downregulation of different microRNAs were described in patients with CAD and ischaemic stroke. The study aims to describe the association of selected microRNAs and biochemical biomarkers with CAD and plaque stability in ischaemic stroke patients.

Methods: Case-control study of consecutive ischaemic stroke patients with CAD admitted to a comprehensive stroke center. A control group consisted of ischaemic stroke patients with no presence of CAD. Plaques were described as unstable (symptomatic) and stable (asymptomatic). Serum levels of microRNAs (mir-21, mir-29b, mir-133b, mir-142-5p, mir-150, mir-499, mir-223-3p) and biochemical biomarkers (lipid profile, glycated hemoglobin, fibrinogen, antithrombin III, creatinine, CRP) were analyzed at admission. The predictive accuracy was assessed by calculating the AUC.

Results: The data of 117 patients were analyzed (67 with CAD, 55 with no CAD, 16 with symptomatic plaque, 46% men, median age 73 years, median NIHSS 6). In the CAD group vs. no CAD group, the mean levels of glycated hemoglobin were 43.76mmol/mol vs. 39.06mmol/mol ($p=0.031$), the mean levels of fibrinogen 3.07g/l vs. 2.68g/l ($p=0.015$). All other biomarkers, including microRNA levels, were not associated with CAD. No tested biomarker was associated with plaque instability.

Conclusion: Elevated levels of fibrinogen and glycated hemoglobin but no microRNAs were associated with carotid atherosclerotic

disease in ischaemic stroke patients. All biomarkers failed to predict plaque stability.

Disclosure: Nothing to disclose.

EPO-247 | Predictors of early seizures in patients with cerebral venous thrombosis: A single center analysis of 109 cases

V. Radisic; T. Svabic; M. Mijajlovic; P. Stanarcevic; V. Padjen; M. Ercegovac; N. Kresojevic; D. R. Jovanovic; I. Berisavac
Neurology Clinic, University Clinical Center of Serbia

Background and Aims: Early seizures (ES) are frequent manifestation of cerebral venous thrombosis (CVT) which complicates the course and impacts the outcome of the disease. The aim of our study was to identify predictors of ES in patients with CVT.

Methods: This retrospective observational study included 109 patients diagnosed with CVT over the 13- year period. Demographic, clinical, and radiological findings were collected and their association with seizure occurrence was studied. The impact of ESS on modified Rankin score at discharge was also explored.

Results: Among 109 patients, 30 (27.5%) had ESS. Bilateral motor seizures with or without clear focal onset were the most frequent (23 patients), whereas focal seizures were noted in 7 patients. Epileptic status was observed in 6 (20%) patients. In 30% of patients, ESS were the presenting feature, while the rest of patients developed seizures during the first two weeks following CVT. Patients who suffered ESS were younger (34 (18–63) vs. 41 (19–76), $p<0.05$). Among clinical characteristics, coma at admission stood out as a predictor of ESS (5 (16.7%) vs. 3 (3.9%), $p<0.05$). Parenchymal supratentorial lesion on neuroimaging and infarction with hemorrhagic transformation were associated with higher risk of seizure occurrence ($p=0.01$, $p<0.05$). ESS were not associated with poor outcome (mRS-3). However, epileptic status was an important factor of morbidity.

Conclusion: Coma at admission and structural lesions on neuroimaging such as parenchymal supratentorial changes and infarction with hemorrhagic transformation stood out as predictors of ESS in patients with CVT.

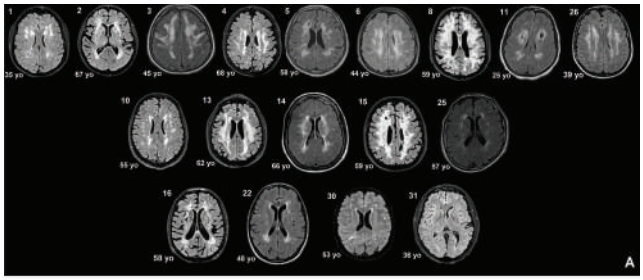
Disclosure: Nothing to disclose.

EPO-248 | Effects of EGFr domain on CADASIL clinical and neuroradiological outcomes: A retrospective study of 115 cases

N. Rifino[1]; B. Storti[1]; I. Canavero[1]; G. Boncoraglio[1]; S. Baratta[2]; F. Taroni[2]; A. Bersano[1]
[1]*Cerebrovascular Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy;* [2]*Unit of Medical Genetics and Neurogenetics, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy*

Background and Aims: Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is a rare heritable small vessel disease caused by a cysteine-altering mutation in one of the thirty-four epidermal growth factor-like repeat(EGFr)-domains of the NOTCH3 gene. CADASIL has a highly variable disease severity. It is supposed that the strongest known disease-modifier may be the NOTCH3cys variant position. In 2023, a new clinical three-tiered EGFr risk classification was proposed. EGFr domains were classified as either low (LR), medium (MR) or high risk (HR). However, it is still unclear how the location of the variants can play a role in CADASIL clinical and neuroradiological phenotype. Herein, we aimed to investigate the influence of mutation site on the clinical and neuroradiological presentation.

Methods: We included patients with a NOTCH3 mutation. Participants were uniformly characterized with a 3Tesla brain MRI (Figure-1A). For each patient, demographic and clinical data were collected (Figure-1B).



EGFr domain risk	HR (n=71)	MR (n=32)	LR (n=13)
Age at last visit, mean (SD)	49,9 (13,2)	58,1 (12,9)	59,5 (11,7)
Men, n (%)	35 (49,2)	15 (46,8)	5 (38,5)
Clinical symptoms			
Ischaemic stroke, n (%)	24 (33,8)	11 (34,4)	3 (23,1)
Intracerebral haemorrhage, n (%)	5 (7,1)	1 (3,1)	1 (7,7)
Neuroradiological features			
Fakezas score, mean (SD)	2,5 (0,9)	2,4 (0,8)	2,2 (0,9)
Lacune number, mean (SD)	4,8 (6,4)	4,4 (5,2)	2,7 (4,1)

B

FIGURE 1A Representative brain MR FLAIR imaging of one patient for each EGFr domain clustered by high (first line), medium (second line) and low risk (third line) 1B. Demographic, clinical and neuroradiological data of HR, MR and LR patients

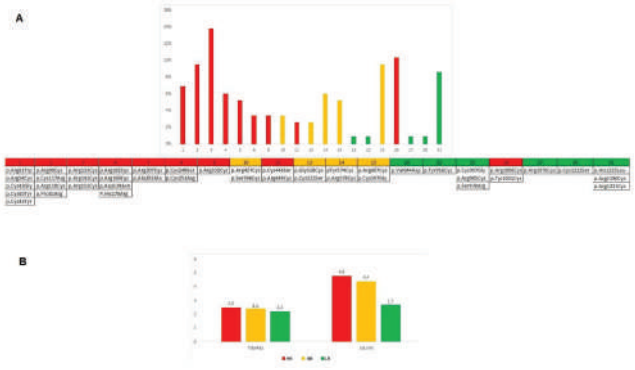


FIGURE 2A Distribution and type of NOTCH3 variants across the three risk groups in our cohort 2B. Average Fazekas score and number of lacuna in the three risk groups.

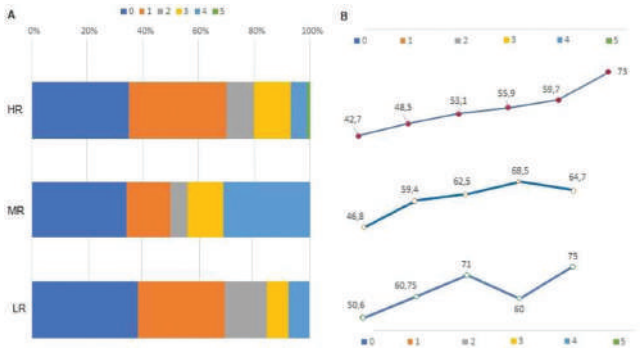

FIGURE 3A Disability for each risk group, according to modified Rankin Scale (mRS) 3B. Mean age for each patient group according to EGFr risk classification and mRS value.

Results: Between 2008 and 2023, a total of 115 individuals with 43 unique NOTCH3 variant were included (Figure-2A). Mutations clustered on the HR-domains were associated with an increased risk of stroke compared to the LR (odds ratio [OR]:1.55; 95% CI: 5.53–0.44) and MR-domains (OR: 1.15; 95% CI: 2.71–0.49) (Figure-1B). On brain MRIs, patients carrying a HR-variants had slightly higher mean Fazekas score and more lacuna than MR and LR-patients (Figure-2B). Furthermore, LR-EGFr individuals had less disability, even though they were significantly older than MR and HR-EGFr patients (Figure-3).

Conclusion: Patients with NOTCH3 HR-EGFr variants had not only an increased risk of stroke and earlier disability but also a more severe neuroradiological picture compared to the LR and MR-domains.

Disclosure: Nothing to disclose.

EPO-249 | Optimal duration of dual antiplatelet therapy after carotid artery stenting: A nationwide cohort study

K. Seo[1]; J. Yoo[2]; H. Lim[3]; D. Kim[4]

[1]Department of Neurology, National Health Insurance Service Ilsan Hospital, Goyang, Republic of Korea; [2]Department of Neurology, Yongin Severance Hospital, Yonsei University College of Medicine, Yongin, Republic of Korea; [3]Department of Research and Analysis, National Health Insurance Service Ilsan Hospital, Goyang, Republic of Korea; [4]Department of Rehabilitation Medicine, Kangdong Sacred Heart Hospital, College of Medicine, Seoul, Republic of Korea

Background and Aims: In carotid artery stenosis patients not eligible for carotid endarterectomy, carotid artery stenting (CAS) serves as an alternative. Dual antiplatelet therapy (DAPT) after CAS aims to prevent ischemic stroke, but the optimal duration remains unclear. We aimed to determine the optimal duration of DAPT by identifying differences in clinical events that occur depending on the DAPT maintenance period.

Methods: We obtained all data from the nationwide database of Health Insurance Review & Assessment Service from 2007 to 2020. The patients who received CAS, identified by procedure codes, The patients were divided into two groups according to the duration of DAPT: those who maintained DAPT for at least 90 days but less than 6 months (short-DAPT group) and those who maintained it longer (long-DAPT group). The primary outcome was a composite of ischemic stroke, gastrointestinal bleeding, and intracranial hemorrhage (ICH) within 12 months post-switch to single antiplatelet therapy.

Results: Of 12,034 CAS patients, 2,529 were in the short-DAPT group and 9,505 were in the long-DAPT group. In the short-DAPT group, ischemic stroke, gastrointestinal bleeding, and ICH occurred in 53 (2.1%), 24 (0.9%), and 4 (0.2%), respectively. In the long-DAPT group, ischemic stroke, gastrointestinal bleeding, and ICH occurred in 184 (1.9%), 142 (1.5%), and 6 (0.1%), respectively. The primary outcome did not significantly differ between groups (3.0% vs. 3.4%; adjusted hazard ratio 1.104; 95% CI 0.866–1.406, $p = 0.4252$).

Conclusion: The short-duration DAPT can be recommended as it shows no difference from long-duration in terms of clinical efficacy and adverse events after CAS.

Disclosure: None.

EPO-250 | Non-coding RNA expression profiling of the peripheral blood for patients with cervical artery dissection using RNA-seq

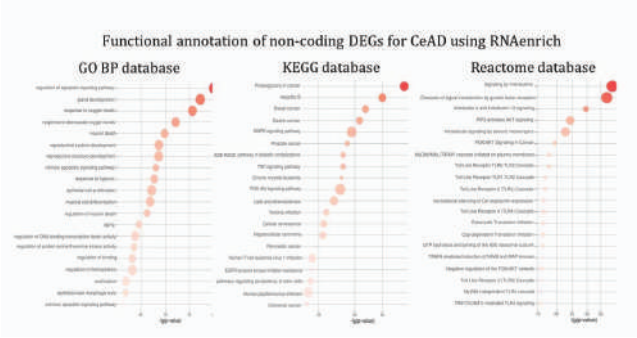
P. Shlapakova; L. Dobrynina; L. Kalashnikova; M. Danilova; M. Gubanova; E. Gnedovskaya

Research Center of Neurology, Moscow, Russian Federation

Background and Aims: Cervical artery dissection (CeAD) is the main cause of young ischemic stroke. We performed bulk RNA-seq of the peripheral blood from patients with CeAD and healthy volunteers. As we analyzed previously, the expression profile of protein-coding genes for CeAD was associated with nucleolar stress, senescence-associated secretory phenotype and mitochondrial malfunction. Our new research goal is to evaluate functional properties of differentially expressed non-coding genes (ncDEGs) in peripheral blood for CeAD.

Methods: RNA was extracted from peripheral blood of 19 CeAD patients (37.6 ± 3.95 y.o.) and 18 healthy volunteers (30.1 ± 6.65 y.o.) using the Qiagen© RNeasy Mini Kit. 1000 ng of the RNA (RIN>7.0) were used to prepare each library with the Illumina© TruSeq Stranded Total RNA Library Prep Gold kit. 30–50 million paired-end reads per sample were sequenced on the Illumina© NovaSeq 6000. 80% of the reads were aligned to the human reference genome using STAR. 60% of the aligned reads were counted in the features (genes) using Htseq-count. Differential expression analysis with covariate adjustment (for age, sex and batch factors) was performed in EdgeR (CeAD vs Norma; adj.p-value < 0.05). Enrichment analysis for ncDEGs was performed using RNAenrich against Reactome, KEGG and GO BP.

Results: We identified 62 upregulated and 302 downregulated ncDEGs for CeAD, which are most significantly involved in the pathways relevant to carcinogenesis and angiogenesis: epithelial cell proliferation, cellular senescence, regulation of apoptosis and response to oxygen levels, VEGFA-VEGFR2/PI3K-AKT/MAPK signaling.



Enrichment bubble plots for the top representative pathways enriched in ncDEGs for CeAD. The pathways from GO BP, KEGG and Reactome databases are shown.

Conclusion: Functional profiling of ncDEGs for CeAD confirms our previous results about the probable intersection of CeAD with paraneoplastic mechanisms.

Disclosure: Nothing to disclose.

EPO-251 | Large artery atherosclerosis association with tissue-level collaterals and outcomes in mechanical thrombectomy patients

P. Wrona[1]; D. Wrobel[2]; J. Jozwik[2]; K. Jakobschy[2]; T. Popiela[3]; T. Homa[4]; A. Slowik[1]

[1]*Department of Neurology, Jagiellonian University Medical College, Krakow, Poland;* [2]*Student Scientific Group in Cerebrovascular Diseases, Jagiellonian University Medical College, Krakow Poland;* [3]*Department of Radiology, Jagiellonian University Medical College, Krakow, Poland;* [4]*Department of Neurology, University Hospital, Krakow, Poland*

Background and Aims: Large artery atherosclerosis (LAA) is responsible for approximately 15% of acute ischemic strokes (AIS). Studies showed that LAA foster leptomeningeal development. We aimed to determine whether LAA is associated with better tissue-level-collaterals (TLC), denoted by lower computed tomography perfusion (CTP)-derived hypoperfusion intensity ratio (HIR), as well as smaller early infarct volume (EIV) and if HIR and EIV affect functional outcomes.

Methods: We retrospectively analyzed 460 consecutive patients with AIS in anterior circulation treated with MT in Comprehensive Stroke Center in Krakow (2019–2023). We included 120 (26.09%) patients with LAA and 340 (73.91%) with cardioembolic AIS etiology. We obtained pre-stroke risk factors and performed CTP followed by post-processing analysis with RAPID software. HIR was defined as ratio of T10max/T6max; EIV as tissue with cerebral blood flow < 30% on admission, good functional outcome (GFO) as modified Rankin Score < 3 at day 90.

Results: LAA was associated with male sex (75% vs 41.2%, $p < 0.001$), smoking history (42.5% vs 14.5%, $p < 0.001$), younger age (66 [59–71 years]vs 76 [69–84 years], $p < 0.001$), lower initial National Institutes of Health Stroke Scale score (15 [10–18] vs 17 [10–20], $p = 0.003$) and lower HIR (0.26 [0.1–0.434] vs 0.386 [0.204–0.521], $p < 0.001$). Despite that, LAA was not associated with lower EIV (8 ml [0–32] vs 7 ml [0–22], $p = 0.502$). LAA etiology predicted GFO in univariate analysis (73.3% vs 60.6%, $p = 0.012$), although significance was lost after adjustment for confounders ($p = 0.394$).

TABLE 1 Characteristics of patients with LAA vs cardioembolic ischemic stroke etiology

	LAA (N=120)	Cardioembolic (N=340)	*P* value
Demographics			
Male, n (%)	90 (75)	140 (41.2%)	<0.001
Age, years, median [IQR]	66 [59-71]	76 [69-84]	<0.001
Stroke risk factors			
Hypertension, n (%)	76 (63.3)	271 (79.7)	<0.001
Diabetes Mellitus, n (%)	22 (18.3)	79 (23.2)	0.474
Hiperlipidemia, n (%)	15 (12.5)	72 (21.2)	0.037
History of stroke/TIA, n (%)	8 (6.7)	47 (13.8)	0.038
Smoking, n (%)	51 (42.5)	49 (14.5)	<0.001
Clinical characteristics			
Baseline NIHSS, median [IQR]	15 [10-18]	17 [10-20]	0.003
Time from LKW to puncture, median [IQR]	324 [245-419.5]	298 [21..25-370]	0.021
Time from LKW to imaging, median [IQR]	256 [197-357]	245 [172-306]	0.032
Intravenous thrombolysis, n (%)	74 (61.7)	157 (46.2)	0.004

COVID-19

EPO-252 | Long-COVID-19: A biomedical model of post-viral chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME)

A. Chaudhuri; A. Goldsmith Lister

Department of Neurology, CFS/ME Unit, Queen's Hospital, Romford, UK

Background and Aims: The pathogenesis of post-viral chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is poorly understood. Long-COVID-19 is a post-viral syndrome that shares clinical features of CFS/ME.

Methods: We reviewed the data of 487 adults (age range 16–70 years) with CFS/ME seen in our clinic al unit with the clinical features of adult post-COVID-19 population from literature search.
Results: Symptoms of post-viral CFS/ME and long-COVID-19 were remarkably similar; fatigue, headache, cognitive deficit and chronic pain were common in both groups and tended to be more pervasive for those with longer symptom durations. Quality of life was severely impacted by physical fatigue with post-exertional malaise, cognitive impairment that did not progress over time, and neuropsychiatric symptoms from low mood and anxiety.
Conclusion: Population with CFS/ME and post-COVID-19 experience persistent central fatigue, pain and non-progressive cognitive deficits. Modification of post-translational cell signalling by viral infection and host immune response leading to metabolic reprogramming and consequent alterations in synaptic and ion channel functions is a possible explanation and further work is required for better understanding of biomedical mechanisms of post-viral syndromes to develop effective therapy. Long COVID-19 is a valid biomedical model of post-viral CFS/ME and post-viral syndromes are not primarily a somatoform or functional neurological disorders.
Disclosure: There is no competing interest.

EPO-253 | SARS-CoV-2 impact on disability in Southern Italy's MS patients: Tertiary center findings

C. Di Monaco[1]; A. Esposito[1]; E. Zappulo[2]; I. Di Filippo[2]; A. Spiezia[1]; M. Pretracca[3]; V. Nicolella[1]; F. Novarella[1]; R. Lanzillo[1]; M. Moccia[1]; A. Buonomo[2]; I. Gentile[2]; V. Brescia Morra[1]; A. Carotenuto[1]
[1]*Department of Neurosciences, Reproductive and Odontostomatological Sciences, Federico II University, Naples, Italy,* [2]*Department of Clinical Medicine and Surgery, Division of Infectious Diseases, "Federico II" University hospital, Naples, Italy,* [3]*Department of Human Neurosciences, Sapienza University, Rome, Italy*

Background and Aims: In Multiple Sclerosis (MS) patients, the occurrence of COVID-19 has been associated with worsening clinical course. This study aimed to assess the incidence of SARS-CoV2 infection during various pandemic waves and evaluate risk factors for clinical disability worsening in the post-COVID-19 era within an MS setting.
Methods: A retrospective study was conducted on patients with MS and neuromyelitis optica spectrum disorder (NMO) at the Multiple Sclerosis Center at the University of Naples "Federico II" between March 2020 and October 2023. Patients were monitored for virologically documented SARS-CoV2 infection during follow-up. Data on Expanded Disability Status Scale (EDSS) scores were collected at MS diagnosis, the latest follow-up before March 2020, and the last available follow-up
Results: Among 276 patients enrolled, 46% (127 patients) were infected with SARS-CoV2, predominantly during the Omicron BA1/2 wave. Infected patients had a lower EDSS at MS diagnosis (3.0 [2.5–3.5] vs. 3.5 [2.5–4.5], $p=0.015$) and at the last follow-up (4.5 [3–6] vs. 5.5 [3.5–6.5], $p=0.03$). No significant differences in EDSS change were observed between infected and non-infected patients. Multivariate Cox analysis revealed that EDSS worsening was associated with age younger than 50 years (HR=3.57, $p=0.03$), while anti-CD20 treatment was protective against disability accrual (HR=0.09, $p=0.04$).
Conclusion: 46% of MS or NMO patients experienced SARS-CoV2 infection while under mAb treatment. Infected individuals exhibited lower motor impairment, suggesting that higher disability might be protective due to increased awareness of fragility status or limited outdoor and social activities. Importantly, COVID-19 infection did not seem to impact the disease course

EPO-254 | SARS-CoV-2-induced type I interferon signalling dysregulation in the olfactory-amygdala pathway

G. Vavougios[1]; T. Mavridis[2]; T. Doskas[3]; O. Papaggeli[4]; P. Foka[4]; G. Hadjigeorgiou[1]
[1]*Department of Neurology, Medical School, University of Cyprus, Nicosia, Cyprus;* [2]*Tallaght University Hospital (TUH)/The Adelaide and Meath Hospital, Dublin, incorporating the National Children's Hospital (AMNCH), Dublin, Ireland;* [3]*Athens Naval Hospital, Athens, Greece;* [4]*Hellenic Pasteur Institute, Athens, Greece*

Background and Aims: Previous works from our group have proposed a model where peripheral induction of IFN-I may be relayed to the CNS, even in the absence of fulminant infection. The aim of our study was to identify significantly enriched IFN-I signatures and genes along the transolfactory route, utilizing published datasets of nasal mucosa, olfactory bulb amygdala transcriptomes of COVID-19 patients. We furthermore sought to identify in these IFN-I signature gene networks associated with Alzheimer's disease pathology and risk.
Methods: Gene expression data involving the nasal epithelium, olfactory bulb and amygdala of COVID-19 patients and transcriptomic data from Alzheimer's disease patients were scrutinized for enriched Type I interferon pathways. Gene set enrichment analyses and gene – Venn approaches were used to determine genes in IFN-I enriched signatures. The Agora web resource was used to identify genes in IFN-I signatures associated with Alzheimer's disease risk based on its aggregated multi-omic data.
Results: Pathways associated with type I interferon signalling were found in all samples tested. Each type I interferon signature was enriched by IFITM and OAS family genes. A 14 gene signature

associated with COVID-19 CNS and the response to Alzheimer's disease pathology, whereas 9 genes were associated with increased risk for Alzheimer's disease.

Conclusion: Our study provides further support to a type I interferon signalling dysregulation along the extended olfactory network as reconstructed herein, ranging from the nasal epithelium and extending to the amygdala. We furthermore identify the 14 genes implicated in this dysregulated pathway with Alzheimer's disease pathology, conferring increased risk for the latter.

Disclosure: None declared.

EPO-255 | Serum interleukins in children with neurological complications of SARS-CoV-2 infection

E. Capestru[1]; S. Hadjiu[1]; C. Calcii[3]; O. Constantin[1]; I. Calistru[1]; I. Istratuc[1]; N. Revenco[1]; S. Groppa[2]

[1]State University of Medicine and Pharmacy "Nicolae Testemiţanu" Pediatric Neurology Clinic of the Department of Pediatrics; [2]State University of Medicine and Pharmacy „Nicolae Testemiţanu" Neurology Department No. 2; [3]PMI, Institute of Mother and Child

Background and Aims: Neuroinflammation is one of the key mechanisms involved in the pathogenesis of brain lesions associated with SARS-CoV-2 infection. The aim. To estimate the correlation between serum levels of IL-1beta, IL-10, and nervous system damage in children with SARS-CoV-2 infection.

Methods: We evaluated 100 children (age 29 days – 7 years) with neurological manifestations associated with SARS-CoV-2 (moderate and severe form), divided into two groups: (1) acute neurological complications (CN) and (2) post-acute, in which we evaluated the serum values of IL-1beta and IL-10, by the ELISA method. Clinical manifestations were scored to perform statistical calculations. Statistical processing: *t*-student test, 95 CI confidence coefficient, correlation coefficient (rxy).

Results: In the group with acute CN, 89 (89%; 95 CI 92.13 –85.87) cases were registered, and post-acute CN – 11 (11%; 95 CI 7.87–14.13). In the group with acute CN, encephalopathy (72%; 95 CI 67.51–76.49) and seizures (9%; 95 CI 6.14–11.86) prevailed, compared to those with post-acute CN (2%; 95 CI 0.6–3.4) in which headache predominated (90%; 95 CI 87–93). Serum levels of IL-10 and IL-beta were significantly increased in the acute CN group compared to those with post-acute CN. Strong correlations were found between elevated serum levels of IL-1beta and encephalopathy (rxy = 0.786), IL-1beta and seizures (rxy = 0.824), and between IL-10 and encephalopathy (rxy = 0.758), IL-10 and seizures (rxy = 0.806).

Conclusion: Strong correlations between elevated levels of IL-1β and IL-10 and acute CN suggest the presence of pronounced inflammation and the risk of long-term neurological complications in children who were infected with SARS-CoV-2.

Disclosure: Nothing to disclose.

EPO-256 | Cortical and spinal excitability testing in patients with long-term post-COVID myopathy

G. Fanella[1]; B. Khan[1]; A. De Grado[2]; J. Agergaard[3]; L. Østergaard[3]; B. Schiøttz-Christensen[3]; H. Tankisi[1]

[1]Department of Clinical Neurophysiology, Aarhus University Hospital, Aarhus, Denmark; [2]Unit of Rare Neurological Diseases, Department of Clinical Neurosciences, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy; [3]Department of Infectious Diseases, Aarhus University Hospital, Aarhus, Denmark

Background and Aims: The objective of this study was to investigate cortical and spinal excitability in patients diagnosed with post-COVID myopathy, exploring the possibility of a multisystemic involvement of both muscles and central nervous system (CNS).

Methods: In this case-control study, we compared 32 patients with post-COVID myopathy to 15 age-matched healthy controls. Cortical excitability was assessed using threshold-tracking transcranial magnetic stimulation (TT-TMS), with the following protocols: Short-Interval Intracortical Inhibition (SICI), Short-Interval Intracortical Facilitation (SICF), Long-Interval Intracortical Inhibition (LICI), Intracortical Facilitation (ICF), Short-latency afferent inhibition (SAI). Spinal cord excitability was evaluated by recording H-reflex and long latency reflexes (LLRs). Cognitive status was assessed using Montreal Cognitive Assessment (MoCA) and Symbol Digit Modalities Test (SDMT).

Results: TT-TMS showed a statistically significant decreased SICI across the entire averaged 1–3.5 ms interval range ($t(45) = 2.411$, p-value = 0.01) in patients compared to controls (Fig 1). The most affected ISI was 2.5ms, with values of 9.2% ± 1.9 for patients vs. 21.3% ± 2.3 for controls ($t(45) = 3.761$, p-value = 0.0005). No significant differences were found in SAI, SICF, ICF and LICI between the two groups. Statistically significant differences were observed in

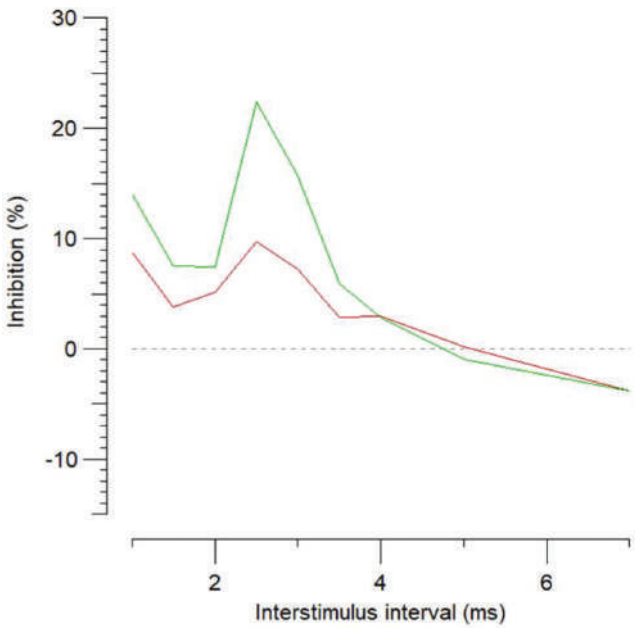

FIGURE 1 Overview of SICI protocol 1–7 ms. Red: patients, Green: healthy controls

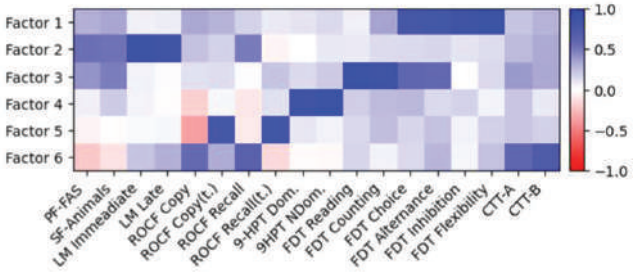
LLR II (U = 126.0, *p*-value = 0.02) and LLR III (U = 53.0, *p*-value = 0.03) amplitudes. MoCA median score was 27 for patients and 29 for controls, showing a statistically significant difference between the two groups (U = 96.50, *p*-value = 0.002). We found no differences in H reflex and SDMT score in the two groups.

Conclusion: This study demonstrates that patients with post-COVID myopathy exhibit reduced cortical inhibition and increased LLR amplitudes. These findings point towards a potential concomitant involvement of CNS in individuals with post-COVID myopathy.

Disclosure: Nothing to disclose.



Weighting matrix of the final factor analysis after ObliMin rotation. PF: Phonetic Fluency, SF: Semantic Fluency, ROCF: Rey-Osterieth Complex Figure test, 9-HPT: nine-hole peg test, FDT: Five-Digit test, CTT: Color Trails test.

EPO-257 | The different neuropsychological phenotypes of Post-COVID subjects

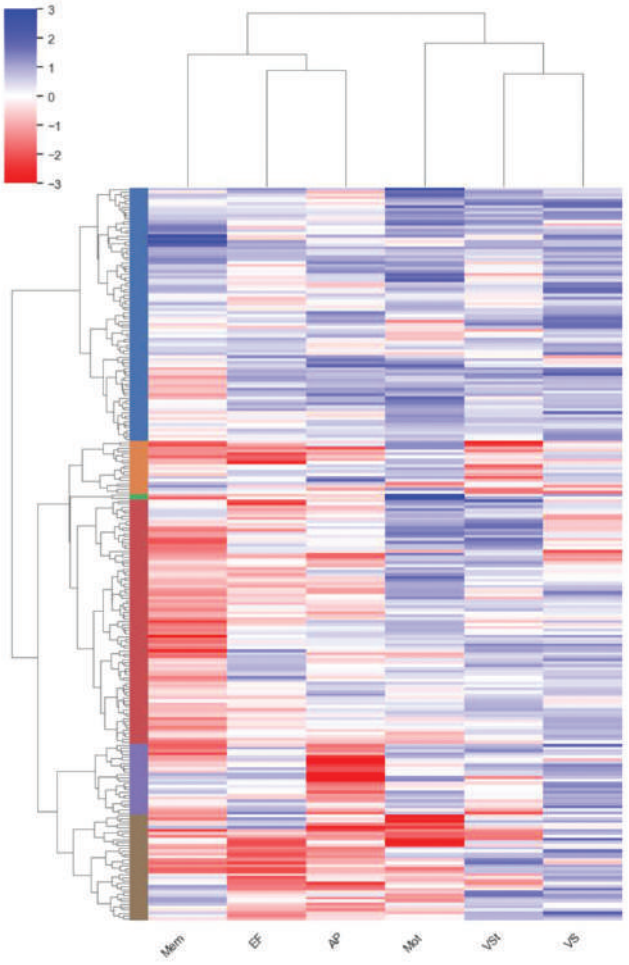
Í. Karmann Aventurato; L. Scárdua-Silva; B. Amorim da Costa; R. Batista João; M. Rabelo de Brito; J. Bechelli; L. Santos Silva; A. Ferreira dos Santos; M. Koutsodontis Machado Alvim; T. Alves Silva Souza; M. Mendes; T. Waku; M. Rocha da Silva; M. Nogueira; F. Cendes; C. Lin Yasuda

Laboratório de Neuroimagem, Departamento de Neurologia, Faculdade de Ciências Médicas, Universidade de Campinas

Background and Aims: Although cognitive dysfunction of patients after COVID-19 infection has been described, a systematic search of neuropsychological subgroups has not been conducted. The present study aims to derive the neuropsychological profile of different subgroups using a data-centric hierarchical clustering method.

Methods: We analyzed the data from the NeuroCovid cohort, comprising different neuropsychological tests (comprising multiple cognitive domains). After outlier removal, a factor analysis was performed to derive the latent cognitive factors in the data. Factor-transformed data were renormalized according to the expected population mean and standard deviation and used in hierarchical analysis with Ward's method. Subjects were compared between clusters regarding demographics, illness severity, depression and anxiety scores.

Results: We applied factor analysis to neuropsychological data from 265 subjects. Data were deemed proper for factor analysis (Kayser-Meyerz-Olkin statistic 0.63), and the number of factors was determined to be 6 by parallel analysis. Factors regarding memory, executive functions (EF), automatic processes (AP), motor, visuospatial construction (VSP) and visuospatial construction speed were identified. One was excluded from the six clusters identified due to insufficient subjects (*n* = 2). The remaining clusters were (A) unimpaired (*n* = 86), (B) visuospatial impaired (*n* = 18), (C) memory impaired (*n* = 83), (D) AP impairment (*n* = 24), and (E) EF impairment (*n* = 36). Cluster C comprised older subjects, whereas subjects were younger in Cluster E. Depression scores (Beck's Depression Inventory-II) were increased in both clusters C and E.



Clustergram of the Hierarchical Clustering analysis applied to factor-transformed renormalized data. Colors under the dendogram (left) divide the data in different clusters.

Conclusion: Our data shows that the individuals with persistent symptoms after mild COVID present a heterogeneous neuropsychological profile with subgroups showing impairments in different cognitive domains.

Disclosure: Nothing to disclose.

EPO-258 | Assessing the potential neurological impact of COVID-19 vaccines: An in-depth examination of reported complications

J. Salimjonov; N. Rashidova; K. Khalimova
Department of Neurology and Medical Psychology, Tashkent Medical Academy, Tashkent, Uzbekistan

Background and Aims: During the COVID-19 pandemic, several types of vaccines were developed, which successfully passed all stages of clinical trials and were used into practice. Like other types of vaccines, COVID-19 vaccines have their own local and systemic side effects, as well as other systemic complications, including neurological ones.
Methods: The medical records of people were examined, who received a full course of vaccination between April 2021 and March 2023 in the Tashkent city. Adverse reactions and neurological complications were identified by retrospective analysis, spontaneous reporting, and stimulated reporting.
Results: A total of 1,585,014 people have been completed the full course of vaccination (minimum age 18 years, maximum 85 years) and 6,796,188 doses of vaccines have been used (Oxford/AstraZeneca 240,144 doses, ZF2001 3,411,125 doses, Sputnik V 257,593 doses, Moderna 1,132 121 doses, Pfizer/BioNTech 1,441,627 doses, Sinovac 251,146 doses, Sputnik Light 51,141 doses, Johnson&Johnson 11,291 doses). Among the neurological complications after vaccination were identified: ischemic stroke (12 cases, 0.00075%), cavernous sinus thrombosis (1 case, 0.00006%), acute disseminated encephalomyelitis (1 case, 0.00006%), meningoencephalitis (3 cases, 0.00019%), sensorineural hearing loss (4 cases, 0.00025%), Guillain-Barré syndrome (4 cases, 0.00025%), Bell's palsy (2 cases, 0.000125%), multisystem inflammatory syndrome (1 case, 0.00006%). No deaths have been reported following vaccination. Neurological complications occurred within 28 days after vaccination.
Conclusion: Given the risk of neurological complications is extremely rare (0.001%), vaccination is the only way to protect against COVID-19. At a time when the COVID-19 infection has enormous complications not only in the nervous system, but also in other systems, even death.
Disclosure: Agree.

EPO-259 | Analysis of IgG antibodies against S1-RBD of SARS-CoV2 in patients with MS treated with DMT in North-Eastern Poland

J. Kulikowska[1]; K. Kapica-Topczewska[1]; M. Gudowska-Sawczuk[2]; A. Kulczyńska-Przybik[2]; M. Bazylewicz[1]; A. Mirończuk[1]; A. Czarnowska[1]; B. Mroczko[2]; J. Kochanowicz[1]; A. Kułakowska[1]
[1]*Department of Neurology, Medical University of Bialystok, Bialystok, Poland;* [2]*Department of Neurodegeneration Diagnostics, Medical University of Bialystok, Bialystok, Poland*

Background and Aims: The coronavirus disease 2019 (COVID-19) course and serological statuses of patients with relapsing-remitting multiple sclerosis (RRMS) treated with disease-modifying therapies (DMTs) is similar to the general population. Over the pandemic course a notable increase in the number of RRMS patients who received vaccination against severe acute respiratory coronavirus 2 (SARS-CoV-2) and those who had COVID-19 was reported. This virus and/or vaccination likely influenced DMT-treated RRMS patients' serological statuses.
Methods: This investigation assessed the presence and levels of the antibody directed against the S1 protein receptor binding domain (S1RBD) of SARS-CoV-2 in 38 DMT-treated RRMS patients. The antibodies were assessed twice: between March-June 2021 (visit 1) and March-June 2023 (visit 2).
Results: Statistical analysis showed that percentages of IgGS1-RBD results between vaccinated and unvaccinated patients with RRMS were not statistically significant (visit 1: $p = 0.089$; visit 2 $p = 0.501$). However, at visit 1, the number of positives was higher in the vaccinated group than in the unvaccinated group, which was significant at the trend level. Moreover, vaccination had a statistically significant effect on anti-S1RBD antibody levels at visit 1 ($p < 0.001$) and visit 2 ($p = 0.038$).
Conclusion: Study group are immunocompetent in terms of the production of neutralizing antibodies. Our research shows that vaccinated group of patients have statistically significantly higher levels of neutralizing antibodies compared to unvaccinated. It was observed over the course of two years of the pandemic. Levels of neutralizing antibodies seem to better reflect the level of protection against the SARS-CoV-2 virus than their presence alone, but this requires further research.
Disclosure: No disclosure.

EPO-260 | Radiological markers of neurological manifestations of post-acute sequelae of SARS-CoV-2 infection: A mini-review

L. Al Qadi[1]; O. Cull[1]; J. Stadler[1]; M. Martin[1]; A. El Helou[2]; J. Wagner[3]; D. Maillet[4]; L. Chamard-Witkowski[5]
[1]*Centre de formation médicale du Nouveau Brunswick, University of Sherbrooke, Moncton, NB, Canada;* [2]*Department of Neurosurgery, The Moncton Hospital, Moncton, NB, Canada;* [3]*Department of Diagnostic Imaging, The Moncton Hospital, Moncton, NB, Canada;* [4]*Vitalité Health Network, Dr. Georges-L.-Dumont University Hospital Centre, Moncton, NB, Canada;* [5]*Department of Neurology, Dr.-Georges-L.-Dumont University Hospital Center, Moncton, NB, Canada*

Background and Aims: The neurological impact of COVID-19 infection is concerning, as patients continue to experience various cognitive and psychiatric symptoms for more than 12 weeks post-infection—a condition known as neurological post-acute sequelae of COVID-19 (Neuro-PASC). Considering significant challenges exist in evaluating its impact, this mini-review aims to provide up-to-date information on the optimal usage, limitations, and benefits of neuroimaging techniques for Neuro-PASC.

Methods: Our search on PubMed and Google Scholar databases used specific equations for each imaging, such as structural MRI (magnetic resonance imaging), functional MRI, diffusion MRI, SWI (susceptibility-weighted imaging), SPECT (single-photon emission computed tomography) imaging, OR PET (positron emission tomography) imaging AND COVID-19. Articles were then selected with 2 independent reviewers.

Results: 18F-FDG-PET/CT and functional MRI demonstrated hypometabolism in cerebral regions directly linked to patient symptoms. Structural MRI studies revealed different findings, such as infarcts, white matter atrophy, and gray matter volume changes. One SPECT imaging study noted frontal lobe hypometabolism, while diffusion MRI showed increased diffusivity in limbic and olfactory cortical systems. The SWI sequence showed abnormalities in white matter near the gray-white matter junction. A study on 18F-amyloid PET/CT found amyloid lesions in frontal and anterior cingulate cortex areas, and a study on arterial spin labeling (ASL) found hypoperfusion in the frontal lobe.

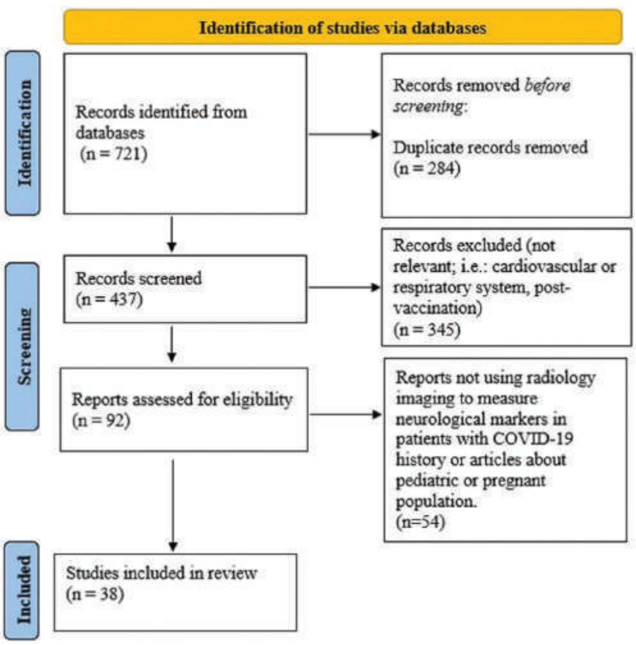


FIGURE 1 Prisma Flowchart

TABLE 1 Summary of the characteristics and findings of the imaging studies included in this review

Authors	Journal	Study design	Number of subjects	Number of controls	Gender distribution male/female	Age (years)	Time since COVID-19 infection	Type of imaging	Main findings in patients
Sollini et al. [illegible]	Springer Nature	Prospective case-control study	13	26	8/5	[illegible]	131 ± 31 days	^{18}F-FDG PET/CT	^{18}F-FDG uptake in "target" and "non-target" tissues. Relative hypometabolism in the right parahippocampus and thalamus. Specific region(s) of hypometabolism in patients with persistent anosmia/ageusia, fatigue, and vascular uptake.
Karimi-Galougahi et al. [illegible]	Academic Radiology	Case study	1	N/A	0/1	27	6 weeks	^{18}F-FDG PET/CT	Hypometabolism in the orbitofrontal cortex.
Donegani et al. [illegible]	Biomedicines	Longitudinal cross-sectional cohort study	22	41	12/10	[illegible]	>1 month	^{18}F-FDG-PET/CT	Relative hypometabolism shown in bilateral parahippocampus and fusiform gyri and in left insula.
Hosp et al. [illegible]	Oxford University Press	Prospective cohort study	29	45	18/11	65.2 ± 14.4	1 month average	3T sMRI and ^{18}F-FDG PET/CT	MRI showed subacute infarcts. ^{18}F-FDG PET/CT showed predominant frontoparietal hypometabolism.
Guedj et al. [illegible]	Springer Nature	Retrospective case control study	35	44	20/15	55.06 ± 11.22	≥3 weeks	^{18}F-FDG PET/CT	Hypometabolism in olfactory gyrus and connected paralimbic/limbic regions, extended to the cerebellum and brainstem.
Dressing et al. [illegible]	The Journal of Nuclear Medicine	Prospective cohort study	14	45	5/9	[illegible] ± 7.2	198.8 ± 63.5 days	^{18}F-FDG PET/CT	No pathological findings found on imaging.
Debs et al. [illegible]	American Journal of Neuroradiology	Retrospective single-center study	45	52	24/21	58 (18–87)	6.57 ± 4.85 months	^{18}F-FDG-PET/CT	Focal hypometabolism peak in cerebellum and in bilateral frontal, parietal, occipital, and posterior temporal lobes, during the first 2 months, nearly resolved at 6 months and disappeared at 12 months. Hypermetabolism in brainstem, cerebellum, limbic structures, frontal cortex, and periventricular white matter shown 2–6 months post-infection.
[illegible] et al. [illegible]	Viruses	Mixed method, cohort study (Action research)	55 (35 for imaging)	N/A	15/40	42.4 (12–79)	13.1 ± 8.9 (recovered mild and severe) 18.3 ± 5.9 (still ill, very severe)	SPECT-CT	SPECT-CT showed cerebral hypoperfusion lesions consistent with the severity of the condition.
Ferrucci et al. [illegible]	Springer Nature	Retrospective case study	7	N/A	4/3	[illegible]	>12 months	^{18}F-FDG PET/CT and ^{18}F-amyloid PET/CT	^{18}F-FDG PET/CT showed various hypometabolism in the left temporal mesial, pontine, and bilateral prefrontal and parietal regions. ^{18}F-amyloid PET/CT done for the patient with the greatest extent of hypometabolism showed significant Aβ deposition in the superior and middle frontal cortex, in the posterior cingulate, and mildly in the rostral and caudal anterior cingulate regions.
Thapaliya et al. [illegible]	Frontiers in Neuroscience	Cross-sectional study	8	10	3/5	43.2 ± 18.7	≤3 months	7T sMRI	Strong negative relationship between midbrain volume and "breathing difficulty". Greater pons and whole brainstem volumes in patients.
Cecchetti et al. [illegible]	Springer Nature	Longitudinal quasi-experimental study	[illegible]	[illegible]	25/11	[illegible]	[illegible]	3T sMRI	No significant differences in total brain, gray, or white matter volumes were found between patients and controls. Greater total of right frontal and right parieto-occipital white matter hyperintensity volumes. Interrelated cognitive, EEG and MRI alterations were observed after two months of COVID-19 resolution.
Douaud et al. [illegible]	Nature	Longitudinal quasi-experimental cohort study	401	384	172/229	62.1 ± 6.7	141 ± 79 days	sMRI, fMRI, dMRI	Reduced total brain size, gray matter thickness and tissue contrast in orbitofrontal cortex and parahippocampal gyrus. Greater changes in patients regarding diffusion measures in areas functionally connected to the primary olfactory cortex.
Kandemirli et al. [illegible]	Academic Radiology	Prospective case study	23	N/A	9/14	[illegible]	1–4 months	Paranasal sinus CT and 3T MRI dedicated to olfactory nerves	CT showed opacification in olfactory cleft. MRI showed olfactory bulb degeneration and changes in shape. MRI also showed diffused increase in signal intensity from the olfactory bulb, scattered hyperintense foci, and microhemorrhages.
Besteher et al. [illegible]	Psychiatry Research	Cross-sectional study	30	20	13/17	[illegible]	8.63 (2–14) months	3T sMRI	Multiple clusters of significant bilateral gray matter volume enlargement in fronto-temporal regions, insula, hippocampus, amygdala, basal ganglia and thalamus.
Hellgren et al. [illegible]	BMJ Open	Ambidirectional observational cohort study	[illegible]	N/A	28/7	[illegible]	7 months	3T SWI, DWI, and sMRI	Multiple findings of white matter lesions near gray-white matter junction in frontal and parietal lobes.
Campabadal et al. [illegible]	Annals of Clinical and Translational Neurology	Prospective cohort study	48	N/A	18/30	[illegible] (normal olfaction) 51.90 ± 7.92 (olfactory dysfunction)	[illegible] months	3T sMRI and DWI	Reduced gray matter volume and increased mean diffusivity in olfactory-related areas explaining persistent olfactory deficits in patients. Greater radial diffusivity in the anterior corona radiata, the genu of the corpus callosum, and uncinate fasciculus in patients with deficits compared to those without.
Yus et al. [illegible]	Acta Neurologica Scandinavica	Cross-sectional study	[illegible]	N/A	24/58	[illegible]	[illegible] months	ASL, sMRI, and DTI	Olfactory dysfunction associated with lower tissue perfusion in orbital and medial frontal areas. Absence of statistically significant findings in brain volumes and diffusion tensor imaging.
Kiatkittikul et al. [illegible]	Nuclear Medicine and Molecular Imaging	Retrospective case study	13	N/A	6/7	[illegible]	>28 days	^{18}F-FDG PET/CT and 3T PET/rsfMRI	^{18}F-FDG PET/CT showed uptake in many organs. ^{18}F-FDG PET showed many areas of hypometabolism in the thalamus, and in parietal, temporal, frontal, and occipital lobes. rsfMRI results showed abnormal brain connectivity which is coherent with ^{18}F-FDG PET findings.
Churchill et al. [illegible]	Frontiers in Neurology	Cross-sectional study	51	15	17/34	41 ± 12	4–5 months average	3T sMRI and fMRI	Lower connections to the thalamus and decreased temporal subcortical functional connectivity in patients.
Ajčević et al. [illegible]	Nature Portfolio	Prospective cohort study	24	22	9/15	[illegible]	≥4 weeks	ASL MRI	Hypoperfusion predominantly in frontal, parietal, and temporal cortex.
[illegible] et al. [illegible]	medRxiv pre-print, not peer reviewed	Prospective cohort group-level study	[illegible]	30	[illegible]	[illegible]	<6 months	3T SWI and sMRI	Higher susceptibility imaging values in the frontal lobe and brainstem in patients. Observed cluster in midbrain and bilateral clusters in white matter near the orbitofrontal gyri and the gray-white matter junctions. Significant clusters negatively correlated with fatigue scores found in frontal lobe, anterior cingulate cortex, and brainstem.

^{18}F-FDG PET/CT, Positron emission tomography with 18 fluoro-D-glucose integrated with computed tomography; SPECT-CT, Single Photon Emission Tomography-Computed Tomography; sMRI, structural MRI; dMRI, diffusion MRI; SWI, susceptibility-weighted imaging; DWI, diffusion weighted imaging; DTI, diffusion tensor imaging; ASL, arterial spin labeling.

Conclusion: While accessibility and cost limit the widespread use of 18F-FDG-PET/CT scans and functional MRI, they appeared to be the most promising techniques. SPECT, SWI sequence, and 18F-amyloid PET/CT required further investigation. Nevertheless, imaging remains a reliable tool for diagnosing Neuro-PASC and monitoring recovery.

Disclosure: Nothing to disclose.

EPO-261 | Functional and cognitive outcomes and trajectories three years after hospitalization for COVID-19

M. Li[1]; T. Wisniewski[1]; Z. Alvarez[1]; N. Bilici[1]; L. Caba Caceres[1]; N. De La Cruz[1]; C. Engelson[1]; J. Greenberg[1]; S. Hammam[4]; J. Hunter[1]; S. Karimi[1]; J. Links[3]; M. Rodriguez[1]; F. Silva[1]; A. Vedvyas[3]; A. Yakubov[1]; Y. Ge[2]; J. Frontera[1]

[1]Department of Neurology, NYU Grossmann School of Medicine, New York, NY, USA; [4]Hunter College at CUNY, New York, NY, USA; [3]Department of Radiology, NYU Grossmann School of Medicine, New York, NY, USA; [2]Alzeimer's Disease Research Center, NYU Grossmann School of Medicine, New York, NY, USA

Background and Aims: Little is known about long-term outcomes and trajectories of recovery after hospitalization for COVID-19.

Methods: We conducted a prospective, longitudinal cohort study of patients hospitalized for COVID-19 between 3/2020 and 5/2020. Healthy control patients with no history of COVID-19 and negative SARS-COV-2 nucleocapsid IgG antibodies were also enrolled. Cognitive and functional outcomes as well as post-COVID symptoms were assessed at 6 and 36 months. Outcomes and symptoms were compared between cases and controls using Mann-Whitney U-test and multivariable logistic regression analyses were performed to evaluate the impact of COVID-19 on 3-year outcomes. Non-parametric paired samples Sign test was performed to evaluate changes in metrics over time.

Results: Of 83 subjects, $N=61$ COVID-19 cases (median age 62, 57% female), and $N=22$ non-COVID-19 controls (median age 75, 23% female) were enrolled. At 3-years, t-MoCA was abnormal in 36% of COVID-19 patients compared to 23% of controls. Multiple neuropsychiatric symptoms occurred at higher frequencies in COVID-19 patients compared to controls ($p<0.001$). eGOS scores were significantly lower in COVID patients compared to controls after adjusting for age and sex (aOR 0.05, 95% CI 0.006–0.440, $p=0.007$). Among $N=24$ patients that completed 6 and 36-month follow-up, mRS scores significantly improved over time ($p=0.003$), while no changes were observed in t-MoCA scores.

Conclusion: At 3 years post-hospitalization for COVID-19, neuropsychiatric symptoms were significantly more prevalent and functional outcomes (eGOS) were significantly worse than in controls, even after adjusting for age and sex, despite improvements in mRS from 6 to 36 months.

Disclosure: Thomas Wisniewski has NIH/NIA R01 grant. Yulin Ge has NIH/NIA R01 grant. Jennifer Frontera has NIH R01 grant and NIH/NINDS funding for COVID research. Melanie Li, Zariya Alvarez, Nadir Bilici, Leomaris Caba Caceres, Natasha De La Cruz, Celia Engelson, Julia Greenberg, Salma Hammam, Jessica Hunter, Sohail Karimi, Jon Links, Miguel Rodriguez, Floyd Silva, Alok Vedvyas, Amin Yakubov, have nothing to disclose.

EPO-262 | Innovative in vitro model of human blood-brain barrier mimicry to study neurological effects of SARS-CoV-2

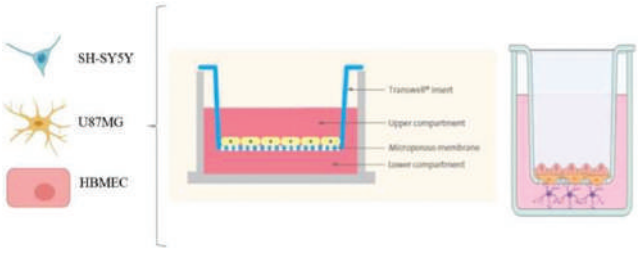
K. Papakosta-Sampatakaki[1]; C. Kaldirimitzian[1]; R. Pontes dos Santos Silva[2]; J. Júnior Ferraz de Magalhães[3]; M. Brito Ferreira[4]; C. Campello Bresani-Salvi[2]

[1]Medical School, National and Kapodistrian University of Athens, Athens, Greece; [2]Laboratory of Virology and Experimental Therapy, Oswaldo Cruz Foundation, Ministry of Health of Brazil, Recife, Brazil; [3]Central Laboratory of Pernambuco, Secretariate of Health of Pernambuco State, Recife, Brazil, Medicine Department, University of Pernambuco, Serra Talhada, Brazil; [4]Neurology Department, Restauração Hospital, Secretariat of Health of Pernambuco, Recife, Brazil

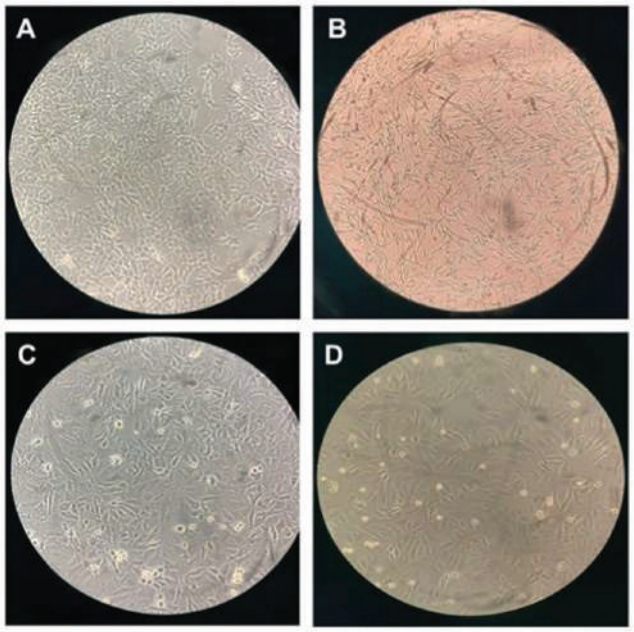
Background and Aims: SARS-CoV-2 is implicated in cerebral manifestations, like meningoencephalitis and stroke. Clinical findings and animal models suggest direct and indirect effects of SARS-CoV-2 on the cerebral microvascular bed. Few studies have applied in vitro models of human BBB to examine interactions between SARS-CoV-2 and the brain. This study aims to validate a novel human BBB model for experiments on molecular and cellular effects of SARS-CoV-2.

Methods: Designed as a triple monolayer membrane, this 2D model includes human cerebral microvascular endothelial cells (hCMEC/D3), human neurons (SH-Sy5y) and human glial cells (U-87MG). Each cell lineage was cultured alongside Vero cells E6 and CCL81, at 37°C and 5% CO2, in flasks with respective medium: 199 (hCMEC); MEM/F-12 (SH-Sy5y); MEM (U-87MG); DMEM-HG (Vero). Each 48–72 h, cells' morphology was checked with an inverted light microscope. Once ≥80% confluency was reached, the cells were expanded by transferring to more flasks, until a maximum of 60 transfers. Eventually, a monolayer of each cell was placed into plates' wells with a semipermeable membrane (Figure 1).

Results: We reached a cell storage (Figure 2) required to plaque 80,000 endothelial cells/mm3 and 150.000 neuronal and glial cells/mm3 per well (concentrations from pilot experiments), and perform all planned experiments: in vitro SARS-CoV-2 exposition, in situ cytokines and chemokines measurements, ex vivo observation of white blood cells from patients.



The transwell plates of 96 wells plus inserts with an 8 µm porous membrane (Corning Life Science, USA); a monolayer of endothelial cells in the top chamber (BBB luminal side), and neural and glial cells in the bottom chamber (BBB parenchymal side).



A. Human Neurons (SH-Sy5y); B. Human Glial Cells (U-87MG); C. Human Cerebral Microvascular Endothelial Cells (hCMEC/D3); D. Vero Cells CCL81.

Conclusion: This is the first in vitro endothelial-neural-glial triple layer model validated to study the interaction between SARS-CoV-2, the neurovascular unit and the immunocytes of patients with cerebrovascular or neuroinflammatory syndromes.
Disclosure: Nothing to disclose.

EPO-263 | Small fiber neuropathy following COVID-19 vaccination: A case series

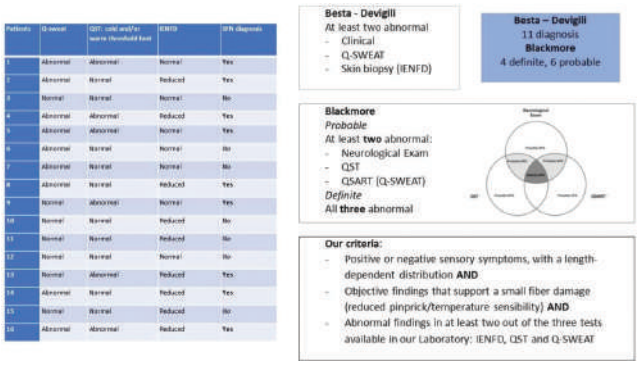
G. Primicerio; M. Bastholm Bille; S. Birk
Clinical Neurophysiology, Rigshospitalet, Copenhagen, Denmark

Background and Aims: In several vaccination contexts, different peripheral neuropathies have been described as possible adverse effects. Small fiber neuropathy (SFN) is no exception. Therefore, we investigated the relation between SFN and COVID-19 vaccination.
Methods: We present a case series of 16 patients (F = 14; M = 2) with age 27–64 (50.1 ± 12.1) referred to our Department of Clinical Neurophysiology, Rigshospitalet, Copenhagen, Denmark, with the suspicion of a SFN related to COVID-19 vaccination, with symptoms 'debut within the first month after vaccination. Patients were vaccinated towards COVID-19 with different vaccines and different doses.
Results: All patients underwent nerve conduction studies to exclude a large fiber polyneuropathy, and the following small fiber tests: quantitative sensory testing (QST), quantitative sudomotor axon reflex test (QSART), cutaneous biopsy for intraepidermal fiber density count (IEFND). Following actual criteria, 9 patients were diagnosed with SFN.

Patients	Gender	Age	Time to onset (days)	Vaccination (Type, dose)	Comorbidities
1	M	64	1	Pfizer, 2nd	**Seronegative Rheumatoid Arthritis**, Spinal stenosis
2	F	49	7	Astra Zeneca, 1st	/
3	F	64	0	Pfizer, 1st	Osteoporosis, Chronic Pyelonephritis
4	F	64	1	Pfizer, 1st	Dystonia
5	F	60	0	Pfizer, 2nd	Depression
6	F	51	15	Pfizer, 2nd	**Lung sarcoidosis**
7	F	61	30	Pfizer, 2nd	/
8	F	37	0	Pfizer, 2nd	ADHD, Tourette, Asthma, Fibromyalgia, Hypothyroidism
9	F	45	7	Pfizer, 2nd	Chronic pain after car accident
10	F	48	7	Pfizer, 1st	/
11	F	28	2	Moderna, 2nd	Sinusitis treated with Bioclavid at the same time of vaccination.
12	F	59	7	Pfizer, 1st	Hypothyroidism, interstitial cystitis.
13	M	43	5	Pfizer, 2nd	Horton's headache
14	F	57	9	Pfizer, 2nd	Constipation, borderline personality with anxiety
15	F	52	5	Pfizer, 2nd	K colon
16	F	27	2	Pfizer, 3rd	/

Demographics and general information of patients. In bold most relevant comorbidities.

Clinical findings: neurological symptoms and signs.



Small Fiber Tests and Small Fiber Neuropathy diagnosis with comparison of different sets of criteria. (Q-sweat, quantitative sweat test; QST: quantitative sensory test; IENFD: intraepidermal nerve fiber density).

Conclusion: Assessing the causality between a vaccination and a supposed adverse effect is very difficult. However, a wealth of evidence supports our hypothesis. Firstly, other single cases with similar findings are described, both in association with COVID and other vaccines. Secondly, other neurological complications are described in association with vaccination, pointing to a common pathogenesis. Lastly, same neurological symptoms/affections are described with COVID-19 infection itself. We therefore underline the importance of post-authorization surveillance to assess adverse effects of vaccines.
Disclosure: Nothing to disclose.

EPO-264 | Patients with neurological or psychiatric complications of COVID-19 have worse long term functional outcomes: COVID-CNS

R. Shil[1]; A. Seed[2]; B. Sargent[3]; G. Wood[1]; Y. Huang[1]; M. Ellul[1]; T. Solomon[1]; B. Michael[1]

[1]*Clinical Infection, Microbiology & Immunology, Institute of Infection, Veterinary and Ecological Sciences, University of Liverpool, Liverpool, UK;* [2]*Liverpool University Hospitals NHS Foundation Trust, Liverpool, UK;* [3]*Department of Psychiatry, University of Oxford, Oxford, UK*

Background and Aims: Patients hospitalised with COVID-19 often have ongoing morbidity affecting activities of daily living (ADLs), employment, and mental health. However, functional outcomes in patients with COVID-19 neurological or psychiatric complications are poorly understood. We aimed to assess post-discharge functional outcomes of these patients relative to those with isolated respiratory COVID-19.

Methods: We conducted a UK multicentre case-control study of patients hospitalised with COVID-19 (controls) and those with acute neurological or psychiatric complications (cases). Data were collected from clinical records and participants followed-up at 13–16 months for assessment of ADLs, employment, anxiety, and depression.

Results: Between March 2020-July 2022, for 651 patients (362 [56%] cases and 289 [44%] controls), where data were available, a higher proportion of cases than controls had impairment in ADLs (199 [68.9%] vs 101 [51.8%], OR [95% CI] 2.01 [1.40–2.98]) and reported symptoms impacting employment (159 [58.2%] vs 69 [35.6%], OR 2.53 [1.72–3.71]). There was no significant difference in depression or anxiety between overall. For cases, impairment of ADLs was associated with increased risk in females, age >50 years and hypertension (OR 5.43 [1.79–16.96], 3.11 [1.17–8.26], and 3.67 [1.06–12.68]). Those receiving either statins or angiotensin converting enzyme inhibitors had a lower risk (OR 0.09 [0.03–0.37], and 0.17 [0.03–0.84]; AUROC 0.794 [0.71–0.88]).

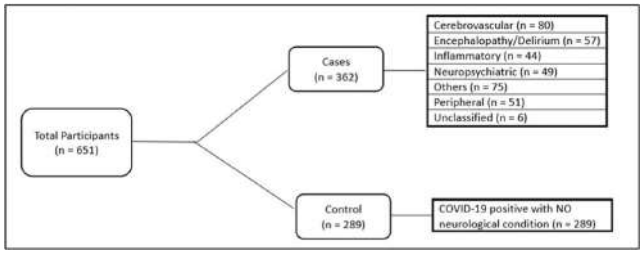


FIGURE 1 Recruitment flowchart

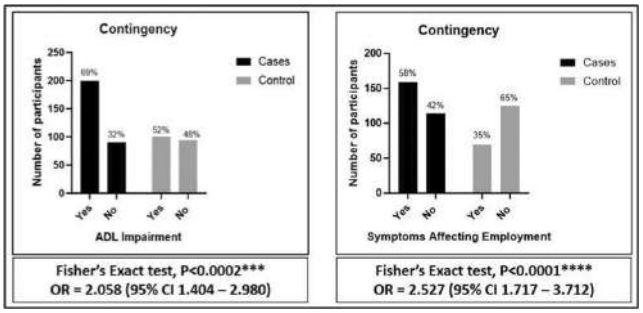

FIGURE 2 Cases vs controls, ADL and Employment. OR: Odds Ratio, CI: Confidence interval

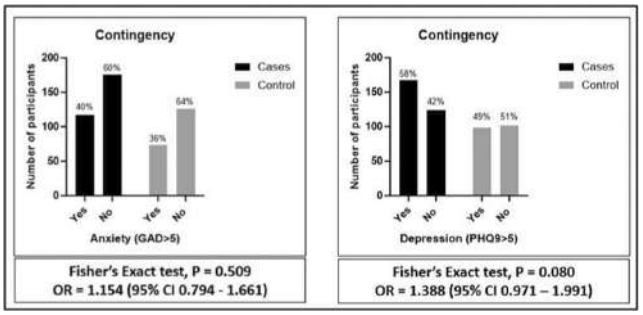

FIGURE 3 Cases vs Controls, anxiety, and depression. OR: Odds Ratio, CI: Confidence Intervals

Conclusion: Patients with neurological or psychiatric complications of COVID-19 had worse functional outcomes than those with respiratory COVID-19 alone in terms of ADLs and employment. Female sex, age >50 years, and hypertension were associated with worse outcomes, and statins or ACE inhibitors with better outcomes.

Disclosure: RS, GK and YH are funded by the UK National Institute for Health Research (NIHR) as NIHR academic clinical fellows and ME as NIHR academic clinical lecturers. YH, TS, ME and BM are funded by the NIHR Health Protection Research Unit (HPRU) in Emerging and Zoonotic Infections at University of Liverpool. BM is supported to conduct COVID-19 neuroscience research by the UKRI/ MRC (MR/V03605X/1). BM is also supported for additional neurological inflammation research due to viral infection by grants from the NIHR (award CO-CIN-01), the Medical Research Council (MC_PC_19059) and by the NIHR Health Protection Research Unit (HPRU) in Emerging and Zoonotic Infections at University of Liverpool in partnership with Public Health England (PHE), in collaboration with Liverpool School of Tropical Medicine and the University of Oxford (award 200907), NIHR HPRU in Respiratory Infections at Imperial College London with PHE (award 200927), the MRC/UKRI (MR/V007181/1), MRC (MR/T028750/1), and Wellcome (ISSF201902/3).

EPO-265 | Longitudinal analysis of 92 subjects reveals structural brain alterations after 1 year of COVID-19

L. Scardua-Silva; I. Karmann Aventurato; R. Batista João; A. Beppler Lazaro Lino; B. Amorim da Costa; M. Koutsodontis Machado Alvim; F. Cendes; C. Lin Yasuda
Neuroimaging Laboratory, Universidade Estadual de Campinas (UNICAMP), Campinas, Brasil

Background and Aims: Although Neuroimaging studies have demonstrated structural alterations (most subacute and chronic changes) in individuals after COVID-19 infection, few studies have assessed brain changes longitudinally. Here, we present a longitudinal analysis of post-infected individuals, comparing individuals after 3 and 12 months and controls.

Methods: we acquired two longitudinal T1-structural 3T-MRI images of 92 post-infected participants (median interval for the first MRI (T1) = 102 days and second MRI (T2) = 388 days; median age = 42 years; 62 women); and an image of 142 controls (median age = 39.5 years; 99 women). We performed a Voxel-Based Morphometry analysis with CAT12 longitudinal tools (http://www.neuro.uni-jena.de/cat/;/SPM12/MATLAB2019b). T-tests were performed (control group [CG], T1-patients and T2-patients) between the different groups (paired t-test T2P–T1P, t-test CG–T1P, t-test CG–T2P). All results were FDR-corrected for multiple comparisons, and we used total intracranial volume, sex and age as covariates (only for independent t-tests).

Results: The CG-T1 analysis showed a trend of atrophy in the left supramarginal atrophy (did not survive FDR correction). The paired comparison (T2P–T1P) revealed atrophy of the right caudate nucleus and hypertrophy of the cerebellum. The CG-T2 comparison exhibited atrophy of the left supramarginal and left postcentral gyri in the post-infected subjects.

Conclusion: Our results suggest persistent left supramarginal gyrus atrophy after one year of infection and signs of progressive right caudate atrophy and cerebellum hypertrophy. Further analysis of larger groups (stratified for severity and symptomology) with longitudinal controls is necessary to confirm persistent and dynamic brain changes over time.

Disclosure: Nothing to disclose.

Neuroimmunology 2

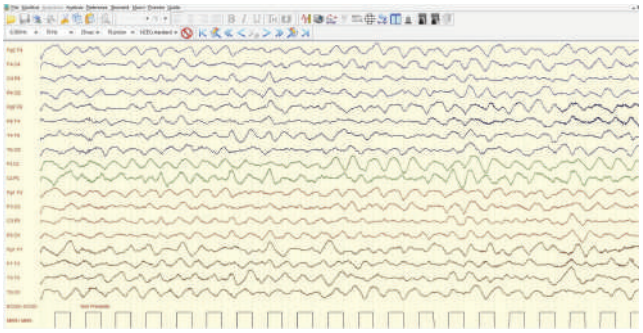
EPO-266 | EEG findings in autoimmune encephalitis-associated epilepsy compared with structural temporal lobe epilepsy

M. Farazdaghi[1]; A. Burini[2]; G. Pauletto[3]; A. Asadi-Pooya[4]; M. Fabris[5]; F. Lavezzi[6]; L. Verriello[3]; M. Valente[2]; A. Vogrig[2]
[1]Epilepsy Research Center, Shiraz University of Medical Sciences, Shiraz, Iran; [2]Clinical Neurology, Department of Medicine (DMED), University of Udine, Udine, Italy; [3]Neurology Unit, Department of Head-Neck and Neuroscience, Azienda Sanitaria Universitaria Friuli Centrale (ASU FC), Udine, Italy; [4]Department of Neurology, Jefferson Comprehensive Epilepsy Center, Thomas Jefferson University, Philadelphia, PA, USA; [5]Clinical Pathology, Department of Laboratory Medicine, Azienda Sanitaria Universitaria Friuli Centrale (ASU FC), Udine, Italy; [6]Neurophysiopathology Unit, Department of Head-Neck and Neuroscience, Azienda Sanitaria Universitaria Friuli Centrale (ASU FC), Udine, Italy

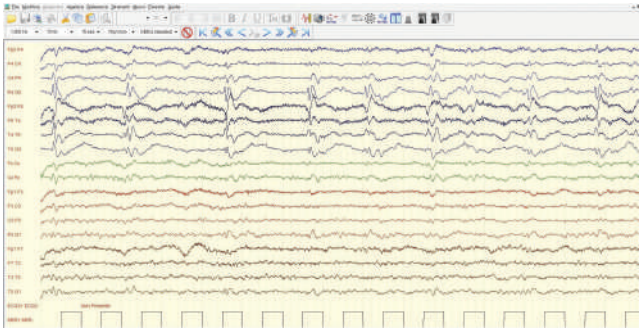
Background and Aims: Autoimmune encephalitis (AE) is a rare yet relevant cause of seizures that requires early treatment to reduce the risk of neurological sequelae and to improve long-term epilepsy outcome. Clinical scores and diagnostic criteria are useful to suspect AE as the aetiology of seizures, but still fail to identify some patients. An extensive description of electroencephalogram (EEG) specificities in AE patients may facilitate an early diagnosis, using an inexpensive and non-invasive test.

Methods: We retrospectively reviewed clinical, neuroradiological, laboratory, and EEG data from 19 patients with AE-associated epilepsy who were treated at Udine University Hospital, Italy. We compared them with a group of 19 consecutive patients with temporal lobe epilepsy (TLE) of structural, non-immune-mediated aetiology. EEG findings were classified according to the American Clinical Neurophysiology Society (ACNS) guidelines.

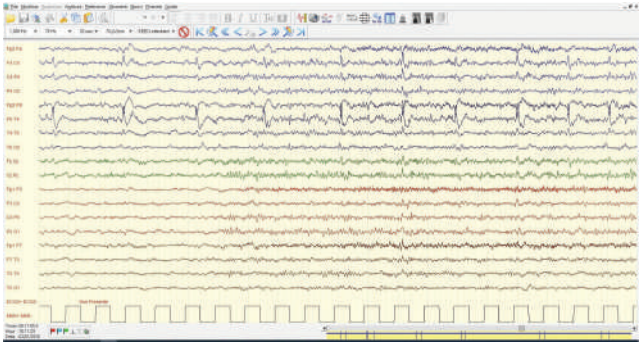
Results: Patients with immune-mediated seizures had a later age at epilepsy onset ($p = 0.024$), likely due to the inclusion of paraneoplastic cases, and had more frequent status epilepticus ($p < 0.001$). Rhythmic and periodic EEG patterns were significantly more frequent in patients with immune-mediated seizures ($p = 0.001$; Figure 1: generalized rhythmic delta activity; Figure 2a and b: lateralized periodic discharges), while the presence of focal polymorphic delta activity was higher in the other group ($p = 0.004$). Seizure outcome was comparable among the two groups: 12/19 seizure-free AE patients and 10/19 TLE patients at their last follow-up ($p = 0.847$).



Generalized rhythmic delta activity in a patient with autoimmune encephalitis-associated epilepsy.



Lateralized periodic discharges in a patient with autoimmune encephalitis-associated epilepsy.



Lateralized periodic discharges in a patient with autoimmune encephalitis-associated epilepsy.

Conclusion: We highlight some EEG features that may help the clinician to suspect AE and might be integrated into future clinical scores and diagnostic criteria to suspect an immune-mediated aetiology for focal seizures.

Disclosure: None.

EPO-267 | Clinicoradiological spectrum of primary CNS vasculitis/primary angitis of CNS (PACNS): A case series

B. Bhattacharya; K. Biswas; S. Banerjee; B. Kanti Ray; A. Pandit; S. Dubey

Department of Neurology, Bangur Institute of Neurosciences, Kolkata, India

Background and Aims: PACNS is a rare and devastating inflammatory disorder affecting the CNS. Although headache, cognitive decline and focal neurologic deficits are the clinical hallmarks of PACNS, the disease can have a heterogeneous presentation, leading to diagnostic dilemma. While brain biopsy is confirmatory, it is invasive and patients often opt out of this procedure. In such cases, clinical profiling with imaging (MR studies and DSA) are paramount for prompt diagnosis and treatment. We present 6 atypical cases of probable PACNS, diagnosed clinicoradiologically, to highlight the clinical heterogeneity of the disease and underscore the importance of brain imaging/angiography in establishing earlier diagnosis, when biopsy is not feasible.

Methods: Number of patients: 6 Period: 2022-2023 Symptomatology: Heterogeneous, suspicious of PACNS (illustrated in attached images) Investigations: Infectious and immune profile, Ophthalmoscopy, MRI (Brain/Cord), MR Vessel Wall, DSA, CSF Study

Results: In MRI, all patients had diffuse white matter lesions with enhancing lesions in 2, ring lesions in 1. Parenchymal and sulcal bleeds were present in 5 patients. 3 patients had evidence of myelopathy, and 2 patients patient had optic neuropathy. All patients showed concentric vessel wall enhancement in MRI with classic beading pattern in DSA. Atherosclerosis and secondary immune causes were excluded in all.

Table 1

Vessel wall MRI showing contrast enhancement in bilateral internal carotid arteries.

Conclusion: The cases highlight the importance of imaging findings of parenchymal/sulcal microbleeds, underscoring the role of vessel wall MRI and angiographic findings in suspected cases of PACNS as virtual biopsy, where histopathology is missing. Further, isolated myelitis and optic neuropathy can be the first or sole presentation of PACNS, as elucidated.

Disclosure: Nothing to disclose.

EPO-268 | Exploring the role of EBV in MS pathogenesis starting from EBV interactome

C. Ballerini[1]; E. Portaccio[1]; E. De Meo[1]; V. Penati[1]; A. Caporali[1]; R. Amoriello[2]; O. Maghrebi[2]; M. Amato[1]

[1]*Department of Neurosciences, Psychology, Drug Research and Child Health (NEUROFARBA), University of Florence, Florence, Italy;* [2]*Department of Clinical and Experimental Medicine (DMSC), University of Florence, Florence, Italy*

Background and Aims: Epstein-Barr virus (EBV) has been described as one of the main risk factors for developing multiple sclerosis (MS). The molecular mechanisms of this association are complex and may involve different immunological routes; however, the ultimate role of EBV in the pathogenesis of MS is still missing. To identify MS associated genes overlapping with EBV interactome and their expression in immune cell subtypes.

Methods: We obtained EBV interactome from p-HIPSTER, the MS associated genes from NHGRI-EBI and the single cell gene expression from B and T-cells, astrocytes, macrophages, granulocytes, monocytes, microglia, dendritic and natural killer cells from the Human Protein Atlas. We overlapped the lists thus obtained by using the geneOverlap R package.

Results: We identified a "core" group of 15 genes resulting from the overlap between EBV interactome and MS associated genes and expressed in all immune cell type selected ($p < 0.001$). We selected transcriptomic studies from GEO that analyze gene expression at glial cell's level.

Conclusion: The present findings suggest a broad range immune system involvement in mediating EBV effect on MS pathogenesis. We find a statistically significant up regulation compared to healthy controls for MINK1 in glial cells, MEF2C for astrocytes and MAPK3 for microglia.

Disclosure: Nothing to disclose.

EPO-269 | Real-world evidence for ofatumumab in multiple sclerosis: A sicilian multicenter experience

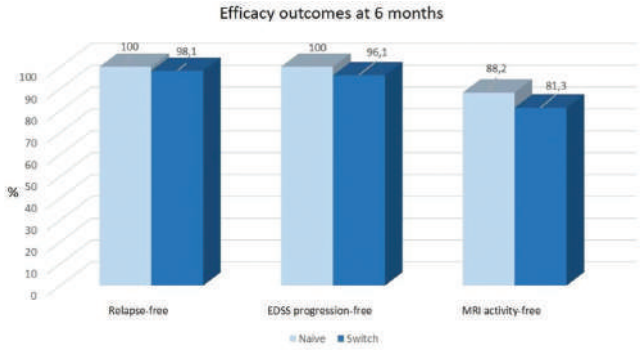
C. Chisari[1]; S. Bucello[2]; S. Cottone[3]; L. Grimaldi[4]; P. Ragonese[5]; S. Realmuto[6]; S. Toscano[7]; G. Salemi[5]; F. Patti[1]

[1]*Department of Medical and Surgical Sciences and Advanced Technologies "G.F. Ingrassia", University of Catania, Catania, Italy;* [2]*Multiple Sclerosis Center, "E. Muscatello" Hospital – ASP8, Augusta (SR), Italy;* [3]*A.R.N.A.S. CIVICO, Palermo, Italy;* [4]*Neurology and Multiple Sclerosis Center, Unità Operativa Complessa (UOC), Foundation Institute "G. Giglio", Cefalù, PA, Italy;* [5]*Department of Biomedicine, Neurosciences and Advanced Diagnostics, University of Palermo, Palermo, Italy;* [6]*Multiple Sclerosis Centre, Neurology Unit and Stroke Unit, AOOR "Villa Sofia-Cervello", Palermo, Italy;* [7]*Department of Neurology, Ospedale Garibaldi Centro, Catania, Italy*

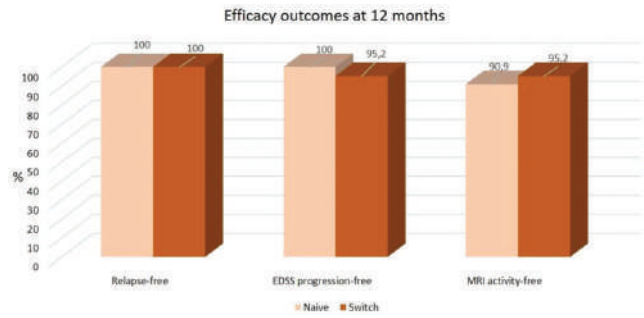
Background and Aims: Ofatumumab (OFA), a human recombinant IgG1 CD20 next-generation monoclonal antibody, was investigated in two phase III trials, showing significant reductions of the relapse-rate and of confirmed disability compared to teriflunomide. However, to date, real world data about the effectiveness of OFA are still scarce. We aimed to evaluate efficacy and safety of OFA in a real-world setting.

Methods: this prospective real-world study consecutively screened all relapsing-remitting Multiple Sclerosis (RRMS) patients from seven Italian MS centers, who were treated with OFA in the period between August 2022 and January 2024. Data about Expanded Disability Status Scale (EDSS), relapses, previous treatments, adverse events (AEs) and magnetic resonance imaging (MRI) were collected.

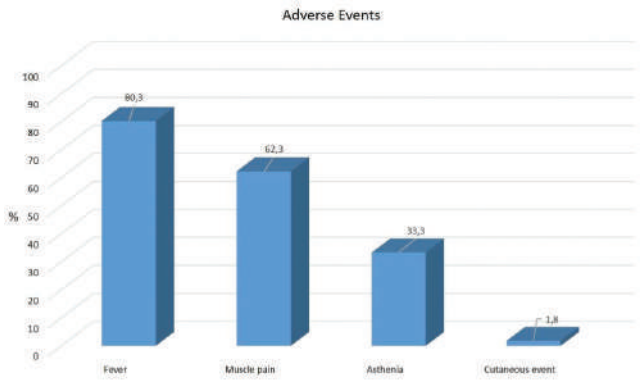
Results: A total of 223 patients (136 [61%] women, mean age of 39.8±10 years), were enrolled. Of these, 68 (30.5%) were naïve to treatment and 155 (69.5%) switched from another DMTs. After 6 months from OFA initiation, 206 (92.4%) of patients were EDSS progression free, 220 (98.7%) were relapse-free and 188 (84.3%) were MRI activity-free. Among 64 (28.7%) who continued treated for 12 months, 62 (96.9%) were EDSS progression free, 64 (100%) were relapse-free and 60 (93.8%) were MRI activity-free. No significant differences were found between naive and switch groups.



Efficacy outcomes after 6 months of treatment with Ofatumumab in naive and switch groups.



Efficacy outcomes after 12 months of treatment with Ofatumumab in naive and switch groups.



Percentage of patients reporting adverse events.

No serious AEs were reported. Particularly, fever at the first administration was the most frequent AE reported in 179 (80.3%) patients.

Conclusion: We confirmed that OFA is effective in reducing risk of progression and disease progression in a real-world cohort of RRMS patients, also demonstrating a favorable safety profile.

EPO-270 | Rituximab as first-line or escalation immunotherapy in aquaporin-4-IgG-positive neuromyelitis optica spectrum disorder

D. Engels[1]; C. Rocchi[2]; M. Forcadela[2]; J. Havla[1]; M. Ringelstein[3]; O. Aktas[3]; K. Giglhuber[4]; A. Berthele[4]; M. Hümmert[5]; C. Trebst[5]; S. Huda[2]; T. Kümpfel[1]

[1]Institute of Clinical Neuroimmunology, LMU Hospital, Ludwig-Maximilians University Munich, Munich, Germany; [2]Department of Neurology, Walton Centre NHS Foundation Trust, Liverpool, UK; [3]Department of Neurology, Medical Faculty and University Hospital Düsseldorf, Heinrich Heine University Duesseldorf, Germany; [4]Department of Neurology, School of Medicine, Technical University Munich, Klinikum rechts der Isar, Munich, Germany; [5]Department of Neurology, Hannover Medical School, Hannover, Germany

Background and Aims: Aquaporin-4-IgG-positive neuromyelitis optica spectrum disorder (AQP4-IgG+ NMOSD) primarily manifests with attacks of optic neuritis or myelitis. Rituximab is highly efficient in reducing the likelihood of NMOSD attacks. However, not all patients receive rituximab as first-line therapy. Here, we compared the treatment efficacy between rituximab as first-line and escalation immunotherapy.

Methods: We analyzed retrospective clinical data from AQP4-IgG+ NMOSD patients from neuroimmunology outpatient clinics in the United Kingdom (Liverpool) and Germany (Duesseldorf, Hannover, Munich).

Results: AQP4-IgG+ NMOSD patients received rituximab as first-line ($n=58$) or escalation ($n=96$) immunotherapy. Administered as first-line immunotherapy, rituximab was associated with a higher probability of an attack-free disease course (beta [95%-CI]=-0.92 [-1.52;-0.33], $p<0.005$, Cox proportional hazards regression coefficient, H0: beta=0). Younger age at diagnosis and being male was associated with a higher probability of an attack-free disease course. Eleven patients showed a significant annualized expanded disability status scale (EDSS) progression (AEP) during rituximab immunotherapy. Higher annualized attack rates (AAR) during rituximab immunotherapy predicted a significant AEP. In contrast, AAR before rituximab immunotherapy, age at diagnosis and whether rituximab was administered first-line or as escalation immunotherapy showed no effect on AEP. Patients who showed significant AEP during rituximab had competing risk factors for attacks such as severe comorbidities, anti-rituximab antibodies or deviations from their treatment protocol (e. g. due to pregnancy).

Conclusion: Early use of highly effective immunotherapies in AQP4-IgG+ NMOSD such as rituximab can reduce further disease activity and thereby potentially prevent disability progression.

Disclosure: DE received speaker honoraria from Alexion and Horizon. CR is currently a clinical and research training fellow funded by ECTRIMS. JH reports a grant for OCT research from the Friedrich-Baur-Stiftung and Merck, personal fees and nonfinancial support from Merck, Alexion, Novartis, Roche, Celgene, Biogen, Bayer and Horizon and nonfinancial support of the Sumaira-Foundation and Guthy-Jackson Charitable Foundation, all outside the submitted work. AB receives funding from the Innovationsausschuss of the German Federal Joint Committee (G-BA; grant 01VSF23040) and from the German Federal Ministry of Education and Research (BMBF; grant 01ZZ2102B). He has received consulting and/or speaker fees from Alexion, Argenx, Biogen, Horizon, Merck, Novartis, Roche and Sandoz/Hexal, and his institution has received compensation for clinical trials from Alexion, Biogen, Merck, Novartis, Roche, and Sanofi Genzyme; all outside the present work. MWH received research support from Myelitis e. V., speaker honoraria from selpers og, Horizon and Alexion, and reimbursement of travel expenses and compensation for serving on an advisory board from Alexion. TK has received speaker honoraria and/or personal fees for advisory boards from Novartis Pharma, Roche Pharma, Alexion/AstraZeneca and Biogen. All other authors have nothing to disclose in relation to this project.

EPO-271 | Cerebral thrombi analysis in cancer-related stroke

B. Dell'acqua[1]; M. Montano[2]; A. Bergamaschi[2]; P. Panni[3]; G. Saliou[4]; P. Michel[5]; L. Roveri[6]; G. Martino[2]; M. Filippi[6]; D. Strambo[5]; M. Bacigaluppi[1]

[1]Neuroimmunology Unit, Division of neuroscience, Department of Neurology, Institute of Experimental Neurology, Stroke Unit San Raffaele Hospital, Milan, Italy; [2]Neuroimmunology Unit, Division of neuroscience, Institute of Experimental Neurology, San Raffaele Scientific Institute, Milan, Italy; [3]Department of Neuroradiology, San Raffaele Hospital, Milan, Italy; [4]Department of Diagnostic and Interventional Radiology, Lausanne University Hospital, Lausanne, Switzerland; [5]Department of Clinical Neurosciences, Stroke Centre, Neurology Service, Lausanne University Hospital, Switzerland; [6]Department of Neurology, Stroke Unit San Raffaele Hospital, Milan, Italy

Background and Aims: Stroke is a frequent complication in neoplastic patients. Lung, gastrointestinal, gynecologic tumors have a higher incidence of cerebral thrombosis. The mechanism undergoing the stroke presentation in active cancer patients is unclear; primary and secondary prevention therapy need further studies.

Methods: We analyzed 20 patients with a diagnosis of active cancer (AC) with large vessel occlusion stroke treated with mechanical endovascular thrombectomy (EMT). Active cancer was defined as a tumor diagnosis <6 months and/or undergoing an active treatment over the past 6 months and/or metastatic cancers. 7 patients had lung tumor, 5 gynecologic neoplasm (breast and ovary), 6 gastrointestinal (pancreatic, gastric, colorectal) and 2 urinary tract cancer. We evaluated the histological composition of AC thrombi compared to 20 matched controls (for sex, age and pre-stroke therapy) with an history of inactive tumor.

Results: The median baseline NIHSS was higher (21) in lung tumor patients (p 0.03). D-dimer values had a higher trend in gastrointestinal tumors, with a major risk of coagulopathy (p 0.04). AC thrombi displayed lower neutrophil (MPO+) counts (p 0.03) and higher platelets (CD61+) counts (p 0.04) compared to controls. No differences were found in term of neutrophil extracellular traps (CITH3+). A statistically significant correlation between acute blood fibrinogen value and the platelets thrombus content (p value 0.01).

Conclusion: Thrombus composition and blood biomarkers could be important tools to understand pathophysiological mechanism and possible secondary prevention therapy in cancer related stroke patients.

Disclosure: Nothing to disclose.

EPO-272 | Comparison of serum NFL values in multiple sclerosis using SIMOA and lumipulse platforms: A real-world study in Greece

D. Tzanetakos[1]; C. Stergiou[2]; J. Kuhle[3]; E. Dimitriadou[1]; A. Akrivaki[1]; G. Papagiannopoulou[1]; S. Giannopoulos[1]; G. Tsivgoulis[1]; S. Tzartos[2]; J. Tzartos[1]

[1]Second Department of Neurology, School of Medicine, Attikon University Hospital, National and Kapodistrian University of Athens, Athens, Greece; [2]Tzartos NeuroDiagnostics, Athens, Greece; [3]Department of Neurology, University Hospital Basel and University of Basel, Basel, Switzerland

Background and Aims: Serum neurofilament light chain (sNfL) as a biomarker of neuronal axonal loss has an emerging value in monitoring disease activity and progression in Multiple Sclerosis (MS). SIMOA™ and Lumipulse™ are two platforms for sNfL measurement. Our aim was to compare sNfL measurements by both methodologies in MS patients investigating for discrepancies in the comparative results.

To compare serum neurofilament light chain (sNFL) measurements by SIMOA and Lumipulse in Multiple Sclerosis (MS) patients.

Methods: sNfL concentrations from 44 patients (57 samples) with Relapsing Remitting (RRMS) and Progressive MS (PMS) from an MS center were measured by SIMOA and Lumipulse. Results were stratified by z-scores in 4 groups: a) low, z-score≤0.84, b) medium, 0.84 < z-score≤1.5, c) high, 1.5 < z-score≤ 2, d) very high, z-score >2.

Results: 33 RRMS and 11 PMS (5 Secondary Progressive, 6 Primary Progressive) were included; median age 36.97 and 47.42 years respectively. In the RRMS-group (46 samples), 31 had sNfL z-scores in agreement between both methods (67.39% agreement): 16 with low, 5 with medium, 4 with high, 6 with very high z-scores. In 15/46 RRMS samples there was disagreement between SIMOA and Lumipulse z-scores; in 10 samples, differences were by one step (low-vs-medium, medium-vs-high, high-vs-very high), in 5 differences were by two steps. In the PMS-group, sNfL-z-scores in 8/11 (72.73%) samples

were in agreement between platforms, whereas in 3 samples there was disagreement by one step.

sNfL z-scores from 33 Relapsing Remitting (RRMS) and 11 Progressive MS (PMS) patients showed a percentage of agreement between both methods 67.39% for the RRMS-group and 72.73% for the PMS-group.

Conclusion: SIMOA- and Lumipulse-measured sNfL z-scores were similar in the ~70% of MS patients (in both PMS and RRMS groups). Our next goal is to elaborate on the sera with different z-scores between methods to compare their clinical value.

SIMOA- and Lumipulse-measured sNfL z-scores were similar in the ~70% of MS patients (in both PMS and RRMS groups).

EPO-273 | Autoimmune screening panel in patients with multiple sclerosis – A Vienna MS database study

F. Foettinger; N. Krajnc; K. Riedl; F. Leutmezer; P. Rommer; B. Kornek; G. Zulehner; T. Berger; G. Bsteh

Department of Neurology, Medical University of Vienna, Vienna, Austria

Background and Aims: Autoimmune screening panel (ASP) is routinely ordered as a part of diagnostic work-up in people with suspected multiple sclerosis (MS). However, data on prevalence and significance of ASP seropositivity in MS is scarce.

Methods: We retrospectively investigated patients from the Vienna MS database (VMSD) who were diagnosed with MS between 2014 and 2023 according to current McDonald criteria and had blood samples drawn for ASP. Autoantibody titers were defined as either negative, or mildly (≤1:160), moderately (1:320-1:640) and strongly (≥1:1280) positive.

Results: We analyzed 212 patients (median age 29 [IQR 25–36] years, 67.0% female). Ten (4.7%) patients had red flags for presence of systemic autoimmune disease (joint pain [$n=4$], dermatitis [$n=3$], sicca syndrome [$n=2$], bronchial asthma/rheumatic fever in childhood [each $n=1$]). Complement levels (C3c and C4) were below the lower reference level in 26/134 (19.4%) and 3/134 (2.2%), respectively, and C4 levels were above the upper reference level in 3/134 (2.2%). Antinuclear antibodies (ANA) were positive in 24/210 (11.4%) with 18 (8.6%), 5 (2.4%), and 1 (0.5%) having mildly, moderately, and strongly positive ANA titers, respectively. Positive autoantibodies were found as follows: anti-Ro (5/211; 2.4%), IgM against cardiolipin (4/205; 2.0%), anti-centromere B (2/211; 0.9%), anti-dsDNA (1/208; 0.5%) and anti-La (1/211; 0.5%). Further evaluation following positive results led to diagnosis of rheumatoid arthritis ($n=2$) and Sjögren's syndrome ($n=1$). (ASP positive predictive value 9.1%, negative predictive value 97.2%)

Conclusion: Rate of ASP seropositivity in MS is low, aligning with the general population. Performance of ASP without clinical suspicion of systemic autoimmune disease appears unwarranted.

Disclosure: Nothing to disclose.

EPO-274 | Retinal neuroaxonal loss and disease progression in multiple sclerosis

F. Burguet Villena[1]; L. Hofer[2]; N. Cerdá Fuertes[2]; S. Sellathurai[2]; S. Schaedelin[2]; K. Schoenholzer[1]; M. D'Souza[1]; J. Oechtering[1]; L. Kappos[3]; C. Granziera[4]; P. Benkert[2]; J. Kuhle[1]; A. Papadopoulou[1]

[1]Department of Neurology, University Hospital Basel, Basel, Switzerland; [2]Department of Clinical Research, University Hospital and University of Basel, Basel, Switzerland; [3]Research Center for Clinical Neuroimmunology and Neuroscience Basel (RC2NB), University Hospital and University of Basel, Basel, Switzerland; [4]Translational Imaging in Neurology (ThINK) Basel, Department of Biomedical Engineering, Faculty of Medicine, University Hospital and University of Basel, Basel, Switzerland

Background and Aims: Progression Independent of Relapse Activity (PIRA) is the main driver of disability in multiple sclerosis (MS). Retinal neuroaxonal loss measured by optical coherence tomography (OCT) is associated with cortical thinning and neurodegeneration. We aimed to evaluate the association between OCT markers and PIRA in patients with MS.

Methods: We included patients from the Swiss MS Cohort Study with ≥1 OCT. Peripapillary retinal nerve fiber layer (pRNFL) thickness, ganglion cell inner plexiform layer (GCIPL)-, and inner nuclear layer (INL) volumes were assessed. Eyes with prior optic neuritis were excluded. Neurological examination was performed every 6-12 months including the Expanded Disability Status Scale. PIRA events were defined as previously described (Table 1). Annualized PIRA rate was the number of PIRA events divided by years of follow-up, during a period of ≥4 years before the OCT (Table 1). We examined the association of OCT markers with annualized PIRA rate in linear regression models adjusted for disease duration, age at disease onset, sex, body mass index, and treatment.

Results: Baseline characteristics at time of OCT are shown in Table 2. The adjusted models estimated that mean pRNFL thickness and GCIPL volume decrease by 28.4 μm respectively 0.53 mm3 with each additional PIRA event per year (Table 3). No association was found for INL.

Table 1: Definitions of PIRA events and annualized PIRA rate

PIRA events	
If baseline EDSS Score:	**EDSS worsening***
0 →	≥ 1.5 points
1.0-5.5 →	≥ 1 point(s)
>5.5→	≥ 0.5 point (s)

*confirmed after 6 months, without relapse in between

Annualized PIRA rate (per patient)

$$\frac{\text{number of PIRA events}}{\text{f—up time in years}}$$

*before OCT, during a period of at least 4 years

EDSS: Expanded Disability Status Scale, f-up: follow-up, OCT: Optical Coherence Tomography, PIRA: Progression Independent of Relapse Activity

Table 2: Baseline clinical characteristics at time of OCT

Parameter	n = 172
Age, years: median [IQR]	51.0 [42.2, 59.7]
Sex, female	64 %
Disease duration, years: median [IQR]	15.9 [10.5, 23.1]
EDSS: median [IQR]	2.5 [1.5, 4.0]
RRMS	87.2 %
Patients on DMT	84.9 %
Patients with PIRA events before OCT	36.6 %

DMT: Disease Modifying Treatment, EDSS: Expanded Disability Status Scale, IQR= interquartile range, OCT: Optical Coherence Tomography, PIRA: Progression Independent of Relapse Activity, RRMS: Relapsing-Remitting Multiple Sclerosis

Table 3: Associations of OCT markers with annualized PIRA rate in unadjusted (upper table) and adjusted models (lower part)

OCT marker	β	95% CI	R^2	p-value
pRNFL, mcm	-20.65	-41.55, 0.24	0.016	0.0527
GCIPL, mm^3	-0.50	-0.87, -0.13	0.036	**0.0079**
INL, mm^3	-0.02	-0.14, 0.10	-0.005	0.6971
Unadjusted models, each with one OCT-marker				
OCT marker	**β**	**95% CI**	**R^2**	**p-value**
pRNFL, mcm	-28.40	-48.90, -7.89	0.197	**0.0069**
GCIPL, mm^3	-0.53	-0.90, -0.17	0.183	**0.0045**
INL, mm^3	-0.01	-0.13, 0.11	0.04	0.8252
Models adjusted for disease duration, age at disease onset, sex, body mass index and treatment *				

β: estimate (beta), CI: confidence interval, GCIPL: ganglion cell inner plexiform layer; INL: inner nuclear layer; OCT: Optical Coherence Tomography; PIRA: Progression Independent of Relapse Activity; pRNFL: Peripapillary retinal nerve fiber layer. *Note that the covariate "treatment" had four categories: untreated, platform, oral, and monoclonal antibodies

Conclusion: Our findings show an association between rate of PIRA and retinal neuroaxonal integrity. pRNFL and GCIPL may represent a sensitive measure of disease progression in MS.

Background and Aims: Inebilizumab is approved for aquaporin-4 seropositive (AQP4-IgG+) NMOSD. Here we evaluate the safety of inebilizumab in AQP4-IgG+ NMOSD participants ≥50 and ≥65 years of age.

Methods: N-Momentum (NCT02200770) was a phase 2/3 trial (randomized 3:1, inebilizumab 300 mg: placebo) with an open-label-extension-period (OLP) ≥2 years. Post hoc analyses were conducted to analyze outcomes in AQP4-IgG+ participants <50, ≥50, and ≥65 years of age.

Results: Of 213 AQP4-IgG+ NMOSD participants, 65 (30.5%) were ≥50 years, 10 (4.9%) were ≥65 years. In the RCP, among inebilizumab participants ≥50 years, 31.3% (15/48) reported ≥1 investigational product related treatment emergent AE (IP-TEAE) versus 35.3% (6/17) in placebo. Among participants <50 years IP-TEAEs were 22.1%(25/113) in the inebilizumab group and 20.0% (7/35) in the placebo group. For patients ≥65 years in the RCP, 66.7% (4/6) inebilizumab and 25% (1/4) placebo patients had IP-TEAEs. Infections were reported in 66.7% (4/6) of inebilizumab and 100% (4/4) of placebo patients ≥65 years. The most frequent AE was urinary tract infection in 50% (3/6) of inebilizumab and 75% (3/4) of placebo participants ≥65 years. No IP-related serious AEs or deaths occurred in the participants ≥50 years in either treatment group of the RCP. The NMOSD related annualized hospitalization rate (95% CI) in the OLP for participants ≥50 years, ≥65 years, and <50 years were 0.16 (0.06 – 0.42, $n=65$), 0.19 (0.04-1.01, $n=10$), and 0.13 (0.08– 0.22, $n=148$) respectively.

Conclusion: This data supports the safety of inebilizumab in AQP4-IgG+ NMOSD participants ≥50 and ≥65 years of age although evaluation of larger populations is needed to confirm these results.

Background and Aims: Diagnosis of MOG antibody-associated disease (MOGAD) relies on the detection of serum MOG-IgG with cell-based assays (CBA). Clinical and diagnostic relevance of CSF MOG-IgG needs further assessment.

Methods: we retrospectively studied consecutive patients with paired serum and CSF samples screened for MOG-IgG using a live CBA. Antigen-specific Antibody Index (AIMOG-IgG) was calculated to assess intrathecal MOG-IgG synthesis (MOG-IgG ITS). An aggregated analysis of literature data on CSF MOG-IgG and findings from another centre were used for comparison with our results.

Results: MOG-IgG were found in 55/960 patients. Serum/CSF MOG-IgG titres showed a significant correlation in patients without ITS (rho = 0.47, $p<0.001$), but not in those with ITS (rho = 0.14, $p=0.65$). There were no clinical-paraclinical differences between MOG-IgG CSF+ vs CSF- patients. Conversely, patients with MOG-IgG ITS showed more frequent pyramidal symptoms (73% vs 32%, $p=0.03$), spinal cord involvement (82% vs 39%, $p=0.02$), and severe outcome at follow up (36% vs 5%, $p=0.02$) than those without MOG-IgG ITS. MOG-IgG ITS was the only predictor of a poor

outcome in the multivariate logistic regression model (OR: 9.87 [CI: 1.22–86.88], $p=0.039$). In cohorts with consecutive patients ($n=3148$), positive predictive value (PPV) was higher for MOG-IgG seropositivity (99.43% [CI: 97.76%–99.86%]), than for CSF-restricted MOG-IgG positivity (83.9% [CI: 72.07% - 91.36%]).

Conclusion: Consistently with physiopathology, our data suggest that the implementation of ITS calculation could enhance clinical, prognostic, and therapeutic purposes of CSF MOG-IgG testing, making a case for its introduction in clinical practice.

Disclosure: Nothing to disclose.

EPO-277 | Evaluating the role of MOG antibodies in pseudotumor cerebri presentations: A clinical perspective

G. Çetin Erci; H. Güdek; D. Çetinkaya Tezer; İ. Güngör Doğan; S. Demir
Sancaktepe Research and Training Hospital, İstanbul, Turkey

Background and Aims: Pseudotumor cerebri (PTC), characterized by symptoms and signs of increased intracranial pressure without an occupying lesion, can overlap clinically with Optic Neuritis (ON) and may co-occur in patients. This study examines the relationship between Myelin Oligodendrocyte Glycoprotein (MOG) antibodies, which can be observed in ON, and PTC in patients presenting with symptoms indicative of increased intracranial pressure.

Methods: The study included 42 patients who were evaluated with a preliminary diagnosis of PTC. Anti-MOG antibodies were assessed using flow cytometry and live cell-based assays.

Results: Findings revealed MOG IgG positivity in 9 female patients, with significantly high titers in two patients. Notably, one patient was initially diagnosed with PTC, but was later identified as having ON and was diagnosed with MOGAD. A significant portion of MOG+ patients met the Dandy criteria for 'Definite PTC', whereas MOG positivity was more prevalent in patients classified as 'Probable' or 'Possible PTC' according to the Friedman criteria but did not meet the Dandy criteria. Common symptoms in both MOG positive and negative groups included transient visual loss and headache, with the former significantly associated with positivity.

Conclusion: This study emphasizes including MOG-AD in PTC differential diagnosis, noting the need for thorough evaluation and exploring MOG antibodies' role in Pseudotumor Cerebri etiology.

Disclosure: Nothing to disclosure.

EPO-278 | Real-world experience of efgartigimod treatment for autoimmune encephalitis

C. Han; B. Zhihong; W. Haotian; Q. Wei; L. Zhengqi; Z. Bingjun
The Department of Neurology, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background and Aims: Efgartigimod, approved in China for AChR Ab+gMG in September 2023, mechanism of action involves binding to FcRn and competitively blocking endogenous IgG binding to FcRn, leading to IgG degradation at lysosomes and subsequent acceleration of IgG clearance in vivo. However, limited evidence in other IgG-mediated disorders like autoimmune encephalitis (AE). This study aims to describe the treatment outcomes of autoimmune encephalitis patients treated with efgartigimod.

Methods: 12 AE patients treated in Neurological Care Unit (NICU) in 2023 were included and categorized into traditional treatment group and add-on efgartigimod treatment group. The latter received efgartigimod at 20mg/kg at weekly intervals. The evaluation relied on electronic medical records, focusing on Modified Rankin Scale (mRS) scores and post-immunotherapy hospitalization duration.

Results: Among the 12 AE patients (median age 23.19 years; 11 with anti-NMDA receptor, 1 with GFAP antibody), baseline treatment averaged 2.16 immunomodulatory therapies (including steroids, IVIG, and plasma exchange). The efgartigimod group demonstrated IgG reduction (average decrease 13.69±5.71 mg/ml) and more mRS score improvement from baseline (mean reduction 21.67% vs 13.33%) compared to the traditional treatment group. Additionally, the efgartigimod group experienced shorter hospital stays (20.83±12.3 days vs. 31.67±8.48 days).

Conclusion: The study is the first to suggest that the addition of efgartigimod to immunosuppression therapy in patients with autoimmune encephalitis may result in a shorter hospital stay and accelerate recovery (evidenced by lower mRS scores). Despite the small sample size, these findings warrant further investigation.

Disclosure: Nothing to disclose.

EPO-279 | Use of rituximab in primary angiitis of the central nervous system: Observational study in a tertiary center

I. Elosua-Bayes[1]; A. Vilaseca[1]; H. Ariño[1]; A. Zabalza[1]; M. Olivé-Gadea[2]; F. Martinez-Valle[3]; E. Martinez-Saez[4]; J. Rio[1]; L. Bollo[1]; J. Castillo[1]; A. Pappolla[1]; A. Cobo-Calvo[1]; M. Comabella[1]; L. Midaglia[1]; C. Nos[1]; B. Rodriguez-Acevedo[1]; C. Tur[1]; A. Vidal-Jordana[1]; G. Arrambide[1]; À. Rovira[5]; J. Sastre-Garriga[1]; M. Tintoré[1]; X. Montalban[1]
[1]Centre d'Esclerosis Múltiple de Catalunya and Neurology Department, University Hospital Vall d'Hebron, Barcelona; [2]Stroke Unit, University Hospital Vall d'Hebron, Barcelona; [3]Internal Medicine Department, University Hospital Vall d'Hebron, Barcelona; [4]Pathological Anatomy Department, University Hospital Vall d'Hebron, Barcelona; [5]Neuroradiology Department, University Hospital Vall d'Hebron, Barcelona

Background and Aims: There is paucity of data on treatment for primary angiitis of the central nervous system (PACNS), especially regarding rituximab. We aim to characterize the cohort of patients diagnosed with PACNS in our center, evaluating radiological and clinical response, comparing rituximab to other treatments.

Methods: Observational retrospective study of patients diagnosed with PACNS (Birnbaum criteria) in a tertiary hospital. Clinical information was obtained from electronic health records. Patients were grouped according to use of rituximab at any time-point. A favorable outcome was defined as a modified Rankin scale (mRS) score ≤2 at

last follow-up. Clinical and radiological response was defined as absence of relapse during treatment.

Results: 23 patients were included (women 65.2%). All patients received several lines of immunotherapy (21 included cyclophosphamide). Median age at onset was 38 years (IQR: 29.9–60.1), 28.0 in the group treated with rituximab ($n=9$, IQR: 21.7-36.8) and 52.8 in the non-rituximab group ($n=14$, IQR: 37.1-65.9, $p=0.019$). mRS at peak was 4 (IQR: 1-5) in rituximab patients and 3 (IQR: 2-4) in non-rituximab ($p=0.369$). At last follow-up, median mRS for rituximab was 1 (IQR: 1-4) and 2 for non-rituximab (1-4) ($p=0.439$). Throughout the duration of treatment, rituximab patients presented a similar clinical and radiological response to the 21 patients receiving cyclophosphamide (77.7% and 45.5% vs. 71.4% and 57.1% respectively).

Conclusion: In our cohort, rituximab and cyclophosphamide presented similar rates of clinical and radiological response. Recognizing age difference between groups, this study suggests rituximab could be a non-inferior alternative to treat PACNS, especially more severe cases.

Disclosure: Nothing to disclose.

Cognitive neurology/neuropsychology 2

EPO-280 | Spontaneous speech alterations and evolution in primary progressive aphasia variants

V. Castelnovo[1]; E. Canu[1]; L. Lumaca[1]; S. Basaia[1]; S. Santicioli[1]; E. Gatti[1]; A. Lamanuzzi[1]; E. Spinelli[2]; G. Cecchetti[3]; F. Caso[4]; G. Magnani[4]; P. Caroppo[5]; S. Prioni[5]; C. Villa[5]; S. Cappa[6]; M. Filippi[7]; F. Agosta[2]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; [2]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy; [3]Neurophysiology Service, Neurology Unit, and Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute Milan, Italy; [4]Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; [5]Fondazione IRCCS Istituto Neurologico Carlo Besta, Unit of Neurology 5 – Neuropathology, Milan, Italy; [6]Department of Humanities and Life Sciences, University Institute for Advanced Studies IUSS Pavia, and Dementia Research Center, IRCCS Mondino Foundation, Pavia, Italy; [7]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: To identify: which features of speech, standard language and gray matter (GM) parameters most effectively distinguish primary progressive aphasia (PPA) variants from each other; how speech evolves over time, and the best combination of features predicting speech evolution.

Methods: 95 PPA patients underwent the "Picnic Scene" test and structural MRI. 34 patients underwent a follow-up. Stepwise-regression-models were used to identify speech, standard-language tests and GM parameters that best distinguished groups. In each PPA group, linear-mixed-effect models were performed for defining speech changes over time, and the prediction analysis was conducted using variables from the best stepwise-models.

Results: The best models to differentiate PPA variants included: left temporal and frontal volumes, and syntax production features when comparing nfvPPA vs svPPA ($R^2=0.89$); lexical contents, syntax complexity, left temporal and insular volumes in nfvPPA vs lvPPA ($R^2=0.81$); left temporal volumes and speech production rates in svPPA vs lvPPA ($R^2=0.86$). Over time, nfvPPA patients showed more phonological errors, which were predicted by syntax production features at baseline. SvPPA and lvPPA showed reduced naming and reduced number of words in sentences, respectively, which were predicted by left temporal volumes.

Conclusion: The speech, standard-language and GM variables that we identified as the most affected at baseline and over time by each PPA variant, may be used in the clinical practice for increasing knowledge on disease progression, patients' prognosis and for planning speech language therapy interventions. EPO-281 | Cognitive deficits in asymptomatic carotid stenosis: A FMRI study

E. Ozdemir Oktem[1]; B. Yulug[1]; D. Sayman[1]; S. Cankaya[1]; A. Ozsimsek[1]; C. Sayman[1]; U. Duran[1]; R. Karaca[1]; L. Hanoglu[2]
[1]*Department o Neurology, Alanya Alaaddin Keykubat University, Antalya, Turkey;* [2]*Research Institute for Health Sciences and Technologies (SABITA), Clinical Electrophysiology, Neuroimaging and Neuromodulation Laboratory, Istanbul Medipol University, Istanbul, Turkey*

Background and Aims: Asymptomatic carotid stenosis may cause cognitive loss in patients. In our study, cognitive status and functional connectivity changes and cognitive functions in patients with asymptomatic carotid stenosis (CS group) were evaluated compared to healthy controls.
Methods: Thirty-five individuals (21 male/ 14 female) were enrolled in the study. Nineteen of the participants had carotid stenosis and 16 were healthy controls. CS group and control groups' carotid stenosis evaluations were done and confirmed by radiologists. Participants' brain morphology alterations were evaluated with non-contrast brain MRI, using Schelten's score. Montreal Cognitive Assessment test (MOCA) and Mini Mental State Examination (MMSE) test were used to evaluate cognitive state. Structural and resting-state fMRI scans were conducted with specific parameters.
Results: The two groups had similar demographic characteristics in terms of age ($p=0.051$), education level ($p=0.786$) and gender ($p=0.557$). In addition, there was no difference between the Schelten scores of the carotid stenosis group and the control group ($p=0.362$). Finally, our analysis revealed that there was a significantly lower MOCA scores in carotid stenosis group compared to control group ($p=0.030$). Our whole-group partial correlation analysis showed a significant correlation between rostral prefrontal cortex prominence. Our findings showed that the CS group exhibited significantly lower MOCA scores and showed a significant correlation with salience networks compared to the control group, suggesting that carotid stenosis leads to consequential cognitive decline.

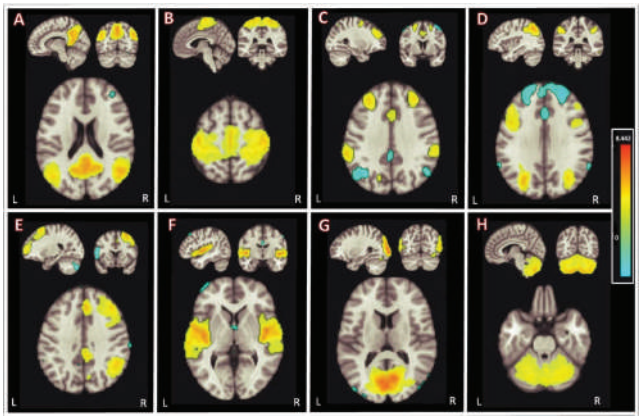

FIGURE 1 Resting-state networks identified via independent component analysis (ICA) A) DMN, B) Sensorimotor, C) Salience, D) Dorsal attention, E) Frontal-parietal, F) Language, G) Visual, H) Cerebellar.

Conclusion: Our study revealed that individuals with asymptomatic carotid artery stenosis had significantly worse cognitive functions which correlated with frontoparietal, and sensorimotor networks.
Disclosure: Nothing to disclose.

EPO-282 | Investigation of functional brain dynamics in Alzheimer's disease with short-term TMS stimulation on the DLPFC and EEG

F. Aydin[1]; S. Yilmaz[2]; H. Velioğlu[3]; B. Güntekin[4]; L. Hanoğlu[5]
[1]*Istanbul Medipol University, Institute of Health Sciences, Department of Neuroscience PhD Program, Istanbul, Turkey;* [2]*İstanbul Medipol Mega University Hospital, Department of Neurology, Istanbul, Turkey;* [3]*Center for Psychiatric Neuroscience, Feinstein Institute for Medical Research, Manhasset, New York, USA;* [4]*Istanbul Medipol University, School of Medicine, Department of Biophysics, Istanbul, Turkey;* [5]*Department of Neurology, Istanbul Medipol University, Istanbul, Turkey*

Background and Aims: Transcranial magnetic stimulation (TMS) and electroencephalography (EEG) are combined and used to investigate the brain network dynamics of neuropsychiatric diseases. Objectives: Our study aims to investigate the changes caused by short-term repetitive TMS stimulation applied to the left DLPFC region in Alzheimer's Disease (AD) on the brain's resting-state electrophysiological activity (Resting-State EEG).
Methods: 26 early/mid-stage AD patients, including active ($n=13$) and sham ($n=13$), were included in the study. 150 pulses of 20 Hz rTMS (two stimulations consisting of 75 pulses; pulse duration = 3.5 sec; time between pulses = 45 sec) were applied to the left DLPFC. Resting-state EEG was recorded at baseline and immediately after TMS to assess the effects of TMS on the functional brain network.
Results: There was no statistically significant difference between the active and sham groups in demographic, clinical, and cognitive characteristics. In the active group, a significant increase in beta activity was observed in the occipital regions after TMS application ($p<0.05$).
Conclusion: Increased beta activity may indicate the neuroplastic effects of TMS stimulation of DLPFC in AD. Monitoring the changes caused by short-term stimulation in resting EEG may play an important role in understanding the nature of brain network dynamics resulting from TMS stimulation in AD and in planning individualized treatments in the future.
Disclosure: This study was supported by TÜBİTAK.

EPO-283 | Vocabulary knowledge as a reliable proxy of cognitive reserve in multiple sclerosis: A validation study

G. Maggi[1]; M. Altieri[1]; M. Risi[1]; V. Rippa[1]; R. Borgo[1]; R. Sacco[2]; D. Buonanno[1]; A. D'Ambrosio[1]; A. Bisecco[1]; G. Santangelo[3]; A. Gallo[1]
[1]*Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, Italy;* [2]*Department of Neurology, Neurocenter of Southern Switzerland (NSI), Regional Hospital of Lugano, Ente Ospedaliero Cantonale, Lugano, Switzerland;* [3]*Department of Psychology, University of Campania "Luigi Vanvitelli", Caserta, Italy*

Background and Aims: Cognitive reserve (CR) operationalization is often limited to the educational/occupational attainment, but the lifetime intellectual enrichment represents a crucial source of CR, estimated by objective measures such as Vocabulary knowledge (VOC) test [2]. Thus, this study aimed to explore the suitability of the VOC as an accurate and reliable proxy of CR by evaluating its psychometric properties and discrimination accuracy compared to other CR measures in Multiple Sclerosis (MS).

Methods: Sixty-eight consecutive people with MS (pwMS) completed a clinical evaluation and a neuropsychological assessment including: VOC, Brief Repeatable Battery of Neuropsychological Tests, Cognitive Reserve Index questionnaire (CRIq), and questionnaires on neuropsychiatric aspects. Reliability, convergent and divergent validity, and discrimination accuracy of the VOC using educational level as reference standard were assessed. The possible effect of sociodemographic and clinical factors on the VOC and its role in predicting the global cognitive status were also explored.

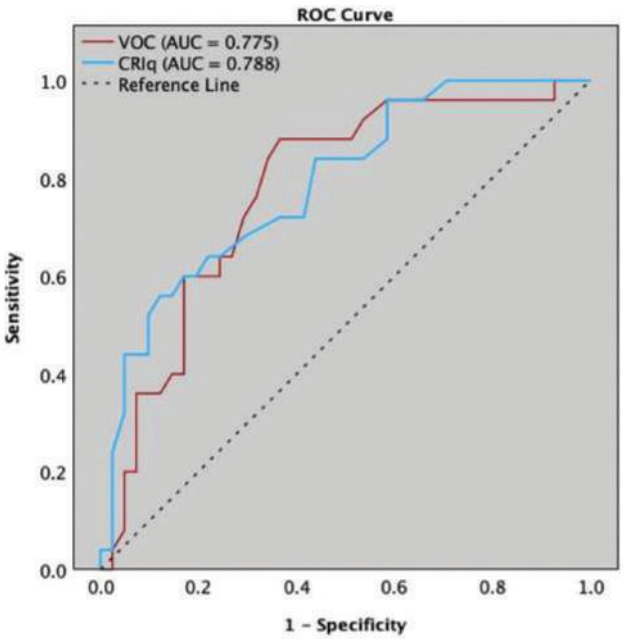

FIGURE 1 ROC of the Vocabulary Knowledge (VOC) and Cognitive Reserve Index questionnaire (CRIq) when discriminating people with Multiple Sclerosis (pwMS) with high and low cognitive reserve measured using educational level as reference standard.

Results: The VOC demonstrated good internal consistency (Cronbach's alpha = 0.894) and an adequate construct validity. It showed a level of discrimination of pwMS with high and low CR comparable to the CRIq score (Figure 1). VOC scores were independent of MS features and predicted, together with MS-related disability, the global cognitive status.

Conclusion: CR should be measured by fixed objective measures independent of brain pathology and clinical features such as the VOC found to be a reliable and valid instrument for CR estimation in pwMS. Early CR estimation may help clinicians in identifying pwMS at higher risk of cognitive decline to plan a strict neuropsychological monitoring and cognitive interventions.

Disclosure: Nothing to disclose.

EPO-284 | Psychophysiological markers of creative thinking: Preliminary findings from an experimental study

J. Giannì; V. Borsa; A. Brugnera; G. Fusi; M. Crepaldi; F. Colombi; A. Compare; M. Rusconi
Department of Human and Social Sciences, University of Bergamo, Bergamo, Italy

Background and Aims: According to the Neurovisceral Integration Model, brain regions involved in self-regulation are implicated in cardiac autonomic activity through the vagus nerve. Previous literature showed that greater parasympathetic activity at rest predicts better cognitive performances, but its association with creative thinking processes is still under-investigated. Moreover, both cognitive control mechanisms and creative thinking appear to be modulated by specific psychological traits. Thus, the aim of this study is to explore the relationship between Heart Rate Variability (HRV) at rest, specific psychological traits, and creative thinking.

Methods: A preliminary sample of 44 participants (age: 25.24 ± 3.74; education: 16.02 ± 2.04) filled out an online survey investigating psychological dimensions; then underwent an experimental procedure that included a baseline, two creative thinking tasks (figural and verbal) and a recovery condition. An electrocardiogram (ECG) was recorded during the procedure and two HRV indices of parasympathetic activity (i.e., Mean HR and RMSSD) were computed. We performed non-parametric correlations between HRV indices at rest, creative thinking scores and psychological traits.

Results: We found a significant, positive correlation between parasympathetic activity and a verbal creative index (i.e. flexibility) associated with executive functioning. Conversely, we found a significant negative correlation between perfectionistic traits and parasympathetic activity.

Conclusion: Results showed a relation between HRV and cognitive performance during a creative thinking task; the more executive component of verbal creative thinking was associated with vagal activity. Additionally, perfectionistic tendencies were associated with a vagal withdrawal at rest, suggesting a possible greater effort expenditure in cognitive control mechanisms in those individuals.

EPO-285 | Vertigoheel promotes rodent cognitive performance in multiple memory tests

K. Ott[1]; T. Heikkinen[2]; K. Lehtimäki[2]; K. Paldanius[2]; J. Puoliväli[2]; R. Pussinen[2]; E. Andriambeloson[3]; B. Huyard[3]; S. Wagner[3]; C. Schnack[4]; A. Wahler[4]; B. von Einem[4]; C. von Arnim[5]; Y. Burmeister[1]; K. Weyer[1]; B. Seilheimer[1]
[1]Heel GmbH, Baden-Baden, Germany; [2]Charles River Discovery Services, Kuopio, Finland; [3]Neurofit SAS, Illkirch, France; [4]Department of Neurology, Ulm University, Ulm, Germany; [5]Department of Neurology, Ulm University, Ulm, Germany and Department of Geriatrics, University Medical Center Göttingen, Göttingen, Germany

Background and Aims: Cognitive deficits associated with old age or various pathological conditions influence up to 3% of the general population. Repurposing drugs that had been safely used for other indications may be a promising approach to reverse or slow down cognitive impairment. Vertigoheel (VH-04) is a multicomponent medication made of Ambra grisea, Anamirta cocculus L., Conium maculatum and Petroleum rectificatum that has been successfully and safely used for several decades in the treatment of vertigo. Here, we explored its potential as a cognitive enhancer.
Methods: We have examined the effects of single and repeated administrations of VH-04 on the performance of mice and rats in several standard behavioral tests assessing different types of memory.
Results: We found that VH-04 positively influenced visual recognition memory in the novel object recognition test and alleviated impairments in spatial working memory and olfactory memory caused by the muscarinic antagonist scopolamine in the spontaneous alternation and social transmission of food preference tests. In addition, VH-04 improved retention of the spatial orientation memory of old rats in the Morris water maze. In contrast, VH-04 did not significantly modify scopolamine-induced impairments in tests of fear-aggravated memory or rewarded alternation. Experiments in vitro showed that incubation with VH-04 stimulated neurite growth of mouse primary hippocampal neurons and possibly reversed the decrease in synaptophysin mRNA expression in the hippocampus of aged rats, which implies that VH-04 may preserve synaptic integrity in the aging brain.
Conclusion: Our findings allow a cautious conclusion that VH-04 may improve cognitive performance in individuals with memory deficits.
Disclosure: This study received funding from Heel GmbH, an international pharmaceutical company that specializes in developing and manufacturing medicines made from natural ingredients. Charles River Discovery Services Finland Oy and Neurofit are contract research organizations. At the time of the study, KW, KO, YB, and BS were employed by Heel GmbH. TH, KL, KP, JP, and RP were employed by Charles River Discovery Services Finland Oy. EA, BH, and SW were employed by Neurofit. CS, AW, BE, and CA were employed by the Ulm University.

EPO-286 | Vocabulary knowledge as predictor of cognitive decline in multiple sclerosis: A long-term follow-up study

M. Altieri[1]; G. Maggi[1]; M. Risi[1]; V. Rippa[1]; R. Borgo[1]; R. Sacco[2]; R. Docimo[1]; A. d'Ambrosio[1]; A. Bisecco[1]; G. Santangelo[3]; A. Gallo[1]
[1]Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, Italy; [2]Department of Neurology, Neurocenter of Southern Switzerland (NSI), Regional Hospital of Lugano, Ente Ospedaliero Cantonale, Lugano, Switzerland; [3]Department of Psychology, University of Campania "Luigi Vanvitelli", Caserta, Italy

Background and Aims: Few studies longitudinally evaluated the effect of Cognitive Reserve (CR) on cognition in people with Multiple Sclerosis (pwMS) [1,2] reporting mixed results. This study assessed changes in CR - evaluated with an objective measure of lifetime enrichment, the Vocabulary subtest (VOC) of WAIS - and cognition after more than 6 years.
Methods: Eighty pwMS (35% males) were evaluated at baseline and after a follow-up of 6.39 (1.84) years. A global cognition score (COG) was computed by meaning all scores of BRB-N and Stroop test. Repeated measures and mixed-design ANOVAs, regression and receiver operating characteristics (ROC) analyses evaluated: 1) changes in VOC over time, 2) demographic/clinical predictors of changes of VOC and COG over time, 3) accuracy of VOC compared to baseline COG in predicting cognitive decline.
Results: We found that higher VOC scores at follow-up evaluation and this change was independent of demographic/clinical aspects. VOC was the only predictor of COG changes. pwMS with high CR reported higher COG scores at both baseline and follow-up; moreover, COG scores improved at follow-up only in pwMS with high CR. ROC analysis (with presence of cognitive decline as gold standard) indicated that VOC predicted future cognitive decline, better than educational level and slightly lower than baseline COG.

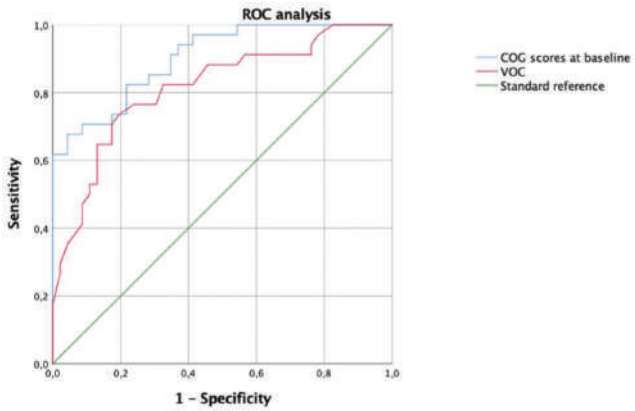

FIGURE 1 ROC analysis of Vocabulary Knowledge and overall cognition score at baseline evaluation as predictors of cognitive decline at follow up evaluation.

Conclusion: The results revealed that CR can be increased over time independently from the effect of disease, and that the measurement

of CR can be useful after MS diagnosis to identify people at risk of future cognitive decline.

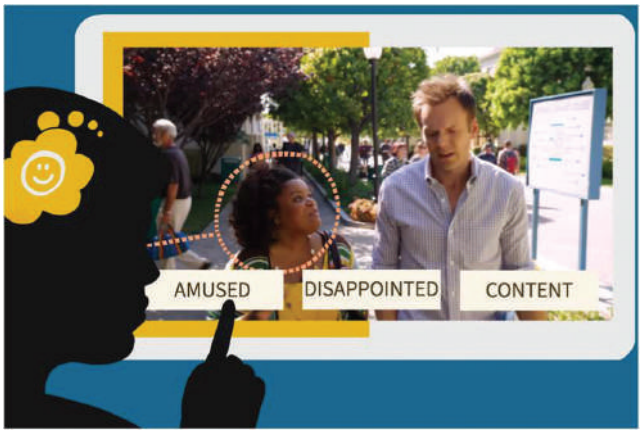
EPO-287 | Advancing neurological assessment: The importance of social cognition screening

M. Eicher; R. Johannessen; A. Hansen; M. Regli; L. Ramseier; T. Hibbert; M. Ruepp; L. Imbach; H. Jokeit
Swiss Epilepsy Centre, Zurich, Switzerland

Background and Aims: Social cognition, the capacity to recognize, understand, and predict emotional and mental states in oneself and others, has gained prominence in the last decade. Acknowledging its impact, the DSM-V includes social cognition as a core neurocognitive domain. However, there is a shortage of screening tools for assessing social cognition in neurological disorders. To bridge this gap, we created the Cognition of Social Interaction in Movies (COSIMO) screening tool – a brief, video-based, ecologically valid, freely accessible, browser-based test providing immediate results (https://cosimo-project.com).



Example of a COSIMO item.

Methods: 1) To explore potential applications in neurology, we conducted a systematic second-order literature review to identify and characterise the nature and extent of social cognitive dysfunction in different neurological conditions. 2) Preliminary data analyses examined COSIMO test scores in healthy controls ($N=900$) and in neurological populations with epilepsy ($N=50$) and multiple sclerosis ($N=100$).

Results: Our systematic second-order review reveals the presence of significant social cognitive deficits in several neurological disorders. Analyses of COSIMO showed satisfactory psychometric properties, with particularly high sensitivity in detecting deficits in patients with temporal lobe epilepsy ($N=25$, $g=1.02$, $p=0.006$).

Conclusion: Neurological disorders can be associated with social cognitive dysfunction, highlighting the urgent need for concise and reliable screening tools for clinical use. COSIMO shows promising potential for the efficient identification of such deficits. We are actively collecting normative data and validating COSIMO across a range of neurological and psychiatric conditions.

Disclosure: Nothing to disclose.

EPO-288 | Longitudinal assessment of cognitive function in non-relapsing MOG-IgG associated disease: A case series

M. Risi[1]; M. Altieri[2]; R. Borgo[1]; A. d'Ambrosio[1]; R. Docimo[1]; C. Marotta[1]; R. Capuano[1]; V. Rippa[2]; M. Cirillo[3]; G. Tedeschi[1]; A. Bisecco[1]; A. Gallo[1]
[1]*Division of Neurology, Department of Advanced Medical and Surgical Sciences (DAMSS), University of Campania "Luigi Vanvitelli", Naples, Italy*; [2]*Department of Psychology, University of Campania "Luigi Vanvitelli", Napoli, Italy*; [3]*MRI Research Center SUN-FISM, University of Campania "Luigi Vanvitelli", Naples, Italy*

Background and Aims: MOGAD is an inflammatory antibody-mediated disease, affecting both white and grey matter of CNS. It is more frequent in children and young adults. The clinical course can be either monophasic or relapsing, often with complete recovery. To date, only few studies explored cognitive function in patients with MOGAD. Patients with relapsing MOGAD have been reported to have impaired reasoning skills and overall response time, compared to healthy controls. To assess longitudinal change in cognitive function in a cohort of six patients with non-relapsing MOGAD.

Methods: we assessed cognitive function with the Rao's Brief Repeatable Battery and the Stroop test after ≥12 months from recovery and after 1-year. Patients who failed ≥2 subtests (Z-scores < -1.5 SD) were defined cognitively impaired (CI). Results were adjusted for age, sex, and education.

Results: as disease onset, 3 had ADEM, 1 had cortical encephalitis, and 2 had optic neuritis. Complete clinical recovery occurred for all patients. Only one received Rituximab due to severity of initial attack. Basal cognitive evaluation revealed a mild multidomain impairment only in the two pediatric-onset patients of the cohort, without worsening over 1-year. Annualized brain atrophy rate was normal for all patients.

Conclusion: differently from patients with relapsing MOGAD, we found no CI subjects within our cohort of non-relapsing adult patients, while the two with pediatric-onset showed a mild cognitive impairment. Interestingly, no patients had worsening in cognitive function and brain atrophy rate over 1-year follow-up. These data suggest that the relapsing course and pediatric onset could be risk factors for cognitive impairment in MOGAD.

Disclosure: The authors declare no potential conflicts of interest with respect to the research, authorship, and/or publication of this work.

EPO-289 | Spontaneous intracranial hypotension presenting as frontotemporal dementia: Two case reports and literature review

M. Del Chicca[1]; D. Viola[1]; E. Bergamin[1]; L. Tommasini[1]; L. Giampietri[1]; E. Del Prete[2]; V. Nicoletti[2]; G. Tognoni[2]; R. Ceravolo[1]; G. Siciliano[1]; F. Baldacci[1]

[1]*Neurology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy;* [2]*Neurology Unit, Department of Medical Specialties, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy*

Background and Aims: Spontaneous intracranial hypotension (SIH) can present with cognitive and behavioral changes resembling behavioral variant-frontotemporal dementia (bvFTD). This study reports two cases of SIH manifesting with behavioral alterations and reviews the existing literature on other reported cases.

Methods: Two male patients experienced subacute orthostatic headache, behavioral changes (disinhibition, apathy) and impaired executive and attentional functions on neuropsychological tests. Brain Magnetic Resonance Imaging (MRI) revealed brain sagging and dural contrast enhancement, leading to an SIH diagnosis. Despite unsuccessful blood patching in one case, subsequent exploration identified a cerebrospinal fluid (CSF)-venous fistula and embolization resolved SIH, improving cognition. In addition the study compares clinical and radiological features, as well as treatment options, of these cases, with existing literature to consolidate our understanding of clinical features, diagnosis and management of this condition.

Results: Radiological and clinical data, in our cases, support a diagnosis of Brain Sagging Dementia (BSD). Literature review identified well-documented cases of BSD, highlighting its rarity and potential reversibility with identified SIH causes and proper treatment.

Conclusion: SIH presenting as bvFTD may result from frontotemporal cortex stretching and/or from venous stagnation at the confluence of the straight sinus and Galenic vein. Given its treatable nature, when symptoms typical of bvFTD coexist with brain sagging without clear cerebral atrophy on MRI, it is crucial to consider BSD. Further investigations are recommended to identify CSF hypotension causes and implement appropriate treatments. Considering the potential reversibility of BSD, such interventions frequently result in the improvement of cognitive disorders.

Disclosure: Nothing to disclose.

EPO-290 | Exploring cognitive function in subarachnoid hemorrhage patients: A mini-mental state examination analysis

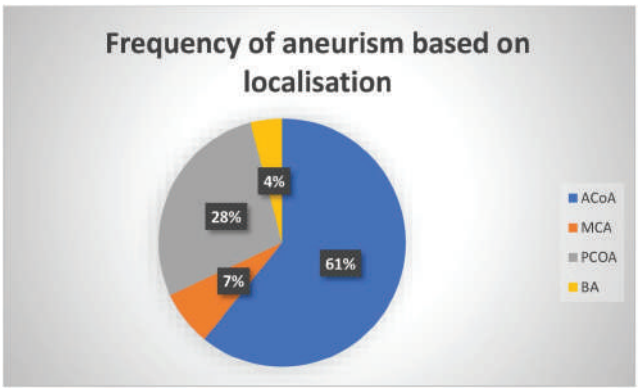
O. Cibuku[1]; V. Leka[1]; E. Enesi[2]; A. Rroji[2]; F. Bilaj[2]; K. Caci[2]; M. Loka[3]; S. Nokshiqi[3]

[1]*Neurologist, American Hospital Tirana, Albania;* [2]*Neuroradiologist, American Hospital Tirana, Albania;* [3]*Medical doctor, American Hospital Tirana, Albania*

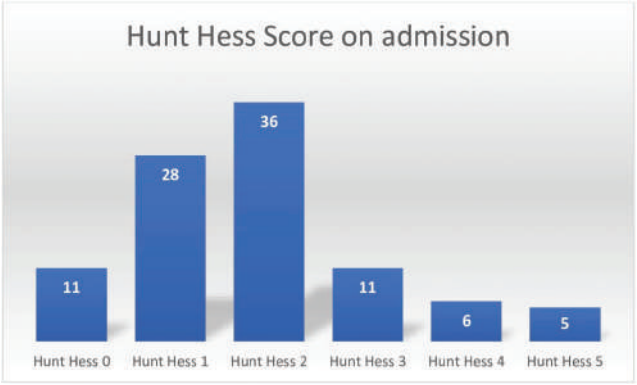
Background and Aims: This study examines the cognitive status of individuals recovering from subarachnoid hemorrhage (SAH) using the Mini-Mental State Examination (MMSE). The findings elucidate the extent of cognitive impairment post-SAH and highlight specific areas of vulnerability

Methods: A prospective study utilizing Mini-Mental State Examination (MMSE) to assess cognitive function in 97 patients diagnosed with subarachnoid hemorrhage (SAH) patients from June 2022-December 2023 in American Hospital in Tirana, Albania. Standardized MMSE protocols applied at discharge and 6 months follow up, with data analyzed for correlations with SAH severity and outcome.

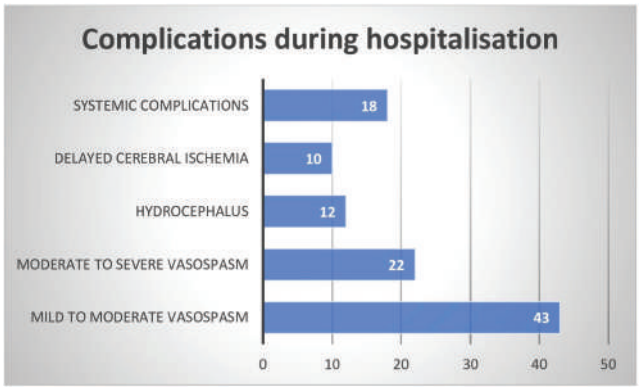
Results: 97 patients diagnosed with SAH from a ruptured brain aneurism, mean age 39.27 (SD17.21), with a female predominance (60.82% female vs 39.18% male). 59 (60.82%) aneurism ACoA, 7 (7.22) aneurism MCA, 27 (27.85) aneurism ACoP, 4 (4.12%) aneurism BA. In patients admitted with Hunt-Hess scores of 0-2, MMSE yielded 3-4 points higher compared to those with Hunt-Hess scores of 3-5.($p < 0.05$). Statistical analysis revealed no significant changes in MMSE scores upon reevaluation after 6 months ($p > 0.01$).



Frequency of aneurism based on localisation.



Hunt Hess score on admission.



Complications during hospitalisation.

Conclusion: MMSE in SAH patients provides valuable insights into cognitive function. While initial scores may correlate with Hunt-Hess severity, long-term stability suggests the need for continuous monitoring and tailored interventions for optimal cognitive outcomes. Study limitations: MMSE may not fully capture subtle cognitive changes, emphasizing the importance of supplementary assessments for a comprehensive understanding of cognitive function in this population

Disclosure: Nothing to disclose.

EPO-291 | Executive functioning training to reduce cognitive intra-individual variability in HIV adults: A case comparison study

O. Odii[1]; S. Brooks[1]; N. Wright[1]; A. Azuero[1]; P. Fazeli[1]; C. Chapman Lambert[1]; D. James[2]; E. Kay[1]; J. Lee[3]; D. Vance[1]

[1]School of Nursing, University of Alabama at Birmingham; [2]Edson College of Nursing and Health Innovation, Arizona State University; [3]Department of Psychiatry and Behavioral Neurobiology, University of Alabama at Birmingham, Birmingham, Alabama, USA

Background and Aims: As people with HIV (PWH) age, they experience increased risk of developing cognitive impairments. To mitigate these challenges, healthcare professionals must create intervention strategies. An emerging concept in the realm of cognitive vulnerabilities is cognitive intra-individual variability (IIV). Cognitive IIV pertains to the variations observed in cognitive performance, offering predictive insights beyond conventional mean-based cognitive assessments. In the context of HIV, cognitive IIV has shown associations with the prediction of cognitive decline, cortical atrophy, and mortality. Based on the Executive Dysfunction Hypothesis, improvement in executive functioning could reduce cognitive IIV.

Methods: In our feasibility study, a two-group pre/posttest randomized controlled trial involving 120 PWH, participants are randomized into either the executive functioning training group or a no-contact control group. The training group undergoes 20 hours of computerized exercises aimed at enhancing executive function. To characterize this study, an interim case comparison was performed, focusing on the initial two participants who completed the training and two demographically matched control participants.

Results: Utilizing the Connor's Continuous Performance Test 3rd Edition, a computerized assessment of reaction time and cognitive IIV, the findings indicated significant enhancements in reaction time (i.e., Hit RT) and cognitive variability (i.e., HRT SD, Variability) within the training group when compared to the no-contact control group.

Conclusion: While preliminary, these initial promising findings imply that delving deeper into cognitive IIV could offer insights into enhancing cognition in aging PWH. This provides a new avenue for cognitive interventions, specifically targeting the reduction of cognitive IIV.

Disclosure: Nothing to disclose.

EPO-292 | Accelerated TMS for Alzheimer's disease; bilateral DLPFC stimulation twice daily for 5 days: Randomized controlled trial

S. Yilmaz[1]; F. Aydin[2]; C. Parlatan[2]; E. Uluçam[3]; U. Benli[3]; H. Velioğlu[4]; L. Hanoğlu[5]

[1]Department of Neurology, İstanbul Medipol Mega University Hospital, Istanbul, Turkey; [2]Department of Neuroscience PhD Program, Institute of Health Sciences, Istanbul Medipol University, Istanbul, Turkey; [3]School of Medicine, Istanbul Medipol University, Istanbul, Turkey; [4]Center for Psychiatric Neuroscience, Feinstein Institute for Medical Research, Manhasset, New York, USA; [5]Department of Neurology, Istanbul Medipol University, Istanbul, Turkey

Background and Aims: Different protocols have been developed to affect mood, anxiety, cognition, memory, executive functions, and behavioral and motor symptoms in Alzheimer's patients. Our aim with this study is to investigate the changes of short-term intensified rTMS on cognitive, behavioral and daily living activities in AD patients.

Methods: 31 early and mid-term AHD were included in the rTMS Group ($n = 19$) and the control group ($n = 12$). Before and after rTMS; Mini Mental State Test and Alzheimer's Disease Assessment Scale, Geriatric Depression Scale, Activities of Daily Living Scale and

neuropsychometric inventory were used. In the rTMS group, 20 Hz rTMS was applied to bilateral DLPFC.

Results: The average age of the rTMS group is 72.36 ± 3.81; the control group is 68.50 ± 7.72. The average education year of the rTMS group is 8.36 ± 5.15. The average education year of the control group is 10.25 ± 4.88. Intra-group and intergroup analyzes of rTMS and control groups are shown in Tables 1&2 and 2 and Table 3.

Table 1: rTMS GROUP ANALYSIS

rTMS Group	Pre-evaluation (Mean ± SD)	Post-evaluation (Mean ± SD)	p Value
MMSE	19,57 ± 5,12	19,84 ± 5,10	0,69
GDS	5,05 ± 3,90	3,73 ± 3,29	0,12
ADAS-COG	22,64 ± 10,72	22,71 ± 12,83	0,96
ADCS-ADL	56,94 ± 14,08	62,89 ± 9,99	0,004*
NPQ	8,73 ± 7,68	4,05 ± 5,63	0,013*
NPQ - Severity	5,36 ± 4,99	2,36 ± 3,51	0,000*

MMSE: Mini-Mental State Examination; GDS: Geriatric Depression Scale; -COG: The Alzheimer's Disease Assessment Scale–Cognitive Subscale; ADCS-ADL: Alzheimer's Disease Cooperative Study–Activities of Daily Living; NIQ: Neuropsychiatric Inventory Questionnaire; ADAS. SD: Standart Deviation (p <0.05)

Table 2: CONTROL GROUP ANALYSIS

Control Group	Pre-evaluation (Mean ± SD)	Post-evaluation (Mean ± SD)	p Value
MMSE	19,00 ± 6,82	19,08 ± 7,15	0,93
GDS	5,00 ± 4,61	4,58 ± 3,62	0,66
ADAS-COG	26,30 ± 10,82	23,64 ± 13,83	0,14
ADCS-ADL	58,00 ± 10,74	56,91 ± 12,03	0,60
NPQ	7,91 ± 7,52	12,66 ± 16,98	0,17
NPQ - Severity	5,41 ± 6,14	8,16 ± 8,99	0,15

MMSE: Mini-Mental State Examination; GDS: Geriatric Depression Scale; -COG: The Alzheimer's Disease Assessment Scale–Cognitive Subscale; ADCS-ADL: Alzheimer's Disease Cooperative Study–Activities of Daily Living; NIQ: Neuropsychiatric Inventory Questionnaire; ADAS. SD: Standart Deviation (p <0.05)

Table 3: *ANOVA (group × time)*

	rTMS Group		Control Group			
	Pre-evaluation (Mean ± SD)	Post-evaluation (Mean ± SD)	Pre-evaluation (Mean ± SD)	Post-evaluation (Mean ± SD)	p Value	f
MMSE	19,57 ± 5,12	19,84 ± 5,10	19,00 ± 6,82	19,08 ± 7,15	0,755	0,099
GDS	5,05 ± 3,90	3,73 ± 3,29	5,00 ± 4,61	4,58 ± 3,62	0,18	1,877
ADAS-COG	22,64 ± 10,72	22,71 ± 12,83	26,30 ± 10,82	23,64 ± 13,83	0,33	0,976
ADCS-ADL	56,94 ± 14,08	62,89 ± 9,99	58,00 ± 10,74	56,91 ± 12,03	0,095	2,97
NPQ	8,73 ± 7,68	4,05 ± 5,63	7,91 ± 7,52	12,66 ± 16,98	0,98	0,000
NPQ - Severity	5,36 ± 4,99	2,36 ± 3,51	5,41 ± 6,14	8,16 ± 8,99	0,88	0,023

MMSE: Mini-Mental State Examination; GDS: Geriatric Depression Scale; -COG: The Alzheimer's Disease Assessment Scale–Cognitive Subscale; ADCS-ADL: Alzheimer's Disease Cooperative Study–Activities of Daily Living; NIQ: Neuropsychiatric Inventory Questionnaire; ADAS. SD: Standart Deviation (p <0.05)

Conclusion: After the rTMS, there were positive changes in the behavioral and daily living activities of individuals with AD. The main goal is to slow or stop the progression of the disease as a result of TMS stimulation. Although magnetic stimulation does not compensate for the loss of cell number resulting from atrophy, it is thought that TMS increases the synaptic connectivity between neurons and thus plays a role in slowing down the progression.

Disclosure: This study was supported by TÜBİTAK.

EPO-293 | Late-onset vs adult-onset multiple sclerosis: Comparison of clinical and cognitive features and sex-related differences

N. Tedone[1]; P. Preziosa[2]; D. Mistri[1]; M. Azzimonti[2]; M. Filippi[3]; M. Rocca[2]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; [2]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy; [3]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: The proportion of patients with multiple sclerosis (MS) experiencing disease onset after 45 years (late-onset [LO] MS) is increasing. Although previous studies suggested different clinical features between LOMS and adult-onset (AO) MS patients, a comprehensive evaluation including cognitive profiles and sex influence has not been investigated yet. This study compares clinical and cognitive characteristics between LOMS and AOMS patients and explores sex-related differences.

Methods: Sixty-one LOMS patients (females=31) and 122 sex-matched AOMS patients (females=62) underwent neurological and neuropsychological assessments. Differences in clinical (onset type, disability status, 9-hole Peg Test, Timed 25-Foot Walk [T25FWT]) and neuropsychological features (performance and frequency of impairment of global cognitive function and specific domains, presence and severity of fatigue and depression) were evaluated, also considering sex differences.

Results: Compared to AOMS, LOMS patients exhibited higher motor onset prevalence, worse T25FWT and visual memory performance ($p \leq 0.036$). LOMS males had more frequent motor onset, worse T25FWT, higher prevalence of depression and cognitive impairment compared to AOMS males ($p \leq 0.030$). LOMS females performed worse in visual memory ($p \leq 0.006$) and had lower fatigue compared to AOMS females ($p \leq 0.005$). Compared to AOMS females, males showed worse performance in global cognitive function, attention, and verbal memory with higher prevalence of impairment in the latter ($p \leq 0.011$). Compared to LOMS females, males showed higher prevalence of depression and impairment in attention ($p \leq 0.035$).

Conclusion: LOMS patients exhibited worse clinical and cognitive features compared to AOMS patients, regardless from sex. Male patients showed more severe clinical and cognitive impairment in both AOMS and LOMS.

Disclosure: N Tedone, D Mistri, M Azzimonti have nothing to disclose. P. Preziosa received speaker honoraria from Roche, Biogen, Novartis, Merck, Bristol Myers Squibb, Genzyme, Horizon and Sanofi. He has received research support from Italian Ministry of Health and Fondazione Italiana Sclerosi Multipla (FISM). M. Filippi received compensation for consulting or speaking activities services from Alexion, Almirall, Biogen, Bayer, Celgene, Chiesi Italia SpA, Eli Lilly, Genzyme, Janssen, Merck, Neopharmed Gentili, Novartis, Novo

Nordisk, Roche, Sanofi, Takeda, and TEVA; participation in Advisory Boards for Alexion, Biogen, Bristol-Myers Squibb, Merck, Novartis, Roche, Sanofi, Sanofi-Aventis, Sanofi-Genzyme, Takeda; scientific direction of educational events for Biogen, Merck, Roche, Celgene, Bristol-Myers Squibb, Lilly, Novartis, Sanofi-Genzyme; he receives research support from Biogen Idec, Merck-Serono, Novartis, Roche, Italian Ministry of Health, Italian Ministry of University and Research, and FISM. MA Rocca received consulting fees from Biogen, Bristol Myers Squibb, Eli Lilly, Janssen, Roche; speaker honoraria from AstraZaneca, Biogen, Bristol Myers Squibb, Bromatech, Celgene, Genzyme, Horizon Therapeutics Italy, Merck Serono SpA, Novartis, Roche, Sanofi and Teva; research support from MS Society of Canada, Italian Ministry of Health, Italian Ministry of University and Research, and FISM.

EPO-294 | The development of a multimodal AI-assisted Thai mini-mental state examination (MMSE-T) framework for Thai population

C. Sirilertmekasakul[1]; W. Rattanawong[1]; A. Gongvatana[1]; T. Tongloy[2]; A. Srikiatkhachorn[1]

[1]Faculty of Medicine, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand; [2]College of Advanced Manufacturing Innovation, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

Background and aims: With approximately 50 million people affected globally, dementia prevalence is expected to triple by 2050. Early detection, traditionally reliant on manual, paper-based cognitive screening, is shifting towards digitized, artificial intelligence (AI)-assisted methods. This study aims to develop a multimodal AI-assisted neurocognitive assessment framework, using the MMSE-T 2002 as a model, and compare its effectiveness with the traditional version.

Methods: MMSE-T was completed by 233 individuals who visited the medical center of King Mongkut Institute of Technology, Ladkrabang (KMITL). Data were captured via videos and images. AI models for 11 MMSE-T test batteries were developed using 150 dataset. Speech-based and handwritten answers were converted to digital text using Microsoft Azure's speech-to-text (STT) and Google Cloud AI's optical character recognition (OCR), respectively, and scored by the ChatGPT. The deep learning (DL) algorithms-based object detection were trained to detect drawing and action-based answers. The primary outcome of the correlation between the scoring of MMSE-T by traditional paper-based and digital AI-assisted versions was analyzed using the intraclass correlation coefficient (ICC).

Results: Of 83 records analyzed, a high correlation between traditional and digital AI-assisted versions was observed ($r=0.85$; $p<0.001$). Among 11 test batteries, the eye-action test battery has the highest correlation of $r=1$ ($p<0.001$). The AI-assisted version demonstrated sensitivity, specificity, positive (PPV) and negative predictive values (NPV) of 68.7%, 89.6%, 61.1%, and 92.3%, respectively, compared to human grading.

Conclusion: The study indicates a high correlation between traditional paper-based and digital AI-assisted MMSE-T, suggesting the effectiveness of AI integration in cognitive screening for dementia.

EPO-295 | REKLAIM, a novel Phase Ib clinical trial of intravenous FBX-101 (AAVrh10.GALC) after UCBT for infantile Krabbe disease

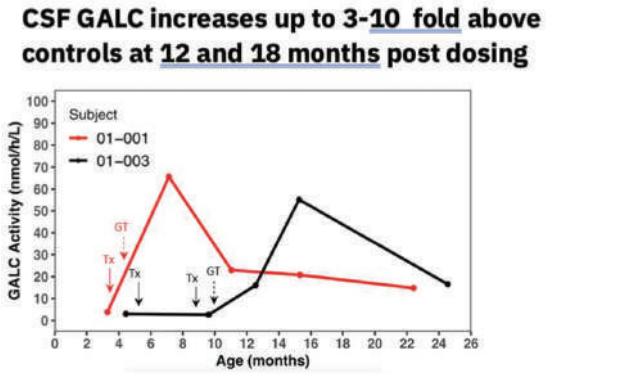
M. Escolar[1]; M. Poe[1]; J. Ruiz[1]; M. Vander Lugt[2]; R. Wang[3]; P. Sabolcs[4]

[1]FORGE BIOLOGICS, Grove City, OH, USA; [2]University of Michigan Medical Center, Ann Arbor, MI, USA; [3]Children's Hospital of Orange County, Orange County, CA, USA; [4]Paul Szabolcs, University of Pittsburgh, Pittsburgh, PA, USA

Background and Aims: REKLAIM is a novel intravenous AAVrh10.GALC gene therapy administered after umbilical cord blood transplantation (UCBT) for Krabbe disease. We report on the first 5 subjects treated. Infantile Krabbe is a neurodegenerative disorder due to galactocerebrosidase (GALC) deficiency that results in psychosine toxicity to myelinating cells and death by 2 years. UCBT in pre-symptomatic neonates halts brain disease, but motor function declines due to progressive peripheral neuropathy. We hypothesized that FBX-101 administered during myeloablation for UCBT will override the antibody response to the vector's capsid and transgene and increase GALC.

Methods: REKLAIM is a Phase 1b dose-escalating intravenous gene therapy of FBX-101 given >21 days after UCBT during myeloablation or immune suppression approved by an independent committee. It includes a protocol using Rituximab, Serolimus and Prednisolone adjusted to subject needs.

Results: Five subjects with IKD treated with FBX-101 low dose (1.6 x1013 gc/kg). FBX-101 was well tolerated, with no treatment-related serious adverse events or development of antibodies to the transgene after follow up of 4 to 24 months. In the 2 subjects treated during myeloablation, there were no AAV antibodies, plasma and CSF GALC significantly increased, psychosine dropped below detection and subjects achieved normal gross motor skills. The three subjects treated during immune suppression developed total antibodies to AAV with no humoral or cellular toxicity and improved gross motor skills.



CSF GALC activity post-FBX-101 administration. The red and black lines depict the longitudinal measure of CSF GALC activity in each subject. Normal range ~6 nmol/hr/L (n=1). Arrows indicate time of transplant (Tx) and gene therapy (GT) administration.

CSF GALC

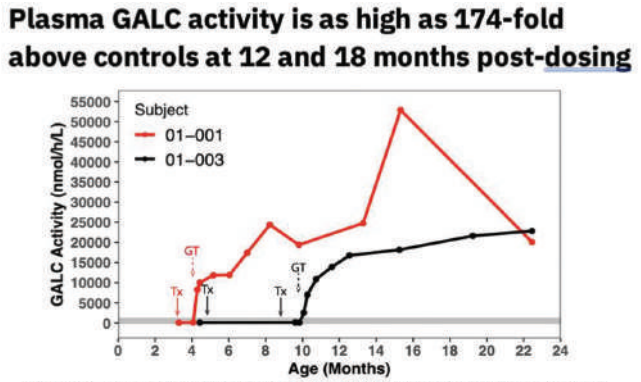


Figure 4. The red and black lines depict the longitudinal measure of plasma GALC activity in each subject. Grey line represents the GALC activity levels in the normal range ~300 nmol/hr/L (n=4). Arrows indicate time of transplant (Tx) and gene therapy (GT) administration.

Plasma GALC activity

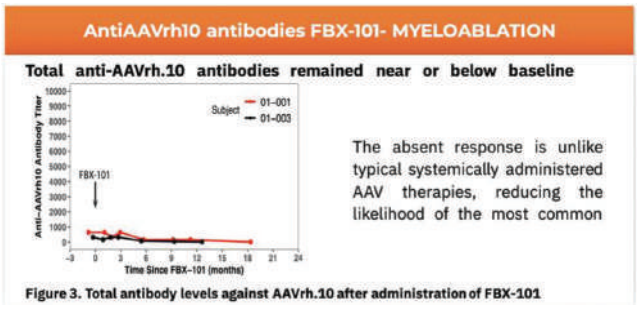

Figure 3. Total antibody levels against AAVrh.10 after administration of FBX-101

Anti AAVrh antibodies

Conclusion: FBX-101 leverages the myeloablation and immune suppression after UCBT, resulting in efficient AAV transduction and increased GALC enzyme supporting brain myelination and gross motor development

Disclosure: M. Escolar is an inventor on the patent application describing FBX-101 (WO2018/136710), licensed by Forge Biologics from the University of Pittsburgh. Dr. Escolar receives salary from Forge Biologics. Adjunct Professor of Pediatrics, University of Pittsburgh.

EPO-296 | Case report: DYNC1H1 mutation as a rare mimic of spinal muscular atrophy (SMA) type 3

M. Baldauf; A. Felbecker; T. Hundsberger
Department of Neurology, Cantonal Hospital, St. Gallen, Switzerland

Background and Aims: Our patient developed weakness of the legs at the age of 6y, being slowly progressive over decades. Since childhood, he was diagnosed of suffering from spinal muscular atrophy (SMA) type 3 (never genetically confirmed). At the age of 48y, he was admitted to us. He reported, that his mother, sister and niece have similar symptoms (onset ~5-7 years).

Methods: Neurological examination, ENMG, genetics

Results: Clinically he presented with proximally pronounced pareses of both legs with areflexia. Interestingly, atrophy was distally pronounced. There were no sensory or cognitive deficits. Nerve conduction studies were normal, but EMG detected severe chronic denervation with partial reinnervation. Genetically, there was no deletion of the SMN1 gene. Finally, we found a heterozygous mutation in the DYNC1H1 gene, classified as probably pathogenic (ACMG guidelines). It's a c.1793G>T missense mutation leading to an amino acid exchange p.(Arg598Leu). The same mutation was also found in his niece. This mutation was described first in 2015 (Scoto et al.), who found it in 4 patients (2 families) with symptom onset at birth or in childhood. Since then, there are no further reports about that mutation in the literature, to our knowledge.

Conclusion: The clinical picture of SMA3 is similar to that of DYNC1H1 mutation associated lower extremity predominant SMA. The autosomal-dominant inheritance (versus autosomal-recessive in SMA3) is an important clinical hint. Describing the clinical follow up of patients with such rare mutations is essential, to gather information about their prognosis, avoid false diagnosis/treatment and to collect patients for future therapeutic studies.

Disclosure: Nothing to disclose.

EPO-297 | Frequency of LRRK2 p.L1795F variant in Parkinson's disease patients from Central Europe within the CEGEMOD consortium

Background and Aims: Pathogenic variants in LRRK2 are one of the most common high-risk genetic factors for Parkinson's disease (PD). Recently, the lesser-known LRRK2 p.L1795F variant was proposed as a strong genetic risk factor for PD [1], with a functional effect via stimulating the LRRK2 kinase activity [2]. However, further families are currently lacking in the literature.

Methods: A multicentre early-onset and familial PD cohort from 9 movement disorder centres across Central Europe within the CEGEMOD consortium [3] was screened for rare LRRK2 variants using whole exome sequencing data ($n = 219$).

Results: We identified 3 PD cases with heterozygous LRRK2 p.L1795F variant and 1 PD case was additionally identified through standard genetic testing. All 4 patients were from a region close to Slovak-Hungarian borders. The age of onset was 25, 45, 55 and 69 respectively and 3 cases had positive family history with several family members affected. All 4 cases were characterized by early onset of severe motor fluctuations, with 2 of them receiving LCIG therapy and 2 implanted with STN DBS; 3/4 of these cases showed unsatisfactory effect on motor fluctuations.

Conclusion: Our data suggest that the p.L1795F may represent the most common currently known pathogenic LRRK2 variant in Central Europe (AF = 0.0091) compared to more studied p.G2019S (AF = 0.00164), which is lower than in North-West Europe as reported previously [4]. Together with the ongoing clinical trials for LRRK2 inhibitors, this finding emphasizes the urgent need for more ethnic diversity in PD genetic research.

Disclosure: This study was funded by the Slovak Grant and Development Agency under contracts APVV-22-0279 and by the Slovak Scientific Grant Agency under contract VEGA 1/0712/22.

EPO-298 | First description of c.3478 A>G DYNC1H1, a potentially pathogenic variant in a SMALED sibship

M. Boix Codony[1]; Y. Lin Miao[2]; A. Massot-Tarrus[2]; C. Lombardia Gonzalez[3]; L. Ejarque Vila[3]; J. Roige Buixade[3]

[1]Department of Neurology, Hospital Universitari Sagrat Cor, Barcelona, Spain; [2]Department of Neurology, Hospital Universitari Mutua de Terrassa; [3]Department of Genetics, CATLAB clinical Laboratories, Terrassa, Spain

Background and Aims: Pathogenic variants of the DYNC1H1 gene were first identified in 2012 as the cause of a group of autosomal dominant spinal atrophy affecting the lower limbs (SMALED). We describe a previously unreported variant of unknown significance (VUS) with features to suggest a pathogenic loss of function.

Methods: 3 members of the same sibship were assessed in our centre: a female (p1) with a prior diagnosis of SMA type 4 displaying a full SMALED phenotype, another female (p2) with a milder SMALED phenotype and no previous diagnosis and a male (p3) with CNS features of DYNC1H1 dysfunction since childhood (Intellectual disability, seizures, behavioural disturbance). EMG showed features of dHMN in p1 and p2 while MRI of the lower limbs demonstrated a pattern of muscular atrophy typical for SMALED. Brain MRI for p3 showed focal cortical thickening on the left precentral gyrus; however, those were not diagnostic for a neuronal migration disorder.

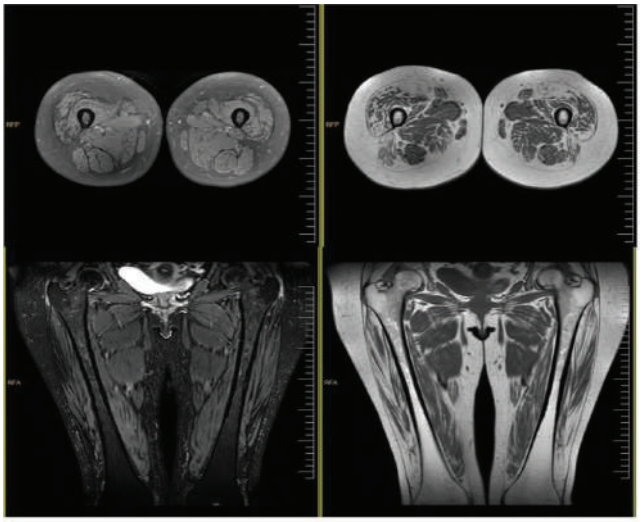
L. Iliopsoas	Femoral	L2-L3	No	No	No	No	No	N	N	N	Reduced
R. Iliopsoas	Femoral	L2-L3	No	No	No	No	No	1-	N	1+	Reduced

EMG findings for p1, demonstrating chronic longstanding denervation. NCS and H reflex were normal.

Results: Genetic testing identified a c.3478 A>G DYNC1H1 VUS in all probands, a single nucleotide polymorphism (SNP) leading to a Thr1163Ala substitution, not currently present in any of the available databases. Protein function modelling using the PolyPhen-2 tool predicted a potentially damaging effect with high confidence.



Thigh MRI images from p2: widespread asymmetrical atrophy and fatty infiltration, sparing the Gracilis and Semitendinosus muscles.

Proband p1 has prominent Genu valgo and pes planovalgus, with significant calf atrophy.

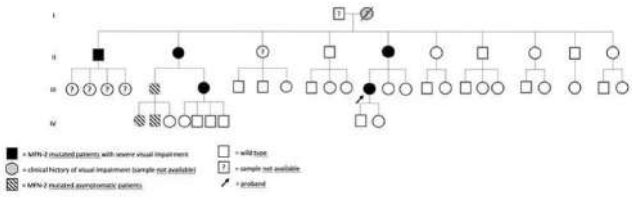
Conclusion: Although the lack of an animal model and limited in-silico modelling does not allow to establish definite pathogenicity according to current ACGM/ACGS scoring, the familiar aggregation, clinical presentation and paraclinical findings would endorse its inclusion on databases at least as a high risk VUS.

Disclosure: Dr Boix Codony has received honoraria (<500€) for contributing to the MAVEN-4 study (MS700568_073), promoted by Merck Serono. The other Authors declare no relevant disclosures.

EPO-299 | Autosomal dominant optic neuropathy without polyneuropathy due to novel c.1988G>A MFN2 mutation

O. Marsico[1]; V. Cianci[2]; A. Pascarella[1]; S. Gasparini[1]; A. Mammì[1]; V. Bova[1]; M. Pasquale[1]; R. Caridi[1]; C. Paleologa[2]; G. Tripodi[2]; D. Abelardo[1]; B. Falcomatà[3]; E. Ferlazzo[1]; U. Aguglia[1]
[1]Department of Medical and Surgical Sciences, Magna Græcia University, Catanzaro, Italy; [2]Regional Epilepsy Centre, Great Metropolitan Hospital, Reggio Calabria, Italy; [3]Department of Ophthalmology, Great Metropolitan Hospital, Reggio Calabria, Italy

Background and Aims: The mitofusin-2 (MFN2) gene (1p36.22) encodes GTPase proteins involved in the fusion of mitochondrial membranes. Numerous MFN-2 mutations have been associated with the axonal form of Charcot–Marie-Tooth (CMT) disease type 2A and hereditary optic atrophies [1, 2]. Here we describe a Southern Italian family with a novel missense c.1988G>A MFN2 variant presenting with painless progressive visual impairment without peripheral motor or sensitive manifestations.
Methods: Twenty-three subjects across three generations underwent serum DNA analysis screening tests with next-generation sequencing (NGS). All MFN2-mutated carriers performed an ophthalmological evaluation with optical coherence tomography (OCT), instrumental evaluation with visual evoked potentials (VEP) and electroneurography (ENG).
Results: Serum DNA analysis revealed the MFN2 c.1988G>A variant in 8 out of 23 (5F, median age: 41.5 years, IQR: 20.5-65) patients (see pedigree chart, figure 1). In silico analysis by PolyPhen-2, Mutation Taster and Align-GVGD predicted this variant as pathogenic. Neurological evaluation revealed decreased visual acuity in 5 subjects (2M, 3F mean age: 49 ± 24.1 years), while no abnormalities resulted in three asymptomatic younger carriers (2M, 1F mean age 32 ± 15.1 years). VEP was bilaterally delayed in all five symptomatic patients. One also showed a bilaterally reduced radial nerve fibre layer thickness on OCT. Motor and sensory nerve conductions on ENG were normal in all mutated subjects.



Pedigree of family with MFN-2 c.1988G>A variant, demonstrating an autosomal dominant inheritance.

Conclusion: Our study illustrated a distinctive clinical presentation marked by adult-onset isolated optic neuropathy without peripheral neuropathy, associated with a newly identified c.1988G>A MFN-2 variant exhibiting autosomal dominant inheritance.
Disclosure: Nothing to disclose.

EPO-300 | Clustering analysis of a cohort of primary mitochondrial diseases patients: Novel associations from the GENOMIT registry

P. Lopriore[1]; S. Mazzucato[2]; G. Cecchi[1]; C. Lamperti[3]; V. Carelli[4]; C. La Morgia[4]; M. Valentino[4]; S. Micera[2]; S. Moccia[2]; M. Mancuso[1]; A. Bandini[2]
[1]*Neurological Institute, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy;* [2]*The BioRobotics Institute and the Department of Excellence in Robotics and Artificial Intelligence, Scuola Superiore Sant'Anna, Pontedera (Pisa), Italy;* [3]*Unit of Medical Genetics and Neurogenetics, Fondazione IRCCS (Istituto di Ricovero e Cura a Carattere Scientifico) Istituto Neurologico Carlo Besta, Milan, Italy;* [4]*Department of Biomedical and Neuromotor Sciences, University of Bologna and IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy*

Background and Aims: Primary mitochondrial diseases (PMDs), characterized by a complex genotype-phenotype interplay, demand innovative approaches for comprehension. This study leverages artificial intelligence (AI), specifically clustering techniques, on a polycentric dataset to reveal genotype-phenotype subgroupings, offering valuable insights to enhance clinical decision-making in the intricate landscape of PMDs.
Methods: The dataset includes 770 PMD patients (female: 54%; age of onset: ≤16 yo 21%, >16yo 79%) from 3 Italian centres, extracted from the GENOMIT international clinical registry (https://genomit.eu/). Pre-processing reduced variables to 71 from 802 using clinical knowledge's discriminative capabilities. Principal Component Analysis (PCA) further condensed them to 44 components. Subsequently, K-means clustering was performed, determining optimal clusters via silhouette score, which ensured homogeneity within clusters while maximizing inter-cluster separation.
Results: The optimal cluster count was three. Distinctive genotype patterns include a prevalence of nuclear DNA (44.4%) and mitochondrial DNA single large-scale deletions (24.1%) in cluster 3, which showed the youngest age of onset (53.4% <16 yo), and SURF1 gene mutations prevalence. Regarding phenotypes, apparently similar clinical diagnosis distribution was found, with multisystem involvement more prevalent in cluster 1 and 3 and more diverse systems involved in cluster 2.
Conclusion: This study used clustering analysis for exploring genotype and phenotype distributions in PMDs. Employing unsupervised clustering on a comprehensive dataset identified distinct PMDs patient subgroups but still heterogenous distribution which needs further interpretation. These preliminary findings hold promise for personalized medicine, marking a significant step in unravelling the complexities of these rare diseases through innovative AI-driven approaches.
Disclosure: The authors have no conflicts of interest to declare.

EPO-301 | Ataxia-neuropathy due to a novel mtDNA mutation affecting processing of MT-ATP6 and MT-CO3, subunits of complex 4 and 5

J. Schaefer; A. Saak; S. Jackson
Department of Neurology, Uniklinikum C.G.Carus, Dresden, Germany

Background and Aims: The ataxia-neuropathy spectrum covers a large variety of diseases and also includes hereditary mitochondrial disorders. In mitochondrial disease, the ataxia typically occurs in combination with other central nervous system features, including epilepsy and cognitive decline, or optic atrophy. The nuclear-encoded mutations in mitochondrial polymerase-gamma (POLG) have been recognized as the commonest cause of mitochondrial disease leading to ataxia-neuropathy, but a considerable proportion of patients harbor mtDNA mutations.
Methods: A 41-year old patient developed progressive gait ataxia, sensory neuropathy, bilateral deafness and mild visual impairment. There was a strong family history of an ataxia-neuropathy-deafness syndrome in 1st degree relatives. After exclusion of POLG-mutations, workup of the clinical presentation and sequencing of the entire mitochondrial DNA were performed in the patient and her affected relatives.
Results: The patient, her mother and all affected sibs were found to carry a novel, homoplasmic mutation in MT-ATP6 (m.9198delC). One sib also fulfilled the Barkhof MRI-criteria for Multiple Sclerosis.
Conclusion: We identified a family with a late-onset ataxia-neuropathy-deafness syndrome caused by a unique mtDNA mutation. The mutation leads to the loss of the Stop Codon in MT-ATP6, and thus can also affect the processing of the polycistronic mRNA transcript, consisting of the MT-ATP6 and the MT-CO3 mRNAs. This scenario is expected to reduce the synthesis of both MT-ATP6 and MT-CO3, a subunit of mitochondrial complex 4.
Disclosure: Nothing to disclose.

EPO-302 | Novel homozygous KCNJ10 mutation in sisters with clinical picture of complex hereditary spastic paraparesis

J. Paulasová Schwabová Jaroslava[1]; J. Paulasová Schwabová[2]; A. Uhrová Mészárosová[3]; M. Kuzmiak[1]; L. Novotná[2]; D. Šafka Brožková[3]; M. Vyhnálek[1]
[1]Department of Neurology, Center of Hereditary Ataxias, Second Faculty of Medicine and Motol University Hospital, Charles University, Prague, Czechia; [2]Department of Pediatric Neurology, Center of Hereditary Ataxias, Charles University, Second Faculty of Medicine and Motol University Hospital, Prague, Czechia; [3]Neurogenetic Laboratory, Department of Pediatric Neurology, Second Faculty of Medicine and Motol University Hospital, Charles University, Prague, Czechia

Background and Aims: Mutations in KCNJ10 gene encoding the inwardly rectifying potassium channel Kir4.1 cause a complex syndrome characterized by seizures, sensorineural deafness, ataxia, intellectual disability, and electrolyte imbalance known as SeSAME/EAST syndrome. One patient with non-syndromic early-onset cerebellar ataxia was described. Until now, hereditary spastic paraparesis has not been considered as part of the clinical spectrum of this channelopathy.
Methods: Genetic and clinical investigations were performed in two sisters (S1 and S2) with early-onset progressive spastic paraparesis (combined with focal dystonia in S2) and their asymptomatic father, referred to the Center of Hereditary Ataxia, Motol University Hospital. Clinical data, medical history, neurological examination, laboratory tests, MRI of the brain, and results of other electrophysiological methods and clinical examinations, were collected.
Results: Targeted next-generation sequencing identified previously described homozygous c. 179T>C, p.(Ile60Thr) variant in the KCNJ10 gene (NM_002241.5) in both sisters (S1,S2), with the same heterozygous mutation in the father. In both patients, the clinical picture was dominated by spastic paraparesis, ataxia and suspected cognitive deficit. Sister S1 suffered from the epilepsy from the age of 6 months with gait disturbances appearing in the first decade. Sister S2 observed first difficulties with running at the age of 11. Audiometry and neuropsychological examination confirmed perceptual hearing loss and cognitive deficit in both siblings. Electrolyte imbalance/tubulopathy was absent.
Conclusion: Our findings broaden the clinical and mutational spectrum of KCNJ10-related disorders and suggest that screening for this gene should be performed in patients suspected of having complex hereditary spastic paraparesis.
Disclosure: No disclosure.

EPO-303 | Spatial perspective taking is impaired in spinocerebellar ataxias

S. Karamazovova[1]; M. Laczo[2]; J. Laczo[2]; J. Paulasova-Schwabova[1]; L. Stovickova[1]; M. Kuzmiak[1]; M. Vyhnalek[1]
[1]Department of Neurology, Second Faculty of Medicine, Centre of Hereditary Ataxias, Charles University and Motol University Hospital, Prague, Czechia; [2]Department of Neurology, Second Faculty of Medicine, Memory Clinic, Charles University and Motol University Hospital, Prague, Czechia

Background and Aims: Perspective taking, the ability to imagine the environment from a different viewpoint, is an essential component of spatial navigation. Animal and functional neuroimaging studies have shown that the cerebellum is important for spatial navigation, but studies in patients with cerebellar disorders, including those with hereditary ataxias, are lacking. The current study aimed to investigate perspective taking in patients with spinocerebellar ataxias (SCA) and Friedreich's ataxia (FRDA).
Methods: We recruited 23 SCA patients 19 FRDA patients from the Centre of Hereditary Ataxias, and 34 age-matched healthy controls (HC). All participants underwent the Perspective Taking/Spatial Orientation Test (PTSOT), an established paper-and-pencil test of perspective taking. Participants were asked to imagine standing at one object and facing another. Their task was to indicate the direction to a third object in a circular diagram.
Results: The SCA group performed significantly worse than the HC group. Specifically, the mean angular error was 63.02° compared to 26.01° ($p < 0.001$), and the mean percentage of responses lying in the correct quadrant of the circular diagram was 46.1% compared to 82.8% ($p < 0.001$), respectively. The FRDA group did not differ significantly from the HC group.
Conclusion: Perspective taking is impaired in SCA but not in FRDA patients. This may be due to more pronounced cerebellar grey matter atrophy in patients with SCA. More research is needed on spatial navigation in patients with cerebellar diseases, as navigation impairment may have a negative impact on patients' mobility and independence.
Disclosure: Supported by Charles University Grant Agency (GAUK) projects No. 224522, 309121, and 226423, and project National Institute for Neurological Research (Programme EXCELES, ID Project No. LX22NPO5107). The authors are members of the European Reference Network for Rare Neurological Diseases (ERN-RND).

EPO-304 | The role of serotonergic gene polymorphisms in functional motor disorder: A case-control association study

T. Serranová[1]; D. Záhoráková[2]; L. Nováková[1]; O. Fiala[3]; Z. Forejtova[1]; M. Slovák[1]; E. Růžička[1]; D. Kemlink[1]
[1]*Department of Neurology and Center of Clinical Neuroscience Charles University, 1st Faculty of Medicine and General University Hospital in Prague, Czechia;* [2]*Department of Pediatrics and Inherited Metabolic Disorders, Charles University, 1st Faculty of Medicine, Czechia;* [3]*Institut Neuropsychiatrické péče, Praha, Czechia*

Background and Aims: Understanding the genetic factors contributing to functional motor disorders (FMD) remains limited. A previous study in a small FMD group ($n=69$) found a link between the T allele variant of the tryptophan hydroxylase 2 gene (TPH2) polymorphism c.-703G>T and an earlier onset of FMD symptoms.1 In our case-control study, we aimed to investigate the association between single-nucleotide polymorphisms (SNPs) within the TPH2 and 5-hydroxytryptamine receptor 2A (HTR2A) genes, both involved in serotonin regulation, and FMD, as well as their impact on the age of symptom onset.
Methods: We genotyped 357 FMD patients and 243 healthy controls for 5 SNPs including rs4570625, rs10784941 for TPH2 gene, and rs6311, rs6313, rs6314 for HTRA2 gene using TaqMan Assays. We performed standard association tests, including allelic, genotypic, dominant, and recessive models, as well as the Cochran–Armitage test for trend using the PLINK statistical package v1.9.2 Linear regression and quantitative association tests assessed the influence of selected SNPs on the age of FMD onset.
Results: We found significant associations between rs4570625 (recessive model, $p=0.007$; nominal) and rs6311 (dominant model, $p=0.0030$; nominal) SNPs with FMD. There was no observed link between these genetic variants and an earlier onset of FMD.
Conclusion: These preliminary findings suggest possible involvement of the serotonergic pathway in FMD, but its link to earlier symptom onset was not confirmed. Results emphasize the need for further research in a broader cohort, considering potential confounding factors such as psychiatric comorbidities.
Disclosure: Supported by NU20-04-00332, NW24-04-00456 and Cooperation by Charles University.

EPO-305 | The first clinical and genetic characterization of patients with cerebrotendinous xanthomatosis in Hungary

N. Varga[1]; P. Balicza[1]; D. Zadori[2]; I. Kapas[3]; A. Salamon[2]; Z. Grosz[1]; L. Szpisjak[2]; M. Harangi[4]; Z. Arányi[5]; P. Klivényi[2]; M. Molnár[1]
[1]*Institute of Genomic Medicine and Rare Disorders, Semmelweis University;* [2]*Department of Neurology, University of Szeged;* [3]*Departmen of Neurology and Stroke, St. Janos Hospital;* [4]*Division of Metabolic Diseases, Department of Internal Medicine, Faculty of Medicine, University of Debrecen;* [5]*Department of Neurology, Semmelweis University*

Background and Aims: Cerebrotendinous xanthomatosis (CTX) is a rare lipid storage disorder caused by mutations in CYP27A1 gene which leads to reduced production of chenodeoxycholic acid (CDCA) and excess of cholestanol, causing a wide spectrum of neurological and non-neurological symptoms.
Methods: We aimed to characterize the patients diagnosed with CTX in Hungary and follow the efficacy of the treatment with CDCA.
Results: We present 9 patients from 6 families (two females and seven males (mean age=44.7±8, range=29-52). Mean age at onset was 24.7±12 years. In 3-3 cases the c.1184+1G>A. and c.819delT rare variants of the CYP27A1 caused the disease. The most common clinical manifestations were cerebellar ataxia, polyneuropathy, cognitive impairment and juvenile cataract. Xanthomas were present only in 22.2%. Of the cases, diverse non-neurological findings (diarrhea, severe atherosclerosis) were observed in five patients. Brain MRI detected T2, FLAIR hyperintensity in the dentate nuclei in all patients. ENG and nerve ultrasound revealed neuropathy in all cases, and suspected intraneural cholesterol accumulation in two. Elevated cholesterol and oxysterols were detected in all cases, but the levels didn't correlate with the severity of the disorder. Six patients are on CDCA supplementation for an average of 38±25 months which resulted in the normalization of the cholesterol level and the stagnation of the ataxia score and polyneuropathy.
Conclusion: CDCA supplementation may reverse the pathophysiological process in patients with CTX, especially if treatment is initiated early in the disease process. Therefore, early diagnosis and treatment are crucial in preventing clinical deterioration.
Disclosure: Nothing to disclose.

EPO-306 | Abstract withdrawn

EPO-307 | SCA27B – New ataxia with late onset and response to 4-aminopyridine – First 14 cases diagnosed in the Czechia

M. Vyhnalek[1]; J. Paulasova-Schwabova[1]; M. Kuzmiak[1]; Z. Blichova[1]; E. Vyhnalkova[2]; S. Karamazovova[1]; J. Jerabek[1]; L. Stovickova[3]; A. Zumrova[3]; Z. Musova[2]
[1]*Department of Neurology, Center of Hereditary Ataxias, Second Faculty of Medicine and Motol University Hospital, Charles University, Prague, Czechia;* [2]*Department of Biology and Medical Genetics, Center of Hereditary Ataxias, Second Faculty of Medicine and Motol University Hospital, Charles University, Prague, Czechia;* [3]*Department of Paediatric Neurology, Center of Hereditary Ataxias, Second Faculty of Medicine and Motol University Hospital, Charles University, Prague, Czechia*

Background and Aims: SCA27B is a newly described autosomal dominantly inherited late-onset ataxia caused by the expansion of GAA repeats in the first intron of the FGF14 (Fibroblast growth factor 14) gene. Recently, an excellent response to 4-aminopyridine has been published.
Methods: 28 patients followed at the Center of Hereditary Ataxia, Motol University Hospital with chronic degenerative ataxia of

unknown origin with adult-onset were molecular-genetically examined for the presence of the FGF14 GAA repeat expansion.

Results: The expansion in the FGF14 gene within the pathological range (GAA≥300) was found in 11 (39%) patients, and 3 patients (11%) had a borderline repeat length (GAA250-299) with presumed incomplete penetrance. Eight patients had a positive family history of ataxia in a parent or sibling, and 6 cases were sporadic. The mean age of onset was 52 years. All patients had progressive cerebellar syndrome. Four patients (37%) presented with a parkinsonian syndrome. Significant fluctuations of symptoms during the day were present in 9 patients. Treatment with 4-aminopyridine was initiated in 5 patients, with an excellent effect in 4 of them.

Conclusion: SCA27B is a newly described common cause of hereditary late-onset ataxia in the Czechia. Based on the estimated frequency in the Czech population, we have included targeted molecular genetic testing for SCA27B as a standard investigation in patients with adult-onset chronic ataxia. This step is important not only for accurate diagnosis but also because of the significant therapeutic benefit observed with 4-aminopyridine treatment in SCA27B cases.

EPO-308 | Abstract withdrawn

Epilepsy 2

EPO-309 | Therapeutic drug monitoring of antiseizure medications through quantitative dried blood spot

C. Cancellerini[1]; A. Caravelli[2]; E. Esposito[2]; M. Soldà[2]; L. Vignatelli[2]; F. Bisulli[1]; L. Licchetta[2]; J. Fiori[3]

[1]*Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy*; [2]*IRCCS, Istituto delle Scienze Neurologiche di Bologna, Full Member of the European Reference Network for Rare and Complex Epilepsies (EpiCARE), Bologna*; [3]*Department of Chemistry "G. Ciamician", University of Bologna, Italy*

Background and Aims: Therapeutic drug monitoring (TDM) of antiseizure medications (ASMs) is an essential tool for persons with epilepsy (PWE). Traditional venipuncture for TDM requires high-volume blood and physically mandates patients at hospital1,2. Microsampling requires lower-blood volume through less painful and invasive fingerprick offering a sampling methodology potentially performed at-home. This study aimed to validate the extraction method of ASMs from a quantitative Dried-Blood-Spot microsampling (qDBS)2.

Methods: Carbamazepine (CBZ), lacosamide (LCS), levetiracetam (LEV) lamotrigine (LTG) and valproic acid (VPA) were considered. The quantification of ASMs from 10µl qDBS-device by UHPLC-Mass spectrometry (UHPLC-MS/MS) was performed through an extraction technical validation, according to EMA guidelines3. Bland-Altman analysis and Passing-Bablok regression were performed to compare ASMS concentrations in qDBS collected with leftover venous blood and plasma samples.

Results: The method was proven accurate and precise using the chosen extraction procedure. Indeed, intra and inter-assay reproducibility analyses showed accuracy and precision ≤15% across the calibration range (0.4-15µg/ml CBZ; 0.5-10µg/ml LCS; 0.5-20µg/ml LTG; 1-80µg/ml LEV; 10-120 µg/ml VPA). Recovery was found >85 % and matrix effect <10% for most of the ASMs considered. Stability was tested at 7, 15, 30 days of storage, showing mutual robustness at 7-days room-temperature. Preliminary statistics via Bland-Altman analysis and Passing-Bablok regression indicated a linear correlation for most of the ASMs.

Conclusion: A UHPLC-MS/MS assay was developed and validated according to EMA guidelines for quantifying ASMs-qDBS3. Advantage of this validation allows the potential for utilizing the new microsampling qDBS devices, providing a patient-friendly approach to blood sampling even at-home in PWE.

EPO-310 | Repetitive transcranial magnetic stimulation in refractory and super-refractory status epilepticus: A systematic review

C. Algoet; P. Boon; S. Carrette; R. Raedt; A. Mertens; K. Vonck

4BRAIN, Department of Neurology, Ghent University Hospital, Ghent, Belgium

Background and Aims: Currently, there are no guidelines available on the treatment of refractory status epilepticus (RSE) and super-refractory status epilepticus (SRSE). Therefore, off-label treatments are often used. We performed a systematic review regarding the efficacy of repetitive transcranial magnetic stimulation (rTMS) as a treatment in RSE/SRSE.

Methods: We systematically searched EMBASE, PubMed, Opengre.eu, CENTRAL and conference abstracts from AES and EAN meetings (2005-2023) to identify trials investigating the use of rTMS in RSE and/or SRSE. The following parameters were collected: RSE/SRSE etiology, RSE/SRSE classification, RSE/SRSE abortion, latency to abortion, duration of RSE/SRSE before rTMS.

Results: We identified 32 patients, whereof 15 with epilepsia partialis continua (EPC). 19/32 were classified as focal motor SE, 7/32 as non-convulsive SE and 3/32 as convulsive SE. Cortical malformations were the most frequent cause (10/32), followed by stroke (5/32) and genetic mutations (5/32). NORSE accounted for eight cases. For three and four patients respectively, data were lacking regarding classification and etiology. In 81.25% (26/32) of patients rTMS resulted in cessation of RSE/SRSE. After rTMS, two deaths (6.25%) were reported but considered unrelated to rTMS and attributed to the underlying disease. Median duration of acute/subacute RSE/SRSE and RSE/SRSE in EPC patients before rTMS was 44 days

(range: 0-140 days) and 128 days (range: 28-7300 days) respectively. After rTMS, the latency to abortion ranged from 0-4 days.
Conclusion: rTMS interrupts RSE and SRSE in 81.25% of patients. Data originates from studies graded as level IV with a high risk of reporting bias, warranting further studies.
Disclosure: Nothing to disclose.

EPO-311 | Deep learning-based automated detection of focal interictal epileptiform discharges on electroencephalogram

C. Bour[1]; S. Groppa[2]
[1]*Neurology Department No. 2, "Nicolae Testemitanu" University, Chisinau, Republic of Moldova;* [2]*Institute of Emergency Medicine, Chisinau, Republic of Moldova*

Background and Aims: The lack of specialists in the field, combined with technical and scientific progress, is stimulating interest in developing new methods for diagnosing, classifying, and treating focal epilepsy. In this study, we focus on the use of deep learning neural networks (DLNN) for epileptic discharges detection on electroencephalography during the interictal phase.
Methods: The dataset used in this research comprises interictal electroencephalographic (EEG) recordings from thirteen patients with a diagnosis of focal epilepsy, provided by the Institute of Emergency Medicine, Republic of Moldova. Data preprocessing techniques were applied to EEG signals stored in European Data Format files. This study employed convolutional neural networks (CNNs) and long short-term memory (LSTM) networks, which are most commonly used in the field of EEG processing. The focal discharges on EEG were split randomly into training, validation, and test sets. The accuracy, precision, and F1-score were evaluated on the training, validation, and test sets.
Results: The study had an average accuracy of 95.7%, precision of 0.997 and an average F1 score of 0.94 on the training, validation and test sets.
Conclusion: This study substantiates the potential of DLNN in accurately identifying epileptic seizures through EEG analysis. Nonetheless, it underscores the necessity for the compilation of an extensive learning database for the algorithm, potentially introducing an additional layer of complexity to the deployment process.
Disclosure: Nothing to disclose.

EPO-312 | Stereoencephalography-guided thermocoagulation: Experience in our center

A. Celdrán de Castro[1]; H. Kevin Gil[1]; M. Garcés-Sánchez[1]; A. Gutiérrez[2]; R. Conde[2]; V. Vicente[1]
[1]*Refractory Epilepsy Unit, Neurology Service, Member of ERN EpiCARE, University Hospital La Fe, Valencia, Spain;* [2]*Refractory Epilepsy Unit, Neurosurgery Service, Member of ERN EpiCARE, University Hospital La Fe, Valencia, Spain*

Background and Aims: Stereoelectroencephalography-guided thermocoagulation (SEEG-guided TC) stands as an advanced therapeutic modality in the management of refractory focal epilepsy, boasting a 25% estimated seizure freedom rate, and a >50% seizure reduction rate in 58% at one year of follow-up in some series. We conducted a retrospective analysis of outcomes in our centre.
Methods: We retrospectively analyzed patients undergoing SEEG-guided TC at Hospital Universitario y Politécnico La Fe, Valencia, Spain´s Refractory Epilepsy Unit, spanning from January 2019 to January 2023. Patients with at least one year of follow-up were only included. Clinical data were systematically extracted using a standardized collection form from an electronic database.
Results: The study included 41 patients (20 males, 48.8%) with a median age of 34 (9-63). The mean follow-up duration was 16.42 months (12-36). At the last follow-up, 19 patients (46.64%) remained seizure-free, and the responder rates at 75% and 90% were 65.85% and 60.9%, respectively. In 10 out of 13 patients (76.9%) with follow-ups exceeding two years, a seizure reduction rate of >90% was maintained. Medication was modified for only one patient, with adjustments made in two others, while the remainder maintained their existing therapeutic schedules. Postoperative permanent complications were observed in 1 patient as hemianopsia (2.4%).
Conclusion: In appropriately selected patients, SEEG-guided TC emerges as a promising intervention, demonstrating the potential for sustained outcomes, especially when combined with pharmacological therapy.
Disclosure: Nothing to disclose.

EPO-313 | First experience with cenobamate in the treatment of paediatric patients with epilepsy: A single-centre study

P. Danhofer; O. Horák; M. Ryzí; K. Česká; K. Španělová; H. Ošlejšková
Department of Paediatric Neurology, Faculty of Medicine, Masaryk Center for Epilepsy Brno, University and University Hospital Brno, Czechia

Background and Aims: Cenobamate is a new anti-seizure drug currently indicated for the adjunctive treatment of focal seizures with or without secondary generalization in adult patients with epilepsy without adequate control despite prior treatment with at least 2 antiepileptic drugs.

Methods: Retrospective evaluation of paediatric patients treated at the Department of Paediatric Neurology, Faculty of Medicine, Masaryk University and University Hospital Brno, Czechia starting CNB between 4/2023 and 12/2023. We evaluated dosing and efficacy on seizures in relation to the type of epilepsy.

Results: A total of 16 patients with a mean age of 13.7 years (min 7 years; max 17 years), 8 boys and 8 girls, were included in the study. 6 patients were diagnosed with focal epilepsy, 4 patients with multifocal epilepsy, and 6 patients with LGS. Before CNB deployment, patients tried an average of 2.5 ASMs (min 1, max 4). Patients older than 12 years were dosed at 150-200mg/day, younger patients were titrated to 100mg/day. Seizure reduction of more than 75% was achieved in 5 of 16 patients (31.2%), and seizure reduction of more than 50% was achieved in 8 of 16 patients (50.0%). Interestingly, 4 of the 6 LGS patients were included in the responder group, one of whom experienced a transient 3-month seizure-free period.

Conclusion: The results of our cohort are promising and show that even pharmacoresistant patients with DEE can benefit from CNB medication. Further data regarding pediatric patients and longer follow-up will definitely be beneficial.

Disclosure: Nothing to disclose.

EPO-314 | Epilepsy and co-morbid depression in Northern Rwanda

D. Teuwen[1]; J. Kayirangwa[2]; I. Garrez[1]; J. Umwiringirwa[3]; T. Leers[4]; F. Sebera[5]; P. Boon[1]; P. Dedeken[6]

[1]Department of Neurology, University Hospital, Ghent, Belgium; [2]Department of Mental Health, Ruhengeri Hospital, Musanze, Rwanda; [3]Division of Education, Training and Research, King Faisal Hospital Rwanda, Kigali, Rwanda; [4]Dataroots, Leuven, Belgium; [5]Department of Neurology, Ndera Neuropsychiatric Teaching Hospital, Kigali, Rwanda; [6]Department of Neurology, Heilig Hart Ziekenhuis, Lier, Belgium

Background and Aims: In persons living with epilepsy (PwE), depression is the most frequent co-morbidity. The prevalence of epilepsy in Rwanda ranges between 2.9-7.6%. In a tertiary hospital, depression is observed in more than 22% of PwE. This prospective interventional study determined the prevalence and incidence of depression in PwE in three rural villages in Northern Rwanda.

Methods: PwE enrolled between June 2018 and December 2018. At each study visit, PwE were screened for depression with Patient Health Questionnaire-9 (PHQ-9). If positive, the Hamilton Depression Rating Scale (HDRS) was administered to confirm diagnosis of depression. PwE with moderate to severe depression (MSD), were followed for one year and started on anti-depressant treatment. We report depression prevalence and incidence, baseline characteristics of PwE, and clinical outcomes of PwE with and without depression.

Results: Of 304 PwE enrolled, 25 (8.2%) were diagnosed with MSD during the study. At baseline visit, prevalence of any depression and MSD was 27% and 4.3% respectively. Incidence of any depression or MSD was 245 and 48/1000 patient-years. Improvement in seizure frequency was observed in both PwE with and without depression. There was a significant reduction in HDRS score for PwE with depression from 22.8 at baseline to 7.9 after 12 months, resulting in 94.7% of PwE having no or mild depression.

Conclusion: The Kinyarwanda versions of PHQ-9 and HDRS were successful in screening and diagnosing depression in PwE. Treatment of epilepsy and co-morbid depression resulted in improved outcomes, implementation of depression screening in daily neurology practice in Rwanda is warranted.

Ieme Garrez and Fidèle Sebera received research grants through his institution.

EPO-315 | Effects on memory of chronic hippocampal stimulation in patients with refractory mesial temporal epilepsy

E. Ray Chaudhuri[1]; I. Stavropoulos[2]; D. Wang[3]; M. Cloherty[4]; E. Demosthenous[1]; R. Selway[3]; A. Valentín[2]

[1]Faculty of Life Sciences and Medicine, King's College London, London, England; [2]Department of Clinical Neurophysiology, King's College Hospital, London, England; [3]Department of Neurosurgery, King's College Hospital, London, England; [4]Department of Clinical Neuropsychology, King's College Hospital, London, England

Background and Aims: Chronic, continuous, bilateral, hippocampal stimulation (CHS) is a novel treatment for refractory epilepsy in patients with bilateral independent hippocampal seizure onset unsuitable for resective surgery. This report will present a review of the current use of hippocampal stimulation (Hip-DBS) in clinical practice and the effects of CHS on the memory of two patients with an average of 10 focal impaired awareness seizures per month (pre-CHS).

Methods: Two patients (K1 and K2) were implanted with depth electrodes in both hippocampi for CHS in 2016 and 2017 at King's College Hospital (KCH). Both had continuous bilateral hippocampal stimulation (amplitude 1-1.5mA, pulse duration 300-360 microseconds, frequency 130 Hz) for more than seven years. Neuropsychological assessment was performed pre-CHS: patient K1 had a full-scale IQ (FSIQ) of 96 and patient K2 of 98. We also conducted a review of the use of Hip-DBS and noted outcomes on seizure frequency and memory.

Results: At the follow up at 67 and 84 months, both patients had a marked (>90%) decrease in seizure frequency post CHS. Neuropsychometry found mildly less efficient memory in the context of low mood for patient K1 (FSIQ = 99) and potential improvement in verbal memory for patient K2 with other parameters stable (FSIQ = 103). This is in general agreement with other studies.

Conclusion: Chronic, continuous, bilateral, hippocampal stimulation has not shown clear adverse effects on memory in the literature and

in the two patients implanted at KCH. The reduction of seizures and interictal activity by CHS may instead lead to an improvement in memory.

Disclosure: Nothing to disclose.

EPO-316 | Translation and validation of an epilepsy screening instrument for use in resource-poor settings

E. Darkwa[1]; S. Asiamah[1]; E. Awini[2]; C. Sottie[2]; A. Godi[1]; A. Akpalu[1]; J. Williams[3]; J. Cross[4]; J. Sander[5]; C. Newton[6]; A. Sen[6]; A. Danso-Appiah[1]; P. Adjei[1]

[1]University of Ghana; [2]Ghana Health Service; [3]Dodowa Health Research Centre; [4]UCL Ormond Street Institute of Child Health; [5]UCL Queen Square Institute of Neurology; [6]Oxford Epilepsy Research Group, Nuffield Department of Clinical Neurosciences, John Radcliffe Hospital, Oxford, UK

Background and Aims: The prevalence of epilepsy in sub-Saharan Africa varies considerably and there is little data from peri-urban areas. More community-based studies are required to understand the true burden of epilepsy in these areas and access to Healthcare.

Methods: We developed a 17-item epilepsy screening instrument by modifying validated English language questionnaires. We included questions on convulsive and non-convulsive seizures. Language experts translated and back-translated the survey instrument to two languages spoken in this region: Asante Twi and Dangme. Cases were persons with epilepsy attending healthcare facilities where these languages are spoken. Controls were unaffected relatives of cases or people attending the healthcare centers for other medical conditions.

Results: A total of 100 (50 cases and 50 controls) for Twi and 140 (70 cases and 70 controls) for Ga-Dangme were recruited. The sensitivity and specificity of the questionnaire were: Stage 1; (Twi 98 % and 92%, Ga-Adangme 100% and 80% respectively) and stage 2 (Twi 96% and 94%, Ga-Adangme 98.6% and 85.7% respectively). The two versions reliably indicated epilepsy with positive predictive values of 92.5% and 83.3% for Twi and 83.8% and 87.3% for Ga-Dangme at stages 1 and 2 respectively.

Conclusion: The current data shows that our questionnaire has good validity for the two test languages and can be used for community-based epilepsy surveys in Ghana. The questionnaire can be adapted for other resource-poor settings, although there will need to be iterative in-country testing to ensure validity is maintained.

Disclosure: Nothing to disclose.

EPO-317 | The association of excessive daytime sleepiness with quality of life and mood in adults with epilepsy

E. Balian[1]; L. Atabekyan[1]; N. Nadryan[1]; H. Hovakimyan[2]; Y. Tunyan[1]; S. Khachatryan[1]

[1]Department of Neurology and Neurosurgery, National Institute of Health, Yerevan, Armenia; [2]Somnus Neurology Clinic, Yerevan, Armenia

Background and Aims: Excessive daytime sleepiness (EDS) is considered common in adults with epilepsy (AWE). EDS in AWE is multifactorial, including antiseizure medication (ASM) effects, seizures, poor sleep quality and accompanying affective states. We aimed to study the interconnection of EDS with health-related quality of life (HRQOL) and mood among AWE.

Methods: AWE were examined for EDS using the Epworth Sleepiness Scale (ESS) and divided into two groups: Non-EDS - ESS score <9, EDS - ESS score ≥9. HRQOL was evaluated by SF-36 questionnaire, consisting of 8 domains (Table 1). Sleep quality was assessed using Pittsburgh Sleep Quality Index (PSQI). Validated Armenian versions were used. Hamilton scales for anxiety (HAMA) and depression (HAMD) were also used. Mann-Whitney U test was used for statistical analysis.

Results: We included 169 AWE (mean age-35.3 (18-71) years, males-52.1%), 30 (21.6%) of whom had EDS by ESS. No significant difference according to ASM status was found for EDS (ESS 5.5/4.7, $p > 0.05$). For the groups NonEDS/EDS - BMI = 23.7/25.3kg/m2 ($p > 0.05$), means for SF-36 domains for the groups are presented in Table 1. AWE with EDS had significantly lower levels of HRQOL. AWE with higher scores of the ESS had higher scores of anxiety and depression: HAMA-13.45/20.3 ($p < 0.05$), HAMD-11.5/18 ($p < 0.05$), and poorer sleep quality: PSQI-7.5/9.9 ($p < 0.05$).

SF-36 Domains	Non-EDS	EDS	*p*
D1 Physical Functioning	70.3	58.3	<0.05
D2 Role-Limitations Due to Physical Health	45.1	21.2	<0.05
D3 Role Limitations Due to Emotional Problems	46.4	24.6	<0.05
D4 Energy/Fatigue	55	39.2	<0.05
D5 Emotional Well-Being	55.6	40.5	<0.05
D6 Social Functioning	66.5	45.3	<0.05
D7 Pain	68.2	44.7	<0.05
D8 General Health	49.8	40.3	<0.05

EDS- Excessive daytime sleepiness

Health-related quality of life measured by SF-36 questionnaire in adults with epilepsy with and without EDS.

Conclusion: We found EDS in one-fifth of AWE and it seemed not associated with ASM. AWE with EDS, had more depression and anxiety, their HRQOL was significantly lower. Our study underscores the importance of considering multiple factors behind EDS' significant impact on quality of life in AWE.

Disclosure: Nothing to disclose.

EPO-318 | Status epilepticus as a complication of COVID-19 vaccination: A literature review

G. Evangelista; F. Dono; M. Dasara; C. Corniello; S. Sensi
Department of Neuroscience, Imaging and Clinical Science, "G. D'Annunzio" University of Chieti-Pescara, Chieti, Italy

Background and Aims: Status Epilepticus (SE) stands as a prominent neurological emergency, showing a mortality rate of approximately 20%. Since February 2021, a worldwide vaccination campaign has been settled to fight against the Coronavirus 19 disease (COVID-19) pandemic. Several possible vaccine-related adverse events have been identified including neurological manifestations. SE is beginning to surface in literature as an emergent condition in COVID-19-vaccinated individuals, though defined reasons accounting for this correlation are still missing.
Methods: We performed a systematic search of the literature to identify the consistency of the association between the SARS-CoV-2 vaccine and the SE onset. The following databases: are PubMed, Google Scholar, and EMBASE. Patient data, encompassing demographics, comorbidities, history of epilepsy, type, and dosage of SARS-CoV-2 vaccine, SE semiology, treatment, and prognosis were extracted.
Results: Six studies with a total of seven patients were included. Four patients showed non-convulsive SE, 3 a convulsive one. Four patients received the mRNA-1273 (Moderna) vaccine, 2 patients the BNT162b2 (Pfizer/Biotech), and 1 patient the ChAdOx1-s (AstraZeneca) vaccine. The first vaccine dose (5/7, 71.4%) emerged as the most frequently associated with SE onset which manifested at an average of 4.5 days (±3.4) post-vaccination. Five patients presented a refractory SE and needed continuous intravenous anesthetic drug administration. Resolution of SE was achieved in all cases.
Conclusion: Status Epilepticus appears to be a rare complication associated with both SARS-CoV-2 vaccines. Additional studies are needed to ascertain the potential association between the Sars-CoV-2 vaccine and status epilepticus.
Disclosure: None.

EPO-319 | Patient outcomes in KCNQ2 developmental and epileptic encephalopathy (KCNQ2-DEE): Systematic literature review

G. Maclaine[1]; M. Potashman[2]; D. Pawar[3]; S. Sharma[3]; K. Rudell[3]; J. Lerner[2]; V. Coric[2]; A. Berg[4]; J. Millichap[5]; G. L'Italien[2]
[1]Biohaven Bioscience Ireland Ltd, Dublin, Ireland; [2]Biohaven Pharmaceuticals, Inc, New Haven, CT, USA; [3]Parexel International Limited, London, UK; [4]Department of Neurology, Northwestern University Feinberg School of Medicine, Chicago, IL, USA and DEE-P Connections, Washington, DC, USA; [5]Department of Neurology, Northwestern University Feinberg School of Medicine, Chicago, IL, USA and Precision Epilepsy, PLLC, Chicago, IL, USA

Background and Aims: We conducted a systematic literature review to describe seizure and non-seizure outcomes in KCNQ2-DEE.
Methods: A systematic literature search was conducted, applying Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, to identify and describe seizure and non-seizure outcomes in KCNQ2-DEE patients ≤18 years of age. Case reports/series, observational studies, non-randomised and single arm trials, and surveys were eligible for inclusion. No geographical or publication time restrictions were applied.
Results: Of 92 publications identified, 74 reported individual patient data, of which 41 (55.4%) were case reports or series, from 363 patients. Most patients, where age data available, (42/137, 30.7%) were aged 2-5 years. Seizures had initial onset in the first week of life for 328 (90.4%) patients. Seizure frequency, where data were available, was "multiple daily" for most patients. Seizure freedom was reported for 202 patients with cumulative proportions seizure free of 57% and 66.7% by ages 1 and 2 years respectively. Seizures recurred in 33 of 176 (18.8%) individuals. In 19 individuals for whom data were available, time to recurrence ranged from <1 month to 5 years. Non-seizure outcomes, predominantly developmental and often other neurological and medical, were reported in 348 individuals, among whom communication issues were specified for 63 (18.1%). Other reported non-seizure issues included vision, breathing and bulbar function (typically feeding/eating difficulties), orthopaedic and sleep.
Conclusion: Although seizure control is often achieved in KCNQ-DEE in early childhood or infancy, most patients experience various ongoing challenges related to development, including communication.

DP, SS and KR are employees of Parexel International who conducted the study on behalf of Biohaven Pharmaceuticals, Inc.

EPO-320 | Disability and depression in children and adolescents with epilepsy at a tertiary hospital in Rwanda

I. Garrez[1]; D. Kajeneza[2]; K. Touré[3]; F. Sebera[4]; J. Umwiringirwa[5]; G. Umuhoza[5]; P. Dedeken[6]; P. Boon[1]; D. Teuwen[1]
[1]Department of Neurology, Ghent University Hospital, Ghent, Belgium; [2]Department of Internal Medicine, University Hospital Center, Kigali, Rwanda; [3]Centre Hospitalier Universitaire de FANN, Faculty of Medicine, Pharmacy and Odontology, Université Cheik Anta Diop, Dakar, Sénégal; [4]Department of Neurology, Ndera Neuropsychiatric Teaching Hospital, Kigali, Rwanda; [5]Division of Education, Training, and Research, King Faisal Hospital Rwanda, Kigali, Rwanda; [6]Department of Neurology, Heilig Hart Ziekenhuis, Lier, Belgium

Background and Aims: Epilepsy is one of the most common neurological diseases in children and adolescents. The disorder affects a child's development and increases mental health diseases. We assessed the impact of epilepsy on disability and depression in children and adolescents living with epilepsy (CwE) in Rwanda.

Methods: In 2018, 74 CwE aged ≤20 years were enrolled in an observational study during their monthly neurology consultation at the tertiary Ndera Neuropsychiatric Teaching Hospital. During follow-up in 2022, CwE or their caregivers were contacted to assess disability and to screen for depression using the Kinyarwanda Washington Group-Short Scale (WG-SS) and Patient Health Questionnaire-9.

Results: In 2022, only 29 CwE (39.2%) had continued routine hospital visits. Thirty CwE or caregivers (40.5%) were identified at home and 15 (20.3%) cases remained unascertained. Among 59 CwE, five had died yielding a mortality rate of 24.2/1000 person-years. Mean age of the remaining 54 (46.3% female) was 12.6 ± 5.6 years. Mean age at seizure-onset was 5.7 ± 4.8 years. Generalized-onset seizures occurred in 59.3%, with 97% motor-onset. Focal-onset seizures occurred in 37.0%, with 42.9% exhibiting focal-to-bilateral tonic-clonic seizures. WG-SS revealed a handicap in three (54%) and four domains (23%) and the cognitive domain was mostly affected (71%). Mild and moderate-to-severe depression was present in 38.1% and 14.3%, respectively.

Conclusion: This study documents prominent disability and mental health challenges in Rwandan children and adolescents with epilepsy. Improved healthcare accessibility and holistic care are required to manage disability and prevent mortality.

EPO-321 | Spanish validation of the Epilepsy Self-Stigma Scale

I. Manzanares; M. Olivera; M. Centeno; M. Khawaja; A. Donaire; M. Carreño; E. Conde-Blanco
Hospital Clínic de Barcelona, IDIBAPS, EPICARE

Background and Aims: The Epilepsy Self-Stigma Scale (ESSS) has been developed in Japan for patients with epilepsy (PWE). We aimed to validate the scale into Spanish and examine its reliability.

Methods: We validated the ESSS to the Spanish version (ESSS-S). Recruitment took place in September 2023. PWE also completed the Rosenberg Self-Esteem Scale (RSES), the Hospital Anxiety and Depression Scale (HADS), and the 10-item questionnaire (QOLIE-10).

Results: 260 study questionnaires were completed. A two-factor analysis explained 61.3% of the total variance: factor 1 "perceived discrimination" Cronbach's $\alpha = 0.80$ and factor 2 "social isolation" 0.75. External validity was tested with both anxiety (Cronbach's $\alpha = 0.86$) and depression (Cronbach's $\alpha = 0.86$) sets of the HADS; stigma using the RSES (Cronbach's $\alpha = 0.92$), and quality of life with QOLIE-10 (Cronbach's $\alpha = 0.90$). Perceived discrimination scores were associated with higher anxiety/depression scores ($r = 0.53/0.54$; $p < 0.001$), lower self-esteem (-0.53; $p \leq 0.001$) and lower quality of life ($r = -0.66$; $p < 0.001$). Social isolation scores were also associated with higher anxiety/depression scores ($r = 0.41/0.33$; $p < 0.001$), lower self-esteem (-0.34; $p \leq 0.001$), and lower quality of life ($r = -0.35$; $p < 0.001$). Perceived discrimination scores were inversely correlated with age ($r = -0.12$, $p = 0.045$) and directly with epilepsy duration ($r = 0.20$, $p = 0.001$), while social isolation scores were directly associated with epilepsy duration ($r = 0.15$, $p = 0.013$). The retest was stable ($r = 0.77$) with strong internal validity (ICC = 0.87).

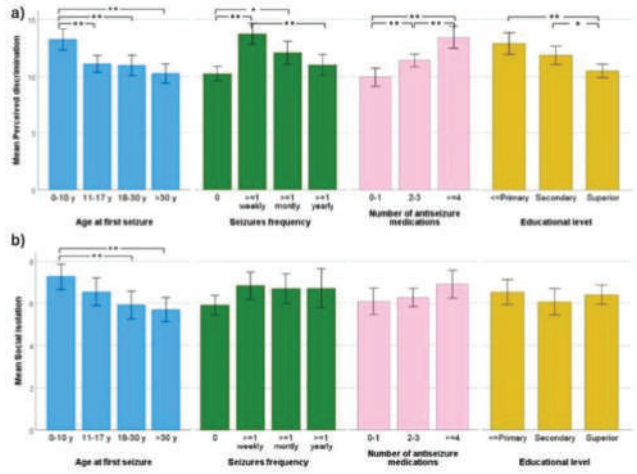

FIGURE 1 Group comparison of Perceived discrimination scores (a), and Social isolation scores (b).

Stigma factors	HADS anxiety	HADS Depression	Rosemberg self-esteem	Qolie-10 quality of life
Perceived discrimination r (p)	0.53 (<0.001)	0.54 (<0.001)	-0.53 (<0.001)	-0.66 (<0.001)
Social isolation r (p)	0.41 (<0.001)	0.33 (<0.001)	-0.34 (<0.001)	-0.35 (<0.001)
Mean (sd)	7.2 (4.4)	5.2 (4.6)	19.1 (6.7)	35.4 (9.2)

TABLE 2 Correlation of stigma factors with anxiety, depression, self-esteem and quality of life, and descriptive. HADS: Hospital anxiety and depression scale.

Conclusion: The E-ESSS is a valid and reliable tool for the assessment of self-stigma in PWE among Spanish speakers.
Disclosure: No disclosures.

EPO-322 | Family history of epilepsy and seizure disorders and age of epilepsy onset in focal cortical dysplasia

I. Mihailović[1]; M. Kovačević[1]; M. Kovačević[2]; D. Sokić[1]; D. Sokić[2]; A. Ristić[1]; A. Ristić[2]; I. Berisavac[1]; I. Berisavac[2]; M. Ercegovac[1]; M. Ercegovac[2]; T. Švabić-Međevdović[1]; T. Švabić-Međevdović[2]; N. Vojvodić[1]; N. Vojvodić[2]
[1]*Neurology Clinic, University Clinical Center of Serbia;* [2]*Faculty of Medicine, University of Belgrade*

Background and Aims: Previous studies have established the familial occurrence and early age of epilepsy onset as predictors of genetic epilepsy but have not evaluated the rate of their occurrence based on structural epilepsy etiology. Our study determines the rate of familial occurrence and age of epilepsy onset (AEO) in patients with FCD compared to patients with known acquired causes of focal epilepsy (FE).
Methods: We retrospectively analyzed 965 patients with FE evaluated in Neurology Clinic, University Clinical Center of Serbia and identified 88 patients with radiologically defined focal cortical dysplasia (FCD). 272 patients with acquired FE (AFE) constituted the control group. Data were obtained from patient records, including sociodemographic data, AEO, family history (FH) and FE lobar diagnosis. Statistical analysis was performed in SPSS version 23.
Results: FCD patients constituted 29.7% of evaluated patients. Mean age at the disease onset was 15.06±13.22 and 20.21±14.80 years in FCD and AFE group, respectively. Positive FH was present in 10 (11.4%) FCD patients and 27 (10.7%) AFE patients, without statistically significant difference ($p=0.85$) and without difference in number or degree of relatives with epilepsy (RWE) (12 RWE in FCD vs. 30 in AFE, $p=0.38$). Disease onset was significantly earlier in patients with FCD and positive FH ($p<0.001$), especially in those with two or more relatives with epilepsy ($p=0.01$) and with insular or posterior quadrant epilepsy ($p<0.001$).
Conclusion: Positive family history of epilepsy and presence of FCD are associated with earlier disease onset due to presumably higher genetic burden, which should be further evaluated by detailed genetic analysis.
Disclosure: The authors have nothing to disclose.

EPO-323 | Antiseizure medication adherence during the COVID-19 Pandemic in South Korea: National Health Insurance data analysis

Y. Kim[1]; Y. Jang[1]; H. Lee[1]; G. Park[2]; Y. Yoon[2]; S. Bong[2]; S. Hwang[3]; H. Son[4]; S. Lee[1]; K. Lee[2]; K. Park[5]
[1]*Department of Neurology, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Republic of Korea;* [2]*Department of Statistics, Seoul National University, Seoul, Republic of Korea;* [3]*Departments of Neurology, Ewha Womans University Mokdong Hospital, Seoul, Republic of Korea;* [4]*Department of Neurology, Eunpyeong St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea;* [5]*Department of Neurology, Seoul National University Hospital Healthcare system Gangnam Center, Seoul National University College of Medicine, Seoul, Republic of Korea*

Background and Aims: Considering the decline in prescription rates for chronic conditions throughout the COVID-19 pandemic, this study was conducted to assess anti-seizure medication (ASM) adherence among epilepsy patients during the pandemic.
Methods: Prevalent groups were defined by epilepsy patients of 2018, 2019, and 2020. Chronic groups of year 2018, 2019, and 2020 were defined by prevalent patients of each year who were prescribed with ASM annually from 2002 to 2010. Acute groups of year 2018, 2019, and 2020 were defined by prevalent patients of each year who were first diagnosed with epilepsy two years ago. For each group, the proportion of days covered (PDC) was analyzed to assess ASM compliance. Patients with ASM adherence more than 0.95 of PDC was categorized as the good compliance group, and others as the poor compliance group. Multifactor analyses were conducted in the prevalent groups.
Results: In 2020, 210.314, 72.051, and 30.097 patients were included in the prevalent, chronic, and acute group respectively. When

compared to the previous year, ASM adherence of the prevalent and chronic group has increased in 2019 and 2020. However, for the acute group, ASM adherence has increased in 2019 but decreased in 2020 compared to the previous year.

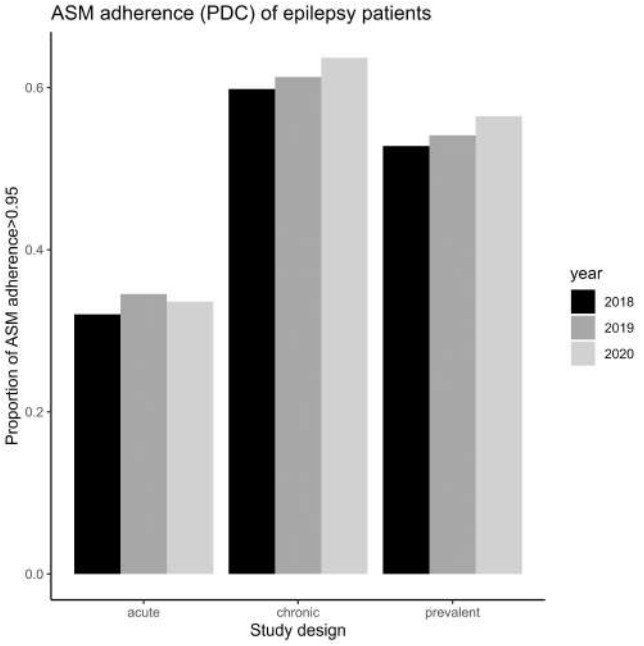

FIGURE 1 ASM adherence of epilepsy patients by year and study design.

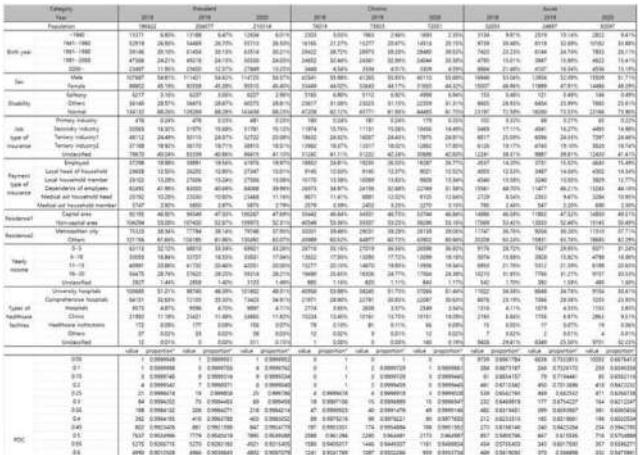
TABLE 1 Demographic profile of prevalent, chronic, and acute groups.



Conclusion: During the COVID-19 pandemic prevailed in 2020, ASM adherence of the epilepsy patients has decreased. Further analysis of relevant subcategory will inform policy design during large-scale pandemics and evaluate factors influencing adherence in the context of remote healthcare environments.

Disclosure: This study was supported by the SNUH Research Fund (Global Excellence center), Korea Health Industry Development Institute, Republic of Korea (RS-2023-00265638) and Samjin Pharm (06-2023-2320).

Headache 2

EPO-324 | Relationship between migraine, eating attitudes, and psychiatric symptoms: A multi-center study in Turkey

R. Ocal[1]; B. Karakurum Goksel[2]; M. Van[1]; C. Ozlem[3]; T. Turkish Headache Study Group[4]

[1]*Department of Neurology,Antalya Training and Research Hospital, Health Sciences University*; [2]*Faculty of Medicine, Baskent University*; [3]*Faculty of Medicine, Gazi University*; [4]*Turkish Headache Study Group*

Background and Aims: Migraine and eating disorders may involve similar biochemical mechanisms. Previous research has indicated a higher prevalence of eating disorders in individuals with migraines compared to the general population. This study, conducted by the Turkey Headache Study Group, aimed to investigate the relationship between migraine severity, depression, anxiety, and irregular eating attitudes.

Methods: This multi-center, prospective, case-control study involved 20 centers across Turkey. Participants underwent assessments using the Eating Attitude Test-26 (short form), was recorded centrally. From a pool of 1200 individuals diagnosed with headaches, a sample of 531 migraine patients meeting diagnostic criteria was selected using propensity score matching. Patient data were compared with those of 531 healthy controls. The Eating Attitude Test-26, Beck Depression, and Beck Anxiety scales were administered to all migraine patients, and the results were compared with the healthy control group.

Results: Migraine patients exhibited significantly higher Eating Attitude Test-26 scores and symptoms requiring referral to a psychiatrist due to eating disorders compared to the control group ($p=0.034$, $p=0.0001$). I. No statistically significant relationship was found between pain severity, attack frequency, and eating attitudes (r: 0.09, $p=0.055$).

Conclusion: This study demonstrated statistically significant higher scores on the Eating Attitude Test-26 in migraine patients compared to a healthy control group. These findings emphasize the need to inquire about eating disorders in individuals with migraines and highlight the importance of addressing eating attitudes in migraine management.

Disclosure: Nothing to disclose.

EPO-325 | H-MR spectroscopy in vestibular and episodic migraine patients

H. Cubuk[1]; C. Cubuk[2]; S. Bicakci[2]; Y. Bicakci[1]
[1]*Department of Radiology, Faculty of Medicine, Cukurova University, Adana, Turkey*; [2]*Department of Neurology, Faculty of Medicine, Cukurova University, Adana, Turkey*

Background and Aims: The study aimed to evaluate the metabolite changes in thalamus in patients with vestibular and episodic migraine.
Methods: Fifteen patients with vestibular migraine and 15 patients with episodic migraine who had been diagnosed at Çukurova University Neurology Department were included in this prospective study. Magnetic resonance spectroscopy (MRS) was obtained at 3 Tesla MR 32-channel head coil. SPSS v20 was used for the statistical analysis.
Results: In cases of vestibular migraine, loss of choline in the left thalamus posterior was detected. The left thalamus posterior N-acetyl aspartate (NAA)/Choline ratio was found to increase in patients with vestibular migraine with no migraine history ($p < 0.05$).
Conclusion: Metabolite changes in thalamus in vestibular and episodic migraine patients could provide information about the pathophysiology of the disease and may help explain the different mechanisms of episodic migraine and vestibular migraine occurrence.
Disclosure: Nothing to disclose.

EPO-326 | Effectiveness and tolerability of eptinezumab: A retrospective analysis at 3 and 6 months in migraine patients

C. Nieves Castellanos; M. Olivier; S. Díaz Insa
Headache Unit, Hospital Universitari i Politécnic la Fe, Valencia, Spain

Background and Aims: Since April 2023, Eptinezumab has been used at our hospital to treat migraine patients, including both anti-CGRP-naïve individuals and those who failed other anti-CGRP therapies. Our objective was to evaluate the response to Eptinezumab after 3 and 6 months of treatment.
Methods: Retrospective study analyzing patients treated with Eptinezumab from April to December 2023. Our analysis includes individuals with chronic and high-frequency episodic migraine. Examining demographic features, prior treatments, migraine frequency, pain intensity (Visual Analogue Scale (VAS)), and patients' global impression of change (PGIC). Additionally, we documented any treatment-related side effects.
Results: We analyzed 121 patients with Eptinezumab, mean age 48 years, 84.3% of women. They have failed 7.5 previous preventive treatments and in 57%, botulinum toxin was used concomitantly. 99 patients reached 3 months of treatment. Among them, 50 had tried 3 anti-CGRP mAbs, 22 with 2, 20 with 1, and 7 had never tried anti-CGRP. Migraine days decreased from 23.6 to 18.6, with a PGIC of 2.75. 65% experienced improvement, and 69% continued treatment after 3 months. 29 patients reached 6 months of treatment and they showed a reduction of an average of 8.6 days of migraine with an average PGIC of 2. Mild side effects occurred in 6% of patients, including two cases of mild hypersensitivity reactions.
Conclusion: Even though many patients suffer from chronic migraine and are highly refractory, a significant percentage showed benefit with eptinezumab. Therefore, we recommend prescribing eptinezumab even in cases where patients have experienced failures with other anti-CGRP agents.
Disclosure: There are no conflicts of interest in this study.

EPO-327 | Comparison of efficacy and safety of anti-CGRP monoclonal antibodies across age groups: A multicenter, real-life study

I. Cetta[1]; R. Messina[1]; L. Zanandrea[1]; F. Genovese[1]; S. Guerrieri[2]; B. Colombo[2]; M. Filippi[1]; I. Study Group[3]
[1]*Neuroimaging Research Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; Vita-Salute San Raffaele University, Milan, Italy;* [2]*Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [3]*IGRAINE Study Group*

Background and Aims: Limited data on anti-calcitonin gene-related peptide (CGRP) monoclonal antibodies (mAbs)'s safety and efficacy across age groups exists. This study investigates efficacy and safety variations among age-related groups treated with mAbs and aims to identify response predictors.
Methods: This Italian, multicentric, prospective, observational study, part of the I-GRAINE registry, categorized patients into age quartiles (1: 18 – 40 years; 2: 40 – 50; 3: 50 – 57; 4: ≥57). Data were collected at baseline (T0) and at 3 (M3), 6 (M6), and 12 (M12) months, including monthly headache (MHD) and migraine (MMD) days, acute treatment intake in terms of days (AMD) and pills (AMP) and adverse events (AEs). At T0, psychiatric comorbidities, medication-overuse headache (MOH) and migraine type (episodic or chronic) were also assessed.
Results: One thousand eight hundred ninety migraine patients participated, predominantly females (80%), median age 49 years (IQR: 18 – 80), 62% were chronic, 58% had MOH and 32% psychiatric comorbidities. All age groups showed significant clinical improvements at M3, M6, and M12 ($p < 0.001$). No significant age-related differences in AEs ($p > 0.05$) were found. Females had favorable treatment responses (OR 1.3 to 3). Psychiatric comorbidity predicted positive response (OR 1.5 to 2.5) from month 6 onward. Chronic migraine (OR 2.1 to 5.8) and MOH (OR 1.8 to 4.7) indicated good response over 12 months.
Conclusion: Our findings confirm mAbs' consistent efficacy across all ages, indicating their suitability for patients with contraindications to oral preventives. Additionally, our study emphasizes considering clinical factors to predict patients' treatment response.
Disclosure: Nothing to disclose.

EPO-328 | The presence of positive signs for functional neurological disorders is associated with migraine frequency

E. Morel[1]; A. Klein[1]; A. Scutelnic[1]; J. Bühler[2]; S. Aybek[3]; C. Schankin[1]

[1]*Department of Neurology, Inselspital, Bern, University Hospital, University of Bern, Bern, Switzerland;* [2]*Psychosomatic Medicine, Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland;* [3]*Faculty of Medicine, University of Fribourg, Fribourg, Switzerland*

Background and Aims: Positive signs (PS) are the hallmark of functional neurological disorders (FND). However, in clinical practice, migraine patients without known FND may also present PS. Our aim was to evaluate the role of PS among migraine patients.

Methods: This study recruited migraine patients without a diagnosis of FND and treated at a tertiary outpatient clinic. We performed a clinical assessment for the following validated PS: give-away, co-contraction, sternocleidomastoid sign, trapezius elevation test, head flexion test, drift without pronation, Hoover I & II, spinal injury test, arm drop test, lip pulling sign, midline splitting, splitting of vibration sign and expressive behavior sign.

Results: Among the 72 recruited patients (mean age: 37.6 ±15.1yo; 75% female), 31 (43.1%) had PS, of which 20 had only one PS. Splitting of vibration was the most common PS (28% of the whole cohort). Compared with patients without PS, patients with PS were older, had more comorbidities, more headache days per month and more headache intensity at the consultation. Even after adjusting for age and comorbidities, the association between the presence of PS and the number of headache days per month remained significant (OR: 1.058; 95% CI (1.000; 1.119); $p=0.049$) as well as between the presence of PS and the subjective headache intensity at consultation (OR 1.277; 95% CI (1.030; 1.582); $p=0.026$).

Conclusion: PS are frequent among migraine patients, mostly as isolated signs. They are associated with headache frequency and intensity. Our findings highlight the complexity of the clinical spectrum of migraine.

Disclosure: None.

EPO-329 | The effectiveness of erenumab and galcanezumab is associated with a decrease in plasma CGRP levels

D. García-Estévez[1]; A. Juanatey-Garcia[1]; N. Sabbagh-Casado[1]; L. Blanco-Garcia[1]; J. Rodriguez-Garrido[2]

[1]*Neurology Service, University Hospital of Ourense, Ourense, Spain;* [2]*Laboratory Service, University Hospital of Ourense, Ourense, Spain*

Background and Aims: It is well established that calcitonin gene-related peptide (CGRP) is involved in the pathophysiology of migraine. Monoclonal antibodies may work by blocking the CGRP receptor (erenumab) or binding to circulating CGRP (galcanezumab). However, how plasma levels of CGRP would be modified with the aforementioned monoclonal antibodies has not been formally studied. Our research group developed a study to determine the influence of treatment with erenumab or galcanezumab on plasma levels of CGRP.

Methods: Seventeen patients (2M/15F) with clinical criteria for high-frequency episodic migraine or chronic migraine (CM) were studied. Previous preventive treatments with neuromodulators (topiramate or zonisamide) and the administration of onabotulinumtoxinA were allowed. Patients were treated with erenumab ($n=9$) or galcanezumab ($n=8$) at the discretion of the neurologist responsible for each patient's care. Plasma levels of CGRP were quantified at baseline and 6 months after follow-up. Statistical analysis was performed using Student's T test for paired samples.

Results: The mean age of the patients was 47.4±7.9 years. Thirteen patients (76%) had the diagnosis of CM. All patients with CM maintained preventive treatment with onabotulinumtoxinA. A statistically significant reduction in the level of CGRP was found at 6 months post-treatment (21.15±13.55 vs 15.04±8.05; $p=0.014$). No significant differences were found between patients treated with erenumab or galcanezumab. Patients experienced a significant reduction in the HIT-6 migraine disability scale (68.9±6.2 vs 63.9±6.9; $p=0.005$).

Conclusion: Our study suggests that the effectiveness of erenumab and galcanezumab in improving the impact of migraine on quality of life is associated with a significant decrease in plasma CGRP levels.

Disclosure: Nothing to disclose.

EPO-330 | Hyperexcitability and precipitation/resolution of migraines. A study by sound induced flash illusions in migraine cycle

F. Brighina[1]; L. Vassallo[1]; A. Torrente[1]; P. Alonge[1]; N. Rini[1]; U. Quartetti[1]; V. Di Stefano[1]; N. Bolognini[2]

[1]*Department of Biomedicine, Neuroscience and advanced Diagnostic (BIND), University of Palermo, Palermo, Italy;* [2]*Department of Psychology & Milan Centre for Neuroscience (NeuroMI), University of Milan-Bicocca, Milan, Italy*

Background and Aims: Sound-induced flash illusions (SIFI) that critically depend on excitability of occipital cortex are reduced in migraine according to a condition of visual cortical hyperexcitability. Here we explored SIFI across the different phases of migraine cycle (ictal, pre- and post-ictal) to assess how changes in cortical excitability can be related to precipitation and resolution of migraine attacks.

Methods: SIFI were evaluated in 78 migraine without-aura patients: 18 interictal, 20 ictal, 20 pre- and 20 post-ictal) and in 25 healthy controls with no different age and sex distribution across groups. Visual stimuli (flashes) and sounds (beeps) were given in different combinations: single flash/multiple beeps to induce "fission" illusion (perception of multiple flashes), multiple flashes/single beep to reduce the perceived flashes ("fusion" illusion).

Results: Fissions were significantly reduced in all migraineurs vs healthy controls ($p:<.001$).The highest level of reduction was

observed in the ictal-migraineurs that was significantly lower with respect to all migraine-group ($p: < .001$ vs interictal, .01 vs pre- and post-ictal); pre- and post-ictal migraineurs perceived significantly less illusions with respect to the interictal group ($p < .01$).

Conclusion: Visual cortex of migraine patients was found to be hyperexcitable interictally. Excitability increases in preparatory phase (preictal), reaches its acme during the attack and then lowers toward attack-end. This suggest a role of cortical excitability in mechanisms of migraine precipitation and ending. Moreover, they shed also light on previous paradoxical RTMS evidence by our study in migraine cycle, supporting the interpretation that the inhibitory responses are likely due homeostatic inhibitory mechanisms.

Disclosure: Nothing to disclose.

EPO-331 | Impact of erenumab treatment duration on cutaneous allodynia in patient with episodic and chronic migraine

F. Genovese[1]; R. Messina[1]; I. Cetta[1]; L. Zanandrea[1]; S. Guerrieri[2]; G. Vaghi[3]; R. De Icco[3]; G. Sances[4]; B. Colombo[2]; M. Filippi[1]

[1]Neurology Unit and Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute; Vita-Salute San Raffaele University, Milan, Italy; [2]Neurology Unit; Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; [3]Department of Brain and Behavioral Sciences, University of Pavia; Headache Science & Neurorehabilitation Center, IRCCS Mondino Foundation, Pavia, Italy; [4]Headache Science & Neurorehabilitation Center, IRCCS Mondino Foundation, Pavia, Italy

Background and Aims: This study aims to evaluate the efficacy of erenumab, a monoclonal antibody targeting the CGRP receptor, over a one-year period in comparison to treatment lasting beyond one year, among patients with episodic and chronic migraine

Methods: In the episodic patient cohort, 25 received treatment over a one-year period (GroupA), while 16 were treated beyond one year, up to a maximum of 21 months (GroupB). Among chronic patients, 71 and 68 were allocated to GroupA and GroupB, respectively. Clinical data were collected at baseline (T0), end of treatment (T1), after an average of 3.5 months of treatment suspension (T2), and 3-month after resuming therapy (T3). Variables encompassed monthly headache and migraine days, acute medication usage, patients' disability, migraine impact, pain intensity (NRS scores) and intra-ictal allodynia (ASC-12 scores). Intra-group variations were assessed using Wilcoxon tests whereas between-group differences of clinical variables modification among timepoints were explored through linear and cumulative effect statistical models.

Results: Both chronic and episodic migraine patients exhibited significant reductions in most clinical variables between T0 and T1, with no differences between the two treatment groups. Notably, in chronic patients, GroupB demonstrated a reduction in ASC12 scores during treatment, maintaining the effect post-discontinuation. Conversely, GroupA showed no reduction during treatment, but a delayed effect during suspension. After resuming therapy all patients showed significant improvement with no differences between groups.

Conclusion: These findings suggest that erenumab could modulate nociceptive networks, contributing to allodynia symptom. However, to achieve and maintain this effect an extended treatment duration is required

Disclosure: Authors have nothing to disclose in relation to this work.

EPO-332 | White matter lesions (WML) in migraine with aura

G. Querzola[1]; A. Galli[1]; A. Sala[2]; F. Frediani[1]

[1]Headache Center, Neurology and Stroke Unit Division, San Carlo Borromeo Hospital (ASST Santi Paolo e Carlo), Milan, Italy; [2]Headache Center, Neurology and Stroke Unit Division, San Carlo Borromeo Hospital (ASST Santi Paolo e Carlo), Milan, Italy; Università degli Studi di Milano, Italy

Background and Aims: Several studies report the presence of WML, also potential vanishing, on brain-MRI in patients with migraine, especially with aura (MA). There is no univocal interpretation: vascular hypothesis seems to be more probable, considering MA as a risk factor for WML and ischemic stroke, but these studies are biased, and there are controversies in literature about the prevalence of WML in MA, compared with general population.

Methods: To reduce vascular co-morbidities, old age, misdiagnosis, and drugs biases, we enrolled 177, highly-selected, young, subsequent patients, afferent to our Headache Center. In 146 patients we performed Brain-MRI studies at enrollment (T0), and 12 months (T1). We compared T0-MRI with MRI of 120 matched "healthy", non-migraineurs subjects, and we evaluated clinical features, co-morbidities, cardiovascular risk factors, and thrombophilia.

Results: We found WML in 29% of the MA patients, and in 27% of the controls. There was not statistically significant difference regarding the incidence of WML, and regarding MRI-WML between T0 and T1. We found neither association between MA features and side or number of lesions.

Conclusion: Available scientific literature about increased WML in MA patients is biased, limited, and controversial. Our study, both control-compared and longitudinal, of highly selected and relatively young patients, shows that MA patients have not more WML than healthy subjects, rejecting the proposed correlation between MA, as an independent cerebro-cardio-vascular risk factor, and ischemic stroke. We are currently performing a further analysis to demonstrate whether the presence of WML is related to other co-morbidities and risk factors.

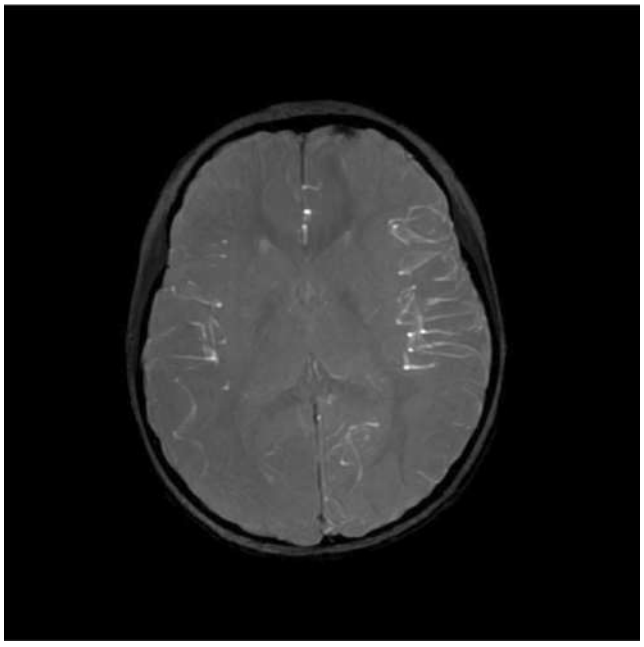
EPO-333 | A novel ATP1A2 gene variant associated with atypical phenotype of SHM identified in a 6-year-old Italian female

G. Fazio[1]; A. Cervellino[2]; M. Tagliente[3]; S. Manieri[3]; M. Di Giacomo[4]; N. Paciello[2]; E. Ferrante[5]; M. Trimboli[6]; E. Chiarella[1]
[1]*Institute of Neurology, Magna Graecia University, Catanzaro, Italy*; [2]*Department of Neurology, AOR San Carlo, Potenza, Italy*; [3]*Department of Pediatrics, AOR San Carlo, Potenza, Italy*; [4]*Department of Genetics, AOR San Carlo, Potenza, Italy*; [5]*Department of Neurology, IRCCS Ospedale San Camillo, Lido Venezia, Italy*; [6]*Department of Neurology, AOU Renato Dulbecco, Catanzaro, Italy*

Background and Aims: Sporadic hemiplegic migraine (SHM) can be caused by a novel mutation in a gene that causes the familial form (CACNA1A,ATP1A2,SCN1A) or by inheritance of a gene mutation from a parent with "non hemiplegic" typical aura (2). Here, we describe a case of SHM, who carries a novel mutation in the ATP1A2gene.
Methods: A 6-year-old female, without family history of migraine, was admitted because she presented pulsating left-sided fronto-temporal headache, associated with photophobia, phonophobia, nausea/vomiting, right-sided weakness and paresthesia, dysarthria, ataxia, acute confusion. Two similar episodes of motor weakness without loss of consciousness and dysarthria, have occurred 3 and 6 months before that admission, with complete/spontaneous resolution after 3 days.
Results: Neurological examination showed confusion, moderate right hemiparesis and hypoesthesia. CT scan was normal; brain MRI showed a slightly prominent draining sulcal veins on the left hemisphere (Fig.1). The EEG showed alteration in the background activity with prominent involvement of the left hemisphere with continuous abnormal frontal and centro-temporal slow waves (Fig.2). SHM diagnosis was made. Sequence analysis detected a novel mutation, c.2456T>C p.(Leus819Ser), into the ATP1A2gene. Right-sided hemiparesis and hypoesthesia disappeared 6 days after the symptoms' onset, dysarthria lasted for 30 days before disappearing. Nimodipine and sodium valproate were introduced after the third attack and no further SHM episodes were recorded at 2-years follow-up.
Conclusion: Early-onset HM should be considered among the causes of focal neurological deficits. We found a novel ATP1A2 mutation, which could be responsible for the atypical phenotype, since different mutations in FHM genes partly account for clinical variability
Disclosure: Nothing to disclose.



Brain MRI swan axial sequence shows a slightly prominent draining sulcal veins on the left hemisphere.

EPO-334 | Headache in acromegaly: Not only a secondary disorder

G. Giuliani[1]; D. Costa[2]; C. Pellicano[3]; M. Altieri[1]; P. Gargiulo[2]; V. Di Piero[1]
[1]*Department of Human Neuroscience, Sapienza University of Rome, Rome, Italy*; [2]*Department of Experimental Medicine, Endocrinology-Pituitary Disease, Sapienza University of Rome, Rome, Italy*; [3]*Department of Translational and Precision Medicine, Sapienza University of Rome, Rome, Italy*

Background and Aims: Headache is frequently associated with pituitary disease, in which it can persist despite effective therapy. To better understand its actual secondary nature, we analyzed the headache characteristics in an acromegalic population.
Methods: 39 acromegalic patients, regularly followed for a long period, were examined to evaluate headache. Headache features were collected retrospectively through a structured interview. We carefully studied its time course and relationship with acromegaly, exploring the influence of adenoma and its treatment.
Results: Out of 39 patients, 27 (69.2%) reported headache. Twenty-one patients (53.8%) met the criteria for a primary headache: 14 had episodic migraine, 4 had chronic migraine while 3 patients presented tension-type headache. No trigeminal autonomic cephalalgia was observed. Six patients (15.4 %) fulfilled secondary headache criteria, with complete headache resolution after acromegaly treatment. Overall, a family history of headache was present in 20 cases (51.3%). Tumor size ($p=0.4$) and treatment of acromegaly ($p=0.67$) did not significantly influence the course of the disease.
Conclusion: In our population, only a small percentage (15.4%) of patients presented a picture consistent with a secondary headache that disappeared after acromegaly treatment. Interestingly, we observed a high prevalence of family history of headache and a high prevalence of migraine in acromegalic patients. A genetic predisposition to primary headache may be present: in this light, acromegaly, by favoring a pro-inflammatory state (1), might act as a trigger for migraine development. Due to the limited effect of acromegaly therapy on migraine course, headache may become disabling comorbidity, requiring careful evaluation and personalized management.
Disclosure: Nothing to disclose.

EPO-335 | 6-months-follow up of migraine patients treated with eptinezumab: Efficiency and tolerance

G. Baille[1]; S. Chabalier[2]; A. Le Floch[3]
[1]*Neurology Department, Hôpital Delafontaine, St Denis, France;* [2]*Biostatistics, Nimes University, Nimes, France;* [3]*Neurology Department, Nimes University Hospital, Nîmes, France*

Background and Aims: Since January 2023, eptinezumab, an intravenous anti-CGRP antibody, is authorized and reimbursed in France to treat severe episodic and chronic migraine patients. Our aim was to assess its efficiency and its tolerance "in real life" at 6 months, in an observational cohort in 2 hospitals (St Denis and Nimes university).
Methods: Patients with severe and chronic migraine, with failure of at least 2 preventive treatments and without cardiovascular comorbidities, were included if they had received 2 intravenous infusions of eptinezumab (every 3 months). The primary endpoint was change from baseline in monthly migraine days (MMDs) over weeks 1-24. Patients completed the following patient-reported outcomes: headache diary, intake of acute treatment for headache, 6-item Headache Impact Test (HIT-6) and the Hospital Anxiety and Depression scale (HAD). Other concomitant preventive treatments was also reported.
Results: 24 patients were included (M/F: 4/20), mean age (43.25 years old (SD 18.73), among them 16 had chronic migraine. The reduction of MMDs was 4.71 (SD 6.52). The >75% and >50% migraine responder rates were respectively 1% and 45.8%. No severe side effects were notified. The medication overuse rate decreased from 72.2% to 43.3%.
Conclusion: In this observational "real life" cohort, we highlighted that eptinezumab is efficient to prevent headaches in severe episodic and chronic migraine patients, with a reduction of medication overuse.
Disclosure: GB: advisory/Lecture for Lundbeck.

EPO-336 | Clinical presentation of occipital neuralgia in a headache unit

I. Ros González; Y. González Osorio; Á. Sierra Mencía; A. Recio García; S. García García; E. Varas Martín; D. García Azorín; Á. Guerrero Peral
Neurology Department, Hospital Clínico de Valladolid, Spain

Background and Aims: Occipital neuralgia is defined as a pain in one or more distributions of the occipital nerves. Case series of this entity are scarce. We aim to describe a large series of patients with occipital neuralgia.
Methods: Prospective registry of patients attended in a headache unit of a tertiary hospital. In those diagnosed with occipital neuralgia we collected demographic and clinical data.
Results: Between January-2008 and January-2024, we included 102 patients (78, 76.5% female) with occipital neuralgia out of 9388 (1.08%) attended in our unit. Age at inclusion was 58.2±16.4 years (range: 17-85) and latency from onset to diagnosis 23.7±47.5 months (1-360). In 39 cases (38.2%) pain affected right side, in 54 (52.9%) the left, and in 9 (8.8%) it was bilateral. 90 patients (88.2%) described a background pain, mostly oppressive (70 patients), and rated as 5.5±1.6 (2-10) on a verbal analogical scale (VAS). In 59 cases (57.8%) we registered exacerbations, mostly stabbing (36 patients) and rated as 8.1±1.5 (3-10) on a VAS. In 11 patients (10.8%) we recorded an event on the onset of pain (trauma in 10 cases). In 92 patients (90.2%) there was dysesthesia upon palpation of the scalp. Neuralgia affected in 18 cases (17.6%) the lesser occipital nerve. Before arriving at our unit 24 patients (23.5%) received an oral preventative with little or no effect.
Conclusion: Occipital neuralgia is a rare entity even in a headache unit. It is necessary to increase knowledge of this neuralgia to avoid diagnostic delays with the use of ineffective treatments.
Disclosure: No disclosure related to this work.

EPO-337 | Patterns of long-term response to anti-CGRP monoclonal antibodies in a 2-year prospective cohort of migraine patients

L. Gómez-Dabó[1]; E. Caronna[2]; R. Mas-de-les-Valls[3]; V. Gallardo[3]; E. Gine-Cipres[2]; A. Alpuente[2]; M. Torres-Ferrus[2]; P. Pozo-Rosich[2]
[1]*Headache Clinic, Neurology Department, Vall d'Hebron Hospital, Barcelona, Spain;* [2]*Headache Clinic, Neurology Department, Vall d'Hebron Hospital; Headache and Neurological Pain Research Group, VHIR, Department of Medicine, Universitat Autònoma de Barcelona, Barcelona, Spain;* [3]*Headache and Neurological Pain Research Group, VHIR, Department of Medicine, Universitat Autònoma de Barcelona, Barcelona, Spain*

Background and Aims: Real-world evidence on long-term response to monoclonal antibodies targeting calcitonin gene-related peptide (anti-CGRP mAbs) in migraine remains limited. Objective: To describe the long-term effectiveness and patterns of response at 2 years of anti-CGRP mAbs in a cohort of migraine patients.
Methods: Prospective unicentric observational study including high frequency episodic and chronic migraine patients treated with anti-CGRP mAbs. Demographics and efficacy variables (monthly headache days-MHD; monthly migraine days -MMD) were collected for 24 months. We defined 4 time points (6-12-18-24 months), matching to the follow-up visits. We defined sustained response (SR) as ≥50% reduction in MHD at all time points; quasi-sustained response (QSR) as a ≥50% reduction in MHD at 3 out of 4 time points; unsustained response (UR) as ≥50% reduction in MHD at 1-2 out of 4 time points; and never response (NR) as <50% at all time points.
Results: 148 patients were included (mean age 47 years [40.8-54], 82.4% (122/218) females). Median basal frequencies were 18 [14, 25.5] MHD, 13 [8, 18] MMD. After 24 months of follow-up, 31% (46/148) had SR; 26% (38/148) had QSR; 23% (34/148) had UR; and 20% (30/148) had NR. Long-term responders (SR+QSR) presented less allodynia (41.7%vs59.4%; $p < 0.04$) and higher baseline MHD

and MMD (median HDM 21 vs 15.5, $p < 0.014$; MDM 15 vs 12.5; $p < 0.016$) compared to non-long-term responders (UR+NR).

Conclusion: Over 50% of migraine patients treated with anti-CGRP mAbs exhibit a long-term response that is sustained over time. Understanding patterns of long-term response could help treatment decisions in the future.

EPO-338 | Assessing the relative utility of a two headache "rescue rooms" and their respective treatment protocols

L. Armistead; A. Koutsandreas; J. Rothrock
Inova Health/University of Virginia, Fairfax, VA, USA

Background and Aims: We compared the relative utility of two treatment algorithms in two separate outpatient clinic headache "rescue rooms" (RRs).

Methods: In two separate university-based RRs we compared clinical outcome, healthcare resource utilization (HRU), RR cost, patient satisfaction and mean RR time/visit using two different treatment algorithms. "A" involved primarily intramuscular (IM) administration of droperidol, and (B) involved an evidence-based sequence of therapies beginning with subcutaneously administered sumatriptan and proceeding as needed to intravenous ketorolac, metoclopramide, DHE/prochlorperazine, metoclopramide, magnesium, divalproex sodium and dexamethasone.

Results: 100 consecutive patients were treated according to algorithm A and 100 according to algorithm B. Clinical outcomes, RR costs, decline in ER utilization and patient satisfaction were similar in the two groups. Mean time required for an RR visit was less in group A than in the group B (47 minutes versus 127 minutes). None of the 100 group A patients treated with IM droperidol exhibited QTc prolongation.

Conclusion: An outpatient headache "rescue room" conveys a high level of clinical efficacy, decreased ER utilization, and a high degree of patient satisfaction. Droperidol IM appears to be a particularly safe, effective and efficient treatment for use in this setting.

Disclosure: Nothing to disclose.

EPO-339 | Transcranial sonography evaluation in patients with cerebellar neurodegenerative ataxias

A. Milovanović[1]; O. Tamaš[1]; M. Mijajlović[1]; T. Švabić[1]; M. Kostić[2]; G. Marić[3]; M. Jeremić[1]; N. Dragašević Mišković[1]
[1]Neurology Clinic, University Clinical Centre of Serbia; [2]Faculty of Medicine, Institute of Mental Health, University of Belgrade, Belgrade, Serbia; [3]Institute of Epidemiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background and Aims: Cerebellar neurodegenerative ataxias are disorders affecting the cerebellum and its pathways. Transcranial sonography (TCS) is widely used for the evaluation of brain parenchymal structures in various diseases especially in neuropsychiatric and neurodegenerative diseases. The objective of this study was to investigate TCS characteristics of patients with neurodegenerative cerebellar ataxias.

Methods: We included a total of 74 patients with cerebellar degenerative ataxia, 36.5% had autosomal dominant, 20.2% with autosomal recessive pattern of inheritance, and 43.3% had sporadic onset. Standardized ultrasonographic planes were used for the identification of brain structures of interest. All patients were clinically evaluated using SARA, INAS, neuropsychological, and psychiatric scales.

Results: The brainstem raphe was discontinued in 33.8% of patients. The substantia nigra (SN) hyperechogenicity was identified in 79.7%. Third and fourth ventricle enlargement had 79.7% and 45.9% of patients, respectively. A positive and statistically significant correlation was found between SN hyperechogenicity with dystonia ($p < 0.01$), rigidity, and dyskinesia ($p < 0.05$). Higher SARA total score statistically significantly correlated with the larger diameter of III ($r = 0.373$; $p = 0.001$) and IV ventricle ($r = 0.324$; $p = 0.005$).

Conclusion: Hyperechogenicity of substantia nigra has been linked to extrapyramidal signs, while raphe discontinuity to depression. Furthermore, severity of ataxia has positively correlated with III and IV ventricle diameter indicating brain atrophy.

Disclosure: None.

EPO-340 | The genetic landscape of Parkinson's disease in an Italian cohort and the need for a standardized approach

A. Cimmino[1]; P. Sanginario[1]; F. Musso[1]; L. Rigon[1]; D. Genovese[2]; A. De Biase[2]; M. Petracca[2]; F. Bove[2]; C. Piano[2]; F. Tiziano[3]; A. Bentivoglio[2]; P. Calabresi[2]; G. Di Lazzaro[2]
[1]*Università Cattolica del Sacro Cuore, Department of Neurosciences, Rome, Italy*; [2]*Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Neurology Unit, Rome, Italy*; [3]*Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Institute of Genomic Medicine, Rome, Italy*

Background and Aims: Advances in genetics have expanded the known spectrum of Parkinson's disease (PD)-related genes, and broadened access to genetic analysis, allowing for rapid sequencing of many disease-associated genes and unraveling a high genetic variability. Our study aimed to determine the genetic characteristics in an Italian cohort of PD patients.
Methods: PD patients with family history, early-onset (≤55 years), and/or atypical phenotype underwent genetic analysis through an NGS panel containing 45 known-PD-causative genes, coupled with MLPA when needed. Variants were interpreted according to ACMG criteria, and reports were categorized as positive (≥1 variant, with definite genetic diagnosis), inconclusive (≥1 variant, insufficient for genetic diagnosis), or negative. Heterozygous pathogenic/likely-pathogenic variants in dominant genes and biallelic pathogenic/likely-pathogenic variants in recessive genes were considered positive. GBA1 variants were considered pathogenic and classified based on PD-development risk. Inconclusive reports underwent reassessment: heterozygous pathogenic variants in recessive genes and VUS with genotype-phenotype mismatch were considered negative; VUS not otherwise interpretable were clarified through family segregation studies.
Results: We recruited 197 patients. 74 (37.6%) reports revealed ≥1 variant. Of the inconclusive reports, after reinterpretation, 1 was considered positive, while 22 negative. Eventually, positive reports were 36 (18.3%), and inconclusive 16 (8.1%). The most common diagnoses were GBA1 (23, 11.7%), LRRK2 (5, 2.5%), PRKN (4, 2.0%), PINK1 (1, 0.5%) FBXO7 (1, 0.5%). The gene with the most reported variants was GBA1.
Conclusion: Our results contribute to a more in-depth understanding of PD genetic spectrum in Italian patients and underscore the importance of a standardized approach for the interpretation of genetic findings.
Disclosure: Nothing to disclose.

EPO-341 | Stigma among Tunisian patients with Parkinson's disease: The hidden side of the burden

A. Rekik; A. Mili; K. Jemai; E. Jarrar; S. Naija; A. Hassine; S. Ben Amor
Department of Neurology of Sahloul Hospital Sousse, Faculty of medicine of Sousse, Tunisia

Background and Aims: Stigma among patients with Parkinson's disease (PD) is multilayered and a determinant of the quality of life. The social and cultural components can modulate efficiently this aspect. Thus, we aim to investigate stigma among PD patients in Tunisia in order to boost their quality of life.
Methods: We have conducted a cross-sectional study including patients with PD who presented to our clinic for regular follow-up from October to December 2023 and consent to participate. We identified general and motor characteristics using UPDRS-III score. We used MMSE for cognitive function and SCOPA-Aut questionnaire to identify dysautonomic features. Stigma was assessed based on the 8-item Stigma Scale for Chronic Illness (SSCI-8) and we used the raw summed score ranging from 8 to 40.
Results: We included 62 patients (sex-ratio = 1.4; mean disease duration of 11; 62%; illiterate). Mean UPDRS-III score was 23.6±5 with tremor-dominant PD being the most frequent (56.5%), followed by postural instability gait disorder (PIGD) phenotype (24%). Mean MMSE score was 21.4±6. Dysautonomia was noted in 66% of cases with gastrointestinal dysfunction being the most prominent (60%). Mean SSCI-8 score was 66.3 [40; 77]. SSCI score correlated positively with illiteracy ($p = 0.023$), higher UPDRS-III score ($p = 0.001$), PIGD-phenotype ($p = 0.048$), tremor-dominant phenotype ($p = 0.026$), cognitive dysfunction ($p = 0.036$) and gastrointestinal dysfunction ($p = 0.042$).
Conclusion: Stigma is frequent and severe among Tunisian patients and exceeds the rates reported from Europa and North America. It is conditioned by educational level, motor and non-motor features. Our findings highlight the necessity of a holistic approach beyond the motor aspect. Raising awareness is mandatory to pave the way for a more tolerable environment.
Disclosure: None.

EPO-342 | Suvecaltamide metabolites are CaV3 modulators and contribute to pharmacological effect

E. Brigham; W. Zeng; N. Shanks; M. Lee
Jazz Pharmaceuticals, Palo Alto, CA, USA

Background and Aims: T-type calcium (CaV3) channels regulate neuronal excitability and are thought to play a key role in mediating pathological tremor-producing oscillations in conditions like essential tremor (ET). Suvecaltamide (JZP385), a potent, selective CaV3 modulator, improved function in adults with moderate-to-severe ET in a phase 2 study (T-CALM/NCT03101241). We

present potency-concentration relationships and combined pharmacological effects for suvecaltamide and its 2 active metabolites (JZZ05000034 = M01, JZZ05000035 = M02; total active moiety [TAM]).

Methods: Automated patch-clamp recordings in HEK293 cells stably overexpressing human CaV3 subtypes were used to generate steady-state inactivation curves with/without analyte treatments; concentration-response curves used protocols enriching for resting or inactivated channel states. Off-target effects were tested in enzyme and receptor binding panels.

Results: All analytes inhibited all CaV3 channels in a concentration- and state-dependent manner (Table) and slowed recovery from inactivation. Selectivity (<50% [10 μM]) was demonstrated for all targets/analytes, except suvecaltamide at CB2 receptor (IC50 = 5.3 μM) and M01 at human PPAR-gamma (54% at 10 μM) and guinea-pig adenosine transporter (IC50 = 2.9 μM), which are likely not relevant at projected therapeutic doses.

Table. Suvecaltamide and Its Active Metabolites Inhibited Ca_V3 in a Concentration- and State-Dependent Manner

Mean Potency (IC_{50}, nM) and State Dependency	Suvecaltamide	M01 (JZZ05000034)[a]	M02 (JZZ05000035)[a]
	(n=25[b])	(n=7[b])	(n=6[b])
Partially Inactivated $Ca_V3.1$ ($V_{0.5}$)	58	40	1050
Resting $Ca_V3.1$	3628	2958	>30,000
Fold difference[c]	98	110	>50
Partially Inactivated $Ca_V3.2$ ($V_{0.5}$)	365	264	8540
Resting $Ca_V3.2$	8015	9607	>30,000
Fold difference[c]	37	46	>4

Fold difference[c]	40	68	35

[a]Metabolite of suvecaltamide.
[b]Refers to number of individual assays performed (n=4 wells/assay).
[c]Mean of individual ratios of resting:partially-inactivated Ca_V3 IC_{50} values.
IC_{50}, concentration resulting in 50% inhibition of peak current.

Suvecaltamide and Its Active Metabolites Inhibited CaV3 in a Concentration- and State-Dependent Manner.

Conclusion: Suvecaltamide and its active metabolites demonstrate selective, state-dependent modulation of all CaV3 subtypes with markedly higher affinity for partially inactivated channels. Modelling TAM shows that, at clinically relevant concentrations, suvecaltamide and its metabolites may selectively inhibit channels enriched under hyperexcitable conditions (eg, pathological neuronal firing) while sparing channels involved in normal signalling, which may contribute to a more optimal clinical profile. Two ongoing phase 2 studies are evaluating suvecaltamide in adults with moderate-to-severe ET (NCT05122650) or residual Parkinson's disease tremor (NCT05642442).

EPO-343 | Reprogramming options after IPG replacement in STN DBS for Parkinson's disease: Is the upgrade worth the cost?

A. Boogers[1]; M. Justich[1]; M. Montiel[1]; I. Alhashyan[1]; S. Naghdlou[1]; S. Kalia[2]; A. Lozano[2]; R. Munhoz[1]; A. Fasano[1]
[1]*Department of Neurology, Toronto Western Hospital, Toronto, Canada;* [2]*Department of Neurosurgery, Toronto Western Hospital, Toronto, Canada*

Background and Aims: People with Parkinson's disease (PD) having motor fluctuations can be treated with deep brain stimulation targeting the subthalamic nucleus (STN DBS)1. The lifetime of non-rechargeable implantable pulse generators (IPG) requires battery replacements every 3-5 years2. Recently, IPGs with more programming features have become readily available.

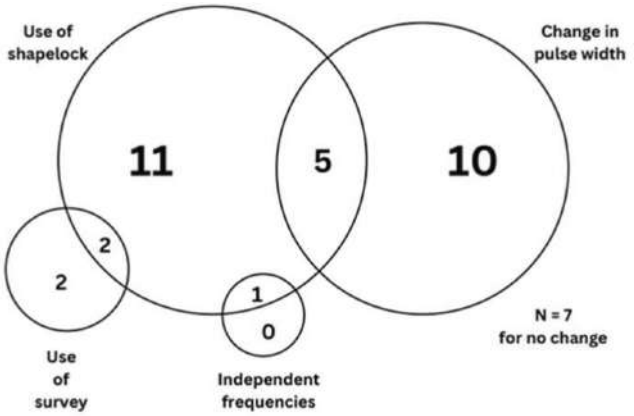
Methods: This double-blind cross-over randomized study recruited consecutive PD patients undergoing IPG replacement surgery in whom the Activa PC was replaced with a Percept PC (Medtronic, Minneapolis, MN, USA). Reprogramming was done to reduce stimulation-induced side effect and/or to lower battery consumption (i.e. avoiding bipolar or interleaving settings). Change of active contact could only be done based on the Brainsense Survey (contact with highest beta peak). Bipolar and interleaving settings were replaced by monopolar, double, triple or quadruple monopolar settings (Shapelock). Pulse width could be shortened beyond 60 mcsec. Change in frequency was only allowed when switching to independent frequencies per hemisphere.

Results: 19 patients (38 STNs) were included (four females). In 19 STNs (50%), the stimulation settings were changed from bipolar or interleaving to a (multiple) monopolar configuration using the Shapelock feature. Pulse width was shortened in 15 STNs (39.5%). A change in contact was done in 4 STNs (10.5%) after an average of 6.5 years on another contact. Eleven patients (57.9%) preferred the novel stimulation paradigm, while 6 patients (31.6%) preferred their established program. Two patients were undecided.

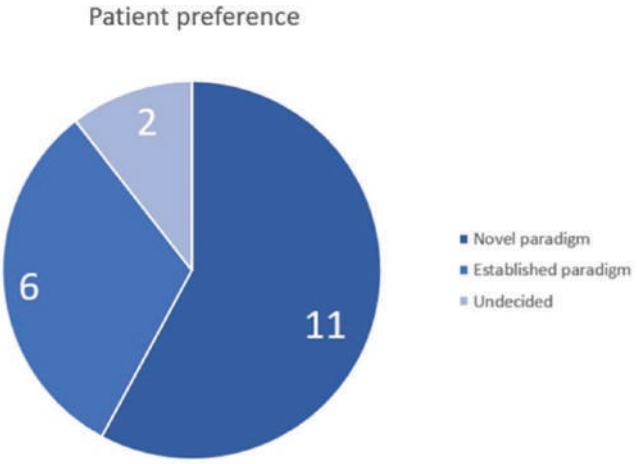
Conclusion: DBS reprogramming using novel additional features after IPG replacement can lead to improved outcomes and/or reduced battery consumption in a sizable proportion of patients.

Disclosure: AL received honoraria and research support from Medtronic. SK received honoraria and research support from

During the baseline visit, patients underwent reprogramming in medication-off condition using novel stimulation features. They were randomized between the established and the novel stimulation paradigm for a month. Thereafter, they were crossed over.



Features used when reprogramming after battery replacement surgery.



Pie chart of patient preference between the novel stimulation paradigm ($n = 11$) and the established stimulation paradigm ($n = 6$). Two patients did not have a preference between the two programs.

Medtronic. AF received honoraria and research support from Medtronic.

EPO-344 | Incidence and risk factors of glaucoma in Parkinson's disease: A population-based study

B. Yoon[1]; S. Jung[2]; Y. Shim[3]; H. Kim[4]
[1]*Department of Neurology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea;* [2]*Department of Neurology, Hallym University Medical Center Kangnam Sacred Heart Hospital, Seoul, Republic of Korea;* [3]*Department of Neurology, The Catholic University of Korea Eunpyeong St. Mary's Hospital, Seoul, Republic of Korea;* [4]*Department of Clinical Epidemiology and Biostatistics, Asan Medical Center, Ulsan University College of Medicine, Seoul, Republic of Korea*

Background and Aims: The potential association between Parkinson's disease (PD) and glaucoma remains unclear. We aimed to investigate glaucoma incidence in PD patients, explore the differences by age and sex, and identify potential risk factors for glaucoma in Korean PD patients.

Methods: We conducted a comprehensive study using data from the Korean National Health Insurance System database, encompassing 97% of the Korean population from 2002 to 2019. We calculated the incidence of newly developed glaucoma among PD patients and estimated the adjusted hazard ratio (aHR) with 95% confidence intervals (CI) using Cox proportional-hazards models to elucidate glaucoma risk factors.

Results: Among 176,673 patients with PD, 9,718 patients developed glaucoma during the follow-up period (3,670 men and 6,048 women), yielding an overall incidence of 8.02 per 1,000 person-years. Stratified by age group and sex, we observed an increasing incidence with age until 80, with minimal sex differences. In particular, older age (aHR = 1.78, 95%CI: 1.55-2.05 in the 60s), diabetes mellitus (DM) (aHR = 1.19, 95%CI: 1.14-1.25), and hyperlipidemia (aHR = 1.06, 95%CI: 1.01-1.10) emerged as significant risk factors for glaucoma in PD patients.

Conclusion: Our study suggests that PD patients face an elevated risk of glaucoma compared to the general population, with no substantial sex differences. Older age, the presence of DM, or hyperlipidemia were identified as risk factors for glaucoma in PD patients. These findings emphasize the significance of considering regular ophthalmologic evaluation as part of their management in PD patients, particularly among those with a history of DM or hyperlipidemia, regardless of age or the presence of visual symptoms.

Disclosure: Nothing to disclose.

EPO-345 | Neuroleptic malignant syndrome in Huntington's disease

B. Ravera[1]; A. Funcis[1]; P. Zinzi[2]; M. Solito[2]; M. Petracca[1]; P. Calabresi[1]; A. Bentivoglio[1]
[1]*Institute of Neurology, Catholic University of the Sacred Heart, Rome;* [2]*Institute of Neurology, Policlinic A. Gemelli Foundation, Rome*

Background and Aims: Huntington's disease (HD) is often treated with tetrabenazine (TBZ) and dopamine receptor blocking agents (DRBAs). Few data are available regarding the likelihood of neuroleptic malignant syndrome (NMS) development in HD patients. In this article we investigate the main risk factors that lead to the development of NMS in HD patients, and discuss the measures to avoid this potentially life-threatening condition.

Methods: We gathered data from the 5th data set of the Enroll-HD study (PDS5), a literature review, and described a case report. We selected HD patients treated with TBZ and/or DRBAs, who presented at least one of the core symptoms of NMS, therefore including atypical forms.

Results: We identified 12 cases of NMS in HD patients in total, three of which showed atypical forms of NMS. Only one out of 5108 patients, treated with DBRA and/or TBZ, was identified in the

Enroll-HD dataset. All patients developed NMS in conjunction with drug-therapy changes, with average onset within a month, except one patient during ongoing treatment with TBZ. Five out of the twelve patients developed NMS while undergoing TBZ. Overall, the patients showed a long clinical history of HD.

Conclusion: NMS is likely underestimated in HD patients partly due to missed diagnosis of cases with atypical presentation. Therefore, careful monitoring of symptoms may allow early detection of this potentially fatal condition. Abrupt changes in therapy, are the main risk factors for NMS development, hence the importance of periodic revision of treatment and cautious drug management, especially in advanced stages of HD.

Disclosure: Nothing to disclose.

EPO-346 | Deep brain stimulation as an effective therapy in atypical two stage evolution adult-onset KMT2B-related dystonia

C. Desjardins; S. Sangla; C. Hubsch

Department of Neurology, Movement Disorders Unit, Fondation Adolphe de Rothschild, Paris, France

Background and Aims: In KMT2B-related dystonia (DYT-KMT2B), onset occurs typically, in the first decade of life with focal involvement progressing to generalized dystonia, prominently affecting the cranial, cervical and bulbar regions. Later onset has been reported, with upper body parts and oromandibular involvement. We report an adult-onset case of severe DYT-KMT2B with improvement after bi-pallidal deep brain stimulation (GPi-DBS).

Methods: We report the phenomenology and genetic data of an adult with DYT-KMT2B.

Results: Cervical dystonia initiated at 33y, evolving through two phases: an initial calm period and a subsequent exacerbation phase. While botulinum toxin injections provided relief from 33 to 47 years, the dystonia significantly worsened from 47 to 49 years, manifesting a cranio-caudal progression with blepharospasm, oromandibular dystonia, upper limb and trunk dystonia, and a myoclonus component (Video). Chewing difficulties necessitated a gastrostomy. The Burke-Fahn-Marsden Movement and Disability Subscales (BFMMS and BFMDS) scores were 30 and 21, respectively, with ineffective conventional therapies and botulinum toxin injections. Genetic analysis unveiled a heterozygous variant in KMT2B: NM_014727.2:c.631T>G/p.(Cys211Gly). GPi-DBS led to a postoperative dystonic crisis, requiring a one-week stay in intensive care. Rapid clinical improvement ensued within a month, with BFMMS and BFMDS scores reduced to 5 and 1, respectively (monopolar stimulation,3.2 mA, 210 μs pulse width, 130 Hertz). Although oral feeding resumed, blepharospasm persisted, prompting medication discontinuation.

Conclusion: Only a few studies demonstrate the benefit of GPi-DBS in adult-onset DYT-KMT2B. Our case highlights that GPi DBS appears to be as effective in adult-onset as in childhood-onset DYT-KTM2B and emphasized the importance of postoperative monitoring.

Disclosure: The authors declare that there are no conflicts of interest relevant to this work.

EPO-347 | Striatal dopamine correlates to spatial gait parameters in dual task conditions

C. Zatti[1]; A. Pilotto[1]; A. Rizzardi[1]; A. Galli[1]; C. Hansen[2]; M. Catania[1]; R. Romijnders[2]; W. Maetzler[2]; A. Padovani[1]

[1]*Department of Clinical and Experimental Sciences, Neurology Unit, University of Brescia, Italy;* [2]*Department of Neurology, Christian-Albrechts-University of Kiel, Kiel, Germany*

Background and Aims: Parkinson's disease (PD) is clinically defined by motor symptoms and the underlying mechanism is determined by loss of dopaminergic neurons in the substantia nigra, leading to dopamine depletion in the basal ganglia circuit. Despite this, the MDS-UPDRS-III, the standard motor assessment, does not correlate with the dopaminergic deficit. The aim of this study was to investigate the relationship between dopamine uptake and motor changes using inertial sensors.

Methods: Forty de novo PD patients were enrolled. They underwent a comprehensive motor assessment including MDS-UPDRS-III and digital assessment of gait parameters in normal, fast and dual-task conditions using mobile health technologies (MHT) in a supervised setting. All patients underwent 123I-FP-CIT-SPECT imaging to quantify dopaminergic uptake. The relationship between motor parameters and dopamine binding was assessed using partial correlations corrected for age, sex and height.

Results: No correlation was observed between MDS-UPDRS-III and dopamine uptake in the striatal circuit. Step length in single and dual task conditions correlates directly with MDS-UPDRS-III (p: 0.001 R: 0.376), while reduced step length in dual task conditions is associated with reduced DAT availability in both putamen and pallidum (p: 0.022 and 0.013 with R: 0.417 and R: 0.428).

Conclusion: Dopamine depletion is known to be the pathological mechanism underlying motor changes in PD. Our study suggests that the use of more sensitive parameters, specifically spatial parameters in dual task conditions, can identify this relationship.

Disclosure: Nothing to disclose.

EPO-348 | Efficacy of safinamide in Parkinson's disease: Focus on gender differences

C. Cattaneo[1]; I. Marjanovic[2]

[1]*Medical Department Zambon SpA, Bresso, Italy;* [2]*Medical Department Zambon SpA, Bresso, Italy*

Background and Aims: There is an increasing evidence of gender differences in the epidemiology and clinical manifestation of both motor and non-motor symptoms of Parkinson's disease (PD). Nevertheless, few data are available on gender differences in the

response to antiparkinsonian drugs. Safinamide has a unique dopaminergic and non-dopaminergic mechanism of action that might improve patients' care in both sexes.

Methods: The gender differences in safinamide efficacy were investigated using the data from two clinical trials, studies SYNAPSES (Europe) and XINDI (China).

Results: 616 (38%) out of 1610 patients enrolled in the SYNAPSES study were women and 994 (62%) men, while in the XINDI study 128 (42%) out of 305 patients enrolled were women and 177 (58%) men. Safinamide significantly improved motor symptoms ($p<0001$), motor fluctuations ($p=0.0007$) and quality of life ($p=0.0014$) in both genders, with a good safety profile and without requiring any change in the concomitant dopaminergic therapy. Moreover, safinamide improved three out of four PD cardinal symptoms and reduced tremor in females and rigidity in males, the two peculiar gender features of PD.

Conclusion: Safinamide, administered as add-on therapy in fluctuating PD patients, improved motor symptoms and motor complications without increasing troublesome dyskinesia in both male and female subjects. Further prospective studies specifically addressing potential gender differences in response to PD therapies are needed to develop tailored management strategies.

Disclosure: Carlo Cattaneo is an employee of Zambon SpA; Ivan Marjanovic is a consultant of Zambon SpA.

EPO-349 | Navigating the maze: Unmasking the influence of cerebral small vessel disease on non-motor symptoms burden in PD

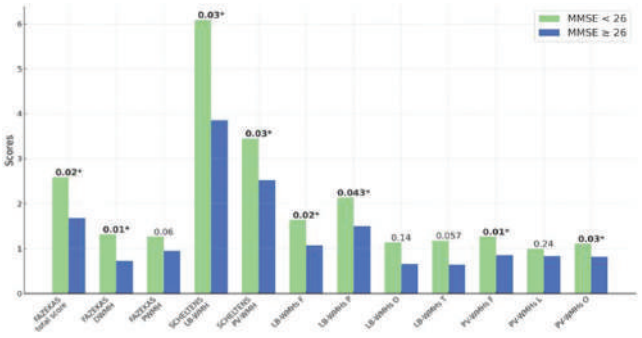
C. Santoro[1]; D. Urso[2]; V. Gnoni[2]; L. Batzu[3]; S. Landolfo[1]; A. Giugno[2]; S. Rota[3]; D. Vilella[2]; R. De Blasi[4]; K. Chaudhuri[3]; G. Logroscino[2]

[1]Department of Basic Medical Sciences, Neuroscience and Organ Sense, University "Aldo Moro", Bari, Italy; [2]Center for Neurodegenerative Diseases and the Aging, Department of Clinical Research in Neurology, University of Bari "Aldo Moro", "Pia Fondazione Cardinale G. Panico", Tricase, Lecce, Italy; [3]Institute of Psychiatry, Psychology and Neuroscience, Department of Basic and Clinical Neuroscience, Division of Neuroscience, King's College London, London, UK; [4]Department of Diagnostic Imaging, Pia Fondazione di Culto e Religione "Card. G. Panico", Tricase, Lecce, Italy

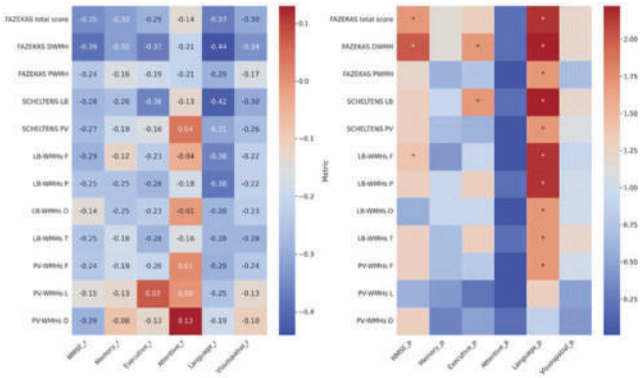
Background and Aims: Managing Parkinson's disease (PD) poses a significant challenge, primarily due to the prevalence of non-motor symptoms (NMS). While the impact of Lewy-Body and Amyloid pathology on PD-related cognitive impairment is known, the role of vascular co-pathology remains uncertain. This study explores potential links between white matter hyperintensities (WMH) and specific NMS-clusters.

Methods: A cohort of 66 PD patients underwent comprehensive assessments, including clinical evaluations of both motor and NMS, neuropsychological tests covering five major cognitive domains and brain 3.0T magnetic resonance imaging. The severity and distribution of WMH were visually rated using Fazekas and Scheltens scales. Statistical analyses, including Mann-Whitney tests and Spearman correlations, were employed to assess associations between WMH burden, cognitive functions, and NMS.

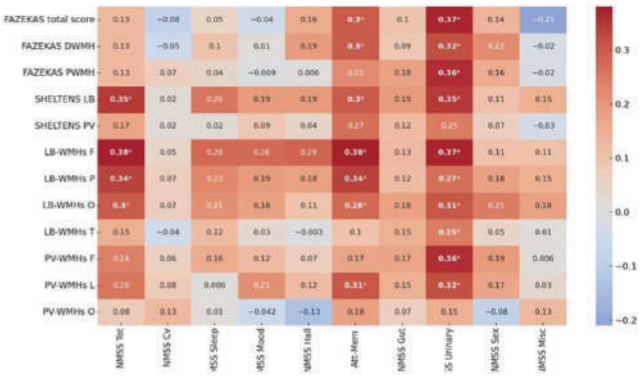
Results: Prominent connections with NMS, particularly urinary dysfunction, were observed in the frontal and parietal lobes. Significant correlations were found between WMH burden and cognitive functions. MMSE scores negatively correlated with Fazekas WMH total



Examining two groups (MMSE < 26, $n=22$; MMSE > 26, $n=44$), this chart reveals significant associations between lower MMSE scores and increased Fazekas and Scheltens total burden and sub-scores especially in the deep lobar areas.



The left heatmap shows Spearman correlation coefficients exploring the interplay between cognitive domains (including MMSE) and white matter lesion severity and distribution; the right one instead highlights *p*-values post-Benjamini correction.



This heatmap illustrates Spearman correlation coefficients (r) examining the relationship between the vascular burden of WMH (measured by Fazekas and Scheltens scales) and various domains of NMS assessed by NMS scale.

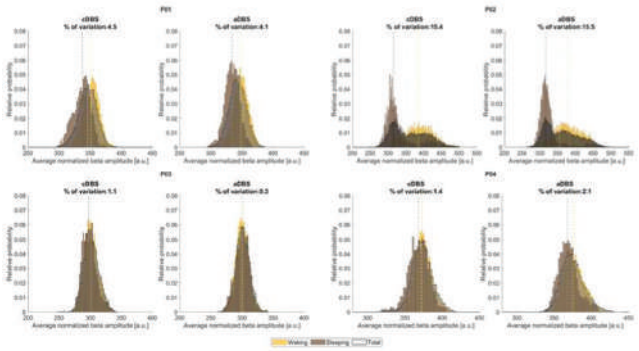
and frontal deep white matter loads. Executive dysfunction was linked to greater Fazekas and Scheltens lobar WMH loads, while language impairment was associated with frontal and parietal WMH burdens.

Conclusion: Our findings suggest significant associations between radiological WMH sites and distinct NMS that might be unintentionally overlooked in clinical contexts. We propose a cortical-subcortical "disconnection syndrome," indicating disruptions in communication between different cortical and subcortical regions. This syndrome may play a crucial role in the development or progression of distinct non-motor and cognitive patterns in PD. Recognizing regional-specific white matter damage enriches cognitive and NMS assessments, offering refined options for personalized medicine.
Disclosure: Nothing to disclose.

EPO-350 | Beta power circadian modulation in patients with Parkinson's disease and conventional or adaptive deep brain stimulation

C. Baiata[1]; S. Manfroni[1]; L. Caffi[2]; M. Locatelli[3]; A. Ampollini[3]; S. Bonvegna[1]; C. Palmisano[4]; I. Isaias[5]
[1]Parkinson Institute Milan, ASST G.Pini-CTO, Milano, Italy; [2]Parkinson Institute Milan, ASST G.Pini-CTO, Milano, Italy; University Hospital Würzburg and Julius Maximilian University of Würzburg, Würzburg, Germany; The BioRobotics Institute, Scuola Superiore Sant'Anna, Pisa, Italy; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; [4]University Hospital Würzburg and Julius Maximilian University of Würzburg, Würzburg, Germany; [5]Parkinson Institute Milan, ASST G.Pini-CTO, Milano, Italy; University Hospital Würzburg and Julius Maximilian University of Würzburg, Würzburg, Germany

Background and Aims: Increased beta power oscillations in the subthalamic nucleus (STN) are a key feature of Parkinson's disease (PD). However, their physiological contribution to motor and non-motor tasks, such as the sleep-awake cycle, is still poorly understood, and may influence the effect of deep brain stimulation (DBS), both in conventional (cDBS) and adaptive (aDBS) modes. The aim of the study is to investigate the impact of cDBS and aDBS on sleep-wake subthalamic beta power fluctuations in PD
Methods: We acquired subthalamic local field potentials (LFP) in four patients with idiopathic PD and implanted with the AlphaDBS device (Newronika SpA). This device can operate in either cDBS, with constant stimulation parameters, or aDBS, adjusting linearly the current amplitude with respect to subthalamic beta power. Patients were recorded consecutively for 10 days in both stimulation modes and with unchanged drugs doses. We calculated the amplitude of the STN-LFP in a patient-specific frequency range centered around the most prominent beta peak with 1 min resolution and analyzed the distribution of the beta amplitude separately for the sleeping and waking time
Results: One patient showed a median reduction in subthalamic beta power during sleep compared to waking hours of 15%, under both



Sleep-awake beta power distribution.

stimulation modes. All other patients had sleep-awake beta power modulation <5% in both stimulation modes. The stimulation modes did not affect the sleep-awake modulation of subthalamic beta power.
Conclusion: Our preliminary data show a variable modulation of subthalamic beta power during sleep-wake cycle in parkinsonian patients with comparable impact of cDBS and aDBS
Disclosure: Nothing to disclose.

EPO-351 | Effects of loading, tapping performance, and ballistic movements on tremor features in patients with essential tremor

D. Birreci; D. Costa; L. Angelini; A. Cannavacciuolo; M. Passaretti; A. Martini; S. Grandolfo; M. De Riggi; G. Paparella; M. Bologna
Department of Human Neurosciences, Sapienza, University of Rome, Rome, Italy

Background and Aims: In recent years, a comprehensive set of neurophysiological tests, including the loading test, tapping performance analysis, and the evaluation of response to ballistic movements, has been proposed to formulate laboratory-supported criteria for diagnosing functional tremor. Our aim is to comprehensively evaluate the effects of these manoeuvres on tremor features in patients with essential tremor (ET).
Methods: ET patients were evaluated using a standardized clinical scale, the Fahn-Tolosa-Marin Tremor Rating Scale (FTM-TRS). A comprehensive tremor evaluation at baseline and during loading, finger tapping (at 1, 3, and 5 Hz), and ballistic movements was conducted using an optoelectronic system. Data were analyzed through non-parametric Friedman Analysis of Variance (ANOVA).
Results: Thirteen ET patients were included (6 females, 64.9±17.6 years), with a mean disease duration of 15.6±10.9 years and a FTM-TRS score of 20.6±10.1. At baseline, postural tremor had a mean frequency of 5.98±1.42 Hz and a mean amplitude of 0.053±0.036 GRMS^2. ANOVA unveiled a difference in amplitude ($p = 0.03$), with lower values during 1 Hz finger-tapping movements, compared to the other conditions. Moreover, we found an inverse correlation between baseline tremor amplitude and the reduction in tremor amplitude during 1 Hz tapping ($p = 0.021$). No variation

in tremor frequency was revealed across different manoeuvres ($p = 0.62$).

Conclusion: Gaining insights into the impact of loading, tapping performance, and ballistic movements on tremor features in patients with ET holds relevance for clinical applications, especially within the diagnostic process. Expanding the analysis to larger patient samples could contribute to a deeper understanding of how clinical factors influence the observed effects.

Disclosure: Nothing to disclose.

EPO-352 | Altered motor cortex excitability in Parkinson's disease patients

P. Ortelli[1]; V. Versace[1]; S. Dezi[1]; A. Precup[1]; S. Buechner[2]; C. Raccagni[2]; L. Saltuari[1]; A. Oliviero[3]; R. Maestri[4]; N. Giladi[5]; D. Ferrazzoli[1]; L. Sebastianelli[1]

[1]Department of Neurorehabilitation, Hospital of Vipiteno (SABES-ASDAA), Vipiteno-Sterzing, Italy; Teaching Hospital of the Paracelsus Medical Private University (PMU), Salzburg, Austria; [2]Department of Neurology, Hospital of Bolzano (SABES-ASDAA) – Teaching Hospital of the Paracelsus Medical Private University (PMU), Bolzano, Italy; [3]FENNSI Group, Hospital Nacional de Parapléjicos, Servicio de Salud de Castilla La Mancha, Toledo, Spain; [4]Istituti Clinici Scientifici Maugeri, IRCCS, Department of Biomedical Engineering of Montescano Institute, Pavia, Italy; [5]Brain Institute, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Background and Aims: In Parkinson's disease (PD), pathological activity of basal ganglia-thalamocortical circuits affect neural networks subtending motor and non-motor symptoms. This disruption could be unveiled by exploring primary motor cortex (M1) with transcranial magnetic stimulation (TMS). We extensively assessed a combined neurophysiological-neuropsychological evaluation in a cognitively spared population of PD patients (PDp).

Methods: 15 PDp and 11 healthy controls (HC) were enrolled. Fatigue was evaluated with Parkinson Fatigue Scale (PFS-16), attention was measured with computerized Sustained Attention Task (SAT) and Stroop Task (ST). Global cognition in PDp was evaluated with Montreal Cognitive Assessment (MoCA). Following TMS of dominant M1, we assessed Resting Motor Threshold (RMT), Motor Evoked Potential (MEP) amplitude and Silent Period (SP) duration. Intracortical activity was explored with Short-Interval Intracortical Inhibition (SICI), Intracortical Facilitation (ICF) and Long-Interval Intracortical Inhibition (LICI).

Results: Mean MoCA score was 24.2 (SD $\pm$3.3). PFS score was higher in PDp ($p = 0.03$). Reaction times were longer in PDp in SAT ($p = 0.002$), ST-incongruent condition and ST-interference ($p = 0.005$ and $p = 0.036$, respectively). In PDp, RMT was higher ($p = 0.43$), MEP amplitude was lower ($p = 0.26$), SP duration was shorter ($p = 0.001$) and LICI at 100 ms interstimulus interval (ISI) was reduced ($p = 0.013$). SICI at 2 and 3 ms ISI was disrupted (MEPs were facilitated) in both groups. No difference was observed in ICF.

Conclusion: Neurophysiological findings suggest that M1 hypoexcitability and altered GABAB activity possibly affect motor control and attention in PD. Aging-related GABAA circuits disruption we found in both groups may contribute to fatigue perception in PD.

Disclosure: Nothing to disclose.

EPO-353 | The influence of deep brain stimulation on saccades in Parkinson's disease: A transversal and longitudinal study

D. Damas[1]; I. Carvalho[1]; S. Matos[1]; A. Jorge[1]; A. Martins[1]; F. Cidade[2]; J. Castelhano[3]; R. Pereira[4]; F. Moreira[1]; J. Lemos[1]

[1]Neurology Department, Coimbra University Hospital; [2]Faculty of Sciences and Technology of the University of Coimbra; [3]Faculty of Medicine of the University of Coimbra; [4]Neurosurgery Department, Coimbra University Hospital

Background and Aims: Saccades are disrupted in Parkinson's disease (PD), both involuntary (i.e., saccadic intrusions [SI]), reflexive (i.e., prosaccades [PS]) and more voluntary (i.e., antisaccades [AS]) saccades, eventually deteriorating vision. Deep Brain Stimulation (DBS) seems to improve saccadic parameters in PD patients. There is need to evaluate if such effect is sustained over time and if saccades' planes are individually influenced by DBS.

Methods: We recruited 23 PD patients (14 males, mean age 65$\pm$8.2 years) with bilateral subthalamic nucleus-DBS that underwent eye-tracking assessment at baseline and one year follow-up, both with DBS on- and off-state. Number of SI, velocity, latency and gain of PS and AS, and AS errors/corrected errors were analysed.

Results: At baseline, when compared to off-state, DBS significantly decreased SI number, increased the gain/velocity of correct horizontal/vertical AS and the gain of corrected horizontal/vertical errors, while decreasing the latency of incorrect vertical AS. At one year follow-up, DBS increased the gain of horizontal PS, the gain/velocity of correct horizontal/vertical AS and the gain of corrected horizontal/vertical errors, while decreasing the latency of correct/incorrect vertical AS. Saccadic parameters remained unchanged in off-state after one year and there was no interaction between DBS status and time of assessment.

Conclusion: DBS significantly improves fixation instability, speeds up and widens predominantly voluntary eye movements in PD patients, in addition to accelerate their start strictly along the vertical plane. Remarkably, these effects are sustained over time. This data highlights the overlooked benefit of DBS on vision of PD patients.

Disclosure: Nothing to disclose.

EPO-354 | HeBA-online Parkinson disease risk factors survey diffusion: Digital versus traditional approaches

D. Pilco-Janeta[1]; A. Garrido[2]; M. De la Cruz-Puebla[1]; F. Farfán Alé[1]; A. Granolles[3]; S. Hajiantilaki[1]; Y. Rodríguez[1]; E. Tolosa[2]; M. Martí[2]
[1]*Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Catalonia;* [2]*Parkinson Disease and Movement Disorders Unit, Neurology Service, Institut Clínic de Neurociències, Hospital Clínic de Barcelona, Barcelona, Catalonia;* [3]*Altoclick Digital Marketing Agency, Barcelona, Catalonia, Spain*

Background and Aims: The Healthy Brain Ageing (HeBA) is a European multicenter project using innovative approaches for early detection and intervention in Parkinson's disease. In the first phase, the project aims to gather comprehensive data through online surveys. This study specifically focuses on evaluating and comparing the effectiveness of various dissemination strategies, particularly digital platforms like META's platforms and Google Ads against traditional media in collecting data from Catalonia's population.

Methods: We gathered data from META campaigns (Facebook, Instagram), Google Ads, and traditional media (radio, press, online press, and television). Analyzed metrics included clicks for HeBA online survey in META and Google, along with audience size for traditional media. Quantitative analysis assessed campaign clicks, and audience engagement trends.

Results: In the context of HeBA diffusion strategies, digital dissemination methods, such as META campaigns, achieved a total of 102,248 clicks (Figure 1A). For Google Ads campaigns, there were a total of 2,089 clicks to the HeBA survey (Figure 1B). Notably, our traditional media campaigns reached an impressive overall audience of approximately 97,432,694. Newspapers emerged as the medium with the highest reach (Figure 1C). Additionally, in the HeBa survey response distribution, we obtained 6,943 complete responses and 6,749 partial responses out of a total of 13,692 responses collected between June 13, 2022, and January 15, 2024 (Figure 1D).

Conclusion: The HeBA Project's media strategy effectively merges the broad audience reach of traditional media with the targeted engagement of digital platforms, providing a valuable blueprint for future health communication campaigns.

Disclosure: Nothing to disclose.

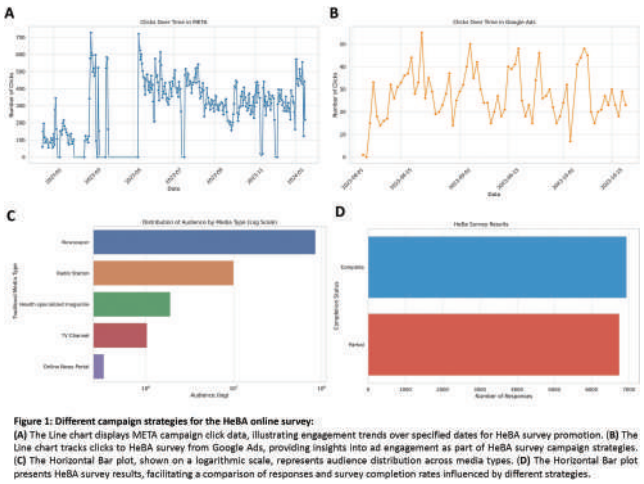

FIGURE 1 Different campaign strategies for the HeBA online survey.

EPO-355 | Clinical features and outcomes of neuroacanthocytosis: A single center experience

Z. Huseynli; B. Samanci; E. Sahin; S. Yusifli; B. Bilgic; H. Hanagası
Neurology, Istanbul Unıversity, Topkapı, Istanbul, Turkey

Background and Aims: Neuroacanthocytosis (NA) is a rare disorder with multisystem involvement, and characterized by progressive basal ganglia degeneration. We aimed to report clinical characteristics and outcomes of NA patients in a Turkish cohort.

Methods: Eleven patients with NA diagnosis of our database were included. Clinical characteristics, laboratory and MRI examinations were recorded.

Results: The mean age of the patients (5 male, 6 female) was 39.5±3.65 years, with symptom onset at 29±4.86 years. Mean follow-up duration was 3.9±2.1 years. Psychiatric symptoms ($n=4$), tics ($n=3$), dystonia ($n=2$), chorea ($n=1$), seizure ($n=1$) were noted as first symptoms. Self-mutilation were observed in 5 patients. In the follow up, vocal ($n=5$) and motor tics ($n=3$), choreiform movements ($n=11$), dystonia ($n=6$), dysarthria ($n=11$), dysphagia ($n=11$), weight loss ($n=11$), psychiatric issues ($n=7$) were observed. Seizures occurred in 10, with 4 focal and 6 generalized. Acanthocytes ratio were seen in 10-50% of blood smears. MRI revealed caudate in all, and parietal atrophy in 2 patients. Three patients had sensory neuropathy, 1 had motor neuropathy, and 2 showed myogenic changes in EMG. VPS13A mutation was detected in 4 patients for whom molecular analysis was available. Six started on olanzapine, five on haloperidol, and two underwent deep brain stimulation for severe dystonia. Significant worsening of involuntary movements and dysphagia was observed in all patients during follow-up, and three patients died after 11±2.82 years follow-up.

Conclusion: It is crucial to assess patients showing multisystem involvement such as early psychiatric issues, self-mutilation, movement disorders, acanthocytosis, and caudate atrophy for an accurate NA diagnosis.

Disclosure: The authors affirm that there are no conflicts of interest pertinent to this study.

EPO-356 | Experience with safinamide in Parkinson's disease patients after STN-DBS

K. Del Giudice; J. Bejarano; F. Valldeoriola; A. Sanchez
Institute of Neuroscience, Neurology Service, Parkinson's Disease and Movement disorders Unit, Hospital Clinic of Barcelona

Background and Aims: Subthalamic nucleus -Deep Brains Stimulation (STN-DBS) has been stablished as a well-defined therapy for treating Parkinson's disease (PD) motor symptoms; however, some non-motor symptoms may not respond as expected, which significantly impact on quality of life of the patients (QoL). Antiparkinsonian drugs with dopaminergic and non-dopaminergic properties like "safinamide" have been suggested to have a positive effect on non-motor symptoms. The aim of this study was to investigate the efficacy of safinamide to improve apathy, fatigue and QoL in PD patients after STN-DBS.

Methods: We studied prospectively 13 PD patients that presented bothersome nonmotor symptoms after intensive setting of electrical parameters, stimulation contacts and optimal drug therapy. Patients were evaluated 32 week after 100mg of safinamide was started. Clinical assessment included Apathy Scale Starktein (AS), Parkinson Fatigue scale-16 (PFS-16) and Parkinson´s Disease Quality of life questionnaire -8 (PDQ-8).

Results: Thirteen PD patients were analyzed. The median age was 59 years old, with a median disease duration of 10 years at surgery. All patients were H&Y 2 in the ON state, and median of 400 levodopa equivalent daily dose. An improvement of 58.3% on the AS, 38% on the PFS-16 and 41.6% on the PDQ-8 was observed.

Conclusion: In this pilot study, safinamide proved to be an effective add-on treatment in PD patients treated with bilateral STN-DBS, leading to an improvement of non-motor complications, such as apathy, fatigue and QoL. Further studies with a higher number of patients are necessary to establish the value of this drug in the clinical practice.

Disclosure: Nothing to disclose.

EPO-357 | Clinicians' information provision during diagnostic consultations regarding Parkinson's disease

E. Kurpershoek[1]; M. Hillen[2]; R. de Bie[1]; J. Dijk[1]
[1]*Department of Neurology, Amsterdam UMC, Amsterdam, The Netherlands;* [2]*Department of Medical Psychology, Amsterdam UMC, Amsterdam, The Netherlands*

Background and Aims: People with Parkinson's disease (PD) have reported feeling insufficiently informed by clinicians during diagnostic consultations, which might hinder patients' ability to manage their day-to-day lives. We aimed to (1) assess the amount and content of provided information during diagnostic consultations; and to test if the provided information is associated with (2) patients' evaluation thereof and (3) clinician and patient characteristics.

Methods: This observational longitudinal study video recorded diagnostic consultations of PD patients at seven neurology outpatient clinics in The Netherlands. We systematically coded the recordings for time spent on pre-defined information topics. Clinician and patient characteristics, a priori information needs, and retrospective perception and evaluation of received information were assessed using questionnaires. Analyses included descriptive statistics and regressions.

Results: Patients' information need was high overall ($M = 4.5 \pm 0.8$, potential range 1–5). Clinicians' information provision varied across patients ($n = 50$) and clinicians ($n = 37$). All patients were provided with information regarding their diagnosis, treatment options, and the follow-up plan. About half were not informed about PD being incurable (44%) and the long-term effects of dopaminergic medication (58%). Patients reported to have perceived quite some information ($M = 2.8 \pm 0.9$, PR 1-5), and were quite satisfied ($M = 3.4 \pm 0.9$, PR 1-5). 30% reported a wish for more information, particularly regarding the prognosis. Regression analyses will be completed at the time of the conference.

Conclusion: Most clinicians mainly focus on treatment during PD diagnostic consultations, and may not sufficiently meet patients' prognostic information needs. We recommend clinicians to actively inquire about patients' information preferences during diagnostic consultations, and tailor their information provision accordingly.

Disclosure: Nothing to disclose.

EPO-358 | Diagnostic accuracy of Parkinson's disease by neurologists in an outpatient setting: The Parklink Bologna cohort

E. Umbertini[1]; L. Vignatelli[2]; F. Baccari[2]; L. Belotti[2]; C. Zenesini[2]; R. D'Alessandro[2]; F. Nonino[2]; G. Giannini[2]; G. Calandra Buonaura[2]; G. Calandra Buonaura[1]
[1]*DIBINEM Dipartimento di Scienze Biomediche e Neuromotorie;* [2]*IRCCS Istituto delle Scienze Neurologiche di Bologna*

Background and Aims: The diagnosis of Parkinson's disease (PD) is still mainly clinical and with variable accuracy in different settings. The Parklink Bologna project is an ongoing record linkage system started in 2015 in the Local Health Trust of Bologna (LHTB), devised for epidemiological and research purposes, including prevalent and incident cases of PD or atypical parkinsonism. The objective of this study is to evaluate the accuracy of the diagnosis of PD recorded by neurologists participating in the Parklink project. Interobserver agreement between two movement disorder experienced neurologists was assessed.

Methods: Diagnostic accuracy cross-sectional study on a random sample of 220 patients representative of the ParkLink cohort. Sensitivity, specificity, positive/negative predictive value (PPV/NPV) were calculated by assuming as reference standard the blinded diagnosis of two movement disorder experienced neurologists, applying Postuma international diagnostic criteria for PD, and as index-test the diagnosis recorded by outpatients neurologists within

the ParkLink project. Interobserver agreement was assessed using Cohen's Kappa.

Results: In 193 patients (mean age 72.8 years) clinical documentation for a diagnosis was available. A sensitivity of 94.1% (95% CI: 88.7-97.4) and specificity of 63.2% (49.3-75.6), PPV of 85.9% (79.3-91.1) and NPV of 75% (59.7-86.8) were found for the first assessor. Interobserver agreement was "substantial" (Kappa 0.77, 95% CI: 0.67-0.87) between the two experts.

	1° assessor	CI 95%	2° assessor	CI 95%
Sensitivity	94.1%	88.7-97.4	92.7%	87.3-96.3
Specificity	63.2%	49.3-75.6	78.6%	63.2-89.7
PPV	85.9%	79.3-91.1	94%	88.8-97.2
NPV	81.8%	67.3-91.8	75%	59.7-86.8

Accuracy parameters

Conclusion: Diagnosis of PD according to the 2015 Postuma criteria showed good PPV and NPV in an outpatient real-world setting. It is possible to build reliable cohorts of people with PD for epidemiological research, based on both community neurologists and neurologists from movement disorder centres.

Disclosure: Nothing to disclose.

EPO-359 | TremAn3: A new tool for the analysis of tremor and other oscillatory movements in video recordings

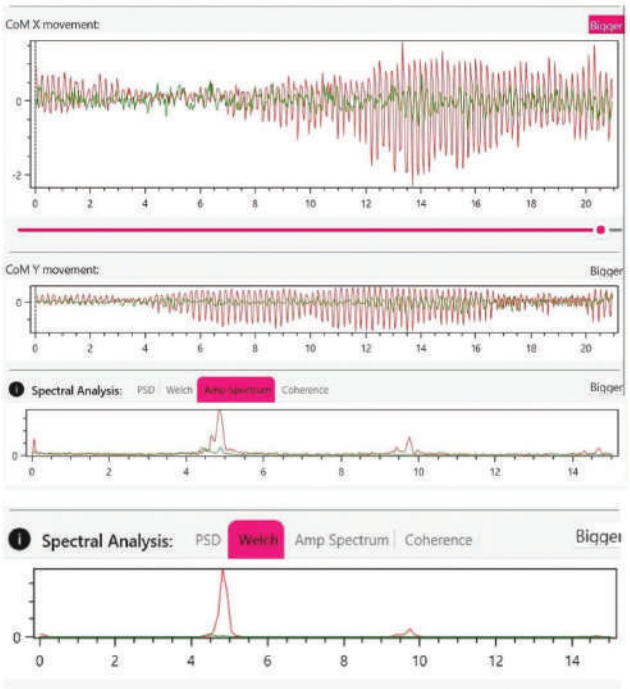
E. Růžička[1]; J. Tesař[2]; T. Serranová[1]; T. Hubená[2]; P. Hollý[1]; Y. Yilmaz[3]; A. Hollmannová[1]; J. Jankovic[3]; R. Krupička[2]

[1]Department of Neurology, Charles University and General University Hospital, Prague, Czechia; [2]Department of Biomedical Informatics, Faculty of Biomedical Engineering, Czech Technical University, Prague, Czechia; [3]Parkinson's Disease Center and Movement Disorders Clinic, Baylor College of Medicine, Houston, Texas

Background and Aims: Neurophysiological techniques used to quantify tremor are not readily available in clinical practice, whereas video recording is a part of routine evaluation. We describe TremAn3, a novel application that enables kinematic analysis of tremor or other rhythmic movements from standard video recordings of patients.

Methods: We analyzed video recordings of 17 patients with essential tremor (ET) and 19 patients with functional tremor (FT) diagnosed at the General University Hospital in Prague, Czechia and of 9 subjects with leg stereotypy syndrome (LSS) recruited at the Baylor College of Medicine in Houston, Texas. In the video recordings, oscillating part(s) of the body are delineated in TremAn3 as the region(s) of interest. The algorithm then calculates the center of motion (CoM) derived from the normalized frame differences and defines the motion trajectory, followed by a fast Fourier transform (FFT) generating an amplitude spectrum of oscillations.

Results: In patients with ET, analysis demonstrated stable frequency spectra with intraindividual variation below 1 Hz. In FT patients, increased intraindividual variability of tremor frequency exceeding 1 Hz was found, with marked distractibility and entrainment by contralateral rhythmic movements. Of the 9 individuals with LSS, regular rhythmic oscillations of the lower limbs were present in 7 cases, ranging between 4.5 and 6.5 Hz, with a variance below 0.5 Hz in individual cases (Yilmaz et al., manuscript in preparation).



Sample output from TremAn3: video analysis of a patient with ET.

Conclusion: TremAn3 appears as a tool suitable for supporting the differential diagnosis of tremor in daily practice and to analyze video recordings obtained in large participant cohorts.

Disclosure: Nothing to disclose.

EPO-360 | Prospective study of gait and multimodal MRI biomarkers Multiple System Atrophy (MSA)

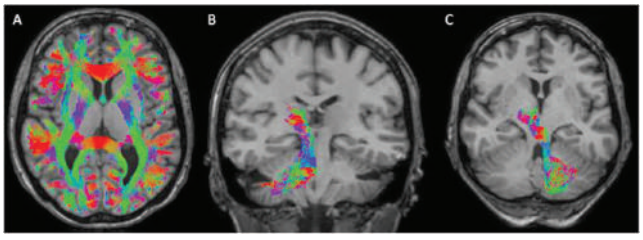
Lille, INSERM, CHU Lille, U1172 – LilNCog – Lille Neurosciences & Cognition, F-59000 Lille, France; Department of Medical pharmacology CHU Lille;* [4]*Department of Clinical Neurophysiology, Bordeaux University Hospital, Bordeaux, France; Institute of Neurodegenerative Disorders, Bordeaux University, Bordeaux, France;* [5]*Univ. Lille, INSERM, CHU Lille, U1172 – LilNCog – Lille Neurosciences & Cognition, F-59000 Lille, France; Department of Neuroradiology CHU Lille*

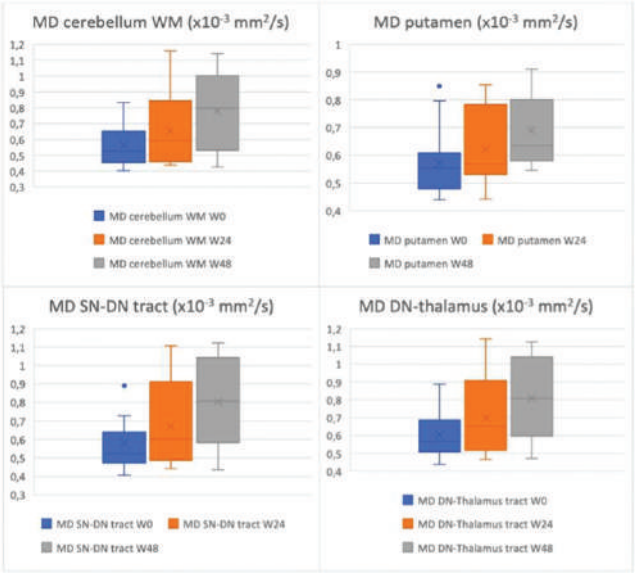
Background and Aims: MSA is a rare neurodegenerative condition characterized by a rapid gait deterioration with severe prognosis. Currently, no treatment is available to slow down disease progression. We aimed to develop new multimodal biomarkers allowing objective monitoring of early MSA progression to improve outcome definition for future neuroprotective trials.

Methods: This analysis focuses on 19 MSA patients, enrolled in the Gait'N'Park multicentric cohort (NCT04653688). Longitudinal data, including clinical scales (UMSARS), unsupervised gait analysis (at home using smart insoles), and multimodal MRI data (volumetric, R2*, QSM for iron load, and DTI for microstructural alterations), were collected at baseline (W0) and 24 weeks (W24).

Results: At W24, there was a significant increase of mean diffusivity in cerebellar white matter (pFDR = 0.029) and in fiber bundles between: Substantia Nigra and Dentate Nuclei (pFDR = 0.0013); and Dentate Nuclei and Thalamus (pFDR = 0.0013). No significant worsening was observed at W24 for other parameters, such as UMSARS, gait speed (95th centile) or stride length (mean), putamen, cerebellum or pons volume, or putamen R2* and QSM values.



Tractography: (A) Whole brain; (B) Substantia Nigra-Dentate Nucleus; (C) Dentate Nucleus-Thalamus.



Mean diffusivity evolution along time (MD = Mean Diffusivity; WM = White Matter; SN = Substantia Nigra; DN = Dentate Nucleus).

MD ($x10^{-3}mm^2/s$)	W0 (median; Q1-Q3)	W24 (median; Q1-Q3)	Difference	p	p_{FDR}	$p_{Bonferroni}$
Cerebellum WM	0.525 (0.460-0.639)	0.592 (0.480-0.767)	+0.067 (+12.8%)	**0.0067***	**0.029***	0.0871
Putamen	0.553 (0.486-0.600)	0.570 (0.533-0.716)	+0.017 (+3.1%)	**0.0293***	0.0596	0.3809
SN-DN tract	0.523 (0.481-0615)	0.602 (0.494-0.850)	+0.08 (+15.2%)	**0.0001***	**0.0013***	**0.0013***
DN-Thalamus tract	0.568 (0.514-0.670)	0.653 (0.529-0.853)	+0.085 (+15%)	**0.0002***	**0.0013***	**0.0026***

Mean diffusivity analysis at W24 vs W0 (MD = Mean Diffusivity; WM = White Matter; SN = Substantia Nigra; DN = Dentate Nucleus).

Conclusion: Our data confirm the low sensitivity to early change of UMSARS, currently use as the gold standard to monitor disease progression. Whereas diffusion imaging of white matter appears to be sensitive to change as early as 6 months of follow-up, with high statistical significance, supporting early involvement of oligodendrocytes. This kind of biomarker should be considered to enhance outcome definition for future neuroprotection trials.

Disclosure: This study was sponsored and funded by H. Lundbeck A/S, FeetMe, France Parkinson, Vaincre Parkinson. Félix Marchand has nothing to disclose.

EPO-361 | Improvement of troublesome dyskinesia in people with Parkinson's disease treated with foslevodopa/foscarbidopa

M. Blaabjerg[1]; T. Liang[2]; E. Peckham[3]; S. Zauber[4]; L. Bergmann[5]; R. Gupta[5]; L. Harmer[5]; M. Shah[5]; F. Bergquist[6]

[1]Department of Neurology, Odense University Hospital, Odense, Denmark; [2]Department of Neurology, Thomas Jefferson University, Philadelphia, Pennsylvania, USA; [3]Central Texas Neurology Consultants, Round Rock, Texas, USA; [4]Department of Neurology, Indiana University School of Medicine, Indianapolis, Indiana, USA; [5]AbbVie Inc., North Chicago, Illinois, USA; [6]Department of Pharmacology, University of Gothenburg, Gothenburg, Sweden; Sahlgrenska University Hospital, Gothenburg, Sweden

Background and Aims: Troublesome dyskinesia, a complication from Parkinson's disease (PD) progression and pulsatile dopaminergic stimulation, impairs daily living. Foslevodopa/foscarbidopa (LDp/CDp), a formulation of levodopa/carbidopa prodrugs delivered as a continuous (24-hour/day) subcutaneous infusion, increased "On" time without troublesome dyskinesia in 2 phase 3 clinical trials. This post hoc analysis evaluated LDp/CDp efficacy by baseline duration of troublesome dyskinesia.

Methods: Patients with levodopa-responsive idiopathic PD aged ≥30 years who were inadequately controlled by current therapy and had ≥2.5 "Off" hours/day received LDp/CDp in a 52-week, phase 3, open-label trial (NCT03781167). The change from baseline (CFB) to final visit was assessed for "On" time with troublesome dyskinesia (PD diary; normalized to 16-hour waking day), time spent with dyskinesias (Movement Disorder Society-Unified PD Rating Scale [MDS UPDRS] Part 4.1), functional impact of dyskinesias (MDS-UPDRS Part 4.2), and 39-item PD Questionnaire (PDQ-39) in patient subgroups with >0.5 and >1.0 hours of troublesome dyskinesia at baseline.

Results: Baseline characteristics were similar across subgroups with >0.5 ($n=83$) and >1.0 hours ($n=66$) of troublesome dyskinesia at baseline; mean (SD) duration of troublesome dyskinesia was 2.7 (2.0) and 3.1 (2.0) hours, respectively (Table). In both subgroups, LDp/CDp led to numerical or significant improvements from baseline in troublesome dyskinesia (mean [SD] CFB −1.4 [3.4] and −2.5 [2.2] hours, respectively; $p<0.05$; Figure1), time spent with dyskinesias ($p\leq0.001$), functional impact of dyskinesias ($p\leq0.001$), and PDQ-39 ($p<0.05$ for >0.5 hour subgroup; Figure 2).

Table. Baseline Demographics and Disease Characteristics by Duration of Troublesome Dyskinesia at Baseline

Characteristic	>0.5 h of Troublesome Dyskinesia[a] n=83	>1.0 h of Troublesome Dyskinesia n=66
Age, years, mean (SD)	63.5 (9.3)	63.9 (9.2)
Sex, male, n (%)	45 (54.2)	33 (50.0)
Race, White, n (%)	71 (85.5)	59 (89.4)
MMSE total score	28.8 (1.8)	28.8 (2.0)
PD duration since onset, years, mean (SD)	12.7 (5.1)	12.7 (5.3)
"Off" time, h, mean (SD)[b]	5.2 (2.3)	5.2 (2.4)
"On" time without troublesome dyskinesia, h, mean (SD)[b]	8.1 (2.8)	7.7 (2.9)
"On" time with troublesome dyskinesia, h, mean (SD)[b]	2.7 (2.0)	3.1 (2.0)
MDS-UPDRS Part II, mean (SD)	16.5 (7.6)	16.6 (7.8)
MDS-UPDRS Part IV, mean (SD)	11.2 (3.1)	11.3 (3.3)
PDQ-39, mean (SD)	37.4 (16.0)	38.0 (16.0)

EPO-362 | Opicapone as first-line strategy for the treatment of wearing-off in Korean patients with Parkinson's disease

J. Lee[1]; J. Ferreira[2]; H. Ma[3]; J. Rocha[4]; B. Jeon[5]
[1]*Department of Neurology, SMG-SNU Boramae Medical Center, Seoul, Republic of Korea;* [2]*CNS Campus Neurológico, Torres Vedras, Portugal and IMM – Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina, Universidade Lisboa, Lisbon, Portugal;* [3]*Department of Neurology, Hallym University Sacred Heart Hospital, Anyang, Republic of Korea;* [4]*BIAL–Portela & Ca S.A, Coronado, Portugal;* [5]*Department of Neurology, Seoul National University Hospital, Seoul, Republic of Korea*

Background and Aims: Opicapone (OPC) proved effective for end-of-dose motor fluctuations in patients with Parkinson's disease (PD) treated with levodopa (L-dopa)/dopa decarboxylase inhibitor (DDCi). This study aimed to explore the efficacy of OPC 50 mg versus an extra 100 mg L-dopa dose to treat early wearing-off in Korean patients with PD.
Methods: This was a prospective, multicentre, randomised, active-controlled study in which 169 levodopa-treated patients with PD and wearing-off were randomly assigned (1:1) to OPC 50 mg once-daily ($n=88$) or an additional 100 mg L-dopa dose ($n=81$). A 1-week screening period was followed by a 4-week maintenance phase. Main endpoint was change from baseline in absolute OFF-time. Secondary endpoints included tolerability, Movement Disorder Society-Unified-PD-Rating-Scale (MDS-UPDRS), 8-item PD Questionnaire (PDQ-8), Clinical Global Impression of Improvement (CGI-I), and Patient Global Impression of Change (PGI-C).
Results: At week 4, mean (standard error [SE]) change from baseline in absolute OFF-time was -62.1 min (9.8) for the OPC 50 mg group and -16.7 min (10.0) for the L-dopa 100 mg group, resulting in a significant difference of -45.4 min ($p=0.0015$). No significant differences were observed in MDS-UPDRS and PDQ-8 scores between the two groups. The OPC group tended to show greater improvements on CGI-I/PGI-C than the L-dopa group. OPC was well tolerated, but adverse events (AEs) were more frequent in the OPC than the L-dopa group (37.9% vs 18.5%), with dyskinesia (6.9%) being the most common drug-related AE.
Conclusion: OPC can be considered a potential first-line therapy to treat early wearing-off versus the standard L-dopa dose increase approach.
Disclosure: Supported by BIAL.

EPO-363 | Early-onset Parkinson's disease in women: A comparison of hormonal exposure with late-onset PD and unaffected controls

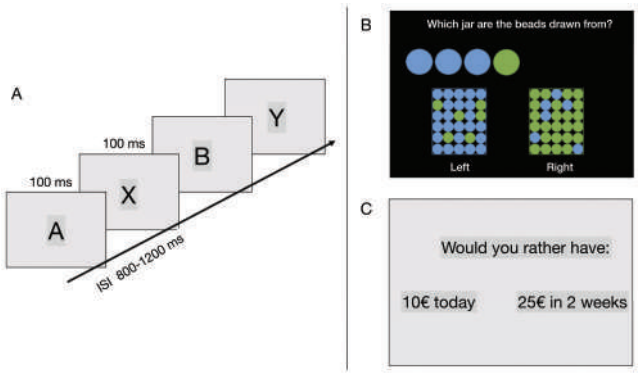
G. Patanè[1]; A. Mullan[2]; C. Piat[1]; P. Turcano[1]; R. Savica[1]
[1]*Mayo Clinic Department of Neurology, Rochester, Minnesota, USA;* [2]*Mayo Clinic Department of Health Sciences Research, Rochester, Minnesota, USA*

Background and Aims: PD is almost twice as common in men than in women. There is a paucity of studies evaluating the role of hormonal exposure in EOPD women. The objective was to compare the demographic characteristics and exposure to endogenous, exogenous estrogens and progestins between patients with EOPD, LOPD, and EOPD-matched unaffected controls.
Methods: We identified all female patients with EOPD in an incident cohort study from 1991 to 2010. EOPD patients were defined as having motor symptoms onset before age 50, after age 50 as LOPD. Each EOPD patient was matched to an unaffected control. Their medical records were reviewed to determine demographic characteristics, medical, reproductive, and menopausal history.
Results: 318 women with EOPD and 170 women with LOPD were identified. Of these, 87 EOPD patients, 91 controls, and 84 LOPD patients had sufficient hormonal exposure data in their records to be included. There were no significant differences in demographic characteristics between the three groups. EOPD patients were significantly more likely to have used hormonal contraception compared to controls and LOPD patients ($p<0.001$). The number of pelvic surgeries and the use of perimenopausal hormonal therapy preceding the onset of motor symptoms (both $p<0.001$) was significantly higher in LOPD compared to EOPD.
Conclusion: Our study reports that there are no significant differences in hormonal exposure between controls and EOPD patients, except for exposure to hormonal contraception. The differences in the history of hormonal contraception, oophorectomy and perimenopausal treatment between EOPD and LOPD are probably linked to the age gap between the two cohorts.
Disclosure: Nothing to disclose.

EPO-364 | Dopaminergic medication and STN-DBS increase motor, but not reflection and cognitive impulsivity in PD

M. Hendriks[1]; S. Vinke[2]; R. Berlot[1]; M. Benedičič[3]; M. Jahanshahi[4]; M. Trošt[1]; D. Georgiev[1]
[1]*Department of Neurology, University Medical Centre Ljubljana, Ljubljana, Slovenia;* [2]*Department of Neurosurgery, Donders Institute for Brain, Cognition and Behaviour, Radboud University Medical Centre, Nijmegen, The Netherlands;* [3]*Department of Neurosurgery, University Medical Centre Ljubljana, Ljubljana, Slovenia;* [4]*Department Clinical and Motor Neurosciences, Institute of Neurology, University College London, London, UK*

Background and Aims: Parkinson's disease is associated with increased impulsivity, which can be divided into several domains: motor (consisting of proactive and reactive subdomains), reflection and cognitive impulsivity. Evidence suggests that both dopaminergic medication and subthalamic nucleus deep brain stimulation can affect impulsivity. Therefore, we set out to investigate the effect of dopaminergic medication and subthalamic nucleus deep brain stimulation on motor, reflection and cognitive impulsivity in PD patients.
Methods: Twenty consecutive Parkinson's disease patients operated with subthalamic nucleus deep brain stimulation were tested ON and OFF dopaminergic medication and ON and OFF subthalamic nucleus deep brain stimulation. They performed three different impulsivity tasks: AX Continuing Performance Task to test for motor impulsivity, Beads Task for reflection impulsivity and Delay Discounting Task for cognitive impulsivity.
Results: The combination of subthalamic nucleus deep brain stimulation and dopaminergic medication led to an increase in motor impulsivity ($p=0.036$), both proactive ($p=0.045$) and reactive ($p=0.006$). There was no effect of either dopaminergic medication or subthalamic nucleus deep brain stimulation on reflection and cognitive impulsivity.



A - AX continuous performance task, B - Beads task, C - Delay discounting task. ISI = Interstimulus interval.

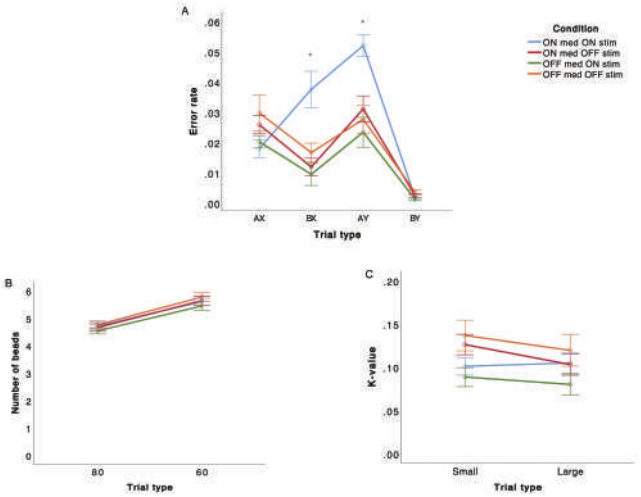


FIGURE 2 The performance on different tasks (A - AX-CPT, B-Beads task, C - Delay Discounting Task) in STN-DBS PD patients in four different conditions are presented.

Conclusion: The combination of dopaminergic medication and subthalamic nucleus deep brain stimulation leads to increased motor, but not cognitive or reflection impulsivity in patients with Parkinson's disease. Both, proactive and reactive motor impulsivity were impaired by the combination of dopaminergic medication and subthalamic nucleus deep brain stimulation.
Disclosure: Nothing to disclose.

EPO-365 | Gender differences in patients with Parkinson's disease treated with STN or GPi DBS: Results from a single center

G. Belluscio[1]; S. Malaspina[1]; M. Avenali[1]; G. Cosentino[2]; C. Pacchetti[3]; R. Zangaglia[3]; F. Valentino[3]
[1]Parkinson's Disease and Movement Disorders Unit, IRCCS Mondino Foundation, Pavia, Italy; Department of Brain and Behavioural Sciences, University of Pavia, Pavia, Italy; [2]Department of Brain and Behavioural Sciences, University of Pavia, Pavia, Italy; Translational Neurophysiology Research Unit, IRCCS Mondino Foundation, Pavia, Italy; [3]Parkinson's Disease and Movement Disorders Unit, IRCCS Mondino Foundation, Pavia, Italy

Background and Aims: We investigated gender-differences in response to DBS of the STN or GPi in a group of patients with advanced PD
Methods: 123 patients with PD (30% F, 70% M) and DBS targeting the STN (93 patients, 32.2 % females) or GPi (30 patients, 23.3% females) were enrolled. At baseline, MDS-UPDRS part III was collected in both OFF and ON state; at 1 year follow up, it was assessed in the ON state with the stimulator turned on. Dopaminergic therapy was converted in Levodopa Equivalent Daily Dose (LEDD)
Results: At baseline, there were no gender differences as regards disease duration, LEDD and MDS-UPDRS part III score. At 1-year follow-up, we found reduced MDS-UPDRS III scores for both GPi- and STN-DBS and a significant LEDD reduction compared to baseline only after STN-DBS ($p=0.0001$), with no gender-specific differences. The percentage of patients with dyskinesias decreased from 86% to 20% in females and from 91% to 50% in males after GPi-DBS. After STN-DBS the decrease was from 93.3% to 66% in females, and from 73% to 34% in males. The percentage of patients with clinical fluctuations decreased from 86% to 14% in females and from 39% to 13% in males after GPi-DBS, while after STN-DBS the decrease was from 56.6% to 27% in females, and from 44% to 28% in males. Overall, the effect of sex was not statistically significant
Conclusion: Bilateral STN- and GPi-DBS are equally effective in males and females as a treatment for motor complications of PD
Disclosure: Nothing to disclose.

EPO-366 | Mapping cortical nodes for targeted neuromodulation in focal dystonia: A TMS-EEG study

G. Leodori[1]; M. Mancuso[1]; M. Costanzo[2]; F. Marchet[2]; S. Pellegrini[2]; C. Santellani[2]; G. Ferrazzano[2]; D. Belvisi[1]; A. Berardelli[1]; G. Fabbrini[1]; A. Conte[1]

[1]Department of Human Neurosciences, Sapienza University of Rome, Rome, Italy; IRCCS Neuromed, Pozzilli, Italy; [2]Department of Human Neurosciences, Sapienza University of Rome, Rome, Italy

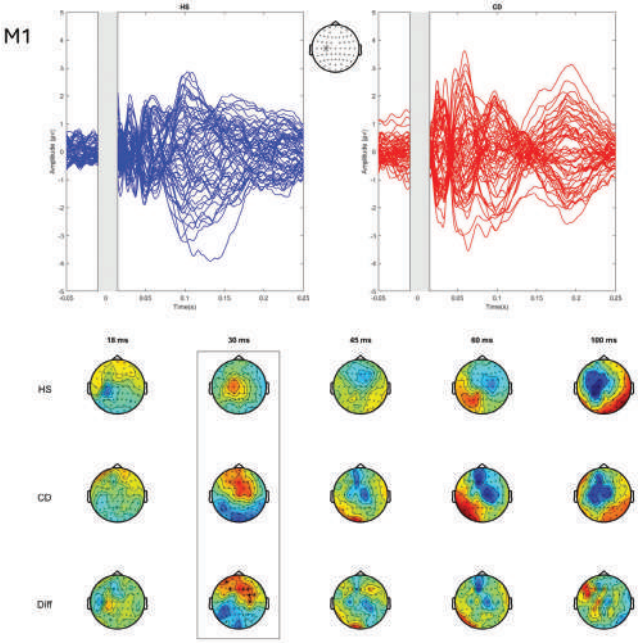
Background and Aims: Focal dystonia (FD) manifests as involuntary movements and abnormal postures in specific body regions, often with non-motor symptoms, due to brain network dysfunctions. Our objective is the therapeutic modulation of these networks using non-invasive brain stimulation. We present preliminary Transcranial Magnetic Stimulation-Electroencephalography (TMS-EEG) findings that identify dysfunctional cortical nodes in motor and non-motor networks of cervical dystonia (CD) patients. Pinpointing these nodes is vital for developing targeted neuromodulatory strategies.

Methods: Eighteen CD patients and 15 healthy subjects (HS) were evaluated using TMS-EEG to record TMS-evoked potentials (TEPs) from the primary motor cortex (M1), supplementary motor area (SMA), and dorsolateral prefrontal cortex (DLPFC), key nodes involved in the pathophysiology of motor and non-motor symptoms in CD. The Toronto Western Spasmodic Torticollis Rating Scale (TWSTRS) was employed for clinical assessment.

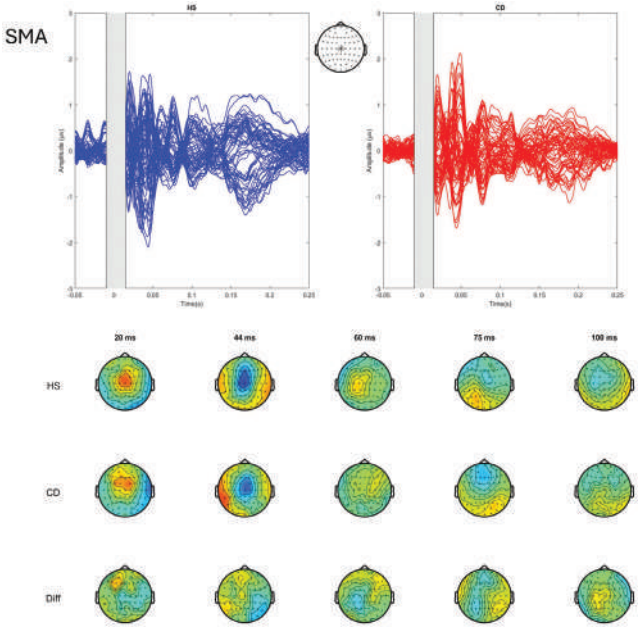
Results: Preliminary findings revealed a significantly larger early local M1 TEP amplitude in CD patients versus HS. Conversely, DLPFC showed a non-significant trend toward reduced early local TEP amplitude in CD patients. SMA TEPs did not differ significantly between groups. No significant correlations were found between TEP amplitudes and TWSTRS scores.

Conclusion: Identifying dysfunctions in specific cortical nodes within CD patients' motor and frontoparietal networks lays the groundwork for developing neuromodulation strategies aimed at symptom relief. This study is ongoing, and it includes data collection from other pathophysiologically relevant areas in various forms of FD, and correlations with an extensive array of clinical parameters.

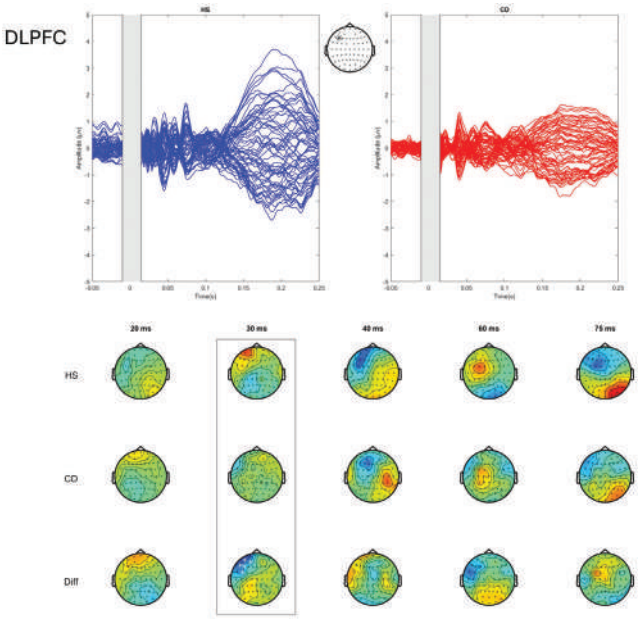
Disclosure: Nothing to disclose.



Butterfly plots (top) and topoplots (bottom) of TEPs from M1 stimulation in cervical dystonia (CD) compared to healthy subjects (HS). Top: Stimulation site marked by an asterisk. Bottom: Asterisks highlight significant electrodes in CD vs HS.



Butterfly plots (top) and topoplots (bottom) of TEPs from SMA stimulation in cervical dystonia (CD) compared to healthy subjects (HS). Top: Stimulation site marked by an asterisk.



Butterfly plots (top) and topoplots (bottom) of TEPs from DLPFC stimulation in cervical dystonia (CD) compared to healthy subjects (HS). Top: Stimulation site marked by an asterisk. Bottom: Asterisks mark electrodes with a trend towards significant comparison.

EPO-367 | Abstract withdrawn

EPO-368 | Olfactory and gustatory function is associated with global cognition in early-stage Parkinson's disease

H. Ma[1]; Y. Kim[1]; J. Baik[2]
[1]*Neurology, Sacred Heart Hospital Hallym University*; [2]*Neurology, Sanggye Baik hospital, Seoul, Republic of Korea*

Background and Aims: Hyposmia and hypogeusia is a prevalent non-motor symptom of Parkinson's disease (PD). Although there have been reports linking hyposmia to the development of dementia in PD, the association between cognitive and olfactory and gustatory function remains largely unexplored. This study evaluate the olfactory, gustatory function in early-stage of PD patients without dementia.
Methods: This study included drug-naive early PD patients with normal cognition (PD-NC) or mild cognitive impairment (PD-MCI). Olfactory function was evaluated using the YSK olfactory function test, which consisted of threshold, discrimination, and identification. The gustatory function was assessed using the YSK function test, which measures thresholds for the sweet, bitter, salty, sour, and umami tastes.
Results: Among the 84 individuals with PD, the average value of the olfactory function test fell within the hyposmia range, while taste function remained within the normal range. The study encompassed 39 patients with PD-NC and 45 with PD-MCI. Notably, no significant disparities were identified in olfactory and gustatory function tests between the two groups, with this trend persisting across the subdomains of each respective test. The result indicated a direct correlation between diminished global cognition (Montreal Cognitive Assessment scores) and decreased performance in both odor discrimination and gustatory function in all patients with early PD.
Conclusion: This study demonstrates that olfactory and gustatory function was associated with global cognition in the early stages of PD without dementia. Further study is warranted to ascertain whether early olfactory or gustatory dysfunction in PD could serve as an indicator for future dementia development.
Disclosure: None.

MS and related disorders 3

EPO-369 | Intrathecal synthesis biomarkers in late-onset multiple sclerosis: Any difference from adult-onset cases?

V. Ciampana[1]; E. Virgilio[2]; L. Paciolla[1]; A. Bianchi[1]; P. Naldi[1]; M. Capobianco[2]; D. Vecchio[1]; R. Cantello[1]; C. Comi[3]
[1]*Department of Neurology, University of Piemonte Orientale, Maggiore della Carità University-Hospital, Novara, Italy*; [2]*Department of Neurology, Santa Croce e Carle Hospital, Cuneo, Italy*; [3]*Department of Neurology, Sant'Andrea Hospital, University of Piemonte Orientale, Vercelli, Italy*

Background and Aims: The clinical and radiological features of Late-Onset Multiple Sclerosis (LOMS), characterized by onset after the age of 50, have been recently described, while limited data are available about fluid biomarkers. This multicenter retrospective study aims to compare intrathecal synthesis index markers between LOMS and Adult-Onset MS (AOMS).
Methods: A total of 152 patients (LOMS $n=39$, AOMS $n=113$) undergoing lumbar puncture for MS-diagnosis were included. We confirmed homogeneity between the groups, except for age, using Pearson's chi-square analysis. We collected Cerebrospinal Fluid (CSF) biomarkers, including kappa-free light chains to calculate K-index, immunoglobulin-G for Link-index, and Oligoclonal Bands (OB). Median (IQR) differences were analyzed using Mann-Whitney analysis (normality excluded with Shapiro-Wilk test).
Results: Among clinical variables (gender, EDSS, brain and spinal lesion load, type of onset, autoimmune comorbidities), only mean age at onset differed between the groups (LOMS: 55.9 ± 5.4; AOMS: 31.3 ± 8.0). The OB-positivity was similar in LOMS and AOMS (82% vs. 93%), whereas we observed significantly lower values of intrathecal synthesis indexes in LOMS, with median K-index at 18.95 (32.35) and median Link-index at 0.5 (0.28), compared to AOMS, with 32.60 (67.44; $p=0.008$) and 0.6 (0.3; $p=0.001$). No other significant differences were found in CSF proteins.
Conclusion: LOMS exhibits lower values of the intrathecal synthesis markers, both K-index and Link-index, whereas they do not differ in OB status. These results may reflect a less pronounced inflammatory component in LOMS. Quantitative markers of intrathecal synthesis may help in understanding pathological differences for LOMS, with future potential therapeutic implications. Larger cohort confirmation is needed.
Disclosure: Nothing to disclose.

EPO-370 | Ten years of Kappa Index: Revision of intrathecal synthesis biomarkers in multiple sclerosis on a cohort of 1,000 cases

D. Vecchio[1]; C. Puricelli[2]; E. Virgilio[1]; G. Bellomo[2]; I. Crespi[2]; P. Naldi[1]; R. Cantello[1]; C. Comi[1]; U. Dianzani[2]
[1]*Neurology Unit, Department of Translational Medicine, Maggiore della Carità University Hospital, Novara, Italy*; [2]*Clinical Biochemistry Laboratory, Department of Health Sciences, Maggiore della Carità University Hospital, Novara, Italy*

Background and Aims: Cerebrospinal fluid (CSF) kappa free light chains (KFLC) are becoming a diagnostic biomarker for multiple sclerosis (MS). We aimed to compare the diagnostic performances of intrathecal synthesis biomarkers to that of oligoclonal bands (OB) in diagnosing MS, radiological and clinical isolated syndromes (RIS-CIS) on a large cohort of patients collected over 10 years.
Methods: We collected 1057 patients (59% females) in 10 years, who underwent CSF analysis for intrathecal synthesis in the diagnostic work-up, and they were classified according to their diagnosis

as: 395 MS, 260 with other neurological inflammatory (including 76 RIS-CIS), and 402 non-inflammatory diseases (excluding lymphoproliferative and infective diagnosis).

Results: MS patients significantly differ from all other groups (including if considering the RIS-CIS cohort) for: CSF KFLC, KFLC intrathecal fraction, Kappa index, and OB. Evaluating diagnostic performance, the Kappa index cut-off was 5.6 for the diagnosis of MS, and 5.7 in predicting OB (that showed the best diagnostic accuracy).

Conclusion: The KFLC index confirmed the accuracy in MS diagnosis in this large Italian cohort, adding information also in the RIS-CIS population.

Disclosure: None.

EPO-371 | Reassessing Balo's concentric sclerosis: Diverse clinical presentations and therapeutic implications

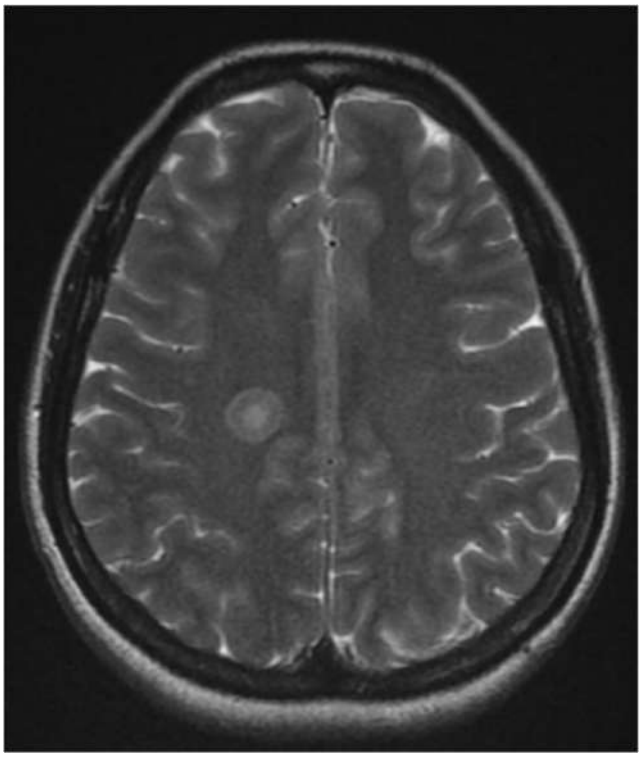
A. Kalfat; R. Zouari; A. Rachdi; D. Ben Mohamed; Z. Saied; F. Nabli; S. Ben Sassi

Neurology Department, National Institute Mongi Ben Hamida of Neurology, Tunis, Tunisia

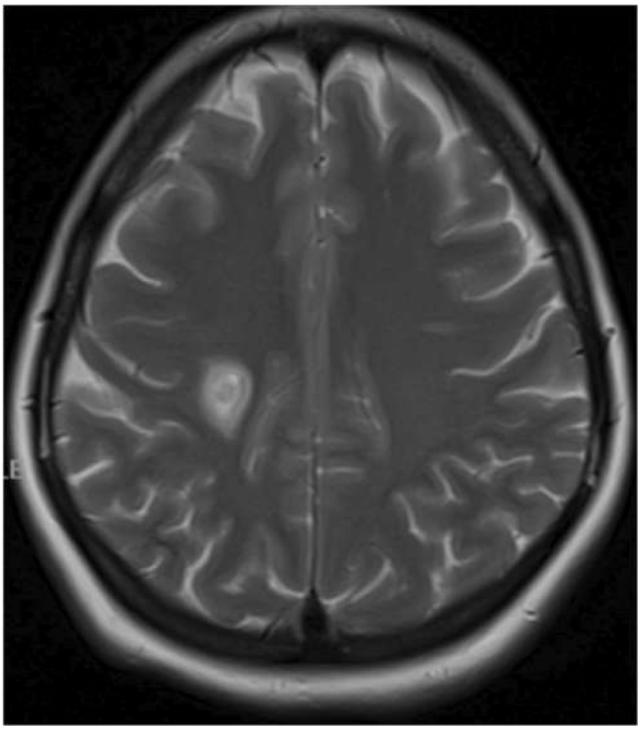
Background and Aims: Balo's concentric sclerosis (BCS) represents a rare variant of multiple sclerosis (MS), characterized by concentric lamellae of alternating demyelinated and partially myelinated tissues. Historically considered to have a severe and often fatal course, recent imaging studies have identified cases with a more benign evolution.

Methods: This descriptive retrospective study involved seven BCS patients from the neurology department at the National Institute Mongi Ben Hamida of Neurology. Demographic, clinical and paraclinical data were analyzed.

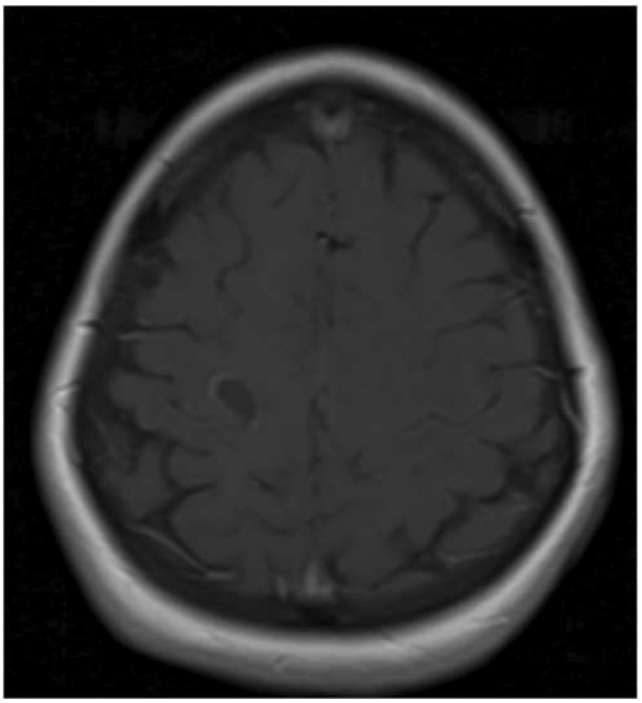
Results: At diagnosis, the average age was 31.71 years [18; 47], with a sex ratio of 2:5. Inaugural relapses included motor ($n=4$), visual ($n=1$), multifocal ($n=1$) presentations, and focal seizures ($n=1$). The initial Expanded Disability Status Scale (EDSS) averaged 2 [1; 4], reaching a maximum of 5.5 during relapse. Imaging revealed a single concentric Balo lesion in most of the cases and multiple Balo lesions in one case, the majority exhibiting contrast enhancement ($n=6$). All cases presented associated lesions in typical MS areas. Treatment outcomes showed that most patients responded well to corticosteroid therapy ($n=6$). One patient with corticosteroid-resistant optic neuritis underwent plasmapheresis with a poor outcome. First-line treatment was initiated for two patients, with an indication for escalation after four years in one case.



Right periventricular hyperintense signal on T2-weighted sequence showing concentric layering.



Hyperintense signal on T2-weighted sequence in the right annular semi-oval center showing typical 'onion-like' appearance.



Peripheral incomplete ring enhancement on T1 post contrast (gadolinium).

Conclusion: This study challenges the historical perspective on BCS, emphasizing the need for ongoing research to refine its clinical course and treatment. For cases meeting MS diagnostic criteria, first-line therapy is recommended, while immunosuppressive treatment may be considered for more severe progression.
Disclosure: Nothing to disclose.

EPO-372 | Analysing B-cell depletion kinetics and clinical outcomes of ocrelizumab and rituximab in multiple sclerosis

A. Roldão Alferes[1]; I. Correia[1]; C. Cecília Nunes[1]; C. Macário[1]; A. Paiva[2]; S. Batista[1]
[1]*Neurology Department, Coimbra Hospital and University Centre (CHUC), Coimbra, Portugal;* [2]*Operational Management Unit of Cytometry, Clinical Pathology Department, Coimbra Hospital and University Centre (CHUC), Coimbra, Portugal*

Background and Aims: Rituximab and ocrelizumab deplete B-lymphocytes from the pre-B stage to the mature B stage and are used for multiple sclerosis (MS) treatment. This study aims to compare their effects on overall lymphocyte levels and subpopulations over 12 months in MS patients and explore possible clinical correlates.
Methods: We included 107 patients with MS, treated with rituximab ($n=84$) or ocrelizumab ($n=23$). We used flow cytometry in the peripheral blood to count total lymphocytes and B-lymphocytes subpopulations, before treatment and after 6 and 12 months.
Results: After 6 and 12 months, patients treated with Rituximab and Ocrelizumab were similar in total B-cell count and in B-cell subpopulations except for Naïve B-cells at 6 months ($p<0.001$) and at 12 months ($p=0.001$) and Memory B-cells at 12 months ($p=0.002$). Regarding EDSS progression, relapse occurrence and treatment discontinuation rate, no significant differences between the two treatment groups were found. In the whole sample, total B-cell count after 12 months of treatment was significantly lower in patients with treatment discontinuation due to infectious complications ($p=0.024$) and with EDSS progression ($p=0.014$). Naïve and Immature B-cells counts after 12 months were also significantly lower in patients with EDSS progression ($p=0.014$ and $p=0.006$ respectively).
Conclusion: Both anti-CD20 treatments equally decreased total B-cell counts in the peripheral blood. No between-treatment difference in clinical outcomes was found. B-cell subpopulation counts may be used as predictors of disability progression and infectious adverse events.
Disclosure: Nothing to disclose.

EPO-373 | Multiple Sclerosis Implementation Network: A patient-engaged practiced based research network to improve patient care

A. Montague[1]; L. Freeman[2]; J. Freeman[3]; M. Fernandez[4]
[1]*Multiple Sclerosis Association of America, Cherry Hill, NJ, USA;* [2]*Dell Medical School, The University of Texas at Austin, Austin, TX, USA;* [3]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA;* [4]*UTHealth Houston Institute for Implementation Science, University of Texas Health Science Center at Houston, Houston, TX, USA*

Background and Aims: The Multiple Sclerosis Implementation Network (MSIN) is a patient-centric collaboration between MS providers, patient advocacy organizations, academia, and industry, aimed at improving MS care and patient outcomes through the development of a practice-based research network.
Methods: The goals for MSIN Phase I are to: 1) establish an MSIN governance structure; 2) develop a practice-based research network composed of a diverse group of clinicians and practice settings providing care for people living with MS, and 3) establish a patient registry providing multilevel data enabling the assessment of both implementation and patient care outcomes across diverse clinical settings. The MSIN leadership designed and administered a survey assessing preliminary interest and capacity for joining the network. In Phase II MSIN will establish an implementation research program focused on the design and evaluation of implementation strategies to accelerate the adoption, implementation and sustainment of evidence-based interventions to improve MS care.
Results: Led by the Multiple Sclerosis Association of America (MSAA), the MSIN governance structure includes people living with MS, the University of Texas Health Science Center at Houston, Dell Medical School at The University of Texas at Austin, and Novartis Pharmaceuticals Corporation. The initial recruitment effort includes 12 providers, with an anticipated 24 providers expected to join the

network in 2024. Through coordinated data collection MSIN will enable rapid cycle implementation research a collaborative learning community.

Conclusion: MSIN will accelerate the translation of best MS practices into routine clinical care, improving the outcomes for people living with MS equitably.

EPO-374 | Longitudinal changes in hippocampal subfield volumes of relapsing remitting multiple sclerosis patients

A. Caporali[1]; E. Portaccio[1]; V. Penati[1]; M. Betti[1]; C. Ballerini[1]; C. Fabbiani[2]; E. Fainardi[2]; R. Bonacchi[3]; E. De Meo[1]; M. Amato[1]
[1]*Department of Neurofarba, University of Florence, Florence, Italy*; [2]*Department of Neuroradiology, Careggi, Florence, Italy;* [3]*Department of Neuroradiology, Vita-Salute San Raffaele University, Milan, Italy*

Background and Aims: Due to the coexistence of neurogenesis and neurodegeneration, the hippocampus represents an interesting structure to analyze the interplay between these two processes in MS patients. We aimed to identify longitudinal trajectories of hippocampal subfield volume loss and its contribution to clinical disability and cognitive impairment.

Methods: We analyzed 3DT1-weighted images from 108 early relapsing remitting MS patients at baseline and yearly for a maximum of 8 years, together with clinical and cognitive evaluation. We segmented hippocampal subfields by using Freesurfer version 7.2.0.

Results: All the hippocampal subfields showed progressive volume loss over disease course, but with different trajectories. On the right hippocampus dentate gyrus and cornus ammonis 1 (CA1) – related to neurogenesis – showed a bimodal pattern: early volume stability, then rapid volume decrease, and finally again stability. We identified an index of relative progression "gamma", considering the shared variance among hippocampal subfields. Significant associations were observed between gamma and performance at visuo-spatial memory and attention.

Conclusion: The different pattern of progression of hippocampal subfield volume loss suggests an initial resilience of hippocampal regions related to neurogenesis, which then experience volume exhaustion after few years of disease. Gamma might become a relevant index for monitoring specific cognitive abilities.

Disclosure: Nothing to disclose.

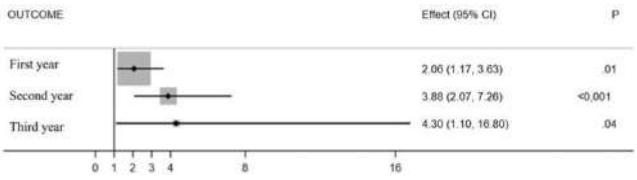
EPO-375 | Predictors of longitudinal cognitive decline assessed using processing speed test in patients with multiple sclerosis

P. Garay Albízuri; F. Rodríguez Jorge; A. Llanes Ferrer; R. Sainz Amo; B. Martínez García; S. Sainz De La Maza; D. Pérez Gil; J. Chico García; G. García Alcántara; C. Moreno López; L. Costa-Frossard; J. Masjuan; E. Monreal
Department of Neurology, Hospital Ramón y Cajal, Madrid, Spain

Background and Aims: Cognitive impairment is highly prevalent in multiple sclerosis (MS) with a profound impact on quality of life and socio-economic levels. Our objective was to longitudinally evaluate predictors of deterioration in the Processing Speed Test (PST) using the CogEval® application.

Methods: A prospective single-center study of MS patients with PST evaluations every 3-6 months from October 2019 to May 2023. Significant deterioration in PST was defined as declines of ≥10% from the baseline value each year. Multivariate logistic regressions were performed for each year of follow-up.

Results: Eight hundred eighty-one patients with ≥1 year of follow-up were included: 604 (68.6%) women, with a mean age of 45.3 (SD±11.41) years in the first test. The majority (79.8%) had relapsing-remitting MS. Follow-up was at least at two and three years was achieved in 455 and 65 patients, respectively. Confirmed worsening on the Expanded Disability Status Scale (EDSS), whether due to relapse or independent of it, was significantly associated with PST deterioration in all models, increasing each year: OR 1.85, 95% CI 1.03-3.32, $p=0.04$ in the first year; OR 2.01, 95% CI 1.1-3.69, $p=0.02$ in the second year; and OR 4.25, 95% CI 1.02-17.6, $p=0.046$ in the third year. Other factors were not consistently associated with cognitive deterioration in all models.



Forest plot graph to estimate the risk of annual decline in PST.

Conclusion: Cognitive impairment measured by PST in MS patients is common and is associated with worsening EDSS, regardless of clinical phenotype, disability acquisition pathways, and treatments received.

Disclosure: None.

EPO-376 | The MS-LOTUS initiative, a digital cohort collecting real-world evidence on multiple sclerosis relying on MSCopilot®

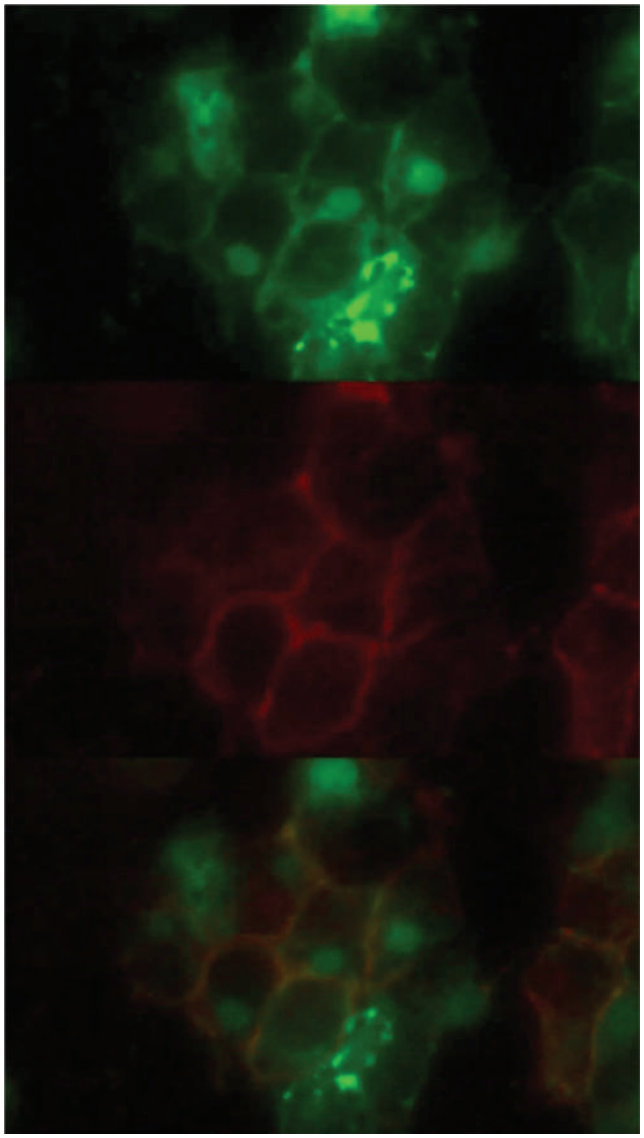
P. Vermersch[1]; G. Comi[2]; L. Leocani[3]; L. Carment[4]; A. Vives[4]; S. Bieuvelet[4]; S. Zinaï[4]; T. Ziemssen[5]
[1]*Univ. Lille, UMR Inserm U1172, CHU Lille, FHU Precise, F-59000, Lille, France;* [2]*Department of Neurorehabilitative Sciences, MS Centre, Casa di Cura Igea, Milan;* [3]*Department of Neurorehabilitative Sciences, MS Centre, San Raffaele Vita-Salute University, Department of Neurorehabilitation Sciences, Casa di Cura Igea, Milan, Italy;* [4]*Ad Scientiam, Paris, France;* [5]*Center of Clinical Neuroscience, Dep. Of Neurology, University Clinic Carl Gustav Carus, TU Dresden, Dresden, Germany*

Background and Aims: Several pharmaceutical companies are actively developing novel treatments for multiple sclerosis (MS). However, there is still a need for a more comprehensive characterization of MS-related disability to achieve a holistic understanding of the disease. Additionally, there are no coordinated patient registries across Europe and North America. The MS-LOTUS cohort will gather valuable insights that will enhance patient care by harnessing the power of digital biomarkers.
Methods: MS-LOTUS is an international, decentralised research initiative facilitating the direct enrolment of patients by their respective hospitals or private neurologists in France, Germany, Italy, Spain, Canada, amongst others. Circa 8000 participants will be recruited around the world. 300 digital biomarkers will be derived from assessments such as mobility, cognition, vision, and hand dexterity through MSCopilot®, a smartphone-based medical device evaluating MS-related disability. Quality of life and treatment-related variables will be assessed using in-app validated scales.
Results: The MS-LOTUS study, with its innovative design, will collect data directly from the patients at home in unsupervised conditions, to complement national registries data. MS-LOTUS will provide new information on the progression of MS and the dynamics of treatments. Healthcare providers will be able to access the data generated by the patients through a web dashboard. Agnostic MS-LOTUS data will be published regularly, to better inform the whole MS community (learned societies, neurologists and rehabilitation specialists, pharmaceutical companies and patient associations).
Conclusion: The interest for MS-LOTUS is strong in the community and presents a promising approach to advance our collective understanding of MS and improve patients' care pathways.
Disclosure: P. Vermersch received honorarium for contributions to meeting from Biogen, Sanofi-Genzyme, Novartis, Teva, Merck, Roche, Imcyse, AB Science, Janssen, Ad Scientiam and BMS-Celgene and research supports from Novartis, Sanofi-Genzyme and Merck. Leocani received research support from Novartis, Almirall, Biogen, Merck and consultancy or speaker fees from Novartis, Almirall, Biogen, Merck, Janssen-Cilag, Bristol-Myers Squibb, Roche. T. Ziemssen reports consulting or serving on speaker bureaus for Almiral, Biogen, BMS, Roche, Novartis, Sandoz, Viatris, TEVA, Merck, and Sanofi as well as research support from Biogen, Novartis, Roche, TEVA and Sanofi. L. Carment, A.Vivès, S. Bieuvelet, and S. Zinaï are employees of Ad Scientiam.

EPO-377 | Late-onset myelin oligodendrocyte glycoprotein antibody-associated disease: An unusual case

P. Dodu; A. Barros Ruiz; N. Ciano Petersen; I. Lopez-Ventura Jimeno
Department of Neurology, Málaga's Regional and University Hospital, Málaga, Spain

Background and Aims: Myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) is an inflammatory disease of the nervous system characterized by a wide range of symptoms that vary according to age. It's usually more common in pediatric-aged patients and young adults, although it can also debut in older patients.
Methods: We present the case of a 72-year-old female patient diagnosed with MOGAD, with uncommon symptoms for late-onset patients.
Results: We have a 72-year-old woman who starts with acute paraparesis and is admitted for complementary tests. Brain resonance showed multiple hyperintense lesions in T2/FLAIR in periventricular white matter, subcortical, both internal capsules and bilateral temporobasal level. At the medullary level there was extensive myelitis, from T2 to L1, with areas of contrast uptake. In the cerebrospinal fluid there was proteinorrachia (48.2 mg/dL), leukocytosis (20 leu/μL) and positivity of anti-MOG antibodies analyzed with indirect immunofluorescence. In blood tests there was also positivity for anti-MOG antibodies at 1/40 titer. After treatment with corticosteroids and plasmapheresis she improved, but after 2 weeks she was readmitted due to a new outbreak.



Indirect immunofluorescence in cerebrospinal fluid. Green = anti-MOG antibodies in native form. Red = patient's antibodies. Yellow = Colocalization of the prior confirming positive to anti-MOG antibodies.

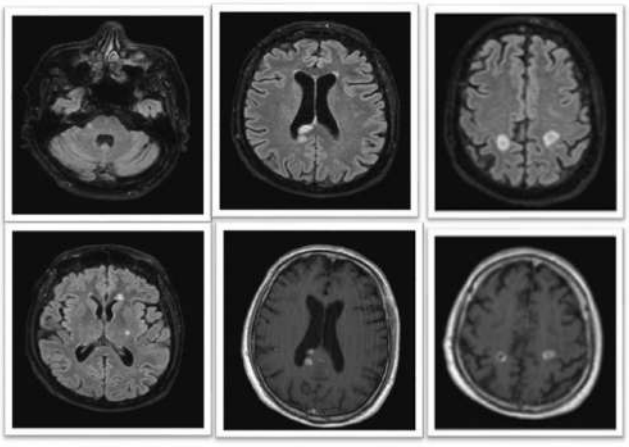
Conclusion: According to the literature, late-onset MOGAD is a rare condition, with a usually more subacute, monophasic clinical picture, with more cerebral symptoms, without many cases of extensive myelitis at the onset and with less inflammatory burden. The patient that we present differs greatly from what has been described so far on late-onset MOGAD. Therefore, we consider that this diagnosis should be kept in mind in elderly patients, although it is not the most common clinical presentation.

Disclosure: Nothing to disclose.

EPO-378 | Longitudinally extensive myelitis in MS: A single centre experience

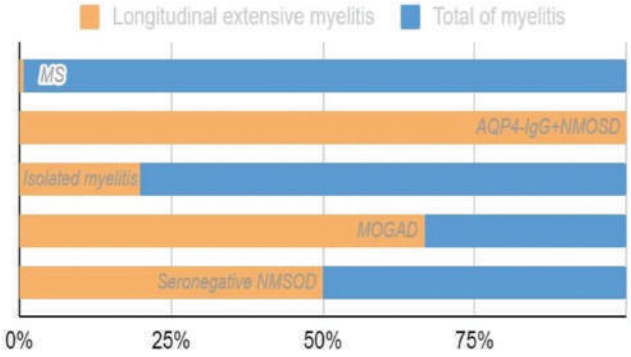
S. Othmani[1]; P. Zara[1]; V. Floris[1]; S. Leoni[2]; P. Solla[2]; E. Sechi[2]
[1]*Department of Medical Sciences and Public Health, University of Cagliari;* [2]*Department of Medical Surgery and Experimental Sciences, University of Sassari, Sassari, Italy*

Background and Aims: The reported frequency of longitudinally extensive myelitis lesions - LEMs in MS varies, ranging from 0% to 32%. Most prior studies, however, predate the discovery of AQP4-IgG and MOG-IgG, potentially resulting in overestimation of LEMs. We sought to determine the frequency of LEMs at first myelitis attack in a single-centre cohort of patients with CNS demyelinating disorders.
Methods: We retrospectively identified patients with CNS demyelinating disorders seen at the University-Hospital of Sassari from January 1, 2017 to December 31, 2022. We included the following inclusion criteria: 1) First myelitis attack; and 2) available spinal cord MRI during the myelitis attack. The frequency of LEMs was determined and classified according to the diagnosis at last follow-up.
Results: Among 336 patients with CNS demyelinating disorders consecutively seen over 6 years, 158 were included in the study. The frequency of LEMs in MS was 0.7% (1/138). The only MS patient with LEMs was a 55-year-old man who developed subacute weakness of right limbs, accompanied by numbness and gait instability. Spinal cord MRI showed a longitudinally extensive T2-hyperintense enhancing lesion extending from C2-D11. Brain MRI showed typical MS lesions. CSF analysis revealed moderate pleocytosis and absence of oligoclonal bands; AQP4-IgG and MOG-IgG were absent in both serum and CSF by live cell-based assay.



Axial T2 FLAIR brain MRI showing brainstem, periventricular and cortico-juxtacortical white matter lesions (A-E), some of which presents gadolinium enhancement (D,F) consistent with multiple sclerosis.

Sagittal T2-weighted spinal cord MRI showing one short cervical lesion (A) and one longitudinally extensive lesion in the thoracic cord extending over >3 contiguous vertebral body segments (C), showing intense gadolinium enhancement in a nodular and ring.



Distribution of LEM in patients with CNS demyelinating diseases with at least one episode of myelitis attack.

Conclusion: LEMs is rare among adult MS patients at first myelitis attack. Although our MS patient with LEMs met the 2017 diagnostic criteria for MS, he showed several atypical features that raise the possibility of an alternative aetiology of the myelitis.

Disclosure: No disclosures.

EPO-379 | Modified Charlson Comorbidity Index as new tool to predict prognosis in multiple sclerosis

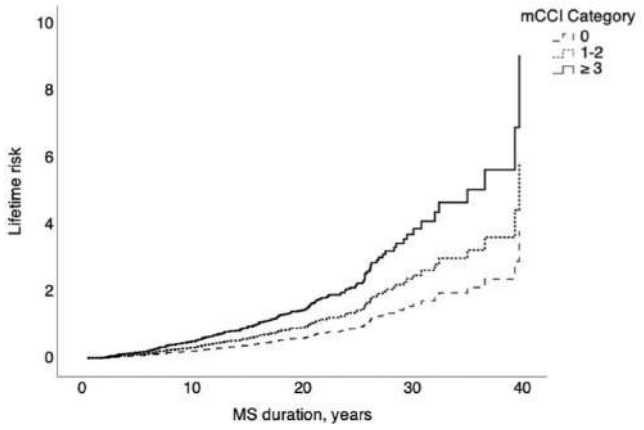
S. Iacono; G. Schirò; P. Aridon; M. Andolina; G. Sorbello; A. Calì; M. D'Amelio; G. Salemi; P. Ragonese

Department of Biomedicine, Neuroscience and Advanced Diagnostics (BiND), University of Palermo, Italy

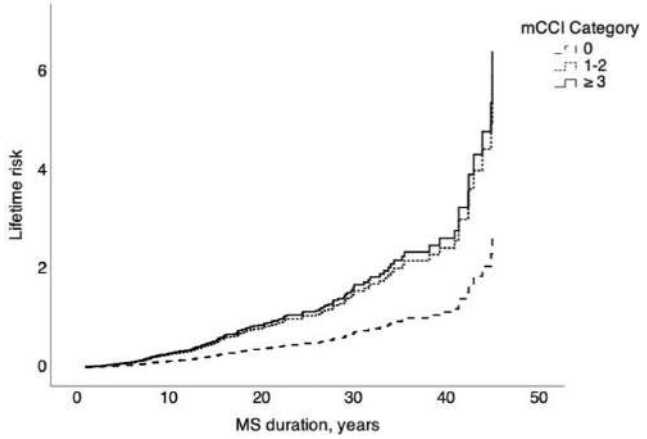
Background and Aims: Comorbidities have recently attracted increasing interest because of their impact in MS outcomes. The aims of this study are to predict the risk of reaching two disability milestones evaluated trough the Expanded Disability Status Scale (EDSS) and the risk of conversion from relapsing-remitting MS to Secondary Progressive MS (SPMS) by using a modified version of the Charlson Comorbidity Index (mCCI).

Methods: comorbidity data of people included in our local MS database were extracted. The mCCI was obtained by incorporating the grade of pyramidal functional system scores into the original CCI version. The capability of mCCI at first visit to predict the reaching of EDSS 4, EDSS 6 and SPMS conversion was estimated by carrying out multivariable Cox regression models.

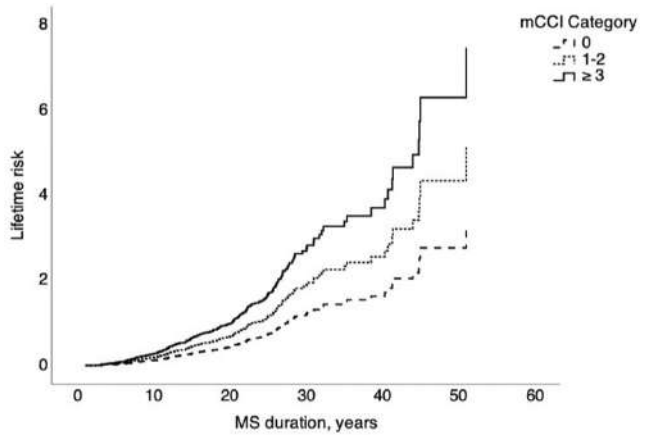
Results: a total of $n=622$ pwMS were included (72.7% women; median age 30.8 years [24-40]). The mCCI at first visit comprised between 1 and 2 was associated with higher risk of reaching EDSS 4 (HR = 1.53 [1.1-2.1], $p=0.011$), EDSS 6 (HR = 2.17 [1.48-2.96], $p<0.0001$) and SPMS conversion (HR = 1.57 [1.16-2.1], $p=0.003$). The mCCI at first visit >3 was associated with higher risk of reaching EDSS 6 (HR = 2.34 [1.44-3.8], $p=0.001$) and SPMS conversion (HR = 2.38 [1.29-4.01], $p=0.004$).



Lifetime risk of reaching the milestone EDSS 4 by mCCI categories according to MS duration on the x axis and the risk on the y axis.



Lifetime risk of reaching the milestone EDSS 6 by mCCI categories according to MS duration on the x axis and the risk on the y axis.



Lifetime risk of reaching the SPMS conversion according to mCCI categories according to MS duration on the x axis and the risk on the y axis.

Conclusion: comorbidity significantly affects MS prognosis as well as patient's age and motor impairment. In this study, the mCCI calculated at first visit appeared a simple and faster tool to predict MS prognosis by estimating the risk of disability worsening and SPMS conversion.
Disclosure: Nothing to disclose.

EPO-380 | The first study of real-world efficacy and safety of Natalizumab (Tysabri) in Iran

M. Shahrbaf[1]; M. Samimi[1]; S. Karimi[1]; Salari[2]; M. Ghaffari[3]; S. Yazdanbakhsh[4]; M. Vosough[1]; S. Nabavi[1]; A. Najafian[4]
[1]Department of Regenerative Medicine, Cell Science Research Center, Royan Institute for Stem Cell Biology and Technology; [2]Neurofunctional Research Center, School of Medicine, Shahid Beheshti University of Medical Sciences; [3]Neurology Department, Shahid Beheshti University of Medical Sciences; [4]Department of Neurology, Tehran University

Background and Aims: This study was aimed to evaluate the real-world effectiveness of Natalizumab in a referral center in Tehran, Iran. This study is the first real world analysis of efficacy and safety of Natalizumab in our country.
Methods: In this retrospective study, patients with RRMS were investigated in a high-volume center in Tehran from 2019 to 2021. MS patients under treatment with Natalizumab who have received at least 3 infusions of the drug and had completed follow-up data, have been evaluated for safety and efficacy of Natalizumab.
Results: 100 patients were included in the final analysis. The mean follow-up time was 20 months (6-33 months). The median EDSS score [1] of patients reached to 2 from 2.5 after the treatment course ($p<0.0001$). The annualized relapse rate (ARR) decreased from 0.81 (95% CI: 0.73-0.87) to 0.023 (95% CI 0.009 – 0.061). The median JCV index [2] remained unchanged before treatment 0.85 (IQR: 0.21-2.41) compare to after the treatment 0.85 (IQR: 0.21-2.31). The number of patients with active brain and cervical MRI lesions decreased significantly ($p=0.001$). NEDA-3 (No evidence of disease activity) was improved from 9% to 87% after the treatment with Natalizumab. No serious adverse events except than one progressive multifocal encephalopathy (PML) case have been found.
Conclusion: Natalizumab is a safe and effective choice in RRMS patients for reducing relapse rate, disability score, active MRI lesion, and improving the NEDA.
Disclosure: Nothing to disclose.

EPO-381 | Treatment failure rates in patients with neuromyelitis optica spectrum disorder included in an Argentinean registry

V. Tkachuk[1]; E. Carnero Contentti[2]; P. López[2]; L. Patrucco[3]; J. Miguez[4]; S. Liwacki[5]; C. Vrech[6]; N. Deri[7]; J. Correale[8]; M. Ysrraelit[8]; F. Leguizamon[9]; G. Luetic[10]; M. Durand, Buenos Aires; [17]Hospital Central de Mendoza; [18]CUEM Ramos Mejía de Buenos Aires; [19]Sanatorio Guemes de Buenos Aires; [20]Hospital Británico de Buenos Aires; [21]CEMIC, Buenos Aires

Background and Aims: Immunosuppressive therapies such as azathioprine (AZA), mycophenolate mofetil (MMF) and rituximab (RTX) are commonly used to prevent relapses in NMOSD. However,

the response rate to these traditional therapies are unknown in Argentina. We aimed to describe and compare treatment failure rates in NMOSD (seropositive and seronegative for aquaporin-4 antibody) patients included in the Argentinean MS and NMOSD registry (RelevarEM, NCT 03375177)

Methods: Retrospective cohort study conducted in NMOSD patients. Only who received AZA or MMF for at least 6 months or RTX for at least 1 month were included. Patients who had initially received AZA, MMF, or RTX and then switched to another 1 of these 3 therapies were included if they met the specified criteria. Data on patient demographics, clinical and neuroradiological findings, and treatments administered were collected. Treatment failure was defined as any new attack/relapse that occurred despite immunosuppressive treatment

Results: We included 139 NMOSD patients: AZA ($n=105$), MMF ($n=5$) or RTX ($n=29$) with a mean follow-up time of 41.3 ±11.4 months and a median EDSS at treatment initiation of 3. We observed a reduction in the annualized relapse rate from pretreatment to post treatment of 56%, 48%, and 79% respectively, with a Hazard Risk relative to RTX (95% CI) of 1.67 (1.34-3.54, $p=0.01$) for AZA and 2.01 (1.86-4.43, $p=0.008$) for MMF. AZA, MMF and RTX failure was observed in 45 (42.8%), 2 (40%) and 3 (10.3%) patients, respectively.

Conclusion: Treatment failure rates were higher for AZA and MMF than RTX in Argentinean NMOSD patients in a real-word setting

Disclosure: Nothing to disclose.

EPO-382 | Treatment strategies for neuromyelitis optica spectrum disorder relapses: A study from a nationwide registry in Argentina

Durand, Buenos Aires; [17]Hospital Central de Mendoza; [18]Sanatorio Güemes, Buenos Aires; [19]Hospital Naval, Buenos Aires; [20]Servicio de Neurología, Hospital Universitario de CEMIC, Buenos Aires

Background and Aims: We aimed to assess treatment strategies selected in patients with neuromyelitis optica spectrum disorder (NMOSD) experiencing relapses: frequency, types, and response after 6 months based on the Expanded Disability Status Scale (EDSS) score.

Methods: We conducted a retrospective study from the Argentinean MS and NMOSD registry (RelevarEM, NCT 03375177). We collected data: patient demographics, clinical and radiological findings, and treatments. Treatment response at 6 months was categorized as "good" if the EDSS score decreased by ≥1 point after a nadir EDSS score ≤3, or by ≥2 points after a nadir EDSS score >3, "poor" if the EDSS score decrease was slighter, and as "absent" if the EDSS score remained unchanged or worsened. We used ordinal logistic regression to identify statistical associations with the outcome

Results: We included 131 patients (120 NMOSD [seropositive $N=75$ and seronegative $N=45$] and 11 myelin oligodendrocyte glycoprotein-antibody-positive [MOGAD]), who experienced 262 NMOSD-related relapses and received 270 treatments. Most common treatment: intravenous methylprednisolone (81.4%), followed by plasmapheresis (15.5%). At 6 months, complete recovery was achieved in 74/102 (74.5%) of the NMOSD patients. In NMOSD we did not observe differences in treatment response based on serostatus. Predictors of "good" response were: younger age at disease onset (OR: 3.54, CI95% 2.45-5.01, $p<0.0001$) and a short delay from onset of relapse to treatment initiation (OR: 1.56, CI95% 1.22-2.13, $p=0.004$)

Supplementary table 3. Predictors of complete remission in NMOSD (positive and negative) patients from relapses

	P	OR	95%CI
Age at disease onset	**0.002**	**2.27**	**2.11-4.12**
Female	0.461	0.57	0.12-2.52
Symptom at onset	0.862	0.77	0.43-1.23
Time from onset of relapse to start of treatment	0.885	0.95	0.82-1.56
Duration of long-term immunosuppressive treatment	0.421	0.88	0.65-1.65
First line treatment for relapse	0.223	1.03	0.67-1.78

Predictors of complete remission in NMOSD (positive and negative) patients from relapses.

Conclusion: In Argentina, plasmapheresis is not commonly used to treat NMOSD relapses. Approximately two-thirds of patients experienced complete recovery, and younger age and a short delay to start treatment were independent predictors of a "good" response.

Disclosure: Nothing to disclose.

EPO-383 | Tocilizumab treatment in naïve adult MOGAD patients: A single center experience

E. Virgilio[1]; A. Dutto[1]; L. Giordano[1]; I. Pastore[1]; F. Franchino[1]; C. Fruttero[2]; L. Infante[2]; N. Fasano[3]; F. Venturi[3]; M. Capobianco[1]
[1]*Neurology Unit, Department of Medicine, ASO Santa Croce e Carle, Cuneo, Italy;* [2]*Pharmacy Unit, ASO S. Croce e Carle, Cuneo, Italy;* [3]*Neuroradiology Unit, ASO S. Croce e Carle, Cuneo, Italy*

Background and Aims: Myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) is a rare autoimmune oligodendrocytopathy. Differential diagnosis from multiple sclerosis (MS) and neuromyelitis optica spectrum disorder (NMOSD) is challenging, and diagnostic criteria have been recently proposed. Moreover, treatment guidelines are still lacking, and traditional MS treatments are ineffective. Several case reports have documented the efficacy and safety of tocilizumab (TCZ), a humanized antibody targeting the IL-6 receptor, as a rescue therapy from other immunotherapies. Experience for naïve patients is otherwise lacking in adult patients.
Methods: In this single-center case series, we report three female (mean age at diagnosis 28±10 years) adult MOGAD naïve patients treated with TCZ. MOG antibodies tested positive on serum using fixed or live cell-based assay. Two patients presented with myelitis and one with bilateral optic neuritis (ON) (median EDSS at diagnosis 4, range 4-9). All patients fulfilled the 2023 diagnostic criteria.
Results: All patients were initially treated with steroids. Myelitis needed plasma exchanges and immunoglobulin for short-term worsening or relapses (one patient with extending myelitis and the other developing bilateral ON). After a mean time of 2.5 (SD1.5) months from diagnosis, TCZ 8 mg/kg every 4 weeks was started. Clinical and radiological stability was obtained for all patients (median EDSS 3.5, range 2-9). No adverse events were recorded.
Conclusion: MOGAD is rare but highly disabling and must be treated effectively early. TCZ is reported as a useful second-line immunotherapy in MOGAD patients. However, our observations highlight its efficacy and safety as a first-line disease-modifying treatment.
Disclosure: Nothing to disclose.

MS and related disorders 4

EPO-384 | Neuromyelitis Optica Spectrum Disorder (NMOSD) and effects of AQP4 status: A multicenter Turkish cohort

İ. Çalışkan[1]; A. Dursun[2]; B. Tay[2]; A. Saysal[3]; C. Boz[4]; M. Terzi[5]; E. Toğrol[6]; N. Bülbül[6]; M. Yetkin[7]; N. Kale[8]; S. Hoca[8]; C. Emir[9]; İ. Aydın Cantürk[10]; A. Altıntaş[11]

Background and Aims: The detection of serum immunoglobulin G (IgG) autoantibodies to aquaporin-4 (AQP-4) is an important diagnostic tool for Neuromyelitis Optica Spectrum Disorder (NMOSD). While the precise mechanisms remain elusive, the pathogenic role of AQP-4 antibodies is well-established. However, the influence of variables such as gestation and menopause on NMOSD remains largely unknown. Exploring these factors within AQP-4 serostatus may reveal a linkage between AQP-4 IgG and hormonal dynamics, namely in the case of pregnancy where hormonal changes are fairly pronounced.
Methods: This retrospective analysis leverages medical records from nine centers in Turkiye, comprising 120 NMOSD patients (94 Females: F, 26 Males: M) diagnosed per the 2015 IPDN diagnostic criteria. A spreadsheet, filled out by the primary neurologists and was analysed using IBM SPSS Statistics Version 28.
Results: In the AQP-4 seropositive group, a significant association was revealed between presenting symptoms and treatment response ($p = 0.043$) (Figure 1, Table 1). In 41 women, 87 pregnancies before the disease onset were evaluated. Pregnancy exhibited a remarkable relationship with the onset age, in which multiple gestations postponed disease manifestation ($p < 0.001$) (Figure 2).

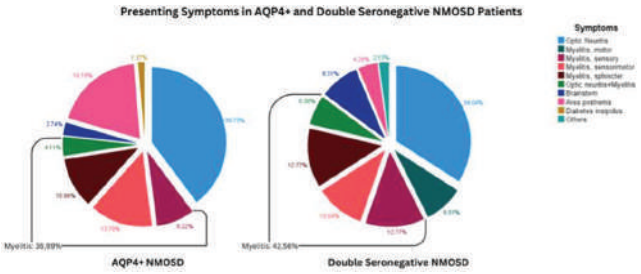

FIGURE 1 Presenting symptom of the first attack of the patients according to serostatus.

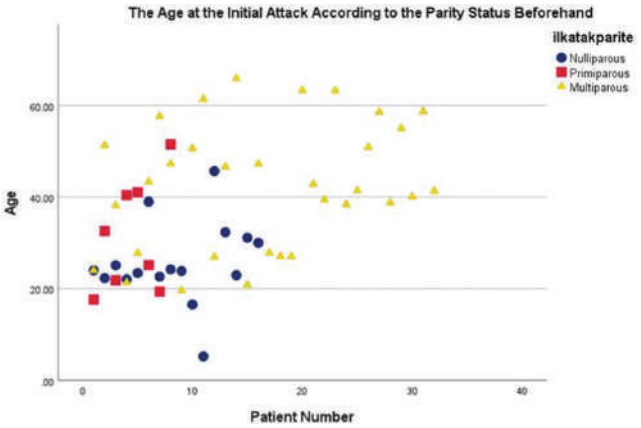

FIGURE 2 The age at the first attack of the patients categorised according to the parity status before the onset of the disease.

	Groups in AQP4+				Groups in DN			
Presenting Symptom / Response to Long Term Treatment	ON	Myelitis	ON+Myelitis	Total	ON	Myelitis	ON+Myelitis	Total
No response	3	1	0	4 (8.7%)	1	3	1	5 (17.9%)
Mild improvement	6	13	1	20 (43.5%)	3	5	1	9 (32.1%)
Moderate improvement	5	3	0	8 (17.4%)	2	4	0	6 (21.4%)
Full recovery	12	1	1	14 (30.4%)	6	2	0	8 (28.6%)
Total	26 (39.1%)	18 (56.5%)	2 (4.3%)	46	12 (50.0%)	14 (42.9%)	2 (7.1%)	28

TABLE 1 Long term treatment responses of the AQP4+NMOSD patients according to their presenting symptoms.

Conclusion: This study provides valuable insights into the interplay of clinical, reproductive, and immunological factors in NMOSD, focusing on serostatus and diverse patient profiles. The AQP4+ serostatus emerges as a potential prognosis predictor, prompting physicians to initiate targeted diagnostic assessments earlier which could guide therapeutic strategies and mitigate disability. Compared to double seronegative (25 F, 13 M), AQP4-NMOSD (66 F, 13 M) predominantly affects females and manifests later in life. Pregnancy initially delays disease onset, potentially influencing prognosis and disability in ways yet to be fully discovered.

Disclosure: Nothing to disclosure.

EPO-385 | Replacing PASAT with SDMT in the MSFC score improves the prediction of thalamic volume in multiple sclerosis

C. Marotta; A. Bisecco; R. Capuano; A. d'Ambrosio; M. Altieri; M. Cirillo; A. Gallo

Department of Advanced Medical and Surgical Sciences, University of Campania Luigi Vanvitelli, Napoli, Italy

Background and Aims: Multiple Sclerosis Functional Composite (MSFC) is a disability measure in Multiple Sclerosis that includes the "Timed 25-Foot Walk" (T25FW) to evaluate leg function, the "9-Hole Peg Test" (9HPT) to evaluate arm function and the "Paced Auditory Serial Addition test 3 seconds" (PASAT) to assess cognitive function. An alternative MSFC version replace the PASAT (MSFCp) with the Symbol Digit Modalities Test (SDMT) (MSFCs), that is less influenced by patient's psychological status. Among other MRI structural measures, thalamic volume is strictly associated to physical/cognitive disability in MS. The objective is to evaluate which is the best predictor of thalamic volume between MSFCs and MSFCp.

Methods: One hundred and fifteen relapsing remitting MS (RRMS) patients and 46 sex, age and education-matched healthy controls (HC) underwent clinical evaluation (EDSS, MSFCp and MSFCs), and a 3T–MRI protocol including high resolution 3D–T1 imaging. Brain and Thalamic volumes were calculated using SIENAX and FIRST tool of the FMRIB Software Library. To compare the different relationship between the thalamic volumes and disability measures we applied linear regression models, introducing the thalamic volumes as dependent variable and EDSS, MSFCp and MSFCs as independent variables.

Results: Compared to HC, MS patients showed a significant thalamic atrophy ($p<0.001$). Thalamic volume was independently predicted only by MSFCs ($\beta=0.67$, t 4.16, $p<0.001$), while not by EDSS and MSFCp.

Conclusion: MSFCs score performs better than MSFCp in prediction of thalamic volume in MS. Therefore MSFCs might be a better outcome measure in clinical trials in MS.

Disclosure: Nothing to disclose.

EPO-386 | Association of CSF levels of osteopontin with cortical atrophy and disability in early multiple sclerosis

D. Marastoni[1]; E. Turano[1]; A. Tamanti[1]; E. Colato[1]; A. Pisani[1]; A. Scartezzini[1]; S. Carotenutoi[1]; V. Mazziotti[1]; V. Camera[1]; D. Anni[1]; S. Ziccardi[1]; M. Guandalini[1]; F. Pizzini[2]; F. Virla[1]; R. Mariotti[3]; R. Magliozzi[1]; B. Bonetti[4]; L. Steinman[5]; M. Calabrese[1]
[1]*Neurology B, Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona, Verona, Italy;* [2]*Neuroradiology & Radiology Units, Department of Engineering for Innovation Medicine, University of Verona, Verona Italy;* [3]*Anatomy and Histology section, Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona, Verona, Italy;* [4]*Neurology A, Azienda Ospedaliera Universitaria Integrata di Verona, Verona, Italy;* [5]*Department of Neurology and Neurological Sciences Stanford University, Stanford CA, USA*

Background and Aims: We aimed to evaluate cerebrospinal fluid (CSF) inflammatory markers of accumulation of cortical damage as well as disease activity in patients with early relapsing remitting MS (RRMS).

Methods: CSF levels of Osteopontin (OPN) and 66 inflammatory markers were assessed using an immune-assay multiplex technique in 107 patients with RRMS (82F/25M, mean age 35.7±11.8 years). All patients underwent regular clinical assessment and yearly 3T MRI scans for 2 years, while 39 patients had a 4-year follow-up. White matter lesion number and volume, cortical lesion (CLs) and volume and global cortical thickness (CTh) were evaluated together with the 'no evidence of disease activity' (NEDA-3) status.

Results: The random forest algorithm selected OPN and CXCL13 as most related to CTh changes after 2 and 4 years. In a regression model, OPN ($p < 0.001$), CXCL13 ($p = 0.001$), and sTNFR1 ($p = 0.024$) were increased in those patients with accumulating atrophy (adjusted R-squared 0.615). The markers were added in a model that included all clinical, demographic and MRI variables: OPN ($p = 0.002$) and IL19 ($p = 0.022$) levels were confirmed to be significantly increased in patients developing more CTh change over the follow-up (adjusted R-squared 0.619). CXCL13 and OPN also revealed the best association with NEDA-3 after two years, with OPN significantly linked to disability accumulation (OR 2.468 [1.46-5.034], $p = 0.004$).

Conclusion: The data emphasize a crucial role of OPN in predicting changes in cortical pathology and disease activity in early MS.

Disclosure: Nothing to disclose.

EPO-387 | Neuro-physiological evidences of cerebellar impairment unrelated to structural damage in early multiple sclerosis

V. Boccia[1]; A. Botta[2]; S. Terranova[1]; E. Cipriano[1]; G. Grasselli[3]; E. Capello[2]; L. Avanzino[4]; M. Inglese[1]
[1]*Department of Neurology, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, Italy;* [2]*IRCCS Ospedale Policlinico San Martino, Genoa, Italy;* [3]*Department of Pharmacy (DIFAR), University of Genoa, Genoa, Italy;* [4]*Department of Experimental Medicine (DIMES), Section of Human Physiology, University of Genoa, Genoa, Italy*

Background and Aims: Despite early radiological involvement, clinically-evident cerebellar impairment (CI) is uncommon in early multiple sclerosis (MS). We used transcranial magnetic stimulation (TMS) to assess cerebellar function and explore its relationship with structural damage in this population.

Methods: Early, right-handed MS patients without clinically-evident CI underwent 3T-MRI and TMS assessment. FLAIR and Double-Inversion Recovery (DIR) sequences were analyzed to detect both white-matter and grey-matter cerebellar lesions (CLs). Cortico-spinal tract (CST) and middle cerebellar peduncle (MCP) masks from Johns Hopkins University atlas were registered to Diffusion-Tensor Imaging (DTI)-maps to obtain mean fractional-anisotropy (FA). CST excitability was studied through TMS recruitment curve (RC). Cerebellar-brain inhibition (CBI) was computed as the ratio between test stimulus and motor evoked potential amplitudes recorded after a paired-pulse protocol stimulating the cerebellum and the primary motor cortex with an interstimulus interval of 5ms.

Results: Seventeen MS patients (F: 12; mean (SD) age: 35.2 (11.3)) with disease-duration 6.7 (2.6) months and ten healthy-controls (HCs) (F: 5; age: 32.7 (11.2)) were included. ANCOVA analysis showed CBI reduction (MS: 0.18 (0.11) mV; HCs: 0.28 (0.12) mV; $p = 0.05$) and RCs slope reduction (MS: 0.56 (0.26) μV/%; HCs: 1.01 (0.36) μV/%; $p = 0.01$) in MS. No differences in CBI were shown comparing MS patients with and without CLs ($p = 0.92$). MCP-FA and CST-FA showed no effect on CBI ($p = 0.86$) and RC slope ($p = 0.28$) reduction respectively.

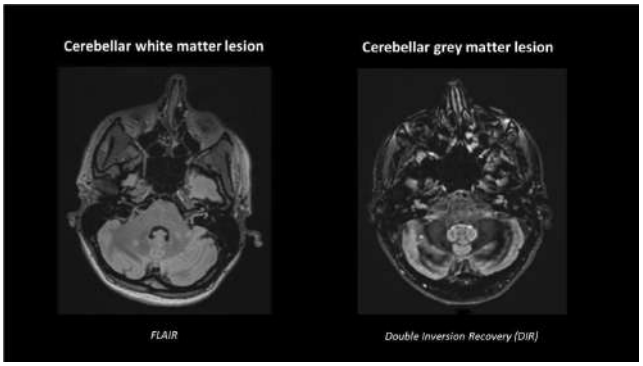

FIGURE 1 FLAIR and Double-Inversion Recovery (DIR) sequences allow for the detection of both white-matter and grey-matter cerebellar lesions.

Conclusion: CBI and RC slope reduction may indicate CI and decreased cortico-spinal excitability in early-MS. TMS-detected functional deficits appeared unrelated to lesion-related and microstructural damage. TMS may unveil distinct intracortical damage mechanism inaccessible to traditional MRI.

Disclosure: This research was funded by the Italian Ministry of Research through the 5x1000 project 'Cortical Excitability and MS.

EPO-388 | Post-pandemic pneumonia cases excess in multiple sclerosis patients treated with intravenous anti-CD 20 drugs

D. Quartana; M. Lo Re; M. Malentacchi; R. Bottero; F. Sperli; A. Oggero; S. Malucchi; A. Di Sapio

CRESM – Hospital Neurology Unit, San Luigi Hospital, Orbassano (Turin), Italy

Background and Aims: Pneumonia is rare in multiple sclerosis (MS) disease-modifying therapies (DMT) trials. In particular pneumonia in ocrelizumab (OCR) was 0.12% in OPERA I and II, 0.41% in ORATORIO trials. In rituximab (RTX) OLYMPUS trial was 1.4%.

Methods: From January 2023 we collected radiologically confirmed pneumonia cases among MS patients. Our cohort included 1543 subjects, distributed among the different DMTs as shown in the graph.

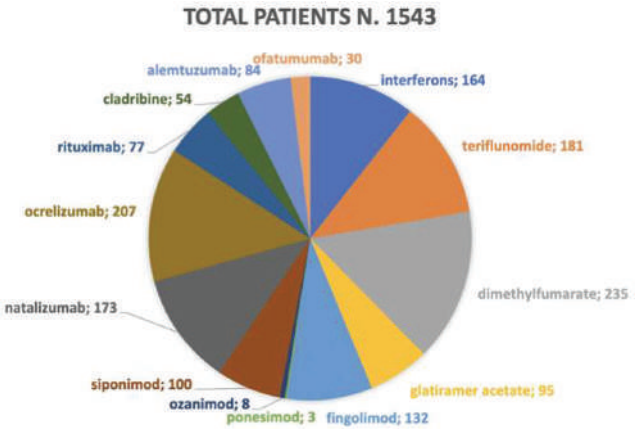

TABLE 1

	Cases	Range	Notes
Total N of Ocrelizumab patients	207	-	
Total N of Rituximab patients	77	-	
Total N of pneumonia cases	17	-	
N in Rituximab (%) among pneumonia cases	6 (35)	-	
N in Ocrelizumab (%) among pneumonia cases	11 (65)	-	
% of pneumonia cases among total patients in rituximab	7,8%	-	
% of pneumonia cases among total patients in ocrelizumab	5.3%	-	
Females (%) among pneumonia cases	15 (88)	-	
Age medium (standard deviation, SD) pneumonia cases	56 (7)	43-69	
Progressive course (%) among pneumonia cases	9 (53)	-	
Relapsing remitting course (%)among pneumonia cases	8 (47)	-	
EDSS medium and median (SD) among pneumonia cases	4.0 (2.0)	1.0-8.0	No differences RTX vs OCR
Medium time between starting anti-CD20 treatment and pneumonia in months (SD)	51 (35)	0-116	
Medium time from last infusion of anti CD 20 and pneumonia in months (SD)	3 (2.65)	0-8	
SARS COV2 pneumonia among all pneumonia cases	3 (18)	-	2 in RTX, 1 OCR
Hospitalisation (%) among pneumonia cases	7 (41)	-	
Hospitalisation (%) among pneumonia cases in rituximab	4 (67)	-	
Hospitalisation (%) among pneumonia cases in ocrelizumab	3 (27)	-	
Orotracheal intubation need (%) among pneumonia cases	1 (5.9)	-	In OCR
Grade 1 Neutropenia (%)among all pneumonia cases	1 (6)	-	In RTX, COVID+
Hypogammaglobulinemia (%)among all pneumonia cases	5 (29)	-	2 (33) in RTX, 3 (27) in OCR
Death by pneumonia (%) among all pneumonia cases	0 (0)	-	

Table 1. Demographic and clinical characteristics of patient with pneumonia in anti-CD 20 treatment.

Results: We found 17 pneumonia cases, 11/207 treated with OCR and 6/77 with RTX (5.3% and 7.8% of total patients respectively). No cases occurred in other DMTs. Three cases were COVID related; 7 patients were hospitalized (one with hypogammaglobulinemia in ICU). All patients recovered. Demographic and clinical data are reported in table 1.

Conclusion: We observed a higher incidence of pneumonia among patients in intravenous anti-CD20 therapies compared with clinical trials data. We suppose that risk of pneumonia increases according to treatment duration. A shorter treatment may account for absence of pneumonia cases in ofatumumab treated patients. Considering the age of pneumonia cases, immunosenescence could have an addictive role in increasing infective risk, while hypogammaglobulinemia does not seem as much. Cases mainly occurred in winter, in accordance with epidemic flu peaks; in long lasting immunosuppressed older patients, the post- pandemia abandoning of the use of masks and social distancing could account for the recent increase of incidence of pneumonia. Further and larger case-control study are needed, focused on others environmental factors like smoking and air pollution. Selection bias could account for imbalance between DMTs.

EPO-389 | Secondary autoimmune diseases in multiple sclerosis after autologous hematopoietic stem cell transplantation

E. Sbragia[1]; G. Boffa[2]; R. Varaldo[3]; A. Raiola[3]; A. Ghiso[3]; M. Gambella[3]; E. Angelucci[3]; G. Mancardi[2]; M. Inglese[4]
[1]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics and Maternal-Child Health (DiNOGMI), University of Genova, Genova, Liguria, Italy and Department of Neurology, Galliera Hospital, Genova, Liguria, Italy*; [2]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics and Maternal-Child Health (DiNOGMI), University of Genova, Genova, Liguria, Italy*; [3]*Division of Hematology and Bone Marrow Transplantation, IRCCS Ospedale Policlinico San Martino, Genova, Liguria, Italy*; [4]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics and Maternal-Child Health (DiNOGMI), University of Genova, Genova, Liguria, Italy and Neurology Unit, IRCCS Ospedale Policlinico San Martino, Genova, Liguria, Italy*

Background and Aims: Autologous hematopoietic stem cell transplantation (aHSCT) has been described as an effective treatment strategy for aggressive multiple sclerosis (MS). Between the possible side effects, secondary autoimmune diseases (SAD) are reported, depending mostly on conditioning regimen (CR) intensity. We aimed to describe the occurrence of both clinical and subclinical SADs in a cohort of MS patients (pwMS) treated with intense immunosuppression followed by aHSCT.
Methods: All pwMS treated at our center with aHSCT with minimum one-year follow-up were included and we analysed clinical-radiological data, blood samples for SADs and lymphocitary-immunophenotype at baseline and every year.
Results: We evaluated 21 pwMS treated from 2015 to 2022. Medium FU was 3.5 years (range 1-7). All patients underwent the same CR (carmustine-cytarabine-etoposide-melphalan plus anti-thymocyte-globulin), besides one that received high-dosage cyclophosphamide (Cy). No clinical SADs were noted. Eight out of 21 (38.1%) patients already presented clinical/laboratorical (lab)-autoimmunity (AI) before aHSCT; of these, in 4 (50.0%) cases lab-AI disappeared or reduced, in 2 (25.0%) lab-thyroid-AI temporarily compared and 2 (25.0%) presented mild anti-cyclic-citrullinated-peptide (CCP) positivity. Of the remaining 13 negative at basal screening, 4 (30.8%) presented transient lab-AI, 4 (30.8%) mild but persistent lab-AI (mostly anti-nuclear antibody, CCP or gastric-parietal-cells; one of these patient received high-dosage Cy as CR) and 5 (38.4%) none. Lab-AI occurred even after long time from procedure (4 years).
Conclusion: Isolated subclinical positivity with no clinical significance can occur in pwMS after aHSCT with myeloablative CR even after a long FU. Interestingly, previous laboratoristic autoantibodies might disappear.
Disclosure: Nothing to disclose.

EPO-390 | Ketogenic diet as a promising intervention for fatigue management in multiple sclerosis: Results of the CHE-FATICA study

Background and Aims: Fatigue is a frequent, disabling and difficult to treat symptom of multiple sclerosis. Low grade inflammation and energetic dysfunction are proposed mechanisms in the pathogenesis of this symptom. Due to its anti-inflammatory and metabolic properties, there is a rational for ketogenic diet application in this setting.
Methods: We conducted a single arm open label interventional study on a strictly selected group of 16 non obese patients with multiple sclerosis who were prescribed a KD for three months.
Results: With respect to baseline, at 3 months we observed a significant reduction of fatigue severity scale (5.18±1.02 v.s. 4.16±0.98; $p=0.042$), Epworth Sleepiness Scale (5.64±2.46 v.s 8.46±3.05; $p<0.001$), Pittsburgh Sleep Quality Index (5.64±3.53 v.s. 7.62±2.59; $p=0.009$), Depression Anxiety Stress Scales-21 depression (3.18±2.93 v.s. 6.15±3.81; $p=0.036$) and anxiety (5.15±4.10 v.s. 1.55±1.92; $p=0.019$) sub-scales, and an improvement in energy sub-scale of Multiple Sclerosis Quality of Life-54 (52.49±12.83 v.s. 37.43±14.26; $p=0.042$).
Conclusion: These findings suggest that ketogenic diet may be useful in the treatment of fatigue and other symptoms frequently encountered in multiple sclerosis.
Disclosure: Nothing to disclose.

EPO-391 | A case of multiple sclerosis combined with polyradiculoneuropathy associated with antiCASPR-1 antibodies

F. Oggiano; A. Manni; R. Vitobello; A. Bianco; P. Iaffaldano; D. Paolicelli
Department of Translational Biomedicine and Neuroscience (DiBraiN), Policlinico of Bari, Bari, Italy

Background and Aims: Multiple Sclerosis (MS) is an inflammatory demyelinating and neurodegenerative disease of the Central Nervous System (CNS) with almost complete sparing of the Peripheral Nervous System (PNS). Chronic Inflammatory Demyelinating Polyradiculoneuropathy (CIDP) is the most common acquired inflammatory polyneuropathy worldwide. It can be associated with Antibodies to molecules of the paranodal complex, such

as Contactin-associated protein-1 (CASPR-1). Cases of CIDP in MS have been reported.

Methods: We report the case of a 50-year-old woman with a ten-years history of CIDP related to Anti-CASPR-1 Antibodies who developed MS.

Results: During the diagnostic work-up for CIDP, to exclude alternative diagnosis, she underwent Magnetic Resonance Imaging (MRI) of the brain in 2010 that was unremarkable. In May 2014 she had diplopia related to right abducens nerve palsy. In November 2014 she had optic neuritis. Therefore she was admitted to our Neurology Department. The neurological examination showed mild right upper limb weakness, facial nerve palsy and absent lower limbs reflexes. Expanded Disability Status Scale was 2.0. She repeated brain and spinal cord MRI that revealed multiple T2 hyperintense lesions involving juxtacortical and periventricular white matter and dorsal segment of the spinal cord. All paraclinical and laboratory tests were normal; the cerebrospinal fluid analysis showed Oligoclonal Bands. A diagnosis of MS was made according to 2017 McDonald criteria.

Conclusion: The co-existence of MS and CIDP has been reported. It can be due to a shared immune pathogenesis with common antigen between CNS and PNS. It may cause an additional disability burden in patients.

Disclosure: Nothing to disclose.

EPO-392 | A multicentric Italian project: Family functioning and multiple sclerosis

F. Bile[1]; L. Lavorgna[1]; G. Miele[1]; M. Ponzano[2]; S. Bonavita[1]; G. Abbadessa[1]; G. Marfia[3]; D. Landi[3]; F. Proietti[3]; M. Inglese[4]; A. Laroni[4]; I. Poire[4]; E. Signoriello[1]; G. [1]Department of Advanced Medical and Surgical Sciences, University of Campania Luigi Vanvitelli, Naples, Italy; [2]Department of Health Sciences – Section of Biostatistics University of Genoa, Italy; [3]Multiple Sclerosis Clinical and Research Unit, Department of Systems Medicine, Tor Vergata, University, Rome, Italy; [4]Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, Italy; [5]Multiple Sclerosis Clinical Care and Research Centre, Department of Neuroscience, Reproductive Sciences and Odontostomatology, Federico II University of Naples, Naples, Italy; [6]Department of Psychology, University of Turin, Turin, Italy; [7]Department of Clinical and Biological Sciences, School of Medicine, University of Turin, Azienda Ospedaliera Universitaria San Luigi Gonzaga, Turin, Italy

Background and Aims: The impact of Multiple Sclerosis (MS) on family dynamics includes effects on both marital relationships and parental bonding1. In this study we aim to evaluate family functioning and related factors in patients with MS and their families.

Methods: To fill-out the questionnaires for MS patients and their families, a dedicated platform was employed2. Families without members reporting chronic diseases were selected as healthy controls (HC), and data on socio-demographics and clinical information were gathered. The administered questionnaires included: The short form of the Family Assessment Measure Third Edition (FAM3), The Hospital Anxiety and Depression Scale (HADS), The Multidimensional Scale of Perceived Social Support (MSPSS), 20-item Toronto Alexithymia Scale (TAS-20), Dyadic Adjustment Scale (DAS) and Inventory of Parent and Peer Attachment (IPPA).

Results: Out 164 MS patients enrolled, we selected those individuals for whom a family member had completed the questionnaires. Two patients were excluded due to language limitations, resulting in a final cohort of 50 individuals. Sociodemographic characteristics are displayed in table 1. Compared with HC, MS patients (>20 years) relatives tend to perceive greater support from "others" ($p = 0.044$), while MS patients partners exhibit a higher dyadic agreement (on finances, leisure time, home organization) ($p = 0.005$)(Table 2). Moreover, young individuals (13 – 20 years), who have at least one family member with MS, have higher overall IPPA scores (table 3).

Family members ≤20 matched with controls based on sex and age.

Conclusion: MS influences dynamics of interpersonal relationships within families, Specifically, it molds relationships with partners, showing an higher level of dyadic consensus and leading to a positive impact on MS younger family members.

Disclosure: Nothing to disclose.

EPO-393 | White matter integrity and the brief repeatable battery: A combined neuropsychological and MRI study

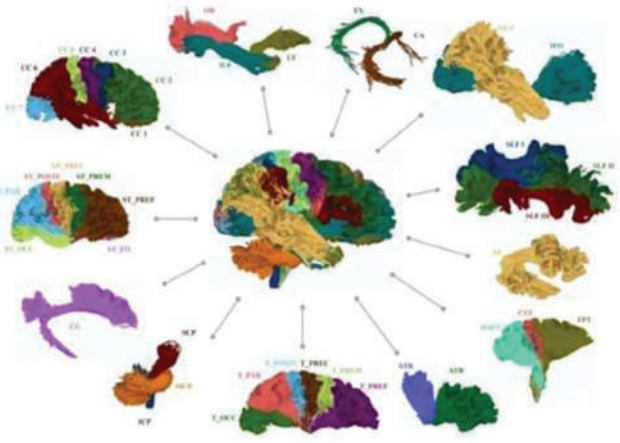
F. Certo[1]; T. Difonzo[1]; L. Sacchi[1]; M. Mancini[2]; C. Scarpazza[3]; G. Verrini[4]; A. Peitroboni[1]; L. Ghezzi[4]; M. De Riz[1]; F. Triulzi[1]; D. Galimberti[5]; C. Saetti[4]; T. Carandini[1]

[1]Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico, Milan, Italy; [2]Cardiff University Brain Research Imaging Center (CUBRIC), Cardiff University, Cardiff, UK; [3]Department of General Psychology, University of Padova, Padova, Italy; [4]University of Milan, Milan, Italy; [5]Department of Biomedical, Surgical and Dental Sciences, Dino Ferrari Center, University of Milan, Milan, Italy

Background and Aims: Cognitive impairment is frequent in people with multiple sclerosis (pwMS) and the brief repeatable battery (BRB) is a sensitive measure for its early detection. Our aim was to test BRB in recently-diagnosed (<2 years from diagnosis) relapsing-MS in association with white matter (WM) integrity as measured by diffusion tensor imaging tractography to find possible correlations between cognitive performances and microstructural WM damage

Methods: BRB and 3T-MRI were acquired in 26 pwMS (16 F, 10 M). WM fibers density and cross-section (FDC) were measured by fixel-based analysis within 72 WM tracts of interest using TractSeg. Correlations between WM-tracts FDC and BRB-scores were assessed by Pearson correlations (setting $p<0.05$) and regression analyses for potential confounders were carried out. Sex differences in Paced Auditory Serial Addition Test (PASAT) scoring were tested by t-test.

Results: BRB scores were not significantly correlated with clinical and radiological activity, EDSS, depression or fatigue. We found a significant correlation between PASAT 3, 2 and word list generation (WLG) scores and FDC within certain WM tracts, as shown in figure 2. Linear regression found that sex significantly affects PASAT scoring, with males showing higher performances (Fig.3).



Overview of the 72 WM tracts. WM fiber density and cross-section (FDC) measures were extracted from 72 WM tracts, by using fixel-based analysis (MRtrix and TractSeg) (picture from Wasserthal J et al. 2018).

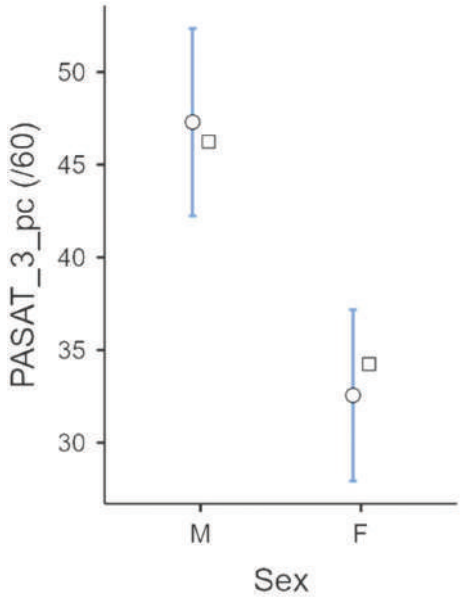
ST_PREM_left	r = 0.423 p = 0.031	r = 0.446 p = 0.022	r = 0.549 p = 0.004

Significant correlation between scoring of PASAT 2, PASAT 3 and WLG with FDC within different WM tract. Pearson correlations were used ($p < 0.05$). *Persistance of statistical significance when inserting sex as a covariant during regression analyses.



T-test shows higher PASAT 3 scores in the male group. The same was confirmed for PASAT 2.

Conclusion: In people with recently-diagnosed-MS, PASAT and WLG scoring are affected by regional WM axonal damage within specific WM tracts as measured by FDC reduction. From our preliminary results sex seems to affect PASAT performance in MS patients. Larger sample is needed to confirm preliminary result.
Disclosure: Nothing to disclose.

EPO-394 | Treatment switch or retreatment with cladribine tablets during CLARIFY-MS & CLARIFY-MS extension studies: Patient profile

F. Piehl[1]; K. Selmaj[2]; E. Havrdova[3]; A. Smyk[4]; B. Keller[4]; X. Montalban[5]; F. Patti[6]; J. Lechner-Scott[7]
[1]Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden; [2]Center for Neurology, Lodz, Poland; Department of Neurology, University of Warmia and Mazury, Olsztyn, Poland; [3]Charles University, First Medical Faculty, Department of Neurology and Center for Clinical Neuroscience, Prague, Czechia; [4]Merck Healthcare KGaA, Darmstadt, Germany; [5]Department of Neurology Neuroimmunology Centre of Multiple Sclerosis of Catalonia (Cemcat), University Hospital Vall d'Hebron, Barcelona, Spain; [6]Department of Medical and Surgical Sciences and Advanced Technologies, GF Ingrassia, University of Catania, and Azienda Ospedaliero Universitaria Policlinico "G Rodolico" – San Marco, University of Catania, Italy; [7]University of Newcastle, Newcastle, NSW, Australia; Division of Neurology, John Hunter Hospital, Newcastle, NSW, Australia

Background and Aims: The objective of CLARIFY-MS Extension (NCT04776213), a follow up study to CLARIFY-MS, was to assess long-term effects on cognition and health-related quality of life in patients with relapsing multiple sclerosis treated with cladribine

tablets (CladT). We also evaluated the individual characteristics of patients who switched to other disease modifying therapies (DMTs) or were retreated with CladT during CLARIFY-MS and CLARIFY-MS Extension.

Methods: We evaluated potential reasons for switching to other DMTs or CladT retreatment during the total 4-year observation period of the CLARIFY-MS Extension study ($N = 280$), during which no CladT treatment was planned, as per protocol. Decisions to switch to other DMTs or re-treat with CladT were based on the investigators´ discretion.

Results: Overall, 37/280 patients (13.2%) switched to another DMT, among whom 33 (89%) showed evidence of disease activity (EDA, i.e., 6-month confirmed disability progression, qualifying relapse, or magnetic resonance imaging [MRI] activity) before switch; MRI activity was the most frequently observed EDA event (28/37; 75.7%). None of the patients switched to another DMT during Year 1 of CladT treatment; 4, 17 and 16 patients switched during Years 2, 3, and 4, respectively. One patient in Year 3 and 7 patients in Year 4 (2.9% in total) were retreated with CladT; all had an EDA event before CladT retreatment. Individual patient profiles and reasons for switching or CladT retreatment will be presented.

Conclusion: A low proportion of patients switched to other DMTs or required CladT retreatment during the CLARIFY-MS and CLARIFY-MS Extension studies, suggesting durable CladT efficacy.

Disclosure: This study was sponsored by Merck (CrossRef Funder ID: 10.13039/100009945). Detailed author disclosures will be included in the presentation.

EPO-395 | Ocrelizumab versus siponimod: A real life comparison study

Background and Aims: Ocrelizumab (OCR) and Siponimod (SIP) are licensed to treat patients with Progressive Multiple Sclerosis with disease activity (paMS). This study aims to compare the effectiveness and side effects of OCR and SIP in paMS patients.

Methods: This is a multicenter, retrospective, real-world study conducted in Italy on paMS patients treated with SIP or OCR. Clinical data, including demographics and laboratory information, were collected at baseline, 6, 12 and 18 months during routine clinical visits. A propensity score matching approach (PSMA) was used to compare the effectiveness and safety of the two treatments.

Results: We enrolled 116 paMS patients treated with OCR and 76 with SIP. These groups showed significant differences in age and annualized relapse rate (ARR) one and two years before treatment. After PSMA, both groups consist of 76 paMS patients, with a mean age of 50.8 (SD 6.95) for the OCR and 51.8 (SD 8.10) for the SIP group (Table 1). No differences in relapses and EDSS scores at 6, 12, and 18 months follow-up, and Gd+ lesions at MRI at 6 and 18 months follow-up. The SIP compared to the OCR group showed lower white blood cells and lymphocytes count at 6, 12, and 18 months ($p < 0.001$); no significant differences were found in the two groups for the number of infections at 6, 12, and 18 months follow-up.

TABLE 1 Demographic and clinic characteristics of paMS patients.

		paMS patients treated with OCR n=76	paMS patients treated with SIP n=76
Age (y)	Mean (SD)	50.8 (6.95)	51.8 (8.10)

Natalizumab		0.7%	1.4%
Ocrelizumab		0%	0.7%
Lemtrade		2%	0.7%
Cladiribine		0%	0.7%
Rituximab		1.4%	0%
Azatioprine		3.4%	0.7%

ARR, annualized relapse rate; paMS, Progressive Multiple Sclerosis with disease activity; OCR, Ocrelizumab; SD, standard deviation; SIP,Siponimod;

Conclusion: Despite a short 18-month follow-up, similar treatment outcomes in elderly paMS patients in SIP or OCR therapy suggest that both treatments are similarly effective and safe in elderly patients.

Disclosure: Nothing to disclose.

EPO-396 | Comparing lymphocyte count among different S1P modulators in multiple sclerosis: A multicenter real-world study

G. Maniscalco[1]; M. Di Gregorio[2]; G. Cafasso[3]; E. Signoriello[4]; S. Bonavita[4]; F. Romano[5]; R. Iodice[6]; R. Fantozzi[7]; P. Bellantonio[7]; A. Zanghi[8]; L. Sinisi[9]; A. D'Ambrosio[10]; V. Busillo[11]; V. Scarano[3]; L. Lavorgna[4]; S. Simona[1]; M. Di Battista[1]; D. Daniele[1]; G. Lus[4]; E. Cassano[6]; P. Di Filippo[8]; G. Sibilia[9]; G. Abbadessa[4]; V. Andreone[1]

Cardarelli" Hospital, Naples, Italy; [2]Neurology Unit, University Hospital "San Giovanni di Dio E Ruggi d'Aragona", Salerno, Italy; [3]Department of Neurology, AORN San G. Moscati, Avellino, Italy; [4]Second Division of Neurology, Department of Advanced Medical and Surgical Sciences, University of Campania Luigi Vanvitelli, Naples, Italy; [5]Multiple Sclerosis Center and Neurological and Stroke Unit, CTO Hospital, AORN Ospedale dei Colli, Naples, Italy; [6]Department of Neurosciences, Reproductive Sciences and Odontostomatology, University Federico II Naples, Italy; [7]IRCCS Neuromed, Pozzilli, Isernia, Italy; [8]Department of Medical and Surgical Sciences, University of Foggia, Foggia, Italy; [9]Department of Neurology and MS Center, San Paolo Hospital, Naples, Italy; [10]Department of Advanced Medical and Surgical Sciences, and 3T MRI-Center, University of Campania "Luigi Vanvitelli", Naples, Italy; [11]MS Centre, Maria SS. Addolorata Hospital, ASL Salerno, Eboli, SA, Italy

Background and aims: Sphingosine-1-phosphate (S1P) modulators are a class of molecules targeting S1P receptors (S1PR) with different S1PR-subtype selectivity. They cause a reduction in circulating lymphocytes by inhibiting lymphocytes egress from lymph nodes. Our study aims to compare the absolute lymphocytes counts (ALCs) of MS patients treated with Fingolimod (FTY), Siponimod (SIP), Ozanimod (OZA), and Ponesimod (PON).

Methods: We enrolled 219 pwMS from eleven Italian Centers. Out of 219 pwMS, 69 (31.5%) were treated with SIP, 62 (28.3%) with OZA, 46 (21%) with FTY and 42 (19.2%) with PON. We excluded patients who had already received previous treatment with S1P modulators.

Results: OZA showed a significantly higher ALCs compared either to SIP in all time points ($p < 0.001$ at T1 and T3; $p = 0.003$ at T6), or FTY at T1 ($p < 0.001$) and T3 ($p = 0.02$). PON showed significantly higher ALCs compared to SIP at T1 and T3 ($p = 0.003$; $p = 0.03$ respectively). Furthermore, we analyzed the percentage of severe lymphopenia (including grade 3 and grade 4) among the different S1P modulators. PON and OZA showed a significantly lower percentage of patients with severe lymphopenia (23.8 % $p = 0.006$, 25.8% $p = 0.005$ respectively) compared to FTY (52.2%) and SIP (60.9%).

Conclusion: Despite a short follow-up, our study demonstrated a different degree of induced-lymphopenia among S1P modulators, as OZA and PON showed higher ALCs and a lower percentage of severe lymphopenia in pwMS.

Disclosure: Nothing to disclose.

EPO-397 | Identifying multiple sclerosis patients within a control population using online cognitive and motor assessments

H. Karoui[1]; A. Moura[1]; A. Lerede[1]; R. Middleton[2]; A. Hampshire[1]; R. Nicholas[1]
[1]Brain Sciences, Imperial College London, London, UK; [2]Population Data Science, FHMLS, Swansea University, Swansea, UK

Background and Aims: Multiple Sclerosis (MS) is characterised by a complex interplay of motor, cognitive and neuropsychiatric features which vary between individuals and across time. Whilst MS diagnosis has improved over time, there remains a need for more rapid and reliable diagnostic tools. We use classification algorithms to investigate the feasibility of online cognitive and motor assessments in identifying MS patients from controls.

Methods: We trained a random forest classifier on cognitive metrics from a randomly sampled population of 1777 patients with MS (pwMS), 1189 patients with depression and anxiety (pwDA) and 1777 healthy controls (HC) from Cognitron. The model uses performance metrics (response time and accuracy) from 7 online cognitive tasks specific to MS, as features to predict the participant's group label. We also trained a support vector machine (SVM) classifier on motor performance metrics from pwMS and HC. This model uses the MS Impact Scale (MSIS-29v2) from the UKMS Register to determine the participant's group label.

Results: The random forest classifier discriminates between HC and pwMS (ROC AUC = 0.81), and between pwDA and pwMS (ROC AUC = 0.85) using online cognitive testing metrics. Our SVM classifier robustly distinguished pwMS from HC (ROC AUC = 0.96) using the MSIS-29v2. A sub-analysis of pwMS (five years from onset) also showed high classification accuracy (ROC AUC = 0.94).

Conclusion: Online cognitive testing and motor MSIS-29v2 can accurately distinguish pwMS from controls. Our findings provide a novel data-driven approach to MS identification, offering an opportunity for earlier intervention and tailored treatment approaches in the clinical setting.

Basel, Switzerland;* [12]*Department of Neurology, Mellen MS Center, Neurological Institute, Cleveland Clinic, Cleveland, OH, USA;* [13]*Research Center for Clinical Neuroimmunology and Neuroscience Basel (RC2NB) and MS Center, Departments of Headorgans, Spine and Neuromedicine, Clinical Research, Biomedicine and Biomedical Engineering, University Hospital, University of Basel, Switzerland*

Background and Aims: Ofatumumab demonstrated superior efficacy and favourable safety versus teriflunomide in the Phase 3 ASCLEPIOS I/II trials in people with relapsing multiple sclerosis (pwRMS). Previously reported data showed sustained efficacy and a favourable safety profile of ofatumumab in pwRMS up to 5 years. Here, we aim to present the safety and efficacy of ofatumumab treatment for up to 6 years.

Methods: Efficacy analyses will include all participants randomised in ASCLEPIOS I/II and their data from first dose in ASCLEPIOS I/II, whereas safety analyses will include all participants who received at least one dose of ofatumumab in either ASCLEPIOS I/II, APOLITOS, APLIOS or ALITHIOS (cut-off date: 25-Sep-2023). Efficacy will be analysed by randomised treatment in the core study, with those randomised to ofatumumab referred to as continuous group and to teriflunomide as switch group.

Results: Previously reported 5-year data (cut-off: 25-Sep-2022) showed a sustained low annualised relapse rate (ARR) and almost complete suppression of MRI lesion activity in the continuous group. In the switch group, ARR was markedly reduced from Year 2–3 (0.16–0.06) and remained low through Years 3–5 (0.05), and MRI lesion activity was almost completely suppressed through Years 3–5. At Year 5, 90% of patients reached NEDA-3 in both groups. The safety profile of ofatumumab remained consistent with no new safety signals over 5 years. Updated 6-year efficacy and safety results will be presented at the congress.

Conclusion: These analyses will help inform physicians on the longer-term safety and efficacy profile of ofatumumab in pwRMS.

Disclosure: The study was supported by Novartis Pharma AG, Switzerland. The detailed author disclosures will be presented in the subsequent presentation.

Muscle and neuromuscular junction disorder 2

EPO-399 | Association of the initiation timing of oral steroids with clinical prognosis in adult generalized myasthenia gravis

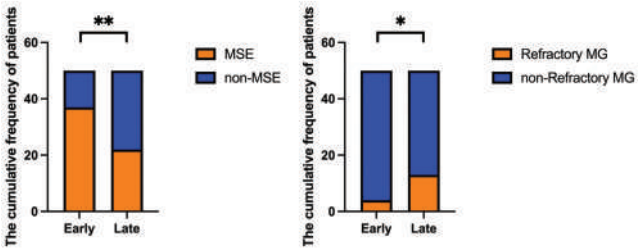
D. He; C. Yan; H. Zhong; Y. Zhou; Y. Zhang; X. Huan; J. Xi; C. Zhao
Department of Neurology, Huashan Hospital, Fudan University

Background and Aims: To explore the association of the initiation timing of oral corticosteroids with the prognosis of adult generalized myasthenia gravis (GMG) patients.

Methods: We retrospectively screened adult GMG patients and divided them into early treatment group (initiation of oral steroids within one year from disease onset) and late treatment group. The clinical information at baseline and one-year follow-up were collected. The propensity score matching (PSM) analysis was used to select the candidates of two cohorts. The prognosis after one year therapy between the two groups was compared after matching.

Results: 50 patients were enrolled in both groups after PSM. Both quantitative MG (QMG) and MG-activities of daily living (MG-ADL) points were significantly lower in the early-treatment group than in the late-treatment group. In particular, the QMG and MG-ADL points of appendicular muscles were significantly lower in the early-treatment group than in the late-treatment group. The proportion of minimal symptom expression (MSE) is significantly higher in early treatment group compared to late treatment group (74% vs 44%, $p = 0.0223$), while the proportion of refractory MG is lower (8% vs 26%, $p = 0.0166$).

	early treatment (N=50)	late treatment (N=50)	P Value
MSE	37 (74.0%)	22 (44.0%)	0.0223
Refractory MG	4 (8.0%)	13 (26.0%)	0.0166
Immunosuppressants	22 (44.0%)	28 (56.0%)	0.2301
QMG, mean±SD	5.4 ± 4.1	8.0 ± 4.6	0.0040
Extraocular and facial muscle	1.0 ± 1.4	1.2 ± 1.7	0.4480
Bulbar muscle	0.1 ± 0.6	0.1 ± 0.4	0.8396
Appendicular muscle	4.3 ± 3.1	6.7 ± 3.7	0.0007
MG-ADL, mean±SD	1.2 ± 2.3	2.2 ± 2.1	0.0330
Extraocular and facial muscle	0.7 ± 1.3	1.0 ± 1.2	0.2022
Bulbar muscle	0.3 ± 0.8	0.4 ± 0.8	0.4453
Appendicular muscle	0.2 ± 0.6	0.7 ± 1.1	0.0051



Clinical prognosis of the patients between early treatment and late treatment groups after propensity score matching. Values are presented as the mean±SD or *n* (%). MSE, minimal symptom expression; MG, Myasthenia Gravis; QMG, Quantitative Myasthenia Gravis.

Conclusion: Adult GMG patients who received corticosteroid therapy within one year of the onset date show a higher rate of MSE and a lower rate of refractory status than the late-treatment GMG patients, indicating that treatment of corticosteroids starting within 12 months gave rise to a more favorable prognosis in GMG patients.

Background and Aims: Efgartigimod (EFG), a human immunoglobulin G (IgG)1 Fc fragment, blocks the neonatal Fc receptor, selectively decreasing IgG levels. The safety profile of intravenous (IV) EFG was assessed across different IgG-mediated diseases.

Methods: EFG IV was assessed in different dosing regimens (10–25 mg/kg IV, including cyclical and continuous weekly dosing) in generalised myasthenia gravis (gMG; Phase 2 trial and Phase 3 placebo-controlled ADAPT and open-label extension ADAPT+ trials), in primary immune thrombocytopenia (ITP; Phase 3 placebo-controlled ADVANCE IV and ongoing open-label extension ADVANCE IV+ [data cut-off: 24 November 2023] trials) and in pemphigus vulgaris and foliaceus (Phase 2 trial). Pooled data represent participants receiving EFG 10 mg/kg IV in the Phase 2, ADAPT and ADAPT+ trials for gMG and in the ADVANCE IV and ADVANCE IV+ trials for ITP.

Results: EFG IV was well-tolerated and demonstrated a consistent safety profile across all indications and doses studied, with comparable rates of treatment-emergent adverse events (TEAEs) to placebo and across indications (Table 1; TEAEs ranged from 77.4–95.6% across studies and pooled analyses). Most TEAEs across studies were mild to moderate in severity. Discontinuation rates due to TEAEs were consistently low across studies and pooled analyses (ranged from 0–9.1%). There was no increase in TEAE or infection event rates with repeated treatment (Table 1). EFG treatment did not reduce albumin levels or increase cholesterol levels.

Table 1 Incidence and event rates of adverse events for intravenous efgartigimod in phase 2 generalised myasthenia gravis, ADAPT, ADAPT+, ADVANCE IV, ADVANCE IV+ and phase 2 pemphigus trials

Indication	Generalised myasthenia gravis				Primary immune thrombocytopenia			Pemphigus foliaceus and pemphigus vulgaris
Phase	Phase 3		Phase 3	Pooled data	Phase 3	Phase 3	Pooled data	Phase 2

EPO-401 | Adverse pregnancy outcomes in myasthenia gravis: A retrospective cohort study in a US health insurance claims database

M. Jacobson[1]; R. Makadia[1]; C. Gary[2]; N. Hall[1]; J. Hardin[1]; S. Huang[3]; R. Sun[4]; R. Zaha[4]; A. Krumme[1]

[1]*Johnson & Johnson, Innovative Medicine, Global Epidemiology;* [2]*Johnson & Johnson, Innovative Medicine, Medical Affairs, Immunology;* [3]*Johnson & Johnson, Innovative Medicine, Immunology;* [4]*Johnson & Johnson, Innovative Medicine, R&D Data Science*

Background and Aims: Pregnancy is common among individuals with autoantibody conditions and adverse perinatal outcomes have been documented. However, previous studies in myasthenia gravis (MG) have produced mixed results.

Methods: We conducted a retrospective cohort study in the United States (US) Marketscan Commercial Claims and Encounters database between 2000-2022. Pregnancies in females aged 18-49 were identified and among live births, maternal and infant records were linked. MG was defined by ≥1 inpatient or ≥2 outpatient diagnoses within a 365-day period, with ≥1 diagnosis required before pregnancy end. The prevalence of six perinatal outcomes was calculated in the MG and total populations: live birth, spontaneous abortion, Cesarean section, preeclampsia, preterm birth, and small for gestational age (SGA). Outcome prevalence in the total population was standardized to the MG population age distribution.

Results: A total of 694 individuals with MG had 900 pregnancies and 3,928,256 individuals in the total population had 5,185,726 pregnancies. The prevalence of live birth (75.0% vs. 73.9%) and spontaneous abortion (20.4% vs. 20.8%) was similar in the MG and age-adjusted total population, respectively. Preeclampsia and Cesarean section were more frequent among MG than the total population (10.7% vs. 7.1%; 42.9% and 35.0%, respectively). The largest differences were noted for preterm birth and SGA, which were more prevalent among MG than the total population (18.0% vs. 9.7%; 4.3% vs. 1.7%, respectively).

Conclusion: MG was associated with a greater burden of certain adverse perinatal outcomes, occurring in both mother and infant. Further research is needed to understand drivers of pregnancy outcomes in MG.

Disclosure: This study was conducted by Johnson & Johnson. All authors are employed by, and hold stock in, Johnson & Johnson.

EPO-402 | Rituximab alone is as effective as associated with steroids on naive patients with generalized myasthenia gravis

C. Héraud[1]; S. Bresch[2]; C. Landes-Château[2]; C. Lebrun-Frenay[2]

[1]*Neurology Department, CHU de Nice, Nice, France;* [2]*Unité de Recherche Clinique Côte d'Azur*

Background and Aims: Rituximab (RTX) has been proven effective in managing refractory generalized myasthenia gravis (MG), and its use is increasing worldwide. MG stabilization may initially require oral corticosteroid (CS) therapy, but its long-term side effects require the shortest duration of treatment. We studied the clinical effectiveness and usefulness of corticosteroids associated with RTX compared to RTX alone on MG remission.

Methods: In a monocentric retrospective cohort in the Nice University Hospital, we compared naïve MG patients treated with RTX as first-line therapy alone (G1) or associated with CS (G2). After the RTX induction, we evaluated efficacy with the Osserman score (OS) and the requirement for any rescue therapy (IgIV or plasmapheresis).

Results: Sixty-eight patients were treated with RTX, of which 19 (27.94%) benefited from an association with at least 0.5 mg/kg of corticosteroids. RTX-CS patients were more severe than RTX alone (OS: G1: 74.1 and G2: 64.94, $p=0.044$). However, OS at three (83.44 and 83.12, $p=0.993$), six (88.69 and 86.36, $p=0.545$), nine (82.91 and 85.73, $p=0.563$), and twelve months (86.6 and 88.69, $p=0.761$) from the treatment induction were similar. Rescue therapy following RTX induction was significantly higher for the RTX-CS (20.41% and 47.37%, $p=0.037$). Regarding safety, adverse event rates were similar in the two groups (0% and 14.29%, $p=0.178$).

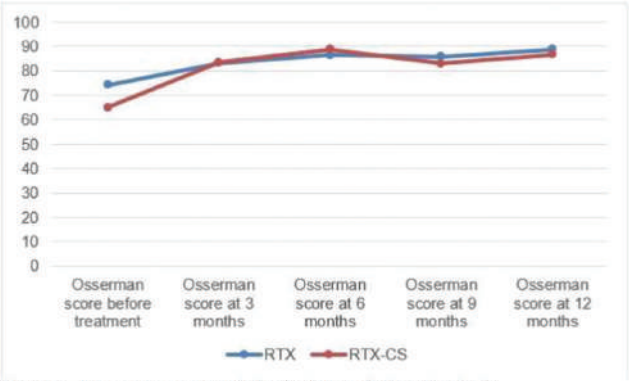

Figure 1 – Osserman score evolution before and after Rituximab

Conclusion: We suggest that RTX alone is as effective as RTX-CS in MG patients, indicating that avoiding steroids could reduce side effects, decrease rescue therapies, and not affect MG outcomes.

Disclosure: The authors have no conflict of interest to declare.

EPO-403 | Intensive care due to exacerbation of myasthenia gravis: Risk factors and prognosis

C. Myllynen[1]; A. Tuulasvaara[2]; S. Atula[2]; S. Laakso[2]
[1]*Department of Neurosciences, University of Helsinki, Helsinki, Finland;* [2]*Department of Neurology, Brain Center, Helsinki University Hospital, Helsinki, Finland*

Background and Aims: Exacerbation of myasthenia gravis (MG) with imminent respiratory failure requires intensive care. We studied the risk factors for intensive care and patients' prognosis thereafter.

Methods: This retrospective registry study covered Helsinki and Uusimaa hospital district from 2008 to 2021. Patients were identified using the ICD-10 code (G70.0) through a data repository search, followed by a chart review of patient medical records. The risk factors for intensive care (intensive care unit or intensive monitoring ward) were evaluated as compared with the patients never in need of in-hospital care for MG (outpatient group) and with those treated at a neurological ward for MG exacerbation. We compared the outcome between MG exacerbation and all reasons of intensive care.

Results: A total of 35 (9%) out of 386 MG patients required intensive care for MG exacerbation, within a median of 5.3 months from diagnosis. The intensive care group had a higher mean age at MG diagnosis and more comorbidities than the outpatient group. Thymoma (OR 4.8; $p = 0.028$) and female sex (OR 2.1; $p = 0.045$) were independent risk factors for intensive care due to MG exacerbation. High modified Rankin scale pre-hospitalization and late-onset MG (LOMG) were associated with prolonged intensive care stay and 6-month mortality (14.3%) was higher in patients with prolonged intensive care stay and older age.

Table 1. Demographic parameters of the study subgroups.

Characteristic	Intensive care group	Neurological ward group	*P*-value	Outpatient care group	*P*-value
N (% of total group)	35 (9.1%)	180 (46.6%)	-	171 (44.3%)	-
Female, n (%)	20 (57.1%)	84 (46.7%)	NS	95 (55.6%)	NS
Age at the diagnosis of MG, mean in years (±SD)	60.5 (±16.1)	53.4 (±20.8)	0.044	48.3 (±20.9)	<0.001
LOMG, n (%)	27 (77.1%)	105 (58.3%)	NS	88 (51.5%)	0.018*
AChR antibodies, n (% of cases with available antibody data)	24 (82.8%)	129 (80.6%)	NS	98 (81.7%)	NS
Thymectomy performed, n (%)	21 (60.0%)	112 (62.2%)	NS	77 (55.0%)	NS
Age at thymectomy, mean in years (±SD)	54.7 (±15.7)	48.2 (±19.5)	NS	39.9 (±18.1)	0.002
Thymoma, n (%)	4 (11.4%)	4 (2.2%)	0.026	2 (1.2%)	0.002
MG alone, n (%)	5 (14.3%)	26 (14.4%)	NS	58 (33.9%)	<0.001
MG with any comorbidity, n (%)	30 (85.7%)	154 (85.6%)	NS	113 (66.1%)	<0.001

Footnote to Table 1. AChR: acetylcholine receptor; AD: autoimmune disease; MG: myasthenia gravis; LOMG late-onset MG; NS: non-significant. P-values for statistically significant difference between the intensive care group and the other subgroups are shown.

Table 2. Data of MG patients in the intensive care group.

	MG patients in the intensive care group
Total number of patients	35
Age at admission (SD)	63.4 (16.9)
Time from diagnosis, median in months (range)	5.3 (-50.9-306.5)
Intensive care episode before MG diagnosis, n (%)	8 (22.9%)
Thymectomy done	21 (60%)
Time between thymectomy and the episode, median in months (range)	36.9 (-61.9-311.6)
First MG symptom	
Ocular	22.9%
Bulbar	54.3%
Weakness in limbs	14.3%
No MG medication before the episode	12 (34.3%)
Immunosuppressive medication before the episode	8 (22.9%)
Triggering factor of MG exacerbation, number of patients (%)†	
Infection	15 (42.9%)
Medications	5 (14.3%)
Surgery or anesthesia	5 (14.3%)
Poor compliance	2 (5.7%)
Unknown	9(25.7%)
Intensive care length of stay in days, median (range)	6 (1-34)
Mechanical or non-invasive ventilation, number of patients (%)	21 (51.4%)
Myasthenic crisis †† , number of patients (%)	25 (71%)
MG rescue therapy, number of patients (%)	
Plasmapheresis of immunoadsorption	21 (60%)
IVIG	3 (8.9%)
IVMP	5 (14.3%)
Immunosuppressive medication at next follow-up	18 (51.4%)
MGFA when entering hospital, median (range)	4 (1-5)
MGFA last follow-up, median (range)	2 (0-4)
Worst MGFA in intensive care, median (range)	5 (3-5)
MGFA next follow-up, median (range)	2 (0-4)
Medication enhancement in last follow-up	10 (33.3%)
Immunosuppression enhancement after the episode	18 (51.4%)
MGFA at 6 months, median (range)	2 (0-3)
mRS at 6 months	2 (0-6)
Age at death (n=17), mean in years (SD)	75.7 (11.9)
Potassium level (mmol/L) at the beginning of ICU episode, mean (SD) (all episodes, n=59)	3.8 (0.4)
Highest CRP level during the episode, mean (SD)	89.8 (84.4)
HUS hospital episode length, mean in days (SD)	22.6 (17.0)

Footnote to Table 2. CRP, C-reactive protein; HUS, the Hospital District of Helsinki and Uusimaa; IVIG, intravenous immunoglobulin; IVMP, intravenous methylprednisolone; MG, myasthenia gravis; MGFA, Myasthenia Gravis Foundation of America, only the numeral level is used; mRS, the Modified Rankin Scale; SD, standard deviation. Intensive care was defined as care given in units with individual patient monitoring and the possibility for respiratory support. †Some patients had more than one triggering factor. †† Myasthenic crisis was defined as an MG exacerbation requiring non-invasive ventilation, intubation, or a nasogastric tube.

Table 3. All episodes of intensive care during the study period and comparison of duration and mortality between MG exacerbation and acute exacerbation of asthma bronchiale treated in the intensive care.

	All intensive care episodes	Acute severe asthma	MG exacerbation
Number of patients	106910	142	35
Age, mean in years (±SD)	61.5 (18.5)	56.0 (20.5)	63.4 (17.2) *
Female, % (n)	43.1%	69.7% (99)	57.1% (20)
First intensive care episode in days, median (range)	1 (0-210)	1 (0-18)	6 (1-34) **
Duration of all intensive care episodes, days	382073	256	462
More than two intensive care episodes, n (%)	30400 (28.4%)	30 (21.1%)	4 (11.4%)
Mortality during intensive care episode, %	7.7% (in 10d)	4.9%	2.9%
Mortality in 6 months after intensive care episode, %	15.9%	7.7%	14.3%

Footnote to Table 3. MG, myasthenia gravis; SD, standard deviation. P-values indicating statistically significant differences between the studied subgroups of MG exacerbation and acute severe asthma are denoted with asterisks, and those not shown were insignificant. * $p = 0.04$, ** $p < 0.001$.

Conclusion: Our study shows an increased risk of intensive care for patients with LOMG or thymoma, occurring usually within six months from diagnosis. Special attention to early treatment choices should thus be given.

EPO-404 | Clinical and genetic features of a cohort of patients with myoadenilate deaminase deficiency: A new mutation

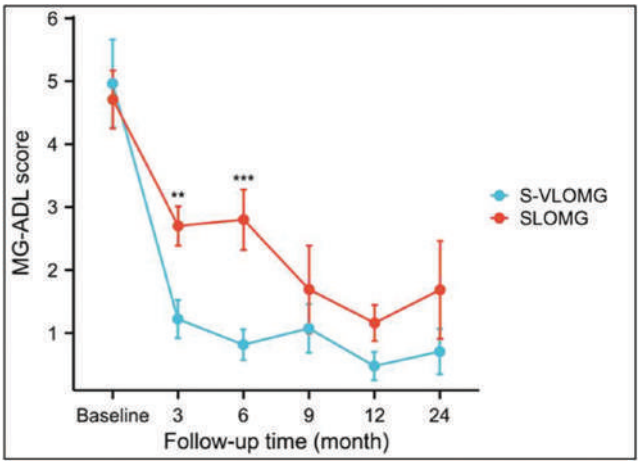
C. Alberti[1]; S. Lucchiari[1]; M. Rimoldi[2]; F. Fortunato[2]; D. Velardo[1]; L. Napoli[3]; M. Moggio[1]; N. Bresolin[1]; G. Comi[1]; S. Corti[1]; E. Abati[1]; M. Moggio[3]; N. Bresolin[2]; G. Comi[2]; S. Corti[3]; E. Abati[2]
[1]*Department of Pathophysiology and Transplantation (DEPT), Dino Ferrari Centre, Neuroscience Section, University of Milan, Milan, Italy;* [2]*Neurology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy;* [3]*Neuromuscular and Rare Diseases Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy*

Background and Aims: Myoadenylate deaminase deficiency is the predominant metabolic disorder affecting skeletal muscles in the Caucasian population, involving approximately 2% of individuals. While the majority of those with the deficiency remain asymptomatic, some experience symptoms induced by exercise, suggesting a link between reduced enzyme activity and muscle function.
Methods: We conducted a cross-sectional analysis on 8 patients harboring mutations in AMPD1 and exhibiting a biochemical deficiency of myoadenylate deaminase (MAD) at histopathological analyses.
Results: Evaluated patients demonstrated a variable age of onset and a broad phenotypic spectrum, with most presenting exercise-induced myalgia and proximal weakness. Routine blood tests showed no significant abnormalities, except for persistent elevation in serum creatine kinase (CK). DNA analysis revealed the nonsense mutation c.34C>T (p.Q45*) in all patients, except for one with a novel compound heterozygous mutations p.Arg494Ser and p.Met511Val. These mutations located at a highly conserved position were predicted to be pathogenic by in silico tools. In comparison to other patients, the carrier of the novel mutation exhibited an earlier onset within the first months of life with primary dropped head syndrome and a more pronounced elevation of serum creatine kinase (CK) levels, which then progressed to proximal, limb-girdle type myopathy.
Conclusion: In conclusion, our work expands the genetic spectrum of MAD deficiency, disclosing a novel mutation and its related clinical effect, and provides a detailed description of the clinical features of a cohort of patients with AMPD1 mutations.
Disclosure: Nothing to disclose.

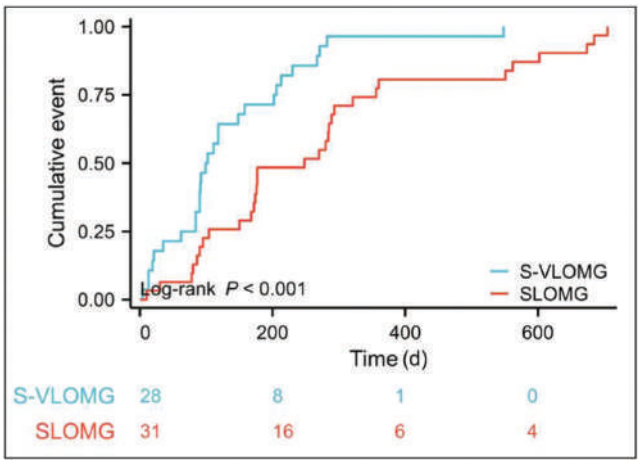
EPO-405 | Short-term and long-term prognoses in sub-very-late-onset and super-late-onset myasthenia gravis patients

N. Xie[1]; Q. Liu[2]; S. Zhang[1]; Q. Wen[1]; Y. Wang[1]; Y. Li[3]; H. Liu[1]; Y. Jiang[1]; Y. Lu[1]; L. Di[1]; M. Wang[1]; M. Xu[1]; H. Chen[1]; . Zhu[1]; X. Wen[1]; X. Shen[4]; Y. Da[1]
[1]*Department of Neurology, Xuanwu Hospital, Capital Medical University, Beijing, China;* [2]*Department of Neurology, Beijing Fengtai You'anmen Hospital, Beijing, China;* [3]*Department of Neurology, Electric Power Teaching Hospital, Capital Medical University, Beijing, China;* [4]*Department of Neurology and Neuromuscular Research Laboratory, Mayo Clinic, Rochester, Minnesota, USA*

Background and Aims: To find the clinical factors that affect the short- and long-term prognosis of myasthenia gravis (MG) patients with onset age ≥65 years.
Methods: This was a retrospective, observational case-control study. Patients were classified into two age subgroups: sub-very-late-onset MG (S-VLOMG, onset age ≥65 and ≤69 years), and super-late-onset MG (SLOMG, onset age ≥70 years). The main outcome was the time to achieve minimal manifestations status (MMS) or better. We used the Cox proportional hazards model to identify factors influencing short- and long-term prognosis in all patients.
Results: A total of 59 patients were included, 28 of S-VLOMG and 31 of SLOMG. All patients reached MMS within 2 years, with a median time to MMS of 168.0 days. In S-VLOMG group, compared to SLOMG group, had lower MG-activities of daily living (MG-ADL) scores at 3rd and 6th months ($p=0.002$, $p=0.001$), and shorter time from treatment to MMS ($p=0.02$). In the COX proportional hazards model, we found that age at onset (≥65 to ≤69, HR=2.339, $p=0.022$), baseline MGFA classification (OMG, HR=2.534, $p=0.020$), baseline MG-ADL≤2 (HR=10.463, $p<0.0001$) and no limb weakness at baseline (HR=3.356, $p=0.004$) were associated with the 6th month prognosis (short-term). The factors affecting the prognosis of patients at 24th months (long-term) were like those at 6th months with the addition of changes of ΔMG-ADL at 6th months (HR=1.155, 95%CI=1.042-1.280, $p=0.006$).



Change in MG-ADL score in two groups over follow-up time. ** = $p \leq 0.01$; *** = $p \leq 0.001$.



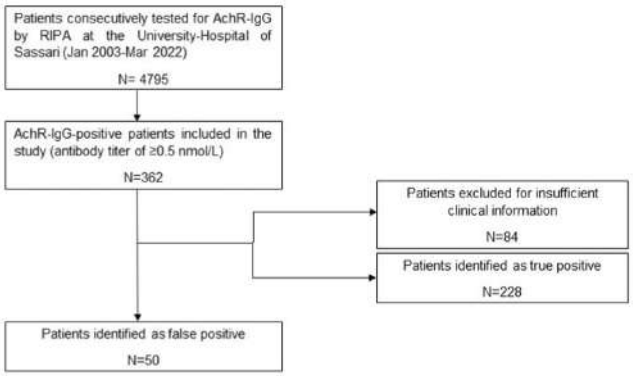
Kaplan-Meier curve of the time from treatment to MMS between two groups.

Conclusion: The patients with S-VLOMG had a better short-term prognosis compared to SLOMG patients, while their long-term prognosis remains similar.
Disclosure: Nothing to disclose.

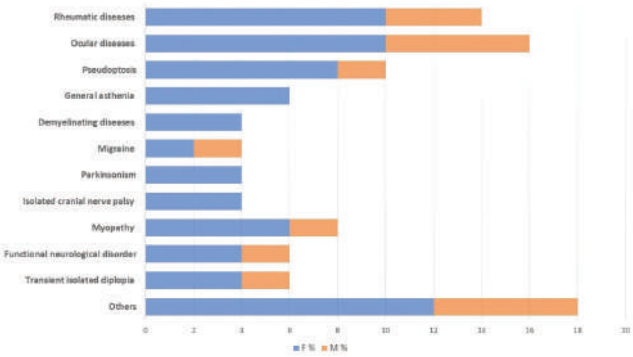
EPO-406 | Positive predictive value of acetylcholine receptor autoantibody testing by radioimmunoprecipitation assay

P. Zara; P. Chessa; G. Deiana; A. Morette; M. Puci; G. Sotgiu; P. Solla; E. Sechi
Department of Medical, Surgical, and Experimental Science, University of Sassari

Background and Aims: Antibodies against the acetylcholine receptor (AChR-IgG) confirm a diagnosis of autoimmune myasthenia gravis (MG). Radioimmunoprecipitation assay (RIPA) is the gold standard for AChR-IgG detection with a reported specificity of ≈99%. However, its accuracy in large, unselected populations has not been fully elucidated. We determined the positive predictive value (PPV) and risk of false AChR-IgG positivity in a real-life setting.
Methods: The retrospective analysis included 4795 patients consecutively tested between 2003 and 2022. Medical records of patients with AChR-IgG positivity (antibody titer of ≥0.5 nmol/L) were reviewed to determine true vs false antibody positivity. AChR-IgG-positive patients with insufficient clinical information were excluded ($n=84$).
Results: Of 362 AChR-IgG-positive patients included in the study, 50 (13.8%) were designated as false positives. Specificity and PPV were 98.9% and 86.2%, respectively. Alternative diagnoses in patients with false AChR-IgG positivity included ocular diseases ($n=8$), rheumatic diseases ($n=7$), and others ($n=35$). Main reasons for antibody testing included isolated diplopia ($n=18$), nonspecific asthenia ($n=16$), or others. Compared to patients with true AChR-IgG positivity, false positive patients were younger, more frequently female and had a lower antibody titer. After stratification by AChR-IgG titers



The flow chart summarizes the steps towards identification of patient with false Ach-R IgG positivity.



The bar graph shows the percentage of alternative diagnoses.

AChR-IgG abtibody titer	Specificity	PPV
≥0.5 nmol/L	98.9% (95% CI, 98.5-99.2)	86.2% (95% CI, 82.2-89.6)
≥1 nmol/L	99.8% (95% CI, 99.6-99.9)	96.6% (95% CI, 94-98.3)

Variation of specificity and PPV after stratification.

of ≥1 nmol/L, specificity and PPV increased to 99.8% and 96.6%, respectively.
Conclusion: Despite the high specificity of AChR-IgG testing by RIPA, the risk of false antibody positivity is not negligible in clinical practice (14% in this study). Caution is needed when low titer AChR-IgG positivity (0.5-0.9 nmol/L) is detected in patients with symptoms that are nonspecific for MG.
Disclosure: Nothing to disclose.

EPO-407 | The safety and efficacy profile of eculizumab in myasthenic crisis: A prospective case series

J. Song[1]; X. Huan[1]; Y. Chen[1]; Y. Luo[2]; H. Zhong[1]; Y. Wang[3]; L. Yang[4]; C. Xi[4]; Y. Yang[5]; J. Xi[1]; J. Zheng[6]; S. Luo[1]; C. Zhao[1]
[1]Huashan Rare Disease Center and Department of Neurology, Huashan Hospital, Shanghai Medical College, National Center for Neurological Disorders, Fudan University, Shanghai, China; [2]Department of Neurology, Ganzhou People's Hospital, Nanchang University, Jiangxi province, China; [3]Department of Blood Transfusion, Huashan Hospital, Fudan University, Shanghai, China; [4]Department of Laboratory Medicine, Huashan Hospital, Fudan University, Shanghai, China; [5]Department of Thoracic Surgery, Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai, China; [6]Department of Infectious Diseases, Huashan Hospital, National Medical Center for Infectious Diseases, Fudan University, Shanghai, China

Background and Aims: Myasthenic crisis (MC) represents a severe exacerbation of myasthenia gravis. While eculizumab has shown promise in case reports, there is a lack of prospective data on its safety and efficacy. This study aims to investigate eculizumab as an adjunct therapy in refractory MC patients.
Methods: We conducted a prospective case series study over 12 weeks, targeting patients with acetylcholine receptor (AChR) subtype refractory MC. Participants were administered eculizumab as an add-on to standard therapy. Outcomes were measured using the MGFA-quantitative MG test (MGFA-QMG) and the MG-Activities of Daily Living (MG-ADL) scale, with additional monitoring of muscle strength across various domains. Additionally, serum anti-AChR antibody titers, CH50, C1q, C5a, and soluble C5b-9 (SC5b-9) levels were measured at the baseline and 12 weeks after eculizumab treatment.
Results: Patients exhibited significant improvements in both MGFA-QMG (baseline: 22.25±4.92, 12 weeks: 7.5±5.74) and MG-ADL (baseline: 18.25±2.5, 12 weeks: 2.75±4.86) scores from the 4-week mark onward. Muscle strength consistently increased across ocular, bulbar, respiratory, and limb/gross domains. One patient succumbed to cardiac failure at 16 weeks, but three cases remained in remission at 24 weeks. There were sustained declines in serum CH50 and soluble C5b-9 levels, with no significant changes in anti-AChR antibody titers, C1q and C5a. No significant side effects were reported.
Conclusion: Eculizumab was well-tolerated and effective in enhancing recovery and reducing disease activity in patients with MC. These findings support further large-scale prospective studies with extended follow-up to establish the safety and efficacy profile of eculizumab in a real-world setting.
Disclosure: Nothing to disclose.

EPO-408 | Real-world reduction in oral corticosteroid utilization following efgartigimod initiation

T. Ruck[1]; N. Goyal[2]; C. Qi[3]; J. Stone[4]; D. Gelinas[3]; M. Jefferson[3]; T. Suthagar[5]; R. R Menon[5]; M. Sato[6]; G. Phillips[3]
[1]Department of Neurology, Heinrich Heine University Düsseldorf, Düsseldorf, Germany; [2]Department of Neurology & Neurological Sciences, Stanford Medicine, Palo Alto, CA, USA; [3]Argenx US Inc., Boston, MA, USA; [4]Department of Clinical Rheumatology, Massachusetts General Hospital, Boston, MA, USA; [5]ZS Associates, Bengaluru, Karnataka, India; [6]ZS Associates, New York, NY, USA

Background and Aims: Reducing or tapering oral corticosteroids (OCS, prednisone equivalent), a common treatment used in generalised myasthenia gravis (gMG), can alleviate risk related to long-term OCS usage. The objective of this study was to evaluate OCS usage following efgartigimod initiation.
Methods: In this retrospective study, patients with gMG using OCS who initiated efgartigimod were identified from a United States medical and pharmacy claims database (based on information licenced from IQVIA: Longitudinal Access and Adjudication Data [LAAD] for the period April 2016–April 2023, reflecting estimates of real-world activity [all rights reserved]). Mean (SD) average daily dose (ADD) of OCS was evaluated during the 3-months prior to, and at 3- and 6-months post-efgartigimod initiation. Any patients enrolled in the "My VYVGART Path" patient support program that had baseline and follow-up myasthenia gravis activities of daily living (MG-ADL) scores available were identified to assess score change.
Results: Among 576 patients who initiated efgartigimod by September 30, 2022, and continued efgartigimod for ≥6 months, 231 (40%) were using OCS at baseline. Mean (SD) OCS ADD was significantly reduced at 3- (15.6 [14.8] mg/day, $p=0.0007$) and 6-months (14.5 [15.5] mg/day, $p=3.99x10\text{-}6$) post-efgartigimod initiation compared with baseline (19.0 [15.1] mg/day). A subset of 75 patients (32%) had MG-ADL scores available both before and during the 6-months following efgartigimod initiation. Among them, significant reduction was observed in best-follow up mean (SD) MG-ADL (from 8.7 [3.7] to 4.5 [3.3], $p=1.2x10\text{-}14$).
Conclusion: Early insights indicate that OCS usage was significantly reduced over 6 months post-efgartigimod initiation, while retaining MG-ADL response.

EPO-409 | Steroid toxicity in adults with myasthenia gravis in the United States based on electronic health records

T. Ruck[1]; N. Goyal[2]; M. Hehir[3]; G. Phillips[4]; J. Stone[5]; C. Qi[6]; M. Stone[7]; D. Gelinas[6]; A. Chamberas[7]; D. Amirthaganesan[8]; R. Kulkarni[9]; A. Whangbo[10]

[1]*Department of Neurology, Medical Faculty and University Hospital Düsseldorf, Heinrich Heine University Düsseldorf, Düsseldorf, Germany*; [2]*Department of Neurology & Neurological Sciences, Stanford Medicine, Palo Alto, CA, USA*; [3]*Department of Neurology, University of Vermont Medical Center, Burlington, VT, USA*; [4]*Argenx BVBA, Ghent, Belgium*; [5]*Harvard Medical School, Massachusetts General Hospital, Boston, MA, USA*; [6]*Argenx US, Inc., Boston, MA, USA*; [7]*Steritas, Concord, MA, USA*; [8]*ZS Associates, Bengaluru, Karnataka, India*; [9]*ZS Associates, Bethesda, MD, USA*; [10]*ZS Associates, Durham, NC, USA*

Background and Aims: While benefits/risks of steroids in myasthenia gravis (MG) have been studied, quantifying steroid toxicity is challenging using real-world data.

Methods: Adults with MG (≥2 MG diagnoses 30-730 days apart between Jan 2014-Sep 2021) were identified in United States (US)-based Optum® de-identified Electronic Health Record data set (Optum® EHR) (Jan 2013-Dec 2022). Index dates were defined as first steroid prescription (for steroid initiators [MG-SI]) or assigned after age/gender match (for steroid-naïve [MG-SN]). Patients with available lab measures for main criteria of the Glucocorticoid Toxicity Index-Metabolic Domains (GTI-MD) were included. GTI-MD scores (Aggregate Improvement Score [AIS] and Cumulative Worsening Score [CWS], higher scores represent higher toxicity) were compared between MG-SI vs. MG-SN cohorts. Multivariate regression assessed the relationship of steroid usage, strength, and timing of follow-up assessment to GTI-MD.

Results: Among 27,157 patients with MG, 377 and 305 were included in the MG-SI and MG-SN cohorts, respectively. 30% of the MG-SI cohort had multiple steroid prescriptions and ≥20mg prescription at index. GTI-MD (SD) scores were higher in MG-SI compared with MG-SN (AIS: 4.9 [34.5] vs. 1.9 [34.3], $p = 0.27$; CWS: 22.6 [22.8] vs. 18.7 [21.2], $p = 0.023$). Regression results showed MG-SI patients with ≥2 records and ≥20mg at index had an average AIS 10.2 higher than MG-SN ($p = 0.01$). Each additional month of follow-up since index was associated with a decrease of 1.5 AIS ($p < 0.001$).

Conclusion: Our results demonstrated steroid toxicity is significantly higher in patients with higher strength and repeated steroid usage. Patients experienced consistent elevation in steroid toxicity over time.

Disclosure: This study was funded by argenx US, Inc. (Boston, MA, USA). TR received honoraria and/or research support from Alexion, Argenx, Biogen, Merck, Novartis and Roche. EPO-410 | Duchenne muscular dystrophy (DMD) patient vignettes development methodology

V. Merla[1]; P. Nathaniel[1]; O. Borecka[2]; S. Vincent[2]

[1]*Pfizer Inc., New York, USA*; [2]*Vitaccess, Oxford, UK*

Background and Aims: Duchenne muscular dystrophy (DMD) is a severe, rare neuromuscular disease with wide-ranging impacts, therefore, accurately describing the quality of life (QoL) of people with DMD can be challenging. This study describes the methodology in the development and validation of DMD patient vignettes prepared for rating by neurologists using the 5-level EQ-5D (EQ-5D-5L) proxy version 1, to derive health-state utility values.

Methods: Eight vignettes representing DMD health states (based on Project HERCULES) were developed. The draft vignettes were developed through an extensive literature search. Following the development of the draft vignettes, two DMD PAG representatives with caregiver experience were interviewed to validate the vignettes. After incorporating PAG feedback, four specialist neurologists were recruited to review and score the vignettes using the EQ-5D-5L.

Results: The feedback obtained from PAG representatives on the draft vignettes was positive and confirmed their overall accuracy. The comments allowed for minor changes to some domains including requirements of 24-hour care in later non-ambulatory stages, a need for specialist equipment to assist with self-care and adjustments to mental health impacts, such as, additional wording around the patient feeling isolated and escalation of the severity descriptor of depression in the last health state.

Conclusion: Development of patient vignettes in rare conditions can be challenging; hence, PAG and specialist clinician feedback can play an important role in more accurately describing the QoL of people with DMD and other severe, rare diseases. The mental health impacts and the intensity of the care and assistance required by people with DMD should not be underestimated.

Disclosure: Val Merla and Nate Posner are employees of Pfizer Inc., and this study was funded by Pfizer Inc. Octavia Borecka and Sally Vincent are employees of Vitaccess Ltd.

EPO-411 | Early real-life experience of Zilucoplan in refractory generalized myasthenia gravis

V. Di Stefano; P. Luppino; P. Alonge; N. Rini; A. Lupica; F. Brighina
Department of Biomedicine, Neuroscience, and advanced Diagnostic (BIND), University of Palermo, Palermo, Italy

Background and Aims: Myasthenia gravis is a rare chronic autoimmune disease affecting the post-synaptic membrane of the muscle junction characterized by debilitating, and potentially fatal, muscle weakness. (1, 2). Treatment options available for generalized myasthenia gravis (gMG) have grown in recent years with the introduction of new drugs, such as the complement factor C5 inhibitors (2, 3). The objective of the Compassionate Use Program (GM0025IT) is to provide early access to Zilucoplan for gMG patients with a high unmet medical need and severe disease burden.

Methods: Zilucoplan was administered by daily subcutaneous self-injection as for protocol (2). Efficacy was assessed by using the MG-ADL scale and QMG. The patients' baseline therapy remained unchanged during the entire course of treatment.

Results: Three female patients (mean age 32 y) affected by AChR-seropositive gMG received Zilucoplan. A reduction in MG-ADL scores was observed in the first week from the first injection compared to baseline with a mean change of – 2.33 points (ranging from -4 to -1). The main change at one month was – 4.0 points. Regarding QMG, a reduction of -2 points was achieved in two patients at one month. All three patients reported a significant improvement in the quality of daily life. No safety issues were identified.

Conclusion: The decline in scores obtained testifies to the efficacy of treatment with Zilucoplan and the rapidity of its action onset. Also, Zilucoplan appears to be very easy to administer and has a favorable safety profile (2). Further data and longer observations are needed to confirm our data.

Disclosure: Vincenzo Di Stefano received compensation for speaking from Alexion, and Alnylam; he is SI in clinical trials for Alexion, Alnylam, Argenx, Dianthus, and Sanofi.

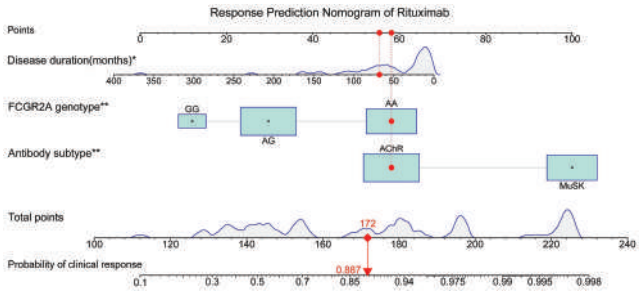
EPO-412 | A predictive nomogram for short-term outcomes of myasthenia gravis patients treated with low-dose rituximab

Y. Zhou[1]; R. Guo[2]; X. Xia[1]; S. Jing[3]; J. Lu[1]; Z. Ruan[2]; S. Luo[1]; X. Huan[1]; C. Zhao[1]; T. Chang[2]; J. Xi[1]
[1]*Department of Neurology, Huashan Hospital, Fudan University, Shanghai, China;* [2]*Department of Neurology, Tangdu Hospital, The Fourth Military Medical University, Xi'an, China;* [3]*Department of Neurology, Banan Hospital, Chongqing Medical University, Chongqing, China*

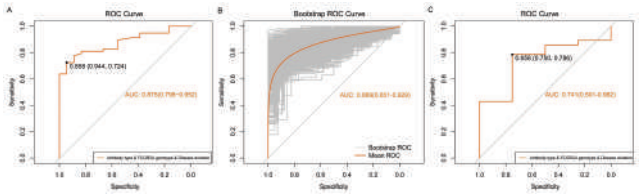
Background and Aims: This study aims to establish and validate a predictive nomogram for the short-term clinical outcomes of myasthenia gravis (MG) patients treated with low-dose rituximab.

Methods: We retrospectively reviewed 108 patients who received rituximab of 600 mg every six months in Huashan Hospital and Tangdu Hospital. Of them, 76 patients from Huashan Hospital were included in the derivation cohort to develop the predictive nomogram, which was externally validated using 32 patients from Tangdu Hospital. The clinical response is defined as a ≥3 points decrease in QMG score within 6 months. Both clinical and genetic characteristics were included to screen predictors via multivariate logistic regression. Discrimination and calibration were measured by the area under the receiver operating characteristic curve (AUC-ROC) and Hosmer-Lemeshow test, respectively.

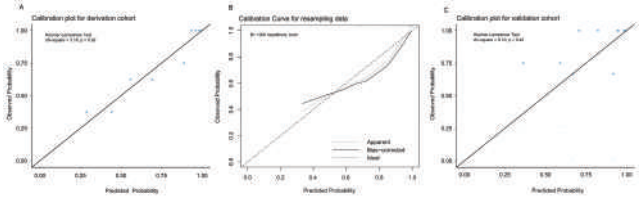
Results: Disease duration (OR = 0.987, $p = 0.032$), positive anti-muscle specific tyrosine kinase antibodies (OR = 19.8, $p = 0.007$), and genotypes in FCGR2A rs1801274 (AG: OR = 0.131, $p = 0.024$; GG: OR = 0.037, $p = 0.010$) were independently associated with clinical response of post-rituximab patients. The nomogram identified MG patients with clinical response with an AUC-ROC (95%CI) of 0.875 (0.798-0.952) in the derivation cohort and 0.741 (0.501-0.982) in the validation cohort. Hosmer-Lemeshow test showed a good calibration (derivation: chi-square = 3.181, $p = 0.923$; validation: chi-square = 8.098, $p = 0.424$).



Nomogram to estimate the probability of clinical response in MG patients after low-dose rituximab treatment.



ROC-AUC of nomogram A. Derivation cohort: ROC-AUC = 0.875, 95%CI: 0.798-0.952. B. Resampling: mean ROC-AUC = 0.889, 95%CI: 0.851-0.929. C. Validation cohort: ROC-AUC = 0.741, 95%CI: 0.501-0.982.



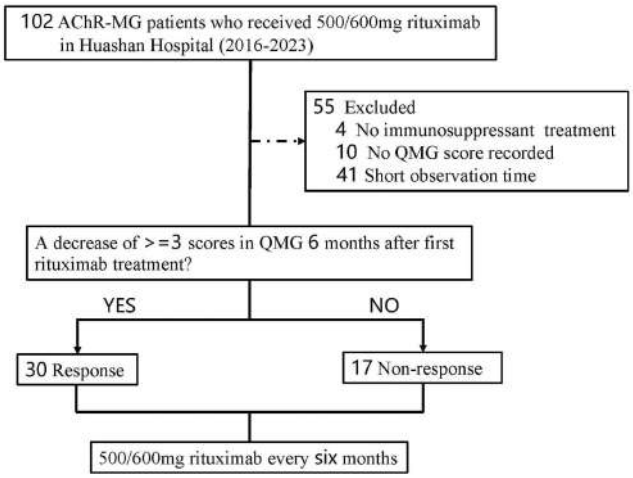
Model calibration of derivation cohort (A), resampling data using bootstrap (B), and validation cohort (C) The x- and y-axes in the graph represent the predicted and actual response probabilities from the nomogram, respectively.

Conclusion: The nomogram achieved an optimal prediction of short-term outcomes in patients treated with low-dose rituximab.
Disclosure: The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

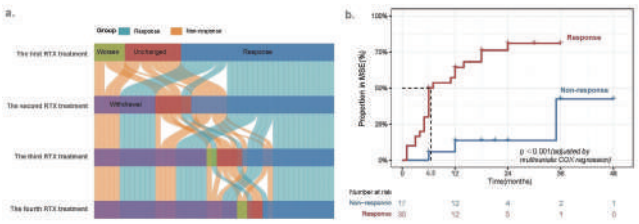
EPO-413 | Response to single rituximab can predict a better outcome of multi-cycle treatment in refractory myasthenia gravis

Y. Zhou[1]; S. Jing[2]; J. Lu[1]; S. Luo[1]; X. Huan[1]; J. Song[1]; C. Yan[1]; C. Zhao[1]; J. Xi[1]
[1]*Department of Neurology, Huashan Hospital, Fudan University, Shanghai, China;* [2]*Department of Neurology, Banan Hospital, Chongqing Medical University, Chongqing, China*

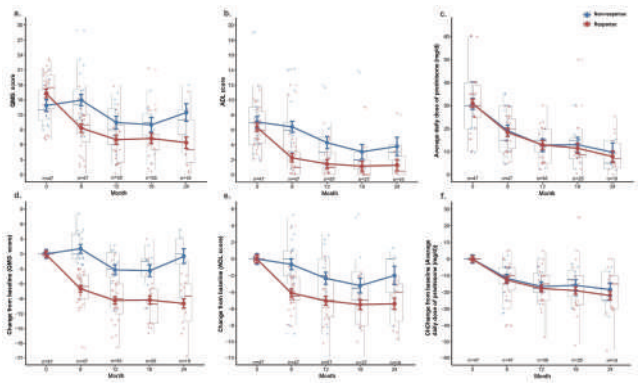
Background and Aims: This study aims to access the long-term clinical outcomes of myasthenia gravis (MG) patients treated with multi-cycle low-dose rituximab.
Methods: This retrospective cohort study with prospectively collected data involved 47 refractory patients who received 500/600 mg rituximab every six months in Huashan Hospital. We divided them into a response group ($n=30$) and a non-response group ($n=17$) based on a decrease of ≥3 scores in Quantitative Myasthenia Gravis (QMG) score 6 months after first rituximab treatment. We compared the change of QMG and Activities of Daily Living (ADL) scores and the time to minimal symptom expression (MSE, i.e., ADL 0-1 score) between the two groups.
Results: There were significant group×visit interactions for QMG score and ADL score. Six months after the fourth rituximab treatment, QMG score was lower for the response group (-6.07; $p=0.005$; 95%CI, -10.26 to -1.88) compared with the non-response group; the equivalent mean changes from baseline were -9.95 (95%CI, -11.78 to -8.12) and -0.45 (95%CI, -3.38 to 2.49), respectively. ADL score was lower for the response group (-2.84; $p=0.006$; 95%CI, -4.83 to -0.852) compared with the non-response group; the equivalent mean changes from baseline were -5.40 (95%CI, -6.74 to -4.05) and -1.99 (95%CI, -4.18 to 0.21), respectively. The median time to MSE was shorter in the response group (6.5 months versus not available; HR: 15.83; 95%CI,3.53-70.91; $p<0.001$).



Recruitment of patients with refractory generalized myasthenia gravis.



Post-treatment status (a) and time to MSE (b) after multi-cycle rituximab treatment in refractory generalized AChR-MG.



Clinical efficacy

Conclusion: The response to single low-dose rituximab can predict a better outcome of multi-cycle treatment in refractory MG.

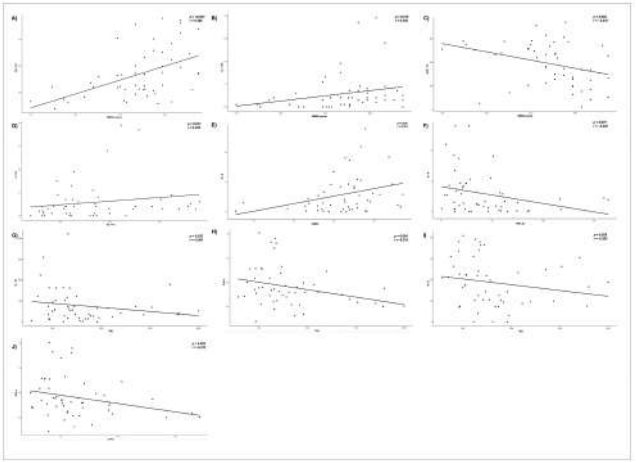
Ageing and dementia 3

EPO-414 | Exploring the interplay among neuroinflammation, neurodegeneration and mitochondrial damage in Alzheimer's disease

D. Plantone[1]; M. Pardini[2]; C. Manco[1]; D. Righi[1]; P. Ali[2]; D. Arnaldi[2]; V. Pelagotti[2]; F. Massa[2]; N. De Stefano[1]
[1]*Department of Medicine, Surgery and Neuroscience, University of Siena, Siena, Italy*; [2]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, University of Genoa, Genova, Italy*

Background and Aims: This study aims to conduct a comprehensive assessment of various biomarkers related to different aspects of AD pathology. These aspects encompass neurodegeneration, glial activation, mitochondrial dysfunction, and immune response. The objective is to correlate these results among them and with the "classic" diagnostic AD biomarkers.
Methods: Neurofilament light chain (NfL), glial fibrillary acidic protein (GFAP) and transactive response DNA binding protein (TDP-43) concentrations were assessed through the use of Simoa technology. Growth Differentiation Factor 15 (GDF-15) was assessed using ELISA. Concentrations of 11 selected cytokines were determined using a multiplex bead-based flow cytometry assay. Non-parametric statistical analyses were performed.
Results: CSF samples of the 52 AD patients were collected. Twenty-four patients were recruited in Genova and 28 patients in Siena. The median age was 74.3 years (25th–75th percentiles, 71.3–77.3) and 35% were male. MMSE score showed a positive correlation with the CSF Aβ1-42 concentrations ($r = 0.485$; $p < 0.001$), as well as with CSF interleukin (IL)-17A concentrations ($r = 0.34$; $p = 0.015$), and a negative correlation with CSF GDF-15 concentrations ($r = -0.418$; $p = 0.002$). CSF IL-17A concentrations also showed a positive correlation with CSF Aβ1-42 concentrations ($r = 0.302$; $p = 0.031$). CSF IL-6 concentrations showed a positive correlation with CSF NfL concentrations ($r = 0.312$; $p = 0.026$) and a negative correlation with CSF TDP-43 concentrations ($r = -0.322$; $p = 0.021$). CSF t-Tau concentrations were negatively correlated with CSF IL-10 ($r = -0.301$; $p = 0.032$;), IFN-gamma ($r = -0.315$; $p = 0.024$), and IL-8 concentrations ($r = -0.305$; p 0.029), CSF p-Tau concentrations were negatively correlated with CSF IFN-gamma concentrations ($r = -0.312$; p 0.026).



Partial correlation between A) MMSE and Aβ1-42; B) MMSE and IL-17A; C) MMSE and GDF-15; D) IL-17A and Aβ1-42; E) IL-6 and NfL; F) IL-17A and TDP-43; G) t-Tau and IL-10; H) t-Tau and IFN-g; I) t-Tau and IL-8; J) p-Tau and IFN-g; with age as control variable.

Conclusion: This ongoing study starts to cast light on the intricate interplay that exists among neuroinflammation, neurodegeneration, mitochondrial damage, and clinical disability in AD.
Disclosure: Nothing to disclose.

EPO-415 | Cholinesterase inhibitors and risk of epilepsy in Alzheimer's disease – Study on 32 121 patients from SveDem

D. Religa; L. Liv Törner Monsenego; M. Eriksdotter; H. Xu
Department of Neurobiology, Care Sciences and Society (NVS) Karolinska Institutet, Stockholm, Sweden

Background and Aims: Alzheimer's disease (AD) is the most common type of dementia and Cholinesterase inhibitors (ChEIs) are the first line symptomatic treatment. Given the increased incidence of epilepsy (EP) in AD, the question arises about whether ChEIs influences the risk of developing EP.
Methods: This cohort study was based on 32,121 patients with AD in the Swedish Dementia Registry SveDem with a study period of ten years. Incidence rates and Cox proportional hazard modeling were applied to the study outcomes epilepsy and mortality, for a total and PS-matched cohort, with ChEI use as the exposure. The primary aim was to explore a possible association between ChEI use and EP in AD. The secondary aim was to examine if ChEI use influences mortality.
Results: No association was found between ChEI use and EP, apart from in patients with a MMSE score above 25 who experienced a decreased EP risk of 30.5% when treated (HR 0.69; 95% CI: 0.49–0.99). A significant association was found between ChEI use and decreased mortality (HR 0.88; 95% CI: 0.85–0.92).
Conclusion: In line with existing research, this study has not identified a link between ChEI and increased EP risk. The association between ChEI use and decreased mortality is coherent with other studies. The decreased EP risk found in patients with early-stage dementia is understandable given disease characteristics and emerging research on an anti-epileptogenic ChEI element, such as the recently

outlined cholinergic anti-inflammatory pathway. Such an element could also constitute an explanation behind the decreased mortality.
Disclosure: None.

EPO-416 | Abstract withdrawn

EPO-417 | Development and use of cognition bolt-ons for the EQ-5D-3L and EQ-5D-5L: A systematic review

F. Rencz[1]; S. Pangestu[2]; B. Mulhern[3]; A. P. Finch[4]; M. F. Janssen[5]
[1]*Department of Health Policy, Corvinus University of Budapest, Hungary;* [2]*Department of Health Policy & Doctoral School of Business and Management, Corvinus University of Budapest, Budapest, Hungary; Faculty of Economics and Business, Atma Jaya Catholic University of Indonesia, Jakarta, Indonesia;* [3]*Centre for Health Economics, Research and Evaluation (CHERE), University of Technology Sydney, Sydney, Australia;* [4]*EuroQol Research Foundation, Rotterdam, The Netherlands;* [5]*Section Medical Psychology and Psychotherapy, Department of Psychiatry, Erasmus MC, Rotterdam, The Netherlands*

Background and Aims: The widely used EQ-5D measures health-related quality of life across five dimensions. Cognition has been one of the earliest and most extensively applied additional dimensions ('bolt-on'). Our aim was to systematically review the literature on cognition bolt-ons for the EQ-5D, categorising existing items and their wordings across various populations.
Methods: We conducted a systematic literature search using PubMed, Web of Science and Google Scholar to identify publications that used cognition bolt-ons for the two adult versions of the EQ-5D (3L and 5L), following the PRISMA guidelines (PROSPERO CRD42023445567).
Results: The included 181 publications (1997-2023) from 137 studies revealed an increasing trend in using cognition bolt-ons. Cognition bolt-ons have been applied in 28 languages across 23 countries, with the Netherlands leading (64%). Overall, 71 different patient populations were included in these studies, with the most common being head or brain injury ($n=13$), dementia ($n=12$), depression ($n=5$), stroke, HIV and burn ($n=4$ each). We identified 52 different wordings (3L: $n=23$ and 5L: $n=29$). The most frequent descriptors, cognition (29%) and thinking ability (19%), included examples such as concentration (60%), memory (39%) and remembering (31%). Most bolt-on items lacked any qualitative input and they commonly deviated from the EQ-5D-format (e.g. extended dimension title, inappropriate examples or not severity-type response scale).
Conclusion: The growing and extensive use of cognition bolt-ons for the EQ-5D signals a demand from users for this bolt-on. The parallel existence of various wordings and the absence of proper development highlight the necessity for future bolt-on development and harmonisation efforts.

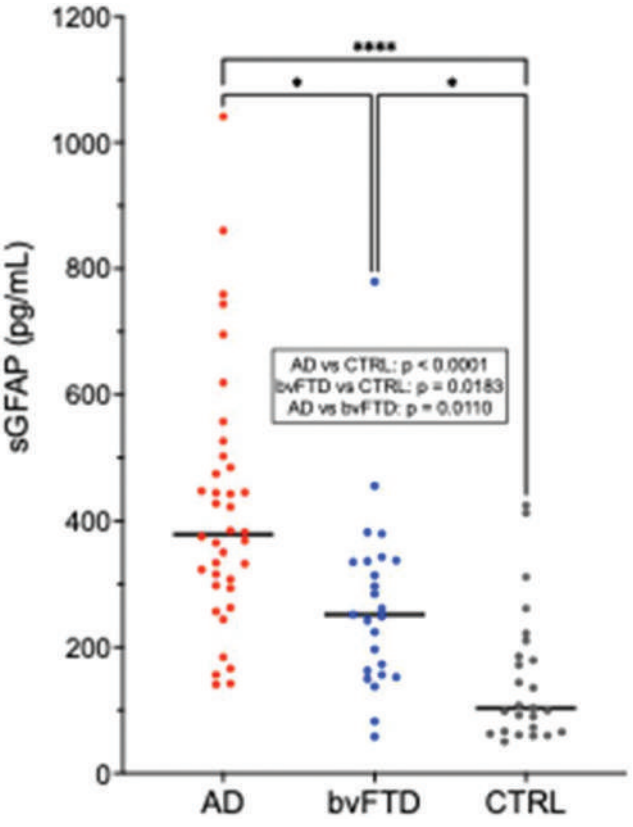
EPO-418 | Serum GFAP levels discriminate between AD and bvFTD but are influenced by renal function

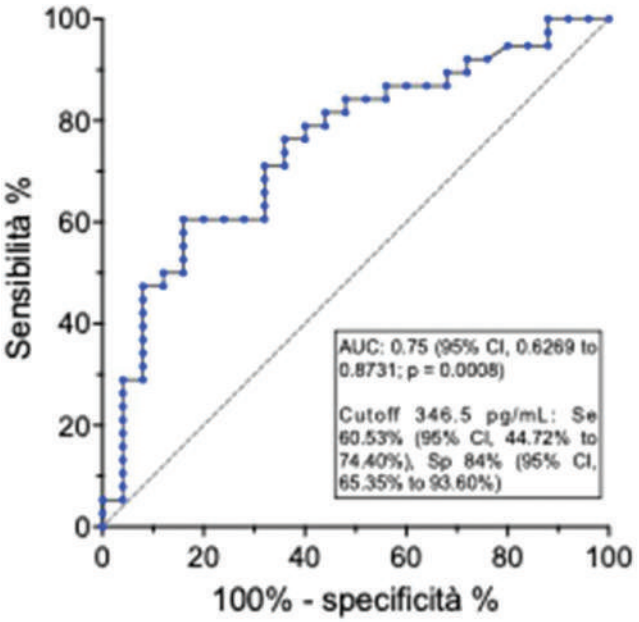
F. Verde[1]; I. Milone[1]; F. Solca[1]; A. Maranzano[1]; S. Torre[1]; A. Dubini[2]; E. Torresani[2]; B. Poletti[1]; A. Ratti[1]; V. Silani[1]; N. Ticozzi[1]
[1]*Neurology Unit and Laboratory of Neurosciences, Department of Neurosciences, IRCCS Istituto Auxologico Italiano, Milan, Italy;* [2]*Laboratory of Clinical Chemistry and Microbiology, Department of Laboratory Medicine, IRCCS Istituto Auxologico Italiano, Milan, Italy*

Background and Aims: Blood levels of GFAP are increased in Alzheimer's disease (AD).
Methods: We measured serum GFAP (sGFAP) in 38 patients with AD, 25 patients with the behavioural variant of FTD (bvFTD), and 25 neurologically healthy controls (NHCs).
Results: sGFAP was increased in AD compared to NHCs and to bvFTD, and in bvFTD compared to NHCs (all $p<0.05$). The ROC curves for the discrimination between AD and NHCs and between AD and bvFTD had AUCs of 0.9095 ($p<0.0001$) and 0.75 ($p=0.0008$), respectively. In (AD + bvFTD) ($N=51$), sGFAP correlated negatively with CSF Aβ42/40 ratio (r=-0.2931) and positively with P-tau181 (r=0.3973) and T-tau (r=0.3355) (all $p<0.05$). Accordingly, sGFAP was higher in neurochemically defined A+ vs. A-, T+ vs. T-, and N+ vs. N- patients (all $p<0.05$). In the whole cohort, sGFAP positively correlated with age (r=0.5111; $p<0.0001$). In (AD + bvFTD + CTRL), sGFAP negatively correlated with estimated glomerular filtration

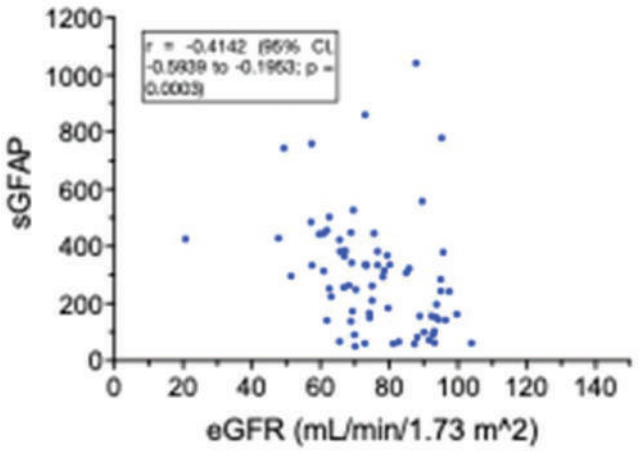


Serum GFAP levels in patients with AD, patients with bvFTD, and neurologically healthy controls.

rate (eGFR) (r = -0.4142; $p = 0.0003$; $N = 72$). Interestingly, in (AD + bvFTD), sGFAP also negatively correlated with the CSF/serum albumin ratio (Q-Alb) (r = -0.3557; $p = 0.0066$; $N = 57$).



ROC curve of serum GFAP for the discrimination between AD and bvFTD.



Negative correlation between serum GFAP and estimated glomerular filtration rate.

Conclusion: sGFAP is a promising biomarker for the discrimination between AD and bvFTD and is associated with neurochemical evidence of both Aβ and tau pathology. The negative correlation between sGFAP and eGFR may be practically important. The negative correlation with Q-Alb deserves further investigation.

Disclosure: Nothing to disclose.

EPO-419 | CSF synaptic proteins and monoaminergic systems in prodromal Alzheimer's disease: Insights from [18F]FDG PET correlations

F. Massa[1]; B. Orso[2]; V. Pelagotti[2]; M. Losa[2]; L. Argenti[2]; L. Lombardo[2]; P. Mattioli[1]; A. Brugnolo[1]; N. Girtler[1]; D. Arnaldi[1]; A. Chincarini[3]; S. Morbelli[4]; G. Sambuceti[5]; M. Pardini[1]

[1]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, and IRCCS Ospedale Policlinico San Martino, Genoa, Italy*; [2]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa*; [3]*Istituto Nazionale di Fisica Nucleare (INFN), Genoa section, Italy*; [4]*Department of Medical Sciences, University of Turin, and Nuclear Medicine Unit, AOU Città Della Salute e Della Scienza di Torino, Turin, Italy*; [5]*Department of Health Sciences (DISSAL), University of Genoa, and IRCCS Ospedale Policlinico San Martino, Genoa, Italy*

Background and Aims: Understanding the interaction between molecular aberrations in prodromal Alzheimer's disease (AD) and diffuse projection systems may foster pharmacological intervention. With this aim, we assessed baseline [18F]FDG-PET metabolism colocalization with PET maps of monoaminergic systems and correlated with cerebrospinal fluid (CSF) biomarkers of AD pathology and synaptopathy in prodromal AD patients.

Methods: We retrospectively analyzed 49 MCI-AD patients with positive CSF AD biomarkers (Aβ42/40, pTau, t-Tau), then grouped by time until dementia (Early MCI,EMCI, $n = 34$ progressing within two years; late MCI,LMCI, $n = 15$ stable/progressing later). Using the JuSpace toolbox, [18F]FDG-PET images were compared voxel-wise against 40 matched healthy controls (HC) to generate hypometabolism maps. Spearman's correlation coefficients evaluated the colocalization strength between hypometabolism and neurotransmitter maps, with negative values signifying heightened disease involvement in cortical regions normally abundant in receptors/transmitters. Coefficients were correlated with CSF standard AD and synaptopathy biomarkers (NPTX2, Neurogranin) in MCI-AD and EMCI/LMCI subgroups.

Results: Voxel-wise analyses showed hypometabolism patterns in MCI-AD, primarily in the temporoparietal and precuneus/posterior cingulate cortices. CSF pTau negatively correlated with hypometabolism-5HT1B receptor colocalization in the MCI-AD group and EMCI (r = −.306, $p = 0.035$ and r = −.394, $p = 0.028$). In the LMCI subgroup, CSF NPTX2 and Neurogranin positively correlated with colocalization strength of hypometabolism with 5HT4- (r = .719, $p = .011$; r = .603, $p = 0.008$) and D1-receptor maps (r = .707, $p = 0.010$; r = .603, $p = 0.038$).

Conclusion: Reduced CSF synaptic biomarker levels in late MCI parallel hypometabolism in regions rich in dopaminergic and serotonergic terminals, consistent with their role in disease staging and suggesting an interplay between synaptopathy and diffuse projection system alterations.

Disclosure: Nothing to disclose.

EPO-420 | Creative thinking as a resource in pathology: A cognitive stimulation training for mild cognitive impairment patients

F. Colombi[1]; G. Fusi[1]; M. Crepaldi[1]; J. Gianni[1]; M. Zanetti[2]; I. Di Fazio[2]; E. Facchi[2]; L. Colautti[3]; A. Antonietti[3]; L. Rozzini[4]; M. Rusconi[1]

[1]*Department of Human and Social Sciences, University of Bergamo, Italy*; [2]*Geriatric Evaluation and Rehabilitation Unit Richiedei Foundation, Palazzolo sull'Oglio, Brescia, Italy*; [3]*Psychology Department, Catholic University of the Sacred Heart, Milan, Italy*; [4]*Department of Clinical and Experimental Sciences, University of Brescia, Italy*

Background and Aims: Considering the increase in life expectancy and the incidence rate of age-related chronic neurodegenerative diseases, non-pharmacological treatments are relevant to prevent and slow cognitive decline in prodromal stages of disease such as dementia. Creative thinking training has shown promising potential. The aim of the present research is to show the efficacy of a creativity-based training on cognitive and psychological variables in patients affected by Mild Cognitive Impairment (MCI).

Methods: An individual 10-sessions training (CREC, CReativity in Everyday life Challenges), based on exercises that stimulate divergent thinking, was administered to a sample of 30 patients with MCI (9 men; age: 77.57 ±3.51; education: 7.07 ±2.70). Other 16 MCI patients (3 men; age: 79.38 ±8.03; education: 5.75 ±1.34) were assigned to an active control group. Specific cognitive functions, divergent thinking abilities and psychological well-being were assessed before and after the training sessions.

Results: Although the study is still ongoing, the first results highlight a significant improvement in the experimental group compared to the control group in semantic fluency abilities. Moreover, both groups show improvement in praxic-constructive skills and in the perception of overall well-being, along with a reduction in anxious symptomatology.

Conclusion: CREC appears to be effective in promoting improvement in cognitive skills such as semantic abilities. These results suggest that creative thinking could be a useful resource against cognitive decline in patients with MCI, playing an important role in reducing or delaying progression of symptoms.

Disclosure: This research was funded by Fondazione Cariplo, grant no. 2018-0792. The authors declare no conflict of interest.

EPO-421 | Usability of tele-medicine and tele-rehabilitation applications in subjects with mild cognitive impairment

G. Arabia[1]; R. Di Lorenzo[2]; F. Abate[3]; L. Arcudi[4]; R. Bruno BOSSIO[5]; N. Caravona[6]; R. Colao[2]; G. Frontera[7]; F. Galati[8]; P. Insarda'[9]; M. Lupo[10]; A. Gambardella[1]; M. Bernardi[11]; N. Vanacore[12]

[1]*Institute of Neurology, Department of Medical and Surgical Sciences, "Magna Graecia" University of Catanzaro, Italy*; [2]*CDCD Lamezia Terme, Italy*; [3]*CDCD Crotone, Italy*; [4]*CDCD Reggio Calabria, Italy*; [5]*CDCD Serraspiga-CS, Italy*; [6]*CDCD Corigliano-Rossano-CS, Italy*; [7]*CDCD Catanzaro, Italy*; [8]*CDCD Vibo Valentia, Italy*; [9]*CDCD Cinquefrondi-RC, Italy*; [10]*CDCD Cosenza, Italy*; [11]*Department of Health Protection, Social and Socio-Health Services, Calabria Region, Italy*; [12]*National Center for Disease Prevention and Health Promotion, National Institute of Health, Rome, Italy*

Background and Aims: Tele-medicine and tele-rehabilitation systems are increasingly proposed approaches to improve or stabilize cognitive functions of patients with mild to moderate cognitive decline. The aim of the present project was to investigate the usability of tele-medicine and tele-rehabilitation systems designed for remote assistance and treatment of patients with mild cognitive impairment (MCI) and in their caregivers.

Methods: The project included two lines of intervention for which usability was analyzed: 1) a program of tele-rehabilitation for the MCI patients, using at home a dedicated software installed on a tablet (Neurotablet), for 4 consecutive weeks; 2) a program of visits in Tele-Medicine for educational and psychological support, for patients and caregivers, for 4 consecutive weeks. Ten Cognitive Disorders and Dementia Centers (CDCD), distributed throughout the Calabria region, in Italy, participated to the project. Usability was evaluated through the System Usability Scale (SUS) and measuring the patients performances using Neurotablet.

Results: All CDCDs consecutively recruited 134 patients with amnestic MCI (46.3% M/53.7% F; mean age 69.5 ±6.8 years; mean education: 9.6 ±3.7 years) and 131 caregivers (28.7% M/71.3% F; age strata (18-45 y): 36.2%, (45-65 y): 35%, (>65 y): 28.8%). As preliminary results on the usability of the system, SUS was good for patients (mean SUS score: 74.01) and excellent for caregivers (mean SUS score: 83.27). Other usability measurements analyses are currently ongoing.

Conclusion: The results of this project allow to highlight the strengths and the limitations of the use of tele-medicine and tele-rehabilitation in patients with MCI and in their caregivers.

Disclosure: This project was founded by the Alzheimer's and Dementia Fund 2021-2023 of the Italian Ministry of Health (Project Line #4) and coordinated by the Italian National Institute of Health.

EPO-422 | Correlation between alterations in rs-functional alterations of brain and CSF markers in patients with AD

H. Zhao; C. Gong
Department of Neurology, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School

Background and Aims: The aim of this study was to explore the correlation between brain functional alterations and CSF pathological biomarkers in AD patients.
Methods: 23 AD patients and 16 control subjects were recruited. All subjects underwent CSF measurement and multimodal MRI scans. Independent component analysis was used to investigate the variations of FC by utilizing RS-fMRI data. Differences in ALFF and ReHo between the two groups were also calculated. Then correlation analyses were used to estimate the possible association between functional alterations and CSF biomarkers.
Results: In the AD group, ALFF decreased in the right Superior Frontal Gyrus, Middle Frontal Gyrus, left superior temporal gyrus, and increased in the right cerebellum anterior lobe, and caudate nucleus as compared to Non-AD CI group ($p<0.001$). In addition, ReHo decreased in the right insula and left middle temporal gyrus ($p<0.001$). Dynamic fluctuations of CSF Tau were observed to be associated with changes in FC between VN and PCC, FC of SMN, as well as the altered ReHo in the right insula and left middle temporal gyrus. Compared the AD group with the non-AD CI group, the aforementioned altered functional brain connectivity, with the exception of FC in the PCC and VN, was significantly associated with a decrease in CSF Aβ1-42.

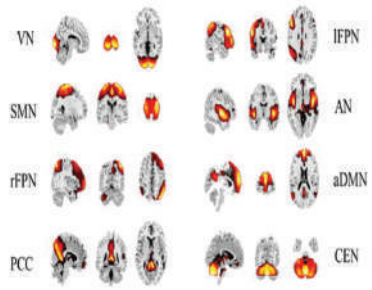


FIGURE.1. Ten ICs derived from the group ICA: anterior default mode network (aDMN), left frontoparietal network (lFPN), right frontoparietal network (rFPN), visual network (VN), sensory-motor network (SMN), posterior cingulate cortex (PCC), cerebellar network(CEN) and auditory network(AN).

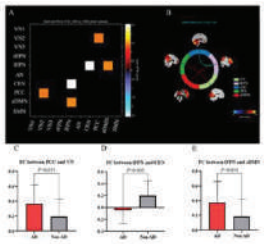

FIGURE.2. Inter-network functional connectivity changes: (A). Group averaged static functional connectivity matrix between nine ICs. (B). Group differences of FC strength in each network. Each square color represents one of the five networks. Blue lines represent decreased connectivity, while red lines represent increased functional connectivity in AD patients compared with controls. (P <0.05). (C). Compared with the control group, AD groups showed higher functional connectivity between the PCC and the VN. (D). Compared with the control group, AD groups showed lower functional connectivity between the lFPN and the celebellar. (E). Compared with the control group, AD groups showed higher functional connectivity between the lFPN and the aDMN.

Conclusion: These functional changes in AD patients are linked to the variations of Tau protein and Aβ1-42 in CSF, with Aβ1-42 having a particularly large impact on brain network function.
Disclosure: Nothing to disclose.

EPO-423 | Neuroinflammation biomarkers and clinical progression in amnestic mild cognitive impairment due to Alzheimer's disease

G. Giuffrè[1]; S. Citro[2]; D. Quaranta[2]; M. Vita[2]; N. Martellacci[1]; P. Calabresi[2]; C. Marra[1]
[1]*Memory Clinic, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy;* [2]*Institute of Neurology, Catholic University of the Sacred Heart, Rome, Italy*

Background and Aims: Ongoing Alzheimer's disease (AD) research has unveiled a promising range of fluid biomarkers with diagnostic and prognostic potential. In addition to established biomarkers of amyloidopathy (A), tauopathy (T), and neurodegeneration (N), novel biomarkers of inflammation (I) such as soluble Triggering receptor expressed on myeloid cells 2 (sTREM2), chitinase-3-like-1 protein (YKL-40), and glial fibrillary acidic protein (GFAP) are gaining attention. This study aims to investigate the role of "A", "T", "N" and "I" biomarkers in predicting clinical progression in mild cognitive impairment (MCI) due to AD.
Methods: Sixty subjects diagnosed with MCI due to AD underwent a comprehensive clinical evaluation, an extensive neuropsychological assessment, and CSF biomarkers analysis. CSF Aβ42/40 ratio, p-tau181, total-tau NfL, sTREM2, YKL-40 and GFAP were quantified using automated immunoassay systems. After a two-year follow-up, forty-nine subjects were re-evaluated and classified as "progressors" or "stable" based on clinical progression to dementia.
Results: Twenty-one subjects were classified as "progressors" and twenty-eight as "stable". The two groups exhibited no significant differences in terms of age, literacy and MMSE score at baseline. When comparing CSF biomarker levels between the cohorts, concentrations of p-tau181, t-tau, NfL and YKL-40 were significantly higher in the "progressors" group.
Conclusion: These results confirmed the importance of "T" and "N" biomarkers in predicting AD progression and identified YKL-40 as a novel potential predictor of cognitive decline since the early stages of AD. Future research should aim on validating these findings in larger cohorts, further exploring the potential role of inflammation biomarkers in refining diagnostics, prognostics, and treatment strategies.
Disclosure: Nothing to disclosure.

EPO-424 | A digitally supported lifestyle program to promote brain health among elderly (LETHE trial): Study design and progress

A. Rosenberg[1]; H. Untersteiner[2]; A. Guazzarini[3]; M. Bödenler[4]; J. Bruinsma[5]; B. Buchgraber-Schnalzer[4]; M. Colombo[6]; R. Crutzen[5]; A. Diaz[7]; D. Fotiadis[8]; H. Hilberger[4]; S. Stögmann[2]; T. Ngandu[1]

[1]Population Health Unit, Finnish Institute for Health and Welfare, Helsinki, Finland; [2]Department of Neurology, Medical University of Vienna, Vienna, Austria; [3]Department of Medicine and Surgery, Section of Gerontology and Geriatrics, University of Perugia, Perugia, Italy; [4]eHealth Institute, FH JOANNEUM University of Applied Sciences, Graz, Austria; [5]Department of Health Promotion, Care and Public Health Research Institute, Maastricht University, Maastricht, The Netherlands; [6]Innovation2Grow (i2G), Milan, Italy; [7]Alzheimer Europe, Luxembourg, Luxembourg; [8]Biomedical Research Institute, Foundation for Research and Technology – Hellas, FORTH-BRI, Ioannina, Greece; [9]Kaasa Solution GmbH, Düsseldorf, Germany; [10]Division of Clinical Geriatrics, Center for Alzheimer Research, Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Solna, Sweden; [11]Combinostics Ltd, Tampere, Finland

Background and Aims: The Finnish Geriatric Intervention Study to Prevent Cognitive Impairment and Disability (FINGER) multimodal lifestyle intervention yielded cognitive benefits in elderly at risk of dementia. The two-year multinational randomized controlled LETHE trial evaluates the feasibility of a digitally supported, adapted FINGER intervention among at-risk older adults.

Methods: The trial includes older adults (60–77 years) with digital readiness and increased dementia risk without substantial cognitive impairment. Participants are enrolled at four sites (Austria, Finland, Italy, Sweden). They were randomized in a 1:1 ratio to: 1) the intervention group (structured multimodal lifestyle program where in-person activities are supported with the LETHE App); or 2) the control group (self-guided program with simplified App and no personalized content). All participants wear smartwatches to gather passive data. Primary outcomes are retention/adherence and change in dementia risk scores. Secondary and exploratory outcomes include changes in lifestyle, cognition, stress, sleep, and dementia-related biomarkers. A sub-study explores the feasibility of novel interactive technology (audio glasses, social robot).

Results: Recruitment took place between September 2022 and June 2023. In total, 156 individuals were randomized (mean age 69 years, 65% women). Vascular/lifestyle risk factors were common (e.g., 65% with hypertension, 39% physically inactive). The trial will be completed by summer 2025. Retention until the first post-baseline visit (after 6 months) is high ($n=2$ discontinued).

Conclusion: LETHE provides crucial information about the feasibility of technology and a digitally supported FINGER program. Digital tools specifically designed for older adults could offer potential for large-scale, cost-effective prevention programs. The trial is registered at ClinicalTrials.gov (NCT05565170).

NK is employed by Kaasa Solution GmbH. JyL is employed by Combinostics Ltd. The LETHE project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement no 101017405.

EPO-425 | Comparing oral anticoagulants for dementia risk in atrial fibrillation: A network meta-analysis

J. Hsu[1]; Y. Li[2]; C. Loh[1]; Y. Tu[3]

[1]Center for Aging and Health, Hualein Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan; [2]Department of Pharmacy, Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan; [3]Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan

Background and Aims: Atrial fibrillation (AF) is a potentially modifiable risk factor for dementia. Research has shown that oral anticoagulant (OAC) use may lower dementia risk in patients with AF. However, few studies have discussed dementia risk in patients with AF who receive different OACs.

Methods: This systematic review and network meta-analysis included randomized controlled trials (RCTs) and observational studies investigating the dementia risk in patients with AF, who were and were not administered OACs. We included studies in which patients received non-vitamin K antagonist oral anticoagulants (NOACs), warfarin, and non-OAC users. *p*-Scores were used to determine the ranking of the association between OAC use and dementia risk.

Results: We analyzed data from 1,096,125 patients (10 RCTs and nine cohort studies). The dementia risk was lower in patients administered NOACs (edoxaban, rivaroxaban, apixaban, dabigatran) and warfarin than in non-OAC users. When compared to warfarin, all NOACs (edoxaban 0.68, 95% CI: 0.54-0.87; rivaroxaban 0.77, 95% CI: 0.65-0.91; apixaban 0.80, 95% CI: 0.66-0.96; dabigatran 0.83, 95% CI: 0.71-0.98) exhibited a reduced dementia risk. NOACs did not show statistically significant intergroup differences. Edoxaban (*p*-score = 0.927) ranked highest in the association of reducing dementia risk in AF patients, followed by rivaroxaban, apixaban, and dabigatran.

Conclusion: The dementia risk was lower in NOAC and warfarin users than non-OAC users, and all NOACs outperformed warfarin. There were no statistically significant differences observed between different NOACs. These findings might highlight that NOAC (particularly edoxaban) administration may be preferred to minimize dementia risk in patients with AF.

Disclosure: Nothing to disclose.

EPO-426 | Effect of long-term exercise and lifestyle multidomain interventions on cognition in older adults: A meta-analysis

I. Reparaz-Escudero[1]; M. Izquierdo[1]; H. Bischoff-Ferrari[2]; M. Lopez Saez de Asteasu[1]

[1]*Navarrabiomed, Hospital Universitario de Navarra (HUN)-Universidad Pública de Navarra (UPNA), IdiSNA, Pamplona, Spain;* [2]*Center on Ageing and Mobility, University Hospital and University of Zurich, Zurich, Switzerland*

Background and Aims: Emerging evidence suggests that multidomain lifestyle strategies including physical exercise may be effective the prevention of dementia. Observational data supports a protective role of physical activity in preserving cognition, yet randomized controlled trials (RCTs) examining physical exercise interventions provide unclear results, potentially due to short-term designs. We investigated the effect of long-term physical exercise and multidomain interventions on the global cognition of older adults.

Methods: Databases of Pubmed, WoS, CINAHL and PsychInfo were systematically searched from inception to May 1, 2023. RCTs enrolling non-demented, community-dwelling older adults (≥55 years) that assessed the effect of long-term (≥12 months) exercise or multidomain interventions on any validated global cognition measure were included. Random-effects inverse-variance meta-analysis with the Hartung-Knapp-Sidik-Jonkman adjustment was performed. Standardized mean differences (SMD) and 95% confidence intervals were calculated. Risk of bias and publication bias were assessed by the Cochrane Risk-of-Bias-2 tool, and Luis Furuya-Kanamori Index (LFKi), respectively. The certainty of the evidence was assessed with GRADE.

Results: We included 12 trials with 9,165 participants (mean age 73.3 [±4.3] years; 64.8% women). The overall risk of bias was low and minor presence of publication bias was observed for exercise (LFKi: 1.9) and multidomain interventions (LFKi: 2.0). Exercise interventions yielded a non-significant effect on global cognition, SMD = 0.05 (95% CI: -0.02 to 0.12, $p = 0.15$), while multidomain strategies had a small beneficial effect, SMD = 0.09 (95% CI: 0.01 to 0.17, $p = 0.04$).

Conclusion: Moderate certainty evidence supports a small impact of multidomain approaches inclusive of physical exercise for the prevention of cognitive decline in the older population.

Disclosure: Nothing to disclose.

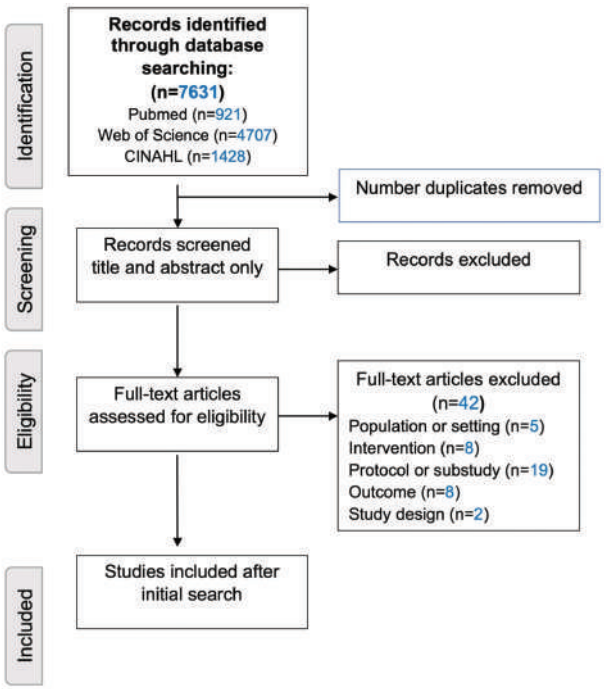

Figure 1. Flow chart of literature search.

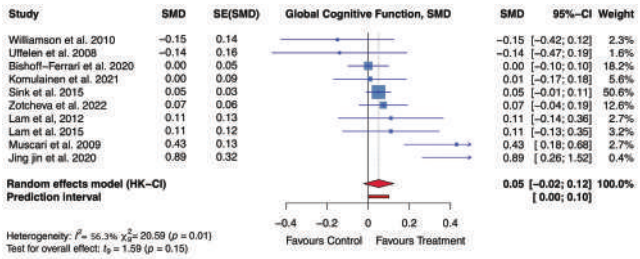
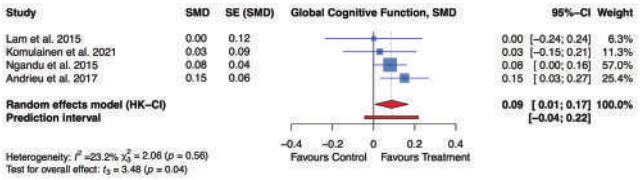
Flow chart of the literature adapted from PRISMA guidelines.



Forest plot showing the effect of long-term physical exercise interventions on global cognitive function. SMD, Standardized Mean Difference. SE, Standard Error. HK-CI, Hartung-Knapp confidence intervals.



Forest plot showing the effect of long-term multidomain interventions on global cognitive function. SMD, Standardized Mean Difference. SE, Standard Error. HK-CI, Hartung-Knapp confidence intervals.

EPO-427 | Association between neuropsychiatric symptoms and biomarkers of Alzheimer's disease

I. Carvalho[1]; F. Gomes[1]; D. Valente[2]; C. Fernandes[1]; F. Millet Barros[1]; C. Bernardes[1]; P. Faustino[1]; J. Durães[1]; M. Lima[1]; I. Baldeiras[1]; M. Tábuas-Pereira[1]; I. Santana[1]

[1]*Neurology Department, ULS Coimbra, Coimbra, Portugal;* [2]*Neurology Department, Centro Hospitalar do Algarve, Faro, Portugal*

Background and Aims: Neuropsychiatric symptoms (NPS) are frequent in patients with Alzheimer's disease (AD). The association between AD pathophysiology and NPS remains unclear. Understanding the biological mechanisms of NPS in AD can expand our understanding and improve treatment. Aim: Evaluate the association between

NPS and the levels of AD biomarkers [CSF amyloid-β protein (Aβ42), total tau (t-tau) and phosphorylated-tau (p-tau)] and serum Neurofilament light chain (NfL) in patients with AD.

Methods: We performed a cross-sectional study, including patients with the diagnosis of AD, supported by CSF biomarkers. The presence of NPS was assessed with Neuropsychiatric Inventory (NPI) and Frontal Behavioral Inventory (FBI) through a structured interview with the patient and the caregiver. Global cognition was evaluated with Mini-Mental State Examination (MMSE).

Results: We included 60 patients (72.0% female). Average age of onset was of 64.3 (±6.8). Median education was 4.0 (IQR = 5.0). Aβ42 was correlated with NPI apathy (r = −0.56, $p = 0.001$), FBI loss of spontaneity (r = −0.54, $p = 0.003$), personal neglect (r = −0.44, $p = 0.019$), loss of insight (r = −0.48, $p = 0.010$) and incontinence (r = −0.51, $p = 0.005$). Aβ42/Aβ40 was correlated with indifference (r = 0.41, $p = 0.033$), personal neglect (r = 0.38, $p = 0.045$), disorganization (r = 0.38, $p = 0.045$), perseveration (r = 0.38, $p = 0.42$) and agitation (r = 0.39, $p = 0.039$). P-tau was correlated with NPI nocturnal behavior (r = 0.259; $p = 0.047$).

Conclusion: Lower levels of CSF Aβ42 were associated with the presence of apathy, loss of spontaneity, personal neglect and loss of insight. Differential relationships between Aβ42 and Aβ40 and some NPS may reflect the different rates of parenchymal vs vascular deposition, and comorbid cerebral amyloid angiopathy, meriting further studies.

Disclosure: Nothing to disclose.

EPO-428 | Plasma biomarkers profiles in Alzheimer's disease and Parkinson's disease

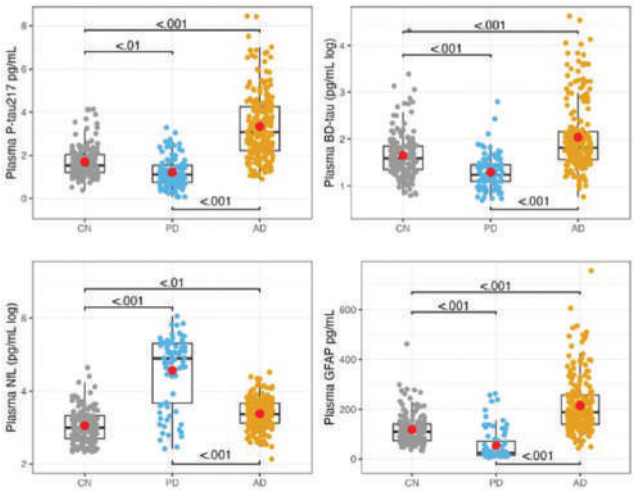
B. Fernandes Gomes[1]; K. Johansen[2]; F. Gonzalez-Ortiz[1]; B. Kirsebom[3]; H. Zetterberg[1]; T. Fladby[4]; K. Blennow[1]

[1]*Department of Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, the Sahlgrenska Academy at the University of Gothenburg, Mölndal, Sweden;* [2]*Department of Neurology, Akershus University Hospital, Lørenskog Norway;* [3]*Department of Neurology, University Hospital of North Norway, Tromsø, Norway;* [4]*Oslo University, Institute for Clinical Medicine, Campus Ahus, Norway*

Background and Aims: Plasma biomarkers are accessible tools that are lacking in neurodegenerative diseases, especially in Parkinson's disease (PD). Biomarkers like phospho-tau217 (p-tau217) and brain-derived tau (BD-tau) have proven to be accurate and robust for Alzheimer's disease (AD) diagnosis. Similarly, glial fibrillary acidic protein (GFAP) and neurofilament light chain (NfL) have been proposed as biomarkers, predicting conversion to dementia and neuronal damage, respectively. To better characterize these biomarkers profiles and their relationship, our goal was to evaluate the levels of plasma p-tau217, BD-tau, NfL, and GFAP in PD and AD.

Methods: Plasma p-tau217, BD-tau, NfL, and GFAP were measured using SIMOA in patients with PD ($n = 108$) and AD ($n = 220$), as well as cognitively normal (NC) controls ($n = 157$).

Results: We found increased levels of p-tau217 and BD-tau in AD, and decreased levels in PD, compared to CN ($p < 0.001$). GFAP was increased in AD, compared to NC, but not in PD ($p < 0.001$). NfL was markedly increased in PD ($p < 0.001$), however with a large variability within the group, while being unchanged in AD, compared to NC. Correlations were found between p-tau217 and NfL, and the Trailmaking test part B (TMT-B) (r = 0.22, $p = 0.001$, r = 0.24, $p < 0.001$, respectively) in the AD, and NfL and Unified Parkinson's Disease Rating Scale (UPDRS) (r = 0.3, $p = 0.01$) in PD. Markers were also highly correlated between each other in both AD and PD.



Plasma p-tau217, BD-tau, NfL, and GFAP levels in CN, AD, and PD individuals.

Conclusion: We found that p-tau217, BD-tau and GFAP are increased in AD, while increased NfL levels were associated with PD, with associations with motor and cognitive impairment.

Disclosure: Nothing to disclose.

Motor neurone diseases

EPO-429 | Takotsubo syndrome in a Sardinian amyotrophic lateral sclerosis cohort

A. Maccabeo; M. Pateri; F. Pili; M. Puligheddu; G. Borghero

Department of Medical Sciences and Public Health, Institute of Neurology, University Hospital D. Casula Monserrato, Cagliari, Italy

Background and Aims: Amyotrophic lateral sclerosis (ALS) is known to be associated with varying degrees of autonomic and cardiovascular dysfunction. Recent case reports showed that ALS may be

linked to Takotsubo syndrome (TTS), an acute heart failure syndrome characterized by left ventricular dysfunction with a peculiar pattern, resulting in apical ballooning. Here we reported and described five ALS patients who developed TTS.

Methods: We retrospectively examined a ten-year incident ALS cohort (2010-2019), identified patients who developed TTS and described their clinical characteristics.

Results: Our Sardinian cohort included 344 ALS patients and five of them (1.45%) developed TTS. All were female and their median onset age was 71.5 years (IQR 62.75-77). No relevant genetic mutation was detected. Three patients had spinal and two bulbar onset, though all had bulbar involvement and were at an advanced stage of disease (ALSFRS ≤ 25, King's ≥3) at TTS diagnosis. We identified a potential physical and emotional TTS trigger in four patients (hospitalization for pneumonia, tracheostomy, PEG placement). Survival time was variable (up to 25 months after TTS).

Conclusion: TTS is not an infrequent condition in ALS and may influence these patients' prognosis. Female sex, bulbar involvement and later age of onset may be important risk factors for developing this cardiac condition and a physical or psychological trigger is often observed. Despite autonomic dysfunction in ALS has been demonstrated, the precise physiopathological mechanism underlying TTS needs to be furtherly clarified.

Disclosure: Nothing to disclose.

EPO-430 | Vitamin D levels and disease severity in ALS patients

A. Alungulese[1]; I. Catalina Alvarez[1]; E. Trasobares Iglesias[2]; A. Lozano Ros[1]; J. Muñoz Blanco[1]

[1]*Department of Neurology, Gregorio Marañón General University Hospital, Madrid, Spain;* [2]*Gregorio Marañón Health Research Institute, Madrid, Spain*

Background and Aims: The hypothesis that vitamin D may play a role in ALS disease mechanisms stems from pre-clinical studies and epidemiological findings in other neurological diseases. The objective of this study was to determine the levels of vitamin D in ALS patients compared with those in control subjects and correlate the levels of vitamin D with disease severity.

Methods: Vitamin D levels were measured in 45 ALS subjects and 45 controls. We estimated associations with ALSFRS-R scores by multivariate linear regression using data from baseline visit. As potential confounders were considered: age, gender, ethnicity, body mass index, smoking, history of performing physical exercise, vitamin D supplements, site of symptom onset, diagnostic delay, familial ALS cases.

Results: The majority of ALS subjects (73.3%) had levels below the recommended level of 30 ng/ml. Vitamin D levels in ALS patients were slightly lower than those in control subjects by a mean difference of −9.5 ng/ml; 95% CI (−15.0; −4.0). Demographics, body mass index, smoking, history of performing physical exercise, site of symptom onset, diagnostic delay did not differ across strata of baseline vitamin D level. The association between vitamin D and ALSFRS-R total scores did not appreciably change after adjusting for multiple baseline clinical characteristics.

Conclusion: We found that people with ALS had vitamin D levels below the recommended level in line with other reports in neurodegenerative disease. Worse severity score at baseline due to vitamin D deficiency, however, is unlikely based on our study.

Disclosure: Nothing to disclose.

EPO-431 | Ulnar CMAP and MUNE in adult SMA patients treated with nusinersen

A. Frączek[1]; E. Sobieszczuk[1]; A. Potulska-Chromik[1]; A. Łusakowska[1]; K. Aragon-Gawińska[1]; M. Burlewicz[2]; Z. Gierlak-Wójcicka[2]; A. Kostera-Pruszczyk[1]

[1]*Department of Neurology, Medical University of Warsaw, Warsaw, Poland;* [2]*Department of Neurology, University Hospital, Warsaw, Poland*

Background and Aims: Spinal muscular atrophy (SMA) is a progressive disease leading to motor neuron loss. Nusinersen treatment in adult patients can halt disease progression. Improvement of compound muscle action potential (CMAP) and estimation of the number of motor units (MUNE) in nusinersen-treated pediatric SMA patients were demonstrated by some authors.

Methods: 17 adult patients with SMA type 2 ($N=1$) or 3 ($N=16$) (35.3%F) treated with nusinersen were included in the study, 70.6% of patients were walkers. Sex- and age-matched healthy volunteers served as the control group (HC). All the patients were assessed at baseline, 6th, 14th months of treatment and consecutive infusions with functional scales (Hammersmith Functional Motor Scale Expanded-HFMSE or CHOP-INTEND and Revised Upper Limb Module-RULM) and CMAP, multipoint incremental MUNE, single motor unit potential (SMUP) of the abductor digiti minimi (ADM). The duration of observation was 30-50 months.

Results: CMAP and MUNE were significantly lower in SMA patients than in HC ($p<0.001$); SMUP was significantly higher in SMA patients than in HC ($p<0.001$). We have observed decrease in mean CMAP and MUNE in SMA patients at 6 months in the first year of treatment, since 14th month of treatment there was an increase and followed by stabilization of those parameters but there was no significant difference between baseline evaluation of CMAP and MUNE and evaluation at next infusions. Only SMUP value was significantly higher after six months in comparison with baseline value ($p=0.039$).

Conclusion: Nusinersen treatment stabilizes CMAP, MUNE and SMUP after 6 months of treatment in SMA adults with SMA2-3 observed for up to 50 months.

EPO-432 | Iron metabolism-genetic interplay in an ALS cohort: A single-center study

B. Risi[1]; B. Labella[2]; F. Caria[1]; S. Damioli[1]; E. Bertella[1]; L. Poli[3]; L. Ferullo[2]; E. Olivieri[2]; I. Bianchi[4]; A. Padovani[2]; I. Zanella[5]; M. Filosto[6]

[1]NeMO-Brescia Clinical Center for Neuromuscular Diseases, Brescia, Italy; [2]Department of Clinical and Experimental Sciences, University of Brescia; Unit of Neurology, ASST "Spedali Civili" of Brescia, Italy; [3]Unit of Neurology, ASST "Spedali Civili" of Brescia, Italy; [4]Medical Genetics Laboratory, ASST "Spedali Civili" of Brescia, Italy; [5]Department of Molecular and Translational Medicine, University of Brescia; Medical Genetics Laboratory, ASST "Spedali Civili" of Brescia, Italy; [6]Department of Clinical and Experimental Sciences, University of Brescia; NeMO-Brescia Clinical Center for Neuromuscular Diseases, Brescia, Italy

Background and Aims: Impaired iron metabolism has been observed in ALS, but it is not known whether it is a cause or a consequence of the disease. The aim of our study is to investigate the interplay between iron homeostasis and ALS by analysing a panel of iron-related genes.

Methods: 20 ALS patients (male, $n=12$) were tested for common variants in iron-related genes, among which the p.Asp358Ala variant in the IL6R (interleukin 6-receptor) gene, known to increase soluble IL6-R levels. Patients were dichotomized into carriers (both heterozygous and homozygous) and non-carriers; all underwent blood sampling for measurement of iron-related molecules. Adjusted ANCOVA and correlation analysis and linear regression (with site of onset, sex, age and disease duration as independent variables) were performed.

Results: Median ferritin levels were 424.2 ng/ml in men (UNL: 400) and 192.4 ng/ml in women (UNL: 150), with 55% of patients having higher than normal levels. Higher ferritin levels were associated with the group of bulbar*fast progressor patients ($p=0.012$) and correlated with the disease progression rate [DPR] ($r=0.518$, $p=0.028$). The IL6R358Ala variant carriers had lower ferritin levels than non-carriers ($p=0.023$). In the multivariate analysis, this variant was found to be the only predictor of ferritin levels ($p=0.013$).

Conclusion: Our preliminary results may suggest a role of the IL6R358Ala variant in reducing ferritinemia. This could be explained by a kind of "buffering" system mediated by higher s-IL6-R levels, dampening the pro-inflammatory IL-6 signalling. These findings may help to better define the relationship between iron metabolism abnormalities and clinical features in ALS.

Disclosure: The authors have no potential conflict of interest to disclose.

EPO-433 | Evaluation of clinical effectiveness of edaravone in the treatment of amyotrophic lateral sclerosis in Uzbekistan

C. Rustamova; M. Yakubova

Neurology department, Doctor M clinic, Tashkent, Uzbekistan, Kichik khalqa yuli street, Takhtapul

Background and Aims: Amyotrophic lateral sclerosis (ALS) is a progressive, neurodegenerative disease of the central nervous system. Despite the positive outcome of clinical trial of edaravone for treatment of ALS, there are limitations which makes it difficult for clinicians to prescribe the drug with an expectation of efficacy. Our study aims to investigate the clinical efficacy of edaravone in the treatment of ALS in Uzbek patients.

Methods: We examined 36 patients with ALS, aged from 24 to 78 years, who were hospitalized between 2019 and 2023. Patients were divided into 2 groups: 1) main group: 25 (70%) patients who received Edaravone; 2) control group: 11 (30%) patients who received standard ALS treatment. All patients underwent a standard examinations: clinical and neurological examination; Electroneuromyography; ALS-FRS-Revised functional rating scale before and after treatment.

Results: The incidence of clinical symptoms in ALS before treatment with edaravone was reduced by 27% after the treatment of edaravone. The incidence of clinical symptoms in ALS before treatment with standard therapy was reduced by 15% after the treatment of standard therapy ($p<0.005$). According to ALS-FRS-R scale, scale index in the patients treated with edaravone significantly increased by 21% (40 +0.93) and the scale index in the patients treated with standard therapy increased by 11% (37+ 0.74), ($p<0.001$). According to ENMG parameters, the maximum amplitude of the M-response increased for all nerves in the edaravone group compared to the control group ($p<0.005$).

Conclusion: Our research showed that 60% of patients with ALS show positive dynamics in the initial stage of focal motor disorders in the treatment with edaravone. The use of edaravone in the therapy of ALS was highly effective, especially in the early stages of the disease, in cervico-thoracic and bulbar forms of ALS.

Disclosure: Nothing to disclose.

EPO-434 | Retrospective study of a cohort of patients with amyotrophic lateral sclerosis from the University of Pisa

C. Meoni; C. Carlesi; F. Bianchi; L. Becattini; L. Fontanelli; G. Vadi; B. Giovannini; G. Siciliano
Department of Clinical and Experimental Medicine, Neurological Clinic, University of Pisa, Pisa, Italy

Background and Aims: Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disorder that involves upper and lower motor neurons. Different phenotypes are possible, with sometimes differences in survival. According to the epidemiological data, bulbar subtypes show a more rapid progression and shorter survival, compared to the spinal subtypes. The objective of our study was to analyze the survival of a cohort of patients with ALS across the different disease phenotypes.
Methods: All patients diagnosed, according to the Gold Coast Criteria, with ALS from January 2021 to January 2024 at our Center for Motor Neuron Disease were retrospectively evaluated. None had been excluded from the study, but 13 patients had been lost during follow-up, thus were excluded from the Kaplan-Meier analysis.
Results: A total of 99 patients were enrolled (median age: 65.1 ±11.5; 46.5% female). Among them, 73.8% had a spinal onset (57.4% male), 25.3% had a bulbar onset (64% female). The time hiatus between the disease onset and diagnosis was 18.6 ±18.7 months on average (14.2 ±12 months for bulbar onset, and 21.1 ±21.2 months for spinal onset). The number of dead patients was 25 (36% of bulbar onset; 22% of spinal onset). The disease duration was on average 34 ±23 months (28 ±15 months for the bulbar form, 37 ±25 months for the spinal form).
Conclusion: Our data are in line with those reported in literature. Patients stratification can help in identify prognostic factors and epidemiological data that may improve clinical, diagnostic, and therapeutic management of this complex disease.
Disclosure: Nothing to disclose.

EPO-435 | Lower Gas6 levels are associated with bulbar phenotype and faster disease progression in ALS patients

F. De Marchi[1]; D. Apostolo[2]; L. Ferreira[2]; D. D'Onghia[2]; F. Vincenzi[2]; L. Mazzini[1]; M. Bellan[2]
[1]*ALS Center, Neurology Unit, Department of Translational Medicine, University of Piemonte Orientale, Novara, Italy;* [2]*Department of Translational Medicine, Università del Piemonte Orientale, Novara, Italy*

Background and Aims: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disorder that primarily affects the motor neurons in the brain and spinal cord. While the exact cause of ALS is not fully understood, a combination of genetic and environmental factors is believed to contribute to its development. Research into the etiology and pathogenesis of ALS is ongoing, and we investigated the role of Growth Arrest-Specific 6 (Gas6) as a possible contributor. This vitamin K-dependent protein has been recognized to enhance survival of oligodendrocytes and neurons and, it has been associated with different kinds of (neuro) inflammatory conditions.
Methods: We conducted a prospective observational study including 65 ALS patients aimed to assess whether circulating serum levels of Gas6 and its soluble receptors (sAxl, sMer, sTyro-3) along with neurofilaments (NfLs) could represent a disease marker in ALS patients.
Results: In our ALS cohort, lower serum levels of Gas6, and concomitantly higher levels of NfL, were associated with a more aggressive disease, expressed with bulbar phenotype (*p*-value for Gas6: 0.03) and faster progression (*p*-value for Gas6: 0.03). Also, serum Gas6 can well distinguish (area under the curve, cut-off 13.70 ng/mL, sensitivity 69.57%, specificity 72.72%) between fast and slow progressors.
Conclusion: Due to neuroprotective properties, our data suggest that Gas6, could be an intriguing biomarker in ALS patients.
Disclosure: No disclosure.

EPO-436 | Validation of the Czech and Slovak versions of questionnaires used to monitor the clinical status of patients with ALS

L. Joppekova[1]; A. Betik[1]; D. Baumgartner[2]; R. Mazanec[2]; M. Turcanova-Koprusakova[3]; I. Martinka[4]; E. Vlckova[1]
[1]*Department of Neurology, ERN-EURO NMD Centre, University Hospital Brno, Czechia;* [2]*Department of Neurology, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Czechia;* [3]*Department of Neurology, Jessenius Medical Faculty of Comenius University and University Hospital Martin, Slovakia;* [4]*Ružinov Hospital, University Hospital Bratislava, Slovakia*

Background and Aims: This multicentre study aimed to validate Czech and Slovak versions of several questionnaires used to monitor patients with amyotrophic lateral sclerosis (ALS). The following scales and questionnaires were used: the ALS Functional Rating Scale – Revised (ALSFRS-R) and its extended version (ALSFRS-R-EX), the ALS Assessment Questionnaire - 40 items (ALSAQ-40), the Borg scale for breathlessness intensity, and the Dysphagia in ALS (DYALS) scale for dysphagia symptoms. Both the clinician-administered version of the ALSFRS-R and the self-administered version were compared.
Methods: All questionnaires and scales were translated using the forward-backward method. The first administration was made during clinical follow-up in four major Czech or Slovak neuromuscular centres (Brno, Prague, Bratislava, Martin), with a repeat administration by telephone after seven days. In both cases, the self-administered version of the ALSFRS-R was used. One week later, the ALSFRS-R+EX questionnaires were administered again by telephone in a non-self-administered version.
Results: The study involved 62 ALS patients (34 men) and showed excellent questionnaire comprehension in both languages. Statistical

analysis revealed no significant differences in scores between administrations, confirming excellent reproducibility and high internal consistency (Cronbach's alpha around 0.98). The intraclass correlation coefficient ranged from 0.905 to 0.994, indicating high agreement between different versions and/or administrations of the questionnaires.

Conclusion: The Czech and Slovak versions of all tested ALS-related questionnaires show high patient comprehensibility, internal consistency and reproducibility between repeated administrations, and excellent agreement between self-administered and clinician-administered versions of the ALSFRS-R questionnaire.

Disclosure: The authors declare no conflict of interest regarding this study.

EPO-437 | Analysis of C9orf72 repeat expansions in Georgian patients with amyotrophic lateral sclerosis

M. Kekenadze[1]; C. Rocca[1]; V. Turchetti[1]; N. Kvirkvelia[2]; S. Vashadze[3]; E. Kvaratskhelia[4]; M. Beridze[4]; R. Kaiyrzhanov[1]; H. Houlden[1]

[1]University College London, Queen Square Institute of Neurology, London, UK; [2]Tbilisi State University; [3]Batumi Shota Rustaveli State University; [4]Tbilisi State Medical University

Background and Aims: Amyotrophic lateral sclerosis (ALS) is a fatal progressive neurodegenerative disorder that affects the upper and lower motor neurons. Several genetic risk factors have been identified in the past decade with a hexanucleotide repeat expansion in the C9orf72 gene being the most significant. However, the presence of C9orf72 repeat expansion has not been examined in the Transcaucasian region, therefore we aimed to analyze its frequency in Georgian patients with ALS.

Methods: We included 74 self-reported Georgian patients with ALS from different parts of the country, fulfilling the Gold Coast criteria. To investigate the presence of an expanded GGGGCC hexanucleotide repeat in the non-coding region of the C9orf72 gene, we performed Repeat-Primed PCR (RP-PCR).

Results: In total, 74 sporadic and two familial ALS cases were identified. Patients were aged 26 to 84 years with a mean age of 58.3 years at disease onset. Bulbar onset was observed in 21.88%, upper limb onset in 34.38%, and lower limb onset in 43.75% of the patients. Frontotemporal dementia (FTD) fulfilling the Strong criteria was diagnosed in seven patients (10.94%). C9orf72 repeat expansion was detected in only one case using RP-PCR; the patient had a family history of dementia.

Conclusion: Our results indicate that C9orf72 hexanucleotide expansion does not belong to the major genetic risk factor of ALS in Georgian patients. Further genetic studies in a bigger study population are needed to reveal the genetic causes of ALS in the Transcaucasian population.

Disclosure: Nothing to disclose.

EPO-438 | Basal metabolism, myokine levels and disease severity in amyotrophic lateral sclerosis

M. Goglia[1]; E. Frezza[1]; G. Greco[1]; F. Gruosso[1]; G. Vietri[1]; I. Petitta[1]; G. Nardino[1]; L. Boffa[1]; A. De Lorenzo[2]; R. Massa[1]

[1]Neuromuscular Diseases Unit, Department of Systems Medicine, Tor Vergata University of Rome, Rome, Italy; [2]Section of Clinical Nutrition and Nutrigenomic, Department of Biomedicine and Prevention, University of Tor Vergata, Rome, Italy

Background and Aims: Amyotrophic lateral sclerosis (ALS) can be considered as a multisystemic disease affecting metabolism and body composition. Abnormal resting energy expenditure (REE) has been reported in ALS patients and could be linked to variations in circulating myokine levels. The aim of this study is to investigate metabolic impairment and plasma myokine levels and their possible connection with disease progression.

Methods: ALS patients underwent ALS-functional rating scale-revised (ALS-FRS-R), MRC sum score and blood detection of myokines (irisin, IL-6) and 181pTau. Indirect calorimetry and dual-X-ray absorptiometry (DEXA) were performed on the same day to assess REE and body composition, respectively.

Results: We enrolled 10 patients and 10 healthy controls. At indirect calorimetry 8 patients were hypometabolic. REE, normalized with fat free mass, directly correlated with irisin levels. We found no correlations between either REE or irisin and functional scales of disease severity, whereas pTau levels were increased in patients ($p < 0.05$) and inversely correlated with MRC sum score ($p < 0.05$). IL-6 directly correlated with disease duration ($p < 0.05$) and inversely correlated with MRC sum score ($p < 0.05$).

Conclusion: Basal metabolism alterations are present in ALS and irisin can be linked to them, independently on disease severity. Conversely, pTau and IL-6 could be indicators of disease progression and severity. Further investigations are required to clarify whether metabolic abnormalities could have a role in ALS pathogenesis and disease progression or represent a consequence of secondary muscle wasting. Moreover, myokines such as irisin could be useful to investigate alterations of resting metabolic state.

Disclosure: Nothing to disclose.

EPO-439 | Study of anthropometric parameters in patients with amyotrophic lateral sclerosis (ALS)

E. Malhina; V. Haliyeyskaya; Y. Rushkevich; I. Pashkouskaya; S. Likhachev

Republican Scientific and Practical Center of Neurology and Neurosurgery, Minsk, Belarus

Background and Aims: Subclinical loss of muscle mass and subcutaneous fat in ALS patients is one of the reasons for the delayed diagnosis of latent protein-energy malnutrition (PEM).

Methods: The study included 49 ALS patients (13 (26%) men, 36 (74%) women), 62.0 [51.0; 67.0] years, BMI 25.2 [23.0; 28.0]. Me duration of the disease 13.2 [9.3; 19.7] months. Me of ALSFRS 46.0 [42.0; 47.0]. The control group 30 patients (10 (33%) men, 20 (67%) women) without neuromuscular pathology, 56.0 [47.0; 61.0] years, BMI 29.7 [25.5; 31.9]. There was no statistical difference in age, gender and BMI.

Results: Significant decreases in circumferences were found in ALS patients (Table 1). Almost all measured parameters among ALS patients were significantly lower (U, $p<0.05$) compared with the control group. No significant reduction in circumference above the ankle was revealed, that is probably due to the hidden edema in ALs patients, which is one of the clinical signs of PEM. The waist circumference in patients with ALS showed good quality of the diagnostic model, AUC=0.732±0.08 (95%CI0.575-0.856), $p=0.006$. The threshold value of waist circumference is ≤98 cm, sensitivity 80%, specificity 67% (Figure 1).

Table 1 – Circumferences in ALS patients in comparison with control group

Parameter, cm	ALS, n=49 Me[LQ;UQ]	Control, n=30 Me[LQ;UQ]	U, p
Chest circumference	96,0[88,0;101,0] *	104,5[97,0;111,00]	0,000177
Waist circumference	91,0[76,0;98,0] *	100,0[81,0;103,0]	0,009001

Shin circumference, D	36,0[34,0;39,0] *	40,0[36,0;41,0]	0,001943
Shin circumference, S	36,0[35,0;38,0] *	40,0[36,0;42,0]	0,000383
Circumference above the ankle, D	23,0[22,0;25,0]	24,0[23,0;26,0]	0,186999
Circumference above the ankle, S	23,0[22,0;24,0]	23, 5[23,0;25,0]	0,175780

* - significant differences at p< 0.05 (according to the Mann-Whitney criterion). D – Dexter, S – Sinister.

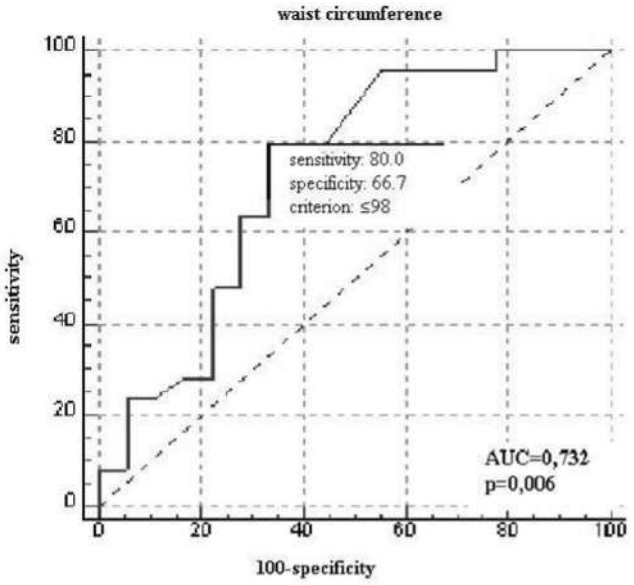

Figure 1 – ROC-waist circumference curve in patients with ALS

Conclusion: Despite the early stages of the disease, the preservation of functional capabilities significant decrease in circumferences were found, that indicates a progressive loss of muscle mass and subcutaneous fat in ALS patients. According to the ROC-analysis in ALS patients with an AUC value greater than 0.7, the threshold level of waist circumference sensitivity is over 80% and can be considered objective sign of PEM.

Disclosure: The authors have nothing to disclose.

EPO-440 | Early diagnosis of ALS using near-fiber EMG

O. Garnes-Camarena[1]; I. Mahillo-Fernandez[2]; O. Lorenzo[2]; P. Martinez-Ulloa[1]; R. Mandeville[3]; D. Stashuk[4]

[1]Jimenez Diaz Foundation University Hospital, Madrid, Spain; [2]Jimenez Diaz Foundation Research Institute, Madrid, Spain; [3]Beth Israel Deaconess Medical Center, Boston, MA, USA; [4]Systems Desing Engineering, University of Waterloo, Ontario, Canada

Background and Aims: Amyotrophic lateral sclerosis is characterized by rapid and progressive motor neuron lesions. The continuous process of denervation and reinnervation is manifested in EMG signals as changes in motor unit potential (MUP) size, temporal dispersion (complexity) and instability. Current methods to assess temporal dispersion and instability are either indirect (MUP turns, jiggle) or time-consuming (single fiber jitter). Near-Fiber EMG (NF-EMG) is a novel way to assess the size, temporal dispersion, and instability of routinely recorded MUPs directly and quantitatively in a semi-automated manner.

Methods: 1441 MUs in 60 muscles of 10 patients at the time of ALS diagnosis (Gold Coast criteria) were sampled using NF-EMG. MUP area and duration and NF-MUP dispersion and segment jitter were studied.

Results: On average, 49.1% of MUs showed increased NF-MUP dispersion and 53.7% exhibited increased NF-MUP segment jitter, whereas 31% of MUs had both increased NF-MUP dispersion and instability. Interestingly, 27% and 30% of MUs with normal sized MUPs had increased NF-MUP dispersion and segment jitter, respectively (3 and 2 times higher than in control subjects), indicating the capability of NF-EMG to detect electrophysiological abnormalities at early stages of the disease.

Muscle	MUPs (muscles)	% incr. NFM_SJ	% incr. NFM_SJ + Normal MUP size (area or dur)	% incr. NFM_Disp	% incr. NFM_Disp + Normal MUP size (area or dur)	% incr. NFM_SJ + NFM_Disp	% incr. EPO-441 | Elevated serum MCP-2 and TARC are associated with increased risk of death in Guamanian ALS patients

R. Chowdhury[1]; L. Shteynman[2]; E. Culver[3]; S. Azam[4]; M. Azam[5]; R. Garruto[6]; K. Wander[6]

[1]*College of Behavioral and Community Sciences, University of South Florida, Tampa, FL, USA;* [2]*Renaissance School of Medicine at Stony Brook University, Stony Brook, NY, USA;* [3]*Colorado Center for Personalized Medicine, University of Colorado-Anschutz Medical Campus, Aurora, CO, USA;* [4]*University at Buffalo School of Medicine and Biomedical Sciences, Buffalo, NY, USA;* [5]*SUNY Upstate Norton College of Medicine, Syracuse, NY, USA;* [6]*Department of Anthropology, Binghamton University (SUNY), Binghamton, NY, USA*

Background and Aims: This study explores the relationship between inflammation and longevity in post-WWII Guam amyotrophic lateral sclerosis (ALS). Characteristics of this focus include sudden high incidence and long lifespan in some cases. Understanding longevity in Guamanian ALS may help elucidate causal pathways and novel therapeutic targets. This research evaluates inflammation in biobanked Guamanian ALS patient serum to understand the relationship between immunoregulator levels and survival time.

Methods: Sera from 69 Guam ALS cases collected within early years of onset by NIH researchers from 1958-1990 were evaluated for 11 regulators of inflammation, using custom multiplex cytokine and single-plex CRP ELISA. Survival analysis with Cox proportional hazards models was used to determine factors associated with time to death.

Results: Factor 2 (MCP-2 and TARC) was associated with a 38% increase in risk of death (HR: 1·38, 95% CI [1·19, 1·65], *p*: 0·00). Individually, MCP-1 (HR: 1·03, 95% CI [1·004, 1·06], *p*: 0·02), MCP-2 (HR: 1·24, 95% CI [1·08, 1·44], *p*: 0·00), IFN-γ (HR: 2·34 95% CI [1·25, 4·36], *p*: 0·01), IP-10 (HR: 1·18, 95% CI [1·065, 1·312], *p*: 0·00), IL-6 (HR: 1·05, 95% CI [0·998, 1·108], *p*: 0·06), and TARC (HR: 1·03 95% CI [1·013, 1·044], *p*: 0·00), were also associated with increased risk of death.

Conclusion: Results suggest increased inflammation in Guamanian ALS is associated with shortened lifespan. Assessing serum levels of MCP-2 and TARC in early stages of disease may predict severity and duration in sporadic ALS. Research on the relationship between pathways associated with TARC, MCP-2 in ALS warrants further investigation.

Disclosure: Nothing to disclose with regard to conflicts of interest. Institutional Board Review (IRB) and Ethics disclosure: As all participant are deceased Binghamton University IRB has classified this as non-human subjects research, which does not require IRB approval.

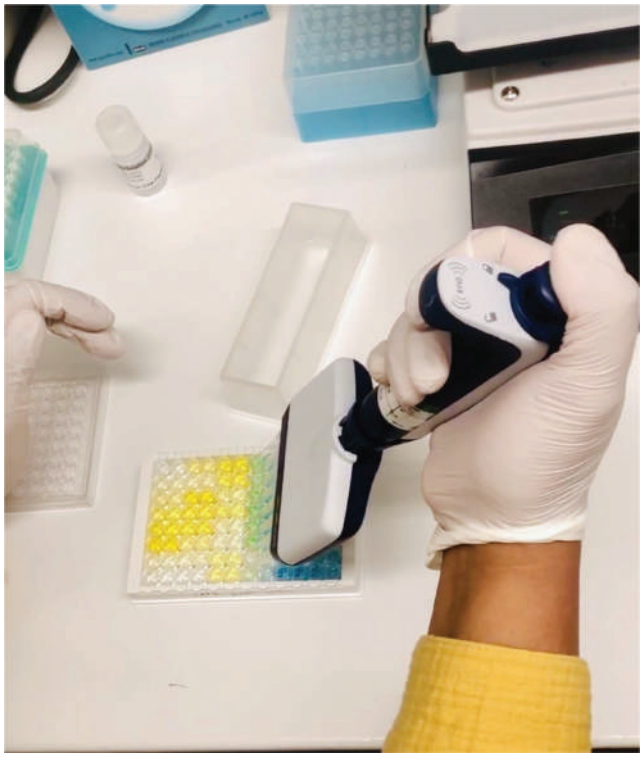

FIGURE 1 C-reactive Reactive Protein ELISA of Guamanian ALS sera.

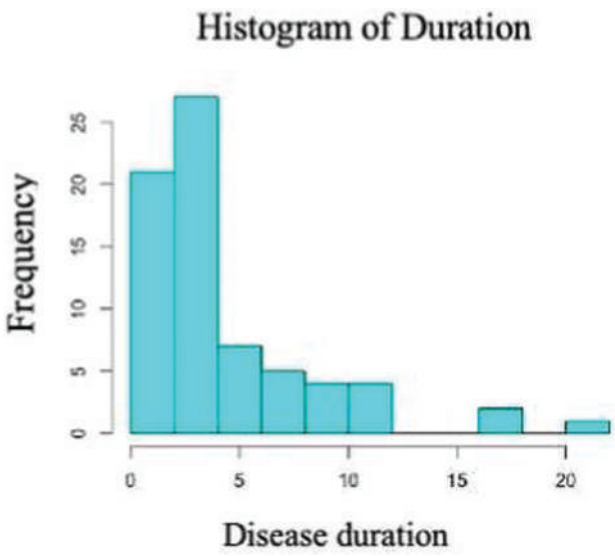

FIGURE 2 Distribution of disease duration: Cases represent a broad range of survival times (1-22 years, $n = 69$).

However, at time of collection, all specimens were obtained with informed written consent from patients following ethical standards set forth by the 1947 Nuremburg Code, the 1965 Declaration of Helsinki, and the 1974 Belmont Report. This research is consistent with the original use for which the samples were collected. All samples included in study were collected prior to 1985 when ALS was still highly prevalent on Guam.

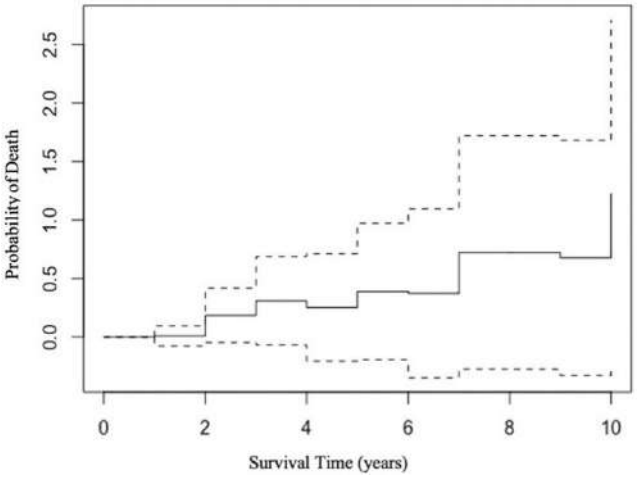

FIGURE 3 Increased probability of death with increase of Factor 2 (MCP-2 & TARC): Horizontal lines in Kaplan-Meier curve depict duration of survival; vertical lines depict change in probability of death; intermittent lines represent 95% confidence intervals.

EPO-442 | Exploring glymphatic system function in the ALS-FTD spectrum

T. Russo[1]; E. Spinelli[2]; T. Domi[1]; P. Schito[3]; Y. Falzone[3]; F. Agosta[4]; A. Quattrini[1]; M. Filippi[5]

[1]Experimental Neuropathology Unit, Institute of Experimental Neurology (INSPE), Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; [2]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; [3]Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; [4]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; Vita-Salute San Raffaele University; [5]Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute; Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute; Vita-Salute San Raffaele University

Background and Aims: Growing evidence suggests that glymphatic function is impaired in patients with several neurodegenerative diseases and neuroinflammation is thought to be entangled with glymphatic function. However, there are few available in vivo data about glymphatic function in patients with amyotrophic lateral sclerosis and/or frontotemporal dementia (ALS-FTD).

Methods: We measured serum levels of osteopontin, a neuroinflammatory biomarker which is thought to be produced by perivascular cells, in a cohort of patients with ALS and FTD, as well as in age-matched healthy controls, and correlated it to clinical features.

Results: Osteopontin serum levels correlated with age and were higher in ALS patients compared to healthy controls. Patients with higher osteopontin serum levels had a trend for a shorter survival.

Conclusion: We confirmed that osteopontin levels are higher in ALS patients compared to controls and correlate with a worse prognosis. Correlation with MRI data will provide information about 1) glymphatic function in patients with ALS-FTD and 2) osteopontin association with glymphatic function.

Disclosure: Nothing to disclose.

EPO-443 | Progression of cognitive impairment in ALS: Preliminary findings from a longitudinal monocentric study in Italy

V. Bettoni[1]; G. Fiamingo[2]; S. Schillaci[1]; M. Collesi[3]; S. Cappa[4]; E. Ballante[3]; L. Diamanti[5]

[1]Department of Brain and Behavioural Sciences, University of Pavia, Pavia, Italy; [2]UOC Neurologia ASST Bergamo Est, Seriate, Italy; [3]IRCCS Mondino Foundation, Pavia, Italy; [4]University School for Advance Studies IUSS, Pavia, Italy; [5]Neuro-oncology unit, IRCCS Mondino Foundation, Pavia, Italy

Background and Aims: The presence of cognitive and behavioral impairment in patients affected by Amyotrophic Lateral Sclerosis (ALS) is now well-established. However, there is no agreement about the worsening of cognitive deficits during disease progression, and the few longitudinal studies on the topic provided inconclusive results. This monocentric, longitudinal study aims at evaluating the cognition at the time of ALS diagnosis and after 12 months.

Methods: 62 Italian subjects (F:M = 0.44; age 63.51 ± 12.46y) with a diagnosis of ALS were subjected to a standardized neuropsychological evaluation at diagnosis through the Edinburgh Cognitive and Behavioral ALS Screen (ECAS) test, the Story-based Empathy Task (SET) test, and the Ekman 60-faces test. The evaluation was repeated after 12 months.

Results: In the overall study population, cognitive decline, as defined by ECAS abnormalities, was observed in 13 subjects (20.97%). Some alterations in emotions recognition emerged from Ekman test (mean 45.49, sd 6.88). Only 27 subjects could be assessed at the second time-point (F:M = 0.22; age 63.81, sd 12.99y). In this follow-up population, cognitive decline at ECAS was observed in 5 subjects at T0 (18.51%) and in 7 subjects at 12-months assessment (25.92%). Changes of ECAS, SET or Ekman test scores after 12 months were not statistically significant.

Conclusion: These preliminary results do not show progression of cognitive impairment. This could be influenced by the small sample size and by the attrition bias in the longitudinal study population (i.e. subjects with a better disease course being over-represented amongst the ones reaching the follow-up visit). More detailed data analysis is still ongoing.

Disclosure: Nothing to disclose.

Coma and chronic disorders of consciousness

EPO-444 | The functional communication measures for assessing communicative abilities in prolonged disorders of consciousness

A. Magliacano[1]; M. Spinola[2]; C. Fasano[2]; B. Campana[2]; A. Estraneo[1]
[1]*IRCCS Fondazione Don Carlo Gnocchi ONLUS, Florence, Italy;* [2]*Polo Specialistico Riabilitativo Fondazione Don Carlo Gnocchi ONLUS, Sant'Angelo dei Lombardi (AV), Italy*

Background and Aims: The present cross-sectional study aimed to investigate the ability of the validated Italian version of the shortened Functional Communication Measures (sFCM) in assessing communication in individuals with severe Acquired Brain Injury (sABI) with and without prolonged Disorders of Consciousness (pDoC).
Methods: Participants: 17 sABI patients consecutively admitted to our sABI Rehabilitation Unit (males = 11; mean age = 60.4±15.3 years; pDoC = 7). Variables collected: i. demographic and anamnestic information at study entry; ii. Levels of Cognitive Functioning (LCF), Disability Rating Scale (DRS), Functional Oral Intake Scale (FOIS) scores, and Coma Recovery Scale-Revised (CRS-R) scores only in patients with pDoC; iii) sFCM scores administered independently by two blinded examiners.
Results: The sFCM inter-rater agreement ranged from perfect to substantial. The sFCM correlated significantly with LCF, DRS and FOIS scores (all $p < 0.05$). In the subgroup of patients with pDoC, the oral comprehension on sFCM correlated significantly with the CRS-R motor subscore ($\rho = .794$; $p = 0.017$). Specifically, patients with higher CRS-R motor subscore were classified by the sFCM as being able to execute simple commands or answer with a "yes/no" code to contextual questions with consistent and maximal facilitation, although they did not meet the CRS-R criteria for consistent command following.
Conclusion: We confirmed that sFCM are a solid and easy-to-administer tool for assessing communication abilities in fully conscious sABI patients. For the first time, we found that the sFCM are able to stratify patients with pDoC based on their language abilities more accurately than the CRS-R.
Disclosure: Nothing to disclose.

EPO-445 | Clinical improvements following transcutaneous auricular vagal nerve stimulation in acute disorders of consciousness

V. Marie[1]; E. Remacle[1]; P. Cardone[1]; A. Regnier[1]; O. Gosseries[1]; N. Lejeune[1]; J. Annen[1]; D. Martin[3]; D. Ledoux[2]; A. Thibaut[1]
[1]*Coma Science Group, University of Liège, Belgium;* [2]*Intensive Care Unit, University Hospital of Liège, Belgium;* [3]*Department of Neurosurgery, University Hospital of Liège, Belgium*

Background and Aims: Patients with disorders of consciousness (DoC) are a challenging population lacking effective treatment options. Among neuromodulation techniques, trans-auricular vagal nerve stimulation (taVNS) may act through a bottom-up manner to modulate thalamo-cortical connectivity and promote the recovery of consciousness.
Methods: We are conducting the first randomized placebo-controlled double-blind clinical trial employing taVNS in 44 acute DoC. Patients randomly receive either 5 days of active bilateral vagal stimulation (45 min; 3mA; 200-300μs current width, 25Hz) or sham stimulation. Behavioural (Coma Recovery Scale-Revised, CRS-R) measures are collected at baseline and at the end of the treatment.
Results: Preliminary results on 30 patients show a significant difference in the behavioral score evolution (post vs pre) between the active and sham groups following the 5-day treatment period ($W = 150$; $p = 0.014$). Patients in the active taVNS group showed significantly increased CRS-R total scores post-treatment compared to baseline (median pre-treatment = 8 [5]; median post-treatment = 11 [12]; $V = 4.5$; $p = 0.021$), while patients from the sham group did not display such difference (median pre-treatment = 6.5 [6.25]; median post-treatment = 6.5 [3]; $V = 16$; $p = 0.83$). Moreover, in the active group ($n = 14$), 7 patients displayed a new sign of consciousness and 4 improved their diagnosis, among which 3 even emerged from DoC. In the placebo condition ($n = 16$), 2 patients improved and only one changed diagnosis.
Conclusion: Our results show that repeated taVNS might promote consciousness recovery in the early phase following severe brain injury. This study will contribute to define the role of taVNS for the treatment of these challenging conditions and identify patients' clusters for responses to treatment.
Disclosure: None.

EPO-446 | Rehabilitation of language and swallowing abilities in patients with severe brain injury: An online international survey

A. Regnier[1]; O. Gosseries[1]; E. Mélotte[1]; S. Gillet[2]; P. Cassar[3]; B. Hakiki[4]; A. Estraneo[4]; A. Magliacano[4]; R. Formisano[5]; C. Schnakers[6]; S. Majerus[7]; E. Noé[8]; R. Llorens[8]; L. Navarro Pérez[8]; K. Fufaeva[9]; Z. Bottaeva[9]; P. Maurer-Karattup[10]; C. Aubinet[1]
[1]*Coma Science Group, GIGA Consciousness, University of Liège, Belgium;* [2]*Department of Speech-Language Pathology, Faculty of Psychology and Educational Sciences, University of Liège, Belgium;* [3]*Hospital Mater Dei, Day Centres, Elderly Homes, Msida, Malta;* [4]*IRCCS Fondazione Don Carlo Gnocchi ONLUS, Florence, Italy;* [5]*Post-Coma Unit, IRCCS and Neuroreabilitation, Fondazione Santa Lucia, Rome, Italy;* [6]*Research Institute, Casa Colina Hospital and Centers for Healthcare, Pomona, CA, USA;* [7]*Department of Psychology, Psychology and Cognitive Neuroscience Research Unit, University of Liège, Belgium;* [8]*IRENEA-Instituto de Rehabilitación Neurológica, Fundación Hospitales Vithas, Valencia, Spain;* [9]*Clinical and Research Institute of Urgent Pediatric Surgery and Traumatology, Moscow, Russian Federation;* [10]*SRH Fachkrankenhaus Neresheim, Neresheim, Germany*

Background and Aims: Patients with severe brain injury and disorders of consciousness (DoC) are unable to communicate and

frequently experience severe dysphagia. The DoC Special Interest Group of the International Brain Injury Association (IBIA) created a survey to identify the tools that are used by (speech-language) therapists, detect their needs and possibly identify new practices to improve language and swallowing rehabilitation in post-comatose patients.

Methods: The survey was developed based on the following structure: (1) Study presentation, (2) Socio-demographic information, (3) General questions regarding speech and language therapies (4) Swallowing assessment and management, (5) Language/communication assessment and management, and (6) Conclusion. The English questionnaire was then translated into 6 other languages, transferred to the Alchemer platform, and massively diffused.

Results: Preliminary data highlight the profile of therapists involved in the rehabilitation of language and swallowing abilities after coma, their degree of concern regarding the assessment and management of such abilities in this specific population, their recommendations as well as the tools they preferentially use in their practice.

Conclusion: This survey highlights the lack of guidelines for speech-therapy practice in patients with severe brain injury and DoC. Early and long-term assessment and management of both language and swallowing abilities should be improved, notably by providing (and/or adapting) new clinical tools.

Disclosure: Nothing to disclose.

EPO-447 | Hyperintense basal ganglia on T1-MRI in two patients with elevated serum manganese due to cirrhosis

A. Tüfekçi[1]; S. Şahin[2]

[1]*Department of Neurology, Faculty of Medicine, Recep Tayyip Erdogan University, Rize, Turkey*; [2]*Department of Neurology, Faculty of Medicine, Recep Tayyip Erdogan University, Rize, Turkey*

Background and Aims: Hepatic encephalopathy is a neuropsychiatric complication of acute or chronic liver disease with symptoms ranging from mild confusion to coma. The pathophysiology of hepatic encephalopathy is multifactorial, ammonia, manganese deposition and inflammation are thought to lead to astrocyte swelling and brain edema. Studies have shown that in patients with end-stage liver disease, increased serum manganese level causes manganese to accumulate in the basal ganglia.

Methods: Patient 1. A 68 -year -old female patient had a diagnosis of liver cirrhosis secondary to non- alcoholic steatohepatity and twice history of hepatic encephalopathy attacks. Neurological examination was unremarkable. The serum manganese level was high and the magnetic resonance images had T1 basal ganglion hyperintensity. Patient 2. A 65 -year -old male patient was detected amnesia, disorientation of time and space and psychomotor retardation. His serum manganese level was high and the magnetic resonance images had T1 basal ganglion hyperintensity. Liver cirrhosis was diagnosed after the investigations.

Results: Studies have shown a significant correlation between serum manganese levels and T1 basal ganglia hyperintensity seen on MRI, but no correlation between serum manganese and liver function or neurological findings has been demonstrated. Also, there is no correlation between T1 basal ganglia hyperintensity and neurological findings.

Conclusion: It would be useful to evaluate brain MRI and serum manganese levels in the hepatic encephalopathy clinic in patients with cirrhosis.

Disclosure: Nothing to disclose.

EPO-448 | Epileptic seizures in prolonged disorders of consciousness: Preliminary data of an Italian multicentre study

B. Hakiki[1]; A. Grippo[1]; S. Pancani[1]; A. Romoli[1]; F. Draghi[1]; D. Maccanti[1]; A. De Nisco[1]; T. Toci[1]; R. Burali[1]; M. Scarpino[1]; A. Magliacano[2]; A. Estraneo[2]; A. Comanducci[3]; J. Navarro[3]; C. Tramonti[4]; P. Baldi[4]; C. Macchi[1]; F. Cecchi[1]

[1]*IRCCS Fondazione Don Carlo Gnocchi ONLUS, Firenze*; [2]*Polo Specialistico Riabilitativo, Fondazione Don Carlo Gnocchi, Sant'Angelo Dei Lombardi*; [3]*IRCCS "S. Maria Nascente" – Fondazione Don Carlo Gnocchi, Milano*; [4]*Polo Riabilitativo del Levante Ligure, Fondazione Don Carlo Gnocchi, La Spezia*

Background and Aims: The occurrence of late-onset epileptic seizures (LES) and epileptiform abnormalities (EA) in prolonged Disorders of Consciousness (pDoC) was poorly and inconsistently reported across studies1. Our aim is to explore the LES/AE prevalence and their influence on consciousness recovery 3 months after admission to rehabilitation units (RUs) in pDoC.

Methods: This analysis was performed in the Italian multicentre PRABI study framework2 including only patients with a pDoC. At admission, the repeated Coma Recovery Scale-Revised-CRS-R and a standard electroencephalogram were performed3. The occurrence of LES was monitored during the RUs stay. The Disability Rating Scale-DRS, the Glasgow Outcome Scale Extended- GOSE and the CRS-R was performed at 3 months.

Results: One hundred eighty-six patients were enrolled (Table 1). At admission, patients presenting LES and/or EA were those with a higher Cumulative Illness Rating Severity Scale at admission ($p = 0.040$) and a higher Acute ES probability ($p = 0.008$). At 3 months, these patients reached lower scores of CRS-R ($p = 0.004$), DRS ($p < 0.001$), and less frequently a GOSE > 5 ($p = 0.03$)). The univariate and multivariate analyses showed the Minimally Conscious State instead of Unresponsive wakefulness syndrome, a lower time post onset, and the absence of LES during the RUs stay were associated with a higher probability to recover consciousness at 3 months (Table 3).

EPO-449 | Prognostication after cardiac arrest: Which is more accurate EEG or ERPs?

I. Holečková; J. Valeš; D. Štěpánek; V. Přibáň
Department of Neurosurgery, University Hospital and Faculty of Medicine UK, Plzeň, Czechia

Background and Aims: Neurophysiological investigations (ERPs and EEG) occupy major place among the tools available for prognostication the patients resuscitated from CA (cardiac arrest). We tested the relationships between neurological outcome after CA (measured by GOS) and ERPs and EEG results measured in coma patient's state.
Methods: All 27 patients (17 men, 10 women, mean age 64 ± 15 years) were enrolled prospectively during the ICU admission after CA. Bedside EEG (standard 19/25 EEG channel system according to the 10-20 system) and ERPs – P3 (with patients own name as deviant stimulus) was recorded in the same day within 4-8 days of CA in unsedated patients who were still comatose during the examination. The resulting state was assessed between 30 - 64 days after arrest by GOS. The PPV, NPV, sensitivity and specificity of EEG (4 patterns) and ERPs – P3 own name (absence, presence) in relation to GOS were calculated.
Results: The presence of ERPs - P3 own name had a high specificity (81%) and sensitivity (67%) for GOS 4-5. Absence of P3 own name also had high specificity (67%) and sensitivity (81%) for GOS 1-2. EEG pattern burst suppression and low voltage pattern had high specificity (90%) but low sensitivity (43%) for GOS 1-2. The delta/theta EEG pattern had low sensitivity (33%) and specificity (33%) for GOS 1-2.
Conclusion: Therefore, ERPs – P3 own name appear to be more advantageous than EEG for prognostication of patients after CA.
Disclosure: Nothing to disclose.

EPO-450 | Quantum 123 pattern: A new quantum graph-based encephalopathy detection using EEG signals

I. Tasci[1]; T. Tuncer[2]; B. Tasci[3]; S. Dogan[2]; G. Akca Tasci[4]; C. Demir[1]
[1]Firat University/Medical School, Department of Neurology, Elazig, Turkey; [2]Firat University/Department of Digital Forensics Engineering, College of Technology, Elazig, Turkey; [3]Firat University/Vocational School of Technical Sciences, Elazig, Turkey; [4]Fethi Sekin State Hospital/Department of Psychiatry, Elazig, Turkey

Background and Aims: The primary aim of our study is to explore the capability of machine learning in detecting encephalopathy through the analysis of electroencephalography (EEG) signals. To achieve this, we have introduced a novel quantum-inspired feature extractor and a self-organized feature engineering model.
Methods: In this investigation, we retrospectively gathered a substantial EEG signal dataset from Firat University Hospital. The dataset consists of two classes: (i) encephalopathy and (ii) no-findings/control. EEG signals were acquired from 54 participants using a multichannel EEG device and segmented into 15-second intervals. For automated encephalopathy detection, our proposed self-organized feature engineering model comprises four main phases: (1) Quantum 123 Pattern (Q123Pat) feature extraction, utilizing a graph resembling quantum circuits to select the most suitable feature extraction method based on the EEG signal structure; (2) feature selection with the neighborhood component analysis feature selector to identify the most informative features; (3) classification using k-nearest

neighbors and support vector machine classifiers; and (4) information fusion employing iterative majority voting and selecting the best outcome with a greedy algorithm. The Q123Pat-based self-organized model was applied to each EEG channel, and the results were used to generate a semantic cortex map.

Results: The proposed Q123Pat-based self-organized model achieved an impressive 97.96% classification accuracy, facilitating the identification of the most informative channels.

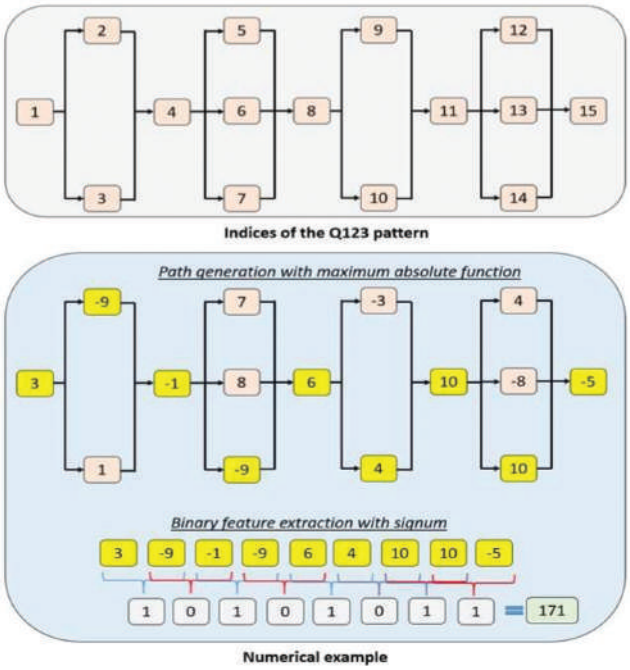

FIGURE 1 The proposed Q123 pattern. In this graph, there are 36 (=1×2×3×1×2×3) patterns, and the most suitable pattern has been selected using the maximum absolute function.

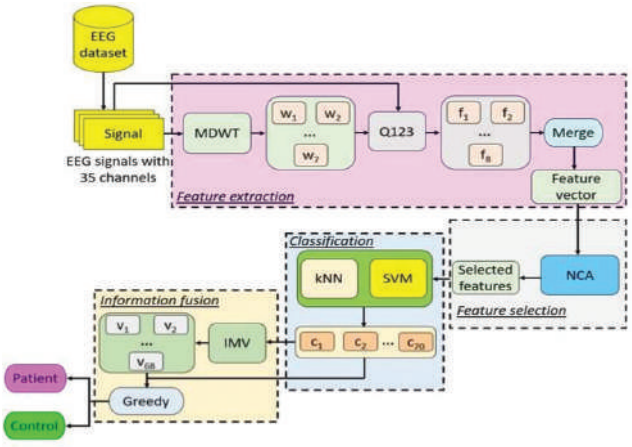

FIGURE 2 Graphical explanation of the proposed Q123-based model. Herein, MDWT: multilevel discrete wavelet transform, w: wavelet band, f: individual feature vector, NCA: neighborhood component analysis, kNN: k-nearest neighbors, SVM: support vector machine.

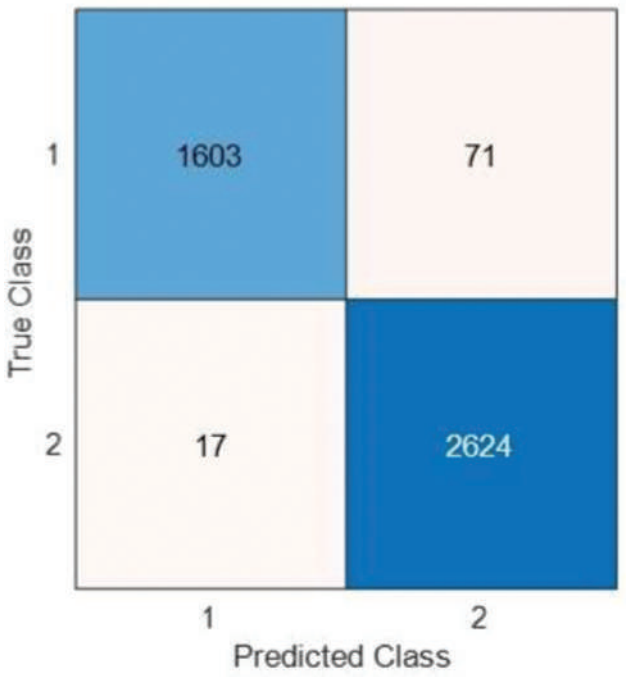

FIGURE 3 Confusion matrix of the final result. Herein, 1: Encephalopathy, 2: No-finding. Per this confusion matrix, the calculated classification performance metrics have been given follows. Accuracy: 97.96%, sensitivity: 95.76%, specificity: 99.36%, precision.

Conclusion: The computed classification performances unequivocally demonstrate the ability of machine learning models to detect encephalopathy using EEG signals. Furthermore, our model provides interpretable results about the cortex by generating a cortex map based on the classification performances of each channel.

Disclosure: Nothing to disclose.

EPO-451 | Exploring the neurophysiological effects of combined electrical and auditory stimulation in healthy subjects

M. Louras[1]; R. Panda[1]; A. Soria-Frisch[2]; R. Salvador[2]; G. Ruffini[2]; M. Nitsche[3]; S. Laureys[1]; M. Carrière[1]; G. Martens[1]; N. Lejeune[1]; A. Thibaut[1]

[1]*Coma Science Group, GIGA-Consciousness, University of Liège, Liège, Belgium;* [2]*Starlab Barcelona SL, Barcelona, Spain;* [3]*Department Psychology and Neurosciences, Leibniz Research Centre for Working Environment and Human Factors, Dortmund, Germany*

Background and Aims: Today, effective treatments for patients suffering from disorders of consciousness are lacking. Transcranial direct current stimulation (tDCS) and music have both shown promise in enhancing signs of consciousness. Given the potential for tDCS effects to be enhanced by complementary stimuli, this study aims to investigate its combination with music in a cohort of healthy participants at the cognitive and neurophysiological levels.

Methods: This randomized controlled double-blind crossover study involved four stimulation conditions: tDCS combined with music (tDCS/music) or white noise (tDCS/noise), and sham-tDCS with music (sham-tDCS/music) or white noise (sham-tDCS/noise), which were applied to 24 healthy human adults (<35 years old). Participants' performance (i.e., accuracy and time response) on Stroop and 3-back cognitive tests was measured before and after each condition. A 20-channel electroencephalogram explored the neurophysiological effects of the interventions.

Results: Cognitive performance (behavioral measures) and power spectral analyses revealed no significant differences between the interventions. A significant increase in global connectivity in the alpha band was found in post- compared to pre-intervention in music ($p=0.0026$) and tDCS/music ($p=0.0028$) conditions. The other conditions did not show any significant changes.

Conclusion: Overall, these findings suggest that a single tDCS session combined with music does not enhance cognitive functions in healthy subjects. However, music alone or combined with tDCS exhibited promise in increasing brain activity associated with cognitive performance. Further research, particularly involving multiple sessions of tDCS with or without music, is necessary to better understand the potential of these interventions, especially in patients with disorders of consciousness.

Disclosure: Nothing to disclose.

EPO-452 | A closed-loop EEG-tDCS approach to improve responsiveness of patients in minimally conscious state

M. Khosravi[1]; A. Barra[1]; G. Martens[1]; D. Ibáñez-Soria[2]; K. Chugani[2]; A. Soria-Frisch[2]; A. Piarulli[3]; O. Gosseries[1]; N. Lejeune[1]; R. Salvador[4]; E. Kroupi[2]; M. Nitsche[5]; S. Laureys[1]; G. Ruffini[4]; A. Thibaut[1]

[1]Coma Science Group, GIGA Consciousness, University of Liège, Liège, Belgium; [2]Starlab Barcelona SL, Barcelona, Spain; [3]Department of Surgical, Medical, Molecular and Critical Area Pathology, University of Pisa, Italy; [4]Neuroelectrics, Barcelona, Spain; [5]Department of Psychology and Neurosciences, Leibniz Research Centre for Working Environment and Human Factors, Dortmund, Germany

Background and Aims: Previous studies have reported mixed effects of transcranial direct current stimulation (tDCS) in patients in a minimally conscious state (MCS). Considering the potential impact of vigilance level on the effectiveness of stimulation, we aimed to compare the efficacy of closed-loop tDCS applied during high, low, and random levels of vigilance (based on online entropy measurements) in MCS patients.

Methods: In this double-blind randomized clinical trial, we aim to include 16 MCS patients. Each patient received three stimulation sessions (2mA for 20 minutes) over the left dorsolateral prefrontal cortex (DLPFC) at high, low, and random levels of vigilance, five days apart. Real-time analysis of spectral entropy was performed using a Starstim 20 EEG-tDCS closed-loop system which determined the triggering time of stimulation based on vigilance level. Patients were evaluated using the Coma Recovery Scale-Revised (CRS-R) before and after each session, together with a 15-minute EEG. Pre- and post-tDCS CRS-R scores were compared using Wilcoxon test.

Results: We included 13 MCS patients (mean age 48±18 years, 5 females). Median CRS-R score for high vigilance stimulation was 11 (8-15) before, and 12 (10-15.25) after stimulation ($p=0.037$). The median pre- and post-stimulation CRS-R scores were not significantly different for the low vigilance (11 [8-15] vs. 11 [8-16], $p=0.88$) and random vigilance groups (10 [8-15] vs. 11 [8-17], $p=0.33$).

Conclusion: These preliminary results suggest that stronger effects of tDCS over the left DLPFC in patients with MCS might be achieved if applied at high vigilance levels. This needs to be confirmed with the entire sample ($n=16$), where EEG data will also be analyzed.

EPO-453 | Ketamine to treat disorders of consciousness: A feasibility study

P. Cardone[1]; A. Bonhomme[1]; V. Bonhomme[2]; N. Lejeune[1]; C. Staquet[2]; A. Defresne[2]; N. Alnagger[1]; P. Ezan[3]; M. Lee[4]; A. Piarulli[5]; S. Van Goethem[6]; J. Montupil[2]; A. Thibaut[1]; C. Martial[1]; O. Gosseries[1]

[1]Coma Science Group, GIGA-Consciousness, University of Liège, Belgium; [2]Anesthesia and Perioperative Neuroscience, GIGA-Consciousness, University of Liège, Belgium; [3]Psychedelic Society Belgium; [4]Department of Biomedical Software Engineering, The Catholic University of Korea, Bucheon, Korea; [5]Department of Surgical, Medical, Molecular, Pathology and Critical Care Medicine, University of Pisa, Pisa, Italy; [6]William Lennox Rehabilitation Center, Ottignies, Belgium

Background and Aims: Patients with post-comatose disorders of consciousness (DoC) have few treatment options, making the investigation for new ones fundamental. We present the results of a feasibility study using sub-anaesthetic doses of ketamine in DoC patients. Ketamine increases brain complexity, and this, according to several theories, should ameliorate DoC consciousness level.

Methods: We ran a double-blind, placebo-controlled, cross-over study (Figure 1) on 3 male patients with DoC (UWS, 32yo, TBI; MCS-, 50yo, subarachnoid haemorrhage; MCS+, 62yo, CO intoxication). We administered increasing concentration of ketamine or placebo intravenously (maximal concentration: 0.75 μg mL-1; steps of 0.15 μg mL-1) in two sessions within a week. Consciousness was assessed behaviourally using the Simplified Evaluation of CONsciousness Disorders (SECONDs). We tested spastic paresis with the Ashworth-Modified Scale (MAS) for two patients. Simultaneously, we recorded EEG (BrainVision, 128Ch) to measure whole-brain complexity with broadband Lempel-Ziv complexity (LZC).

Results: The UWS patient showed a response to a verbal command once during ketamine, which was not observed during placebo nor at baseline. All patients spent more time with eyes open. Spasticity decreased in all three patients after ketamine (Figure 2). No carry-over effects or adverse effects were observed. LZC increases during ketamine (Figure 3).

Conclusion: We demonstrated that ketamine can be safely administered to people with DoC, that it increases arousal and decreases spasticity. Other changes in behaviour should be investigated in a large-scale randomized controlled trial. Ketamine increases LZC in DoC, like what observed in healthy participants.

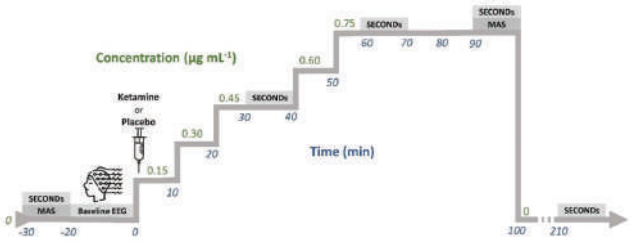

FIGURE 1 Protocol: Visual representation of one session. We assessed behavior via the SECONDs, and spastic paresis with the MAS. During the whole experiment, we recorded the brain activity using high-density EEG. The second session would take place with.

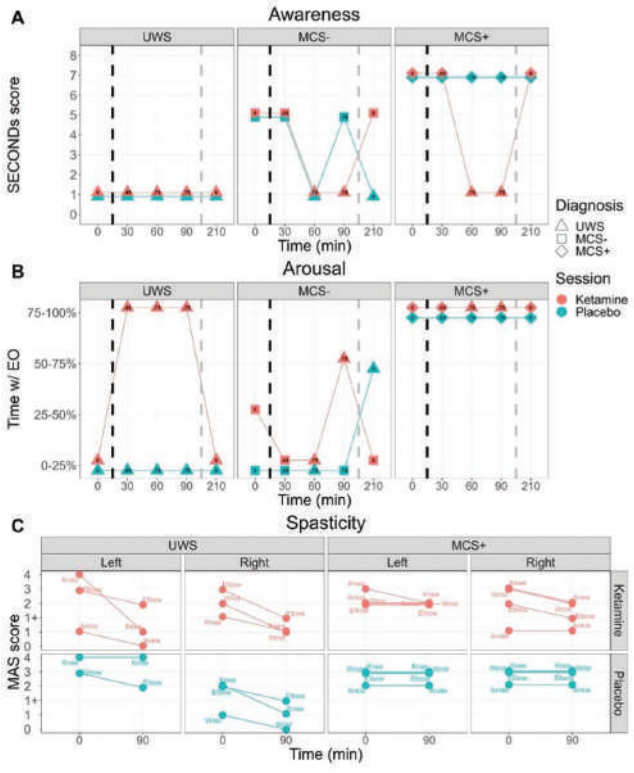

FIGURE 2 Behavioral results. A: SECONDs scores following infusion of ketamine and placebo. UWS scoring are represented as triangles, MCS- as squares, MCS+ as diamonds. For representational purposes, ketamine scores were increased by 0.1, and placebo ones.

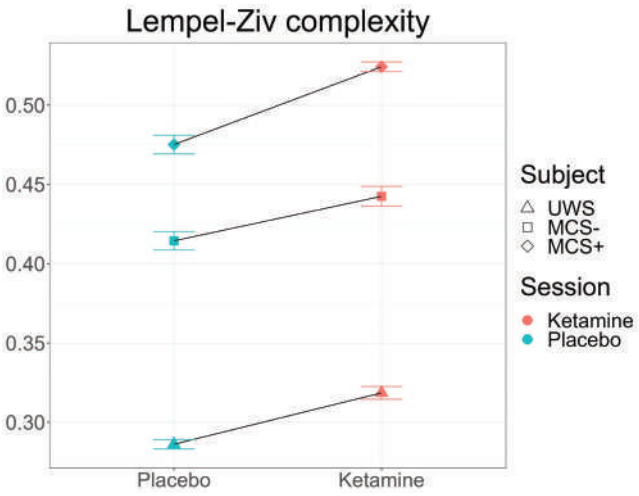

FIGURE 3 Brain Complexity: Distribution of brain complexity measured via whole-brain LZC shown for placebo and ketamine for each patient. Standard errors are calculated over electrodes.

EPO-454 | Reflex eye-opening response in brain death

O. Brengaret Mata[1]; G. Mayà[1]; A. Muñoz-Lopetegi[1]; À. Iranzo[1]; C. Gaig[1]; J. Osorio Trujillo[2]; J. Santamaria[1]

[1]*Neurology Department, Hospital Clinic de Barcelona and Universitat de Barcelona, Barcelona, Spain;* [2]*Pneumology Department, Hospital Clinic de Barcelona and Universitat de Barcelona, Barcelona, Spain*

Background and Aims: The diagnostic criteria of brain death include unreactive coma with absent brainstem reflexes. Pain stimulation should not produce responses attributed to the cranial nerves.

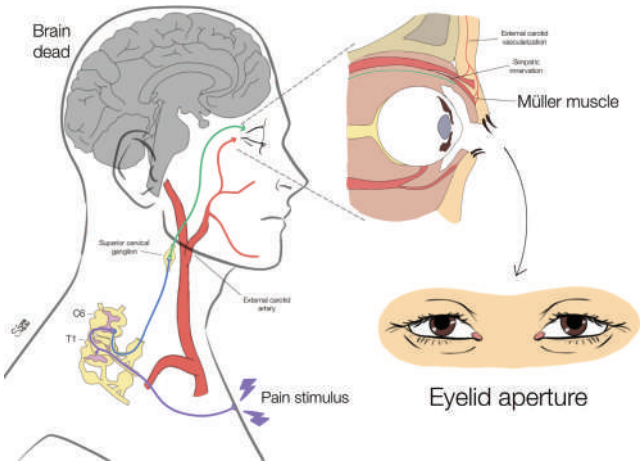
Methods: We report the case of a brain-dead patient with bilateral, slow, partial eyelid opening driven by the autonomic sympathetic response to painful stimulation.

Results: A 41-year-old man was admitted to the ICU after a prolonged cardiorespiratory arrest due to a pulmonary thromboembolism. The neurological examination without sedation after 36 hours revealed a deep unreactive coma and absent brainstem reflexes. However, with bilateral painful nipple stimulation, the patient showed a slow bilateral, partial eyelid elevation, without pupillary size changes and a lack of any motor response. Brain-CT scan revealed extensive hypoxic-ischemic lesions, median nerve somatosensitive evoked potentials showed bilateral absence of thalamocortical responses and the EEG was isoelectric. The patient was diagnosed with brain death.

Conclusion: Eye-opening is determined by the combined action of voluntary and involuntary muscles, the eyelid elevator and the Muller's muscle respectively. The eyelid elevator is innervated by the third cranial nerve originating in the mesencephalon and so, its irrigation depends on the intracranial circulation. In contrast, Muller's

muscle is innervated by the sympathetic autonomic nervous system through the petrosal and viridian nerves originating in the superior cervical ganglion, which are irrigated by external carotid artery branches that do not depend on intracranial circulation. Therefore, slow eyelid elevation driven by Muller's muscle may occur in brain-dead patients due to a pain-induced activation of the sympathetic nervous system.

Image 1 and 2: Slow bilateral, partial eyelid elevation response to bilateral painful nipple stimulation.



Anatomy of the sympathetic pathway of Müller's muscle.

EPO-455 | **Dynamic network analysis reveals lower temporal variability of functional connectivity at unconsciousness**

B. Hakiki[1]; D. Bartolini[1]; P. Liuzzi[1]; A. Romoli[1]; F. Draghi[1]; D. Maccanti[1]; R. Burali[1]; T. Toci[1]; M. Scarpino[1]; A. De Nisco[1]; A. di Palma[1]; A. Grippo[1]; C. Macchi[2]; F. Cecchi[1]; A. Frosini[3]; A. Mannini[1]
[1]IRCCS Fondazione Don Carlo Gnocchi ONLUS; [2]Dipartimento di Medicina Sperimentale e Clinica, Università di Firenze; [3]Dipartimento di Matematica, Università di Firenze

Background and Aims: Severe Acquired Brain Injuries (sABI) may disrupt networks sustaining arousal and awareness, the two essential components of consciousness leading to atypical connectivity in such cortical/subcortical networks [1]. This study aims to use low-density EEG and its high temporal resolution to estimate the temporal variability of functional connectivity in prolonged Disorders of Consciousness (pDoC).

Methods: This analysis has been made in the framework of the PRABI study [2] including sABI patients in intensive rehabilitation unit. Consciousness was diagnosed with repetitive Coma Recovery Scale Revised assessments grouping patients between pDoC and emerged sABI patients. EEG was pre-processed following the PREP pipeline [3]. Debiased weighted Phase Lag Index was computed in the α, θ, and δ bands, at different connection (60%,70%,80%) and electrodes (6, 9, 15, and 19) densities. Burstiness, estimated via the coefficient of variation of the inter-contact times vector (i.e., temporal difference between two consecutive edges in a binarized adjacency matrix) was compared between groups (Mann-Whitney tests), Fig.1.

Results: Two-hundred seventeen sABI patients (median age of 62 years old [IQR = 17.6]; 79 (36.4%) females; 121 (46.4%) eMCS) were included (Tab.1). No significant differences were found for what concerns age, sex, and etiology between the two groups ($p > 0.05$). Burstiness was always found to be negative, leading to non-bursty TVGs. However, emerged patients showed larger periodic temporal

EPO-456 | CSF hydrodynamics in prolonged disorders of consciousness

E. Schmidt[1]; J. Pickard[2]; S. Silva[3]

[1]*Department of Neurosurgery, University of Toulouse, France;*

[2]*Department of Neurosurgery, University Hospital Cambridge, UK;*

[3]*Department of Intensive Care, University Hospital of Toulouse, France*

Background and Aims: Prolonged (i.e. >1 month) disorders of consciousness (PDOC) after brain injury is a major public health problem. Advances in intensive care allow patients to survive after brain injury, however, one third of patients do not regain consciousness. To date, no specific treatment has been shown to be effective in restoring consciousness. Brain imaging in PDOC patients often shows cerebral atrophy and ventriculomegaly, suggesting hydrocephalus due to impaired intracranial fluid circulation. Controversies remain about how to diagnose hydrocephalus in PDOC patients and whether to propose CSF diversion. We hypothesise that CSF hydrodynamics is relevant to better identify hydrocephalus in PDOC patients.

Methods: We retrospectively analysed 41 patients (26M/15W) with i) acute brain injury, ii) PDOC and iii) ventriculomegaly (i.e. Evan's ratio >0.3). These hydrocephalus-suspected PDOC patients were studied with a lumbar infusion test to measure CSF hydrodynamics using ICM+.

Results: Acute brain injury was related to: head trauma (17), subarachnoid haemorrhage (16), intracerebral haematoma (6), cardiopulmonary arrest (1), metabolic (1). The mean CSF outflow resistance (Rcsf) was increased (i.e. ≥12 mmHg/ml/min, see Table 1). 20 patients (49%) had increased Rcsf (i.e. ≥12 mmHg/ml/min above the dashed line) several months (up to 40 months) after brain injury (see Figure 1).

	Age (year)	Time between brain injury and insufion test (month)	ICP baseline (mmHg)	Pulsatility baseline (mmHg)	ICP plateau (mmHg)	Pulsatility plateau (mmHg)	Rcsf (mmHg/ml/min)
Mean	**53,7**	**12,8**	**9,59**	**0,65**	**25,26**	**2,34**	**16,26**
Median	**57,4**	**6,9**	**9,48**	**0,47**	**25,82**	**1,57**	**11,88**
SD	17,5	18,7	3,34	0,54	11,21	1,80	13,34
Min	17,2	0,8	2,66	0,04	1,65	0,11	0,80
Max	79,4	104,9	19,26	2,25	55,05	7,58	50,00

TABLE 1

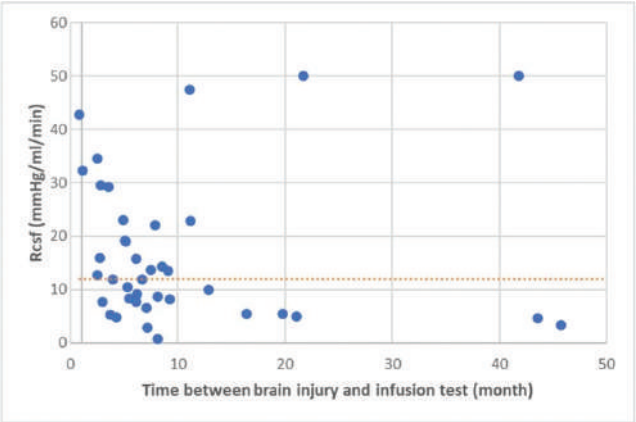

FIGURE 1

Conclusion: Half of the patients with PDOC and ventriculomegaly exhibit altered CSF hydrodynamics. Rcsf seems to be a useful metric that should be implemented in the management algorithm of PDOC patient to better advocate for CSF diversion when hydrocephalus is suspected, even months or years after brain injury.
Disclosure: None.

Infectious diseases

EPO-457 | Meningitis infection: Epidemiological analysis of the disease outcome among Brazilian regions

A. Grande[1]; G. Garute Zenatti[2]; A. Wosniacki Filho[2]; I. Darella Lorenzin Fernandes Neto[2]; R. Endler Iachinski[2]
[1]*Assis Gurgacz University Center – FAG, Cascavel, Paraná, Brazil;* [2]*São Lucas Hospital Center, Cascavel, Paraná, Brazil*

Background and Aims: A large number of pathogens cause Meningitis infection (MI), which accounts for more than 200,000 deaths and 2.5 million cases globally in 2019. After introducing the Meningococcal C vaccine into the national vaccination program (1975), Brazil's incidence and mortality rate has decreased over the years.
Methods: Data were available on the National Notifiable Diseases Information System (SINAN). The different outcomes and male/female rate (M/F) among Brazilian regions were searched from 2012-2023.
Results: MI total cases from 2012-2023 was 158,111, 58.83% male (M/F rate = 1.42). The Southeast region leads with 53.72% (*n* = 84,953), followed by the South, Northeast, North, and Central-West (% = 4.85). The M/F rate medium value was 1.45, highest in the Northeast (M/F = 1.5) and lowest in the Southeast (M/F = 1.93). The discharge rate was 0.85 (*n* = 134,633). Death by MI rate was 0.10 (*n* = 16,116), with an increase observed in the North (% = 15.64) and Central-West regions (% = 13.02), followed by the Northeast, Southeast, and South. Death with MI but by other causes rate was 0.04 (*n* = 7,362), of which 75.4% was distributed in the Southeast (% = 44.41) and South (% = 30.99).

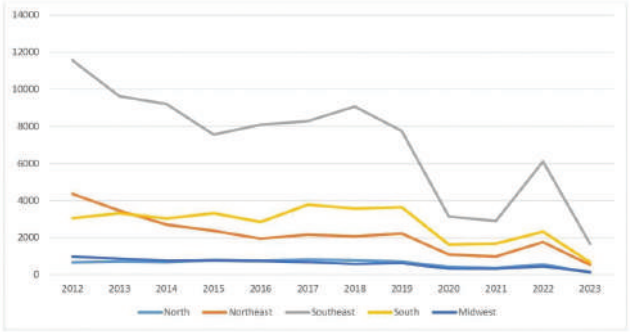

FIGURE 1 Total cases per year between regions.

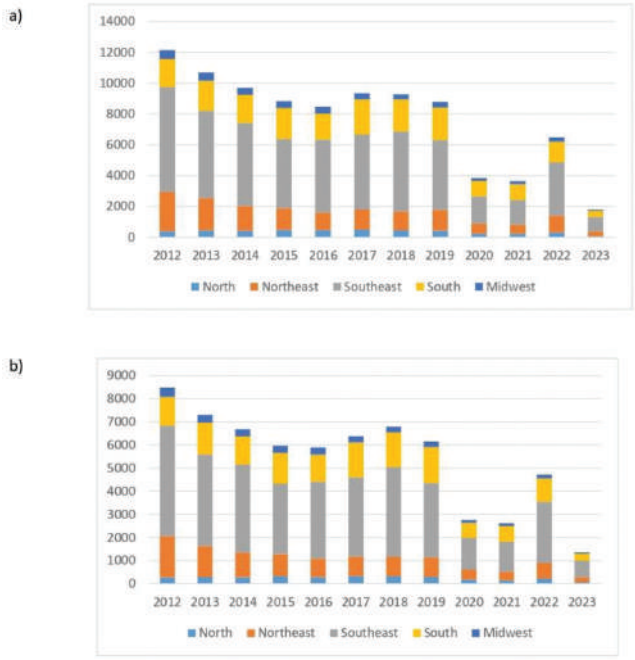

FIGURE 2 (a) Male cases between regions; (b) Female cases between regions.

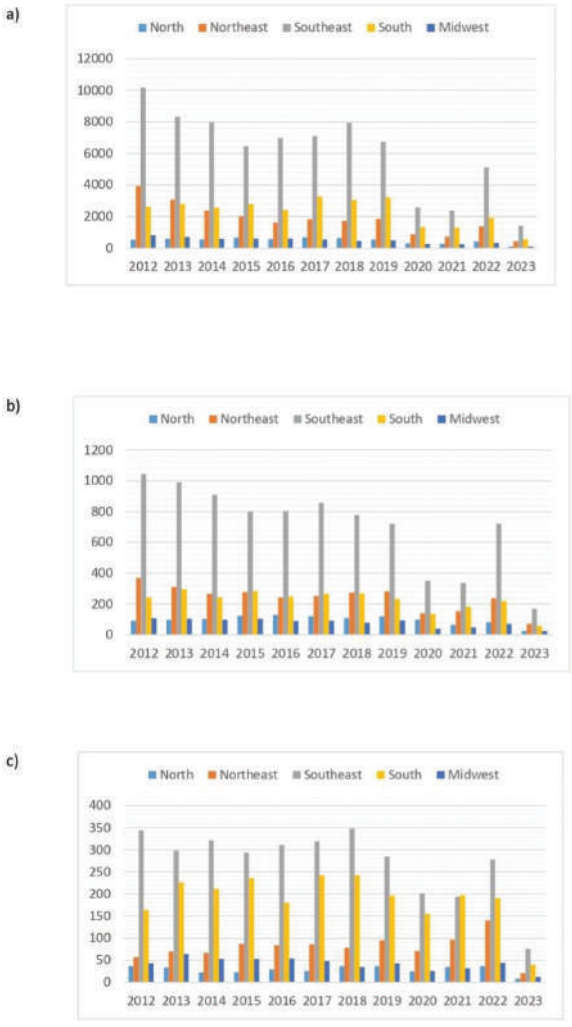

FIGURE 3 (a) Discharge cases between regions; (b) Death by MI between regions; (c) Death by other causes between regions.

Conclusion: A decrease in cases was observed in all regions. Whereas its largest population, the highest prevalence of cases and discharge rate was in the Southeast but it was not the same in the mortality rate, led by the neediest one, North.
Disclosure: Nothing to disclose.

EPO-458 | Dengue-induced acute cerebellitis

A. Grande[1]; A. De Barros Coelho Brandalise[1]; A. Wunsch Dias[1]; G. Garute Zenatti[2]; A. Wosniacki Filho[2]; I. Darella Lorenzin Fernandes Neto[2]; R. Endler Iachinski[2]
[1]Assis Gurgacz University Center – FAG, Cascavel, Paraná, Brazil; [2]São Lucas Hospital Center, Cascavel, Paraná, Brazil

Background and Aims: The incidence of dengue has grown exponentially in recent years and has been associated with several neurological complications, with cerebellar involvement being one of the rarest of them, with few cases found in the literature.
Methods: We present an atypical case, occurring in the south of Brazil, of dengue fever, associated with cerebellar syndrome in a 10-year-old child.
Results: A 10-year-old child admitted due to a change in gait 3 days ago. Medical history of herpetic encephalitis associated with gait alteration, fever, and emesis 1 month ago, treated with IV Acyclovir for 15 days and with total clinical improvement. No comorbidities, medication, or allergies and no family history of neurological diseases. 15 days later, presented with fever and emesis, and after 2 days, gait alterations. Clinically stable on first assessment, complaining of mild headache and gait ataxia. No acute alterations on neuroaxis MRI and CSF. NS1 (Dengue) laboratory test was positive. After a neuropediatrician consult was suggested a post-infectious cerebellitis induced by the Dengue virus. After 5 days of Dexamethasone, analgesics, and antiemetics treatment, the patient had progressive improvement in both clinical and motor conditions and was discharged for follow-up care at an outpatient clinic.

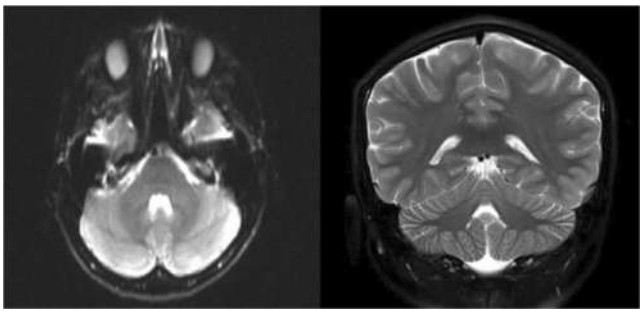

FIGURE 1 Magnetic resonance showing brain parenchyma with usual morphology and signal intensity for the age group.

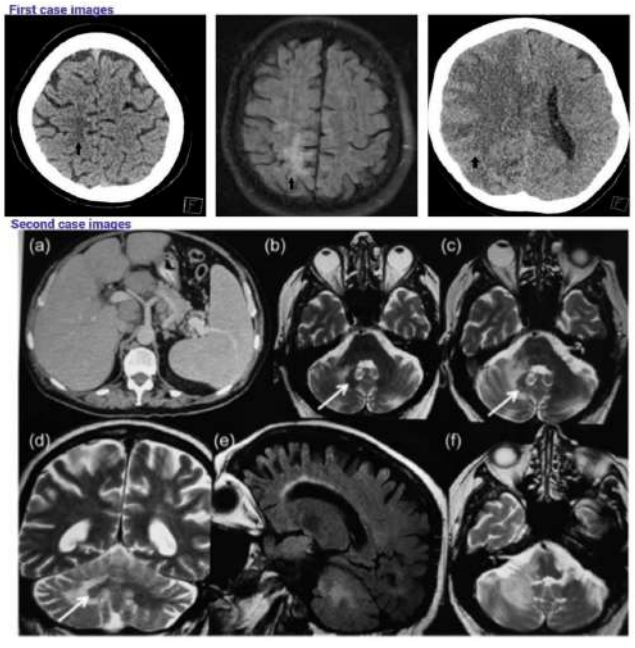
Conclusion: Cerebellar syndrome in children after or during dengue fever is a rare case, being one of the first cases to be reported in the literature until this report was produced. Therefore, it is important to recognize atypical clinical conditions so that the best measures can be taken early without leaving consequences.
Disclosure: Nothing to disclose.

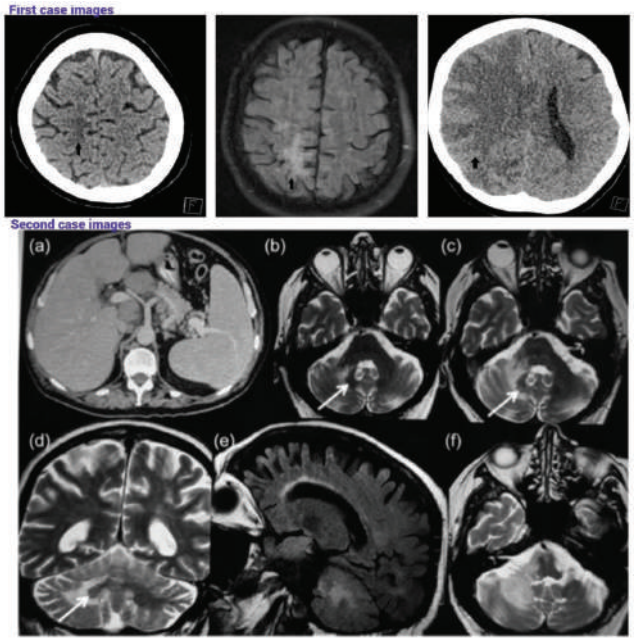
EPO-459 | Unveiling the Mimic: Progressive multifocal leukoencephalopathy presenting as acute ischemic stroke – A dual case report

A. Ali[1]; M. Khan[1]; S. Munshi[1]; M. Nawaz[2]; S. Saleem[2]; S. Sewilam[3]
[1]Nottingham University Hospitals; [2]Sandwell and West Birmingham Hospitals; [3]Torbay and South Devon NHS Foundation Trust

Background and Aims: Progressive multifocal leukoencephalopathy, a demyelinating infectious disorder of the CNS, is seen in immunocompromised individuals with a history of AIDS, hematologic malignancies, or immunosuppressive drug therapy. We present two cases where patients initially diagnosed with acute ischemic stroke were later identified to have PML, as their symptoms mimicked stroke manifestations.
Methods: 1- A 56-year-old woman experienced left-sided numbness escalating to severe weakness in three days. Admission revealed an NIHSS score of 8 and imaging displayed enhancement along the right parietal gyrus. Whole-body CT raised suspicion of haematological malignancy. Inconclusive tumour marker assessment prompted a PML investigation, confirmed by JC Virus. Unexpectedly, HAART initiation led to IRIS, complicating the clinical course. Despite interventions, rapid deterioration ensued with IRIS-related complications. 2-A 79 a patient who present a stroke unit with symptoms that were consistent initially with a posterior circulation stroke. Prior chemotherapy with Rituximab, for a lymphoma, had predisposed the patient to infection with the JC virus.



CT scans and MRI findings



CT scans and MRI findings

Results: PML's subacute presentation can mimic a stroke, emphasizing the importance of understanding its background and potential complications, particularly in patients with HIV/AIDS or other immunocompromised conditions. Delayed diagnosis due to the absence of known immunocompromised status underscores the need for heightened awareness and early initiation of antiretroviral therapy.
Conclusion: In the complex realm of diagnoses, PML often masquerades as a stroke look-alike, demanding nuanced consideration in individuals with HIV/AIDS. Clinicians need a keen eye to distinguish between the two. Those undergoing Rituximab treatment should be made aware of the risk of opportunistic infections, including PML.
Disclosure: Nothing to disclose.

EPO-460 | Acute motor sensory axonal neuropathy as a presentation of Lyme disease

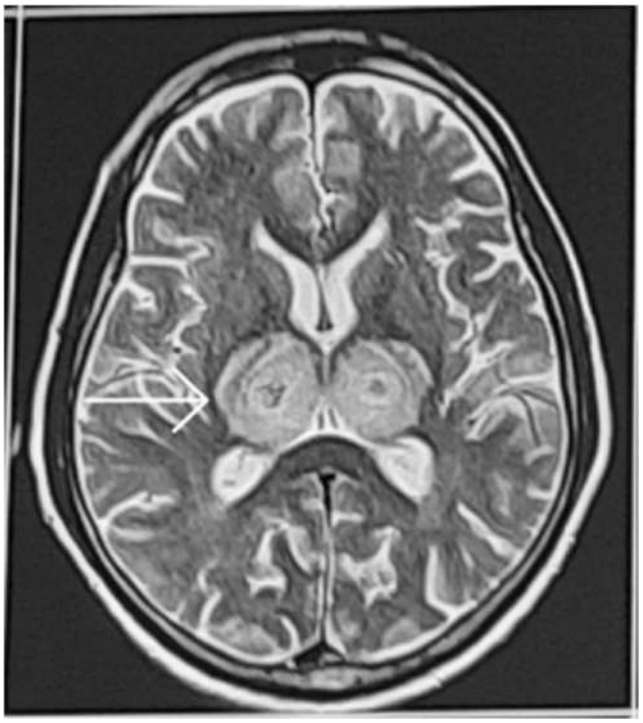
J. Alves; R. Guerreiro; R. Matos; C. Rosado; G. Bonifácio
Department of Neurology, Unidade Local Saude Arrabida EPE, Setubal, Portugal

Background and Aims: Neuroborreliosis affects up to 15% of patients with Lyme disease and usually presents as lymphocytic meningitis, facial nerve palsy or radiculoneuritis. Alternative neurological manifestations are possible, so this diagnosis may easily be overlooked.
Methods: A 36-year-old male, previously healthy, presented to the emergency room with abdominal pain radiating to the back, followed by speech changes, incoordination, diplopia, dysphagia, lower limb weakness, loss of sphincter control and respiratory failure needing invasive ventilatory support. Initial neurological assessment additionally revealed left peripheral facial palsy, flaccid areflexic quadriparesis (lower limbs MRC score 2, upper limbs score 4) and decreased pinprick on both feet. CSF analysis revealed 160 cells/μL (95% lymphocytes) and protein level of 268 mg/dL. Atypical Guillain-Barré Syndrome was assumed, and the patient was started on IV immunoglobulin therapy. Upon reassessment, on day 4 of IVIg, he was clinically worsened, quadriplegic and with ophthalmoparesis. Ceftriaxone was started empirically and then plasmapheresis, without clinical improvement.
Results: Laboratory workup revealed positive Borrelia burgdorferi antibodies in serum and CSF (IgG and IgM); EMG showed severe sensorimotor axonal polyneuropathy and spinal MRI presented with cauda equina roots and dorsal radicular emergences thickening and T1 enhancement following gadolinium administration. Neuroborreliosis was assumed and the patient completed a 4-week course of IV Ceftriaxone, with slow clinical improvement since.
Conclusion: Neuroborreliosis presents as a highly heterogenous, easily overlooked clinical entity, especially upon atypical manifestations. Awareness regarding this condition's many possible presentations is needed to prevent misdiagnoses and start prompt effective treatment, thus minimizing negative outcomes.
Disclosure: Nothing to disclose.

EPO-461 | Double doughnut over and above dengue dystonia

A. Kumar; D. Joshi; V. Singh; A. Pathak; R. Chaurasia; V. Mishra
Department of Neurology, IMS, BHU, Varanasi, India

Background and Aims: The clinical manifestations of dengue range from mild febrile illness to severe dengue shock syndrome and dengue hemorrhagic fever. Recently, its various neurological manifestations have been reported. Dystonia as early presentation in dengue is very rare.
Methods: None.
Results: Results: A 60-year-old male presented with high-grade fever for 5 days associated with arthralgias and myalgias. For the past 3 days, the patient developed gradual deterioration in the sensorium such that he could not communicate although he could comprehend and was lethargic on presentation. On day 4 of admission, he was observed to have developed generalized dystonia. His fever profile was positive for NS1 the (Non-structural protein 1) antigen of Dengue virus. He had raised levels of aspartate aminotransferase alanine aminotransferase and thrombocytopenia. His magnetic resonance imaging showed bilateral thalamic involvement with a “double doughnut sign”. His CSF analysis showed 5 cells with protein 92 mg/dl and sugar 60 mg/dl and opening pressure of 8 cm of water. It was negative for gram stain, CBNAAT for mycobacterium tuberculosis, cryptococcal antigen, and other neurotropic viruses. He was managed with benzodiazepines, tetrabenazine, and pulse steroid therapy. Gradually his dystonia subsided and he could articulate and was discharged in stable condition.



MRI Brain: shows T2 weighted MRI image with double doughnut sign with bilateral thalamic involvement.

Conclusion: A high index of suspicion especially in highly endemic countries required to suspect dengue dystonia. Double doughnut sign in MRI brain will help in identification. Morbidity in dengue dystonia can be reduced by early and prompt treatment.
Disclosure: Nothing to disclose.

EPO-462 | Challenging diagnosis of Creutzfeldt-Jakob disease with atypical early symptoms: A case series

C. Algar Ramírez; H. Antolí Martinez; D. Rodriguez Martínez; P. Dodu
Department of Neurology, Hospital Regional Universitario de Málaga, Málaga, Spain

Background and Aims: Creutzfeldt-Jakob disease (CJD) is a rapidly progressing neurodegenerative disorder whose classical presentation is characterized by the association of dementia, myoclonus and motor impairment in variable degree. However, atypical and non-specific presentations have been described, making the early clinical diagnosis difficult and challenging.
Methods: We present three cases admitted to a tertiary hospital after seeking emergency care for rapidly developing neurological abnormalities.
Results: The first patient experienced a decline in bilateral visual sharpness (Heidenhain variant). The second case showcased alien limb phenomenon, rigidity, cortical sensory loss and apraxia in the left upper limb, resembling a corticobasal syndrome. The third patient, upon examination, displayed restricted coordinated gaze, particularly in the vertical direction, accompanied by short steps and disrupted turns in walking, indicating a progressive supranuclear palsy. Diagnostic tests revealed: EEG findings consistent with paroxysmal focal activity, MRI with diffusion restriction in cortical áreas and fluid analysis showed positive 14-3-3 protein. These findings support the diagnosis of CJD.
Conclusion: The early manifestations of CJD with unusual symptoms are not extensively covered in scientific literature. Consequently, reviewing and underscoring the significance of promptly identifying these cases is essential for appropriate patient care. Results from additional tests may offer guidance in considering this prionic pathology.
Disclosure: Nothing to disclose.

EPO-463 | An atypical presentation of progressive multifocal leukoencephalopathy in a "well controlled" HIV patient

C. Ortega Hiraldo; A. Gómez González; A. Aguilar Monge; M. Vicente Domínguez; J. Sempere Fernández
Servicio de Neurología y Neurofisiología, Hospital Universitario Virgen de la Victoria, Málaga, España

Background and Aims: Progressive Multifocal Leukoencephalopathy (PML) is a demyelinating disease of the central nervous system caused by JC virus, typically seen in inmunocompromised patients. It affects white matter, giving magnetic resonance (MRI) images predominantly involving supratentorial matter. We report a case of PML in an HIV-patient under combination antiretroviral therapy (cART) with an atypical clinical and radiologic presentation, with predominance involvement of the brainstem and cerebellum.
Methods: Case report.
Results: A 46-years old male, HIV well controlled with cART for years, consulted for dizziness, nausea, gait and speech disturbance, that were developed progressively in the last 5 months. Neurological exploration revealed nystagmus, mild paresis of the left hand, right hypoesthesia, exalted reflexes predominantly on the left with Babinski's sign, as well as bilateral dysmetria and gait ataxia. Brain MRI showed T2-hyperintense and T1-hypointense lesions in cerebellar peduncles and pons, with no restricted-diffusion; and a small similar lesion in frontal lobes. Blood tests were normal, CD4 count was preserved, but an inverted CD4/CD8 ratio was observed; and CSF-fluid showed hyperproteinorrachia, with Flow-cytometry, cultures and typical virus PCRs negative. The patient experienced a rapidly progressive course, dying two months later. In the necropsy was diagnosed as PML, with lesions involving brainstem, cerebellum, spinal cord, and supratentorial regions.

T2 hyperintense lesions involving pons and both cerebellar penduncles.

The described lesions extends to the medulla.

Conclusion: Although PML is usually seen in severe immunocompromised patients affecting the supratentorial regions, the clinical and radiological presentation can be unusual sometimes. Furthermore, the presence of an inverted CD4/CD8 ratio is noteworthy as a possible marker of immune dysfunction in an apparently well-controlled HIV patient.

Disclosure: The authors do not have any disclosure of interests.

EPO-464 | Headaches and fever: Disseminated cryptococcosis in an immunocompetent patient: A case report

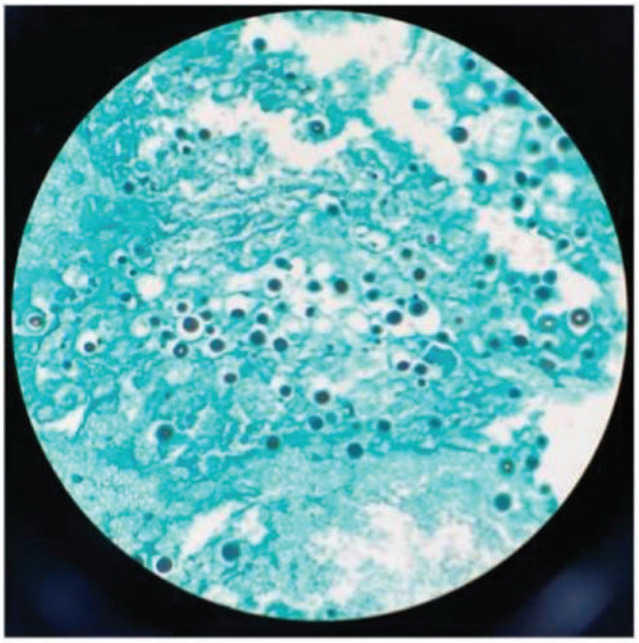
M. Alfonso

Internal Medicine, Amang Rodriguez Memorial Medical Center, Marikina City, Philippines

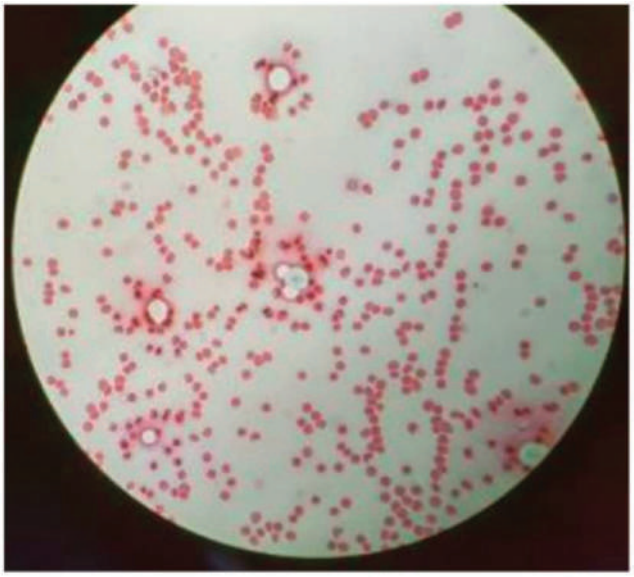
Background and Aims: Cryptococcosis is an opportunistic infection caused by encapsulated yeast Cryptococcus. The two species commonly infecting humans are C. neoformans and C. gatii and it commonly affects immunocompromised patients. Disseminated infection in immunocompetent is rare. In this study, we present a case of disseminated cryptococcus with lung and cerebral involvement in an immunocompetent patient.

Methods: The case is about a 28-year-old female from Marikina City who presented with fever, headaches and cough. Patient was initially treated as a case of Pulmonary Tuberculosis, but no improvement was noted during hospital stay. Further workup was done including chest and cranial CT scans which guided for definitive diagnosis. Cultures of CSF and lung mass biopsy were also done which revealed positive for cryptococcus infection. Patient was also tested for other immunodeficiency tests including HIV where she tested negative. Since the patient was confirmed with cryptococcus infection, patient was treated with systemic anti-fungal medications. Patient improved symptomatically and significantly hence was then discharged and advised follow up at OPD.

Results: Not applicable.



Grams stain of CSF for analysis.



H&E stain of CSF for analysis.

Conclusion: In this study, we present a rare case of disseminated cryptococcosis with lung and cerebral involvement in an apparent immunocompetent patient. Early recognition of the disease and treatment leads to better outcomes.
Disclosure: Nothing to disclose.

EPO-465 | Non-compressive myelopathy complicating acute community-acquired bacterial meningitis

E. Drost; N. Chekrouni; M. Brouwer; D. van de Beek
Department of Neurology, Amsterdam UMC, Amsterdam, The Netherlands

Background and Aims: Bacterial meningitis is a severe disease with high rates of complications and unfavourable outcome. Complications involving the spinal cord, such as myelitis or infarction, are infrequently reported.
Methods: Cases of non-compressive myelopathy were identified when included in a nationwide cohort study of adults with community-acquired bacterial meningitis in the Netherlands. Outcome was scored at discharge using the Glasgow Outcome Scale and a score of 1-4 was considered an unfavourable outcome. Subsequently, we reviewed the literature on non-compressive myelopathy as a complication of bacterial meningitis.
Results: Non-compressive myelopathy was reported in 5 of 3047 episodes of community-acquired bacterial meningitis (0.16%). The median age of these patients was 56 years (range 17-72). Causative pathogens were Streptococcus pneumoniae in 2, and Neisseria meningitidis, Haemophilus influenzae and Streptococcus agalactiae each in 1. Paresis of legs ($n=4$) or arms and legs ($n=1$) were the presenting symptoms during admission, occurring after a median duration of 13 days after admission (range 2-28). Spinal MRI showed T2-weighted abnormalities of the spinal cord in all patients. Outcome was unfavourable in all patients despite additional corticosteroid treatment in two. The literature review yielded 14 cases of non-compressive myelopathy in bacterial meningitis patients. The most reported causative pathogen was Neisseria meningitidis in 8 patients. Outcome was unfavourable in 12 of 14 of reported patients in literature (86%).
Conclusion: Non-compressive myelopathy is an uncommon but severe complication of bacterial meningitis. It is not constrained to one specific pathogen and is associated with high rates of unfavourable outcome.
Disclosure: Nothing to disclose.

EPO-466 | Even the smallest of organisms could change the course of life

I. Llera López[1]; L. Santos Sánchez de las Matas[1]; M. Montalvo Moraleda[1]; A. Saldaña Díaz[1]; I. Navas Clemente[2]; Á. Bonelli Franco[1]; J. Cebrián Escudero[1]; J. Martínez Ramos[1]; D. Landaeta Chinchilla[1]; Z. Ghazizadeh-Monfared Croigny[3]; R. Berigüete Alcántara[3]; M. Domínguez Sepulveda[2]; P. Bermejo Acevedo[2]; N. Barbero Bordallo[1]
[1]Department of Neurology, Hospital Universitario Rey Juan Carlos, Móstoles, Spain; [2]Department of Internal Medicine, Infectious Disease, Hospital Universitario Rey Juan Carlos, Móstoles, Spain; [3]Department of Clinical Neurophysiology, Hospital Universitario Rey Juan Carlos, Móstoles, Spain

Background and Aims: Lumbosacral adhesive arachnoiditis is a serious and rare condition with multiple aetiologies, as it may be related to postoperative changes, inflammatory conditions, or secondary to previous infectious disease. In general, it presents as a polyradiculopathy, being uncommon its presentation as cauda equina syndrome, an entity that is associated with significant disability.
Methods: Case report.
Results: Female, 35 years old. History of fully recovered cytomegalovirus (CMV)-related polyradiculopathy secondary to stage 3 HIV the previous year. Progressive worsening of motor function started 2 months before hospital admission. Neurological examination: paresis of the left lower limb (2/5) and bilateral areflexia in lower extremities, without other alterations. Laboratory tests: CD4+ 226 cells/mm^3, undetectable HIV viral load. CSF: proteinorraquia, mild leukocytorrhea and oligoclonal bands with identical distribution in CSF and serum. Negative infectious and autoimmune panels. MRI of the lumbar spine showed thinning of the L1-2 nerve roots, hyperintensity and thickening of the L2 cauda equina and downward, narrow and adherent nerve roots that resembled an image of an empty L3-S1 thecal sac. The neurophysiological study evidenced active motor denervation, eminently of the distal left lower limb. The study was completed with a biopsy that confirmed focal fibrosis and chronic inflammation of the ligamentum flavum and the lumbar thecal sac.

Conclusion: The final diagnosis was postinfectious adhesive arachnoiditis. To our knowledge, this is the first case described following CMV-related polyradiculopathy. Diagnosis is based on clinical presentation, neuroimaging and biopsy. Pharmacological (e.g. immunoglobulins) and surgical treatments have been described, without clear benefit. Intensive physical rehabilitation is recommended.
Disclosure: Nothing to disclose.

EPO-467 | Neurovascular complications in patients with central nervous system infections

I. Stavila[1]; C. Gutu[1]; E. Manole[2]; O. Grosu[1]; O. Odainic[1]; M. Gavriliuc[2]
[1]*"Diomid Gherman" Institute of Neurology and Neurosurgery, Chisinau, Republic of Moldova;* [2]*"Nicolae Testemițanu" State Universities of Medicine and Pharmacy, Chisinau, Republic of Moldova*

Background and Aims: Neurovascular complications are common with nervous system infections, such as cerebral vascular insult, venous thrombosis, vasculitis and aneurysm formation. The aim of our study was to analyze clinical features of a group of patients with central nervous system (CNS) infection who developed neurovascular complication.
Methods: Prospective observational study collecting all the patients with CNS infections from a tertiary neurology center between 2007 and 2023 was made. Study sample consists of 265 patients with CNS infections and 42 (15.8%) with cerebrovascular complications.
Results: The mean age was 47.21 years, 57.1% men. The most common infections were meningitis (28.6%) and meningoencephalitis (42.9%). Neurovascular complications presented as: ischemic stroke (78.8%), multiple lesions (48%), cerebral vasculitis (30.9%), and cerebral venous thrombosis (31%). The most frequent predisposing factors were bronchopneumonia (52.4%), parameningeal infection (19.0%), and septicemia (16.7%). The pathogens were identified in 35.7% case, mostly cocci species. When compared to patients without neurovascular complications those with stroke presented higher blood sedimentation rate (41.00 vs 32.65mm/h, $p = 0.017$), CSF protein (4.17 g/l vs 1.62, $p < 0.05$), motor deficit (50% vs. 36.3%), seizures (9.5% vs 5.8%), and in-hospital mortality (28.6% vs 22.4%) but fever was less common (66.7% vs 76.7%). Logistic regression model shows that the presence of bronchopneumonia, smoking and pregnancy can predict the occurrence of the neurovascular complication with good probability (B = 1.67o, df = 1, $p = 0.00$, Exp B = 5.310).
Conclusion: Neurovascular complications in CNS infections affect mostly young patients and are more likely to manifest focal neurologic deficit and higher mortality rates.
Disclosure: Nothing to disclose.

EPO-468 | Exploring the neurological outcomes of Nipah virus: A narrative review of state from 1998 to 2023

A. Kayode; A. Moradeyo
Department of Medicine and Surgery, Ladoke Akintola University of Technology, Ogbomoso, Nigeria

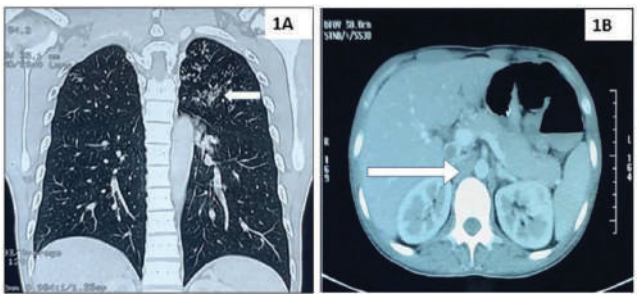
Background and Aims: Nipah virus (NiV) is an emerging zoonotic RNA virus causing severe respiratory and acute febrile encephalitic illness in humans. Pteropus fruit bats serve as reservoirs for the virus which led to human spread via consumption of food contaminated with bat secretion, contact with infected animals and human-to-human spread. This study aims to access the early, late-onset and long-term neurological outcomes of Nipah virus infection among affected individuals.
Methods: Articles from existing literature in PubMed, Medline and Google Scholar databases investigating Nipah virus-associated neurological outcomes were examined. 79 relevant articles were screened for this study using predefined inclusion and exclusion criteria.
Results: NiV infection in humans produces an encephalitic syndrome ranging from headache and pyrexia to brain stem abnormalities; and reduced level of consciousness (55% in Malaysia, 90% in Bangladesh) including tonic-clonic convulsions and segmental myoclonus. Fever with altered sensorium was the most common presentation in Siliguri, India (97%) and Bangladesh (90%), with a case fatality ratio (CFR) of about 40-100% in recent outbreaks. Residual neurological deficits were seen in 10-15% of survivors an average of 8 months after primary encephalitis. Brain MRI showed small discrete hyperintense lesions, widespread in the cortex, subcortical and deep white matter from microinfarctions due to underlying vasculitis of the cerebral blood vessels, seen in acute infections and patchy confluent hyperintense cortical lesions seen in relapsing NiV infections.
Conclusion: Proper education on good hygiene is important to prevent reemergence of the infection in affected areas. Effective neurorehabilitation is also necessary to reduce long-term neurological complications in NiV survivors.
Disclosure: Nothing to disclose.

EPO-469 | Diagnostic deadlock: A case of disseminated tuberculosis with neuroleptospirosis

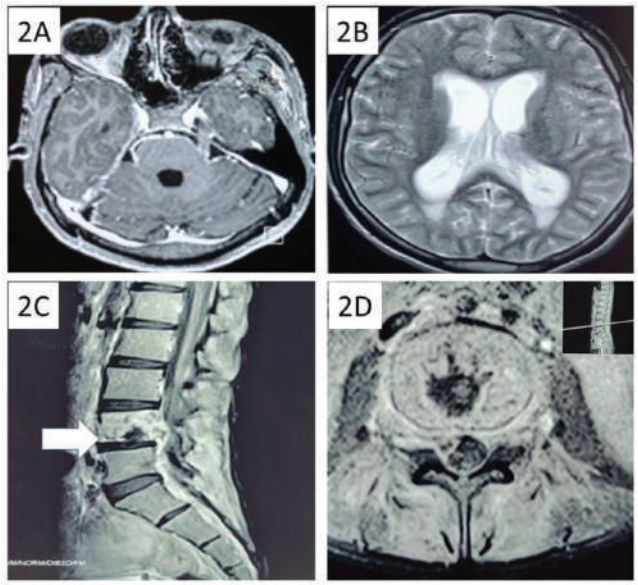
V. Singh[1]; S. Chouksey[2]; P. Batra[2]; R. Chaurasia[3]
[1]*Department of Neurology Institute of Medical Science, Banaras Hindu University, Varanasi, India;* [2]*Department of Neurology, Institute of Medical Science, Banaras Hindu University, Varanasi, India;* [3]*Department of Neurology Institute of Medical Science, Banaras Hindu University, Varanasi, India*

Background and Aims: Neuroleptospirosis may present with features like altered sensorium, GTCS, headache, and focal neurological deficit which are shared with other common neuro-infection like tuberculous meningitis. Coexistence of these two illnesses has not been yet reported.

Methods: A 19-years old male presented with high-grade fever, headache and vomiting for 4 days and right focal to bilateral tonic clonic seizures and altered sensorium for 3 days. On examination, he was febrile (101°F) and GCS score was E2V1M5. There was no papilledema and focal motor deficit. Signs of meningeal irritation were present.
Results: Serum IgM leptospira titre was high [26.4 Units (<9 units)] and creatine kinase [493 U/L (24-195 U/L)] was elevated. Patient received doxycycline with antiepileptic drugs (levetiracetam and lacosamide) for two weeks. There was improvement in sensorium and subsidence of seizure; however, high-grade fever persisted. CECT thorax, abdomen and pelvis revealed disseminated tuberculosis (Figure 1). MRI brain and spine with contrast revealed diffuse leptomeningeal enhancement and basal exudates with hydrocephalus and lytic lesion at L4 vertebrae suggestive of tuberculous meningitis and Pott's spine (Figure 2). Four drugs antitubercular therapy was started. Ventriculoperitoneal (VP) shunting was done. GCS improved to E3V3M5. However, he developed refractory status epilepticus, followed by ventilator associated pneumonia, septic shock and succumbed to the illness.



Contrast enhanced computed tomography of chest and abdomen revealing multiple centrilobular nodules in upper lobe of left lung parenchyma (1A) and multiple enlarged mediastinal, bilateral hilar and intraabdominal (arrow) lymph nodes (1B) suggestive of dis.



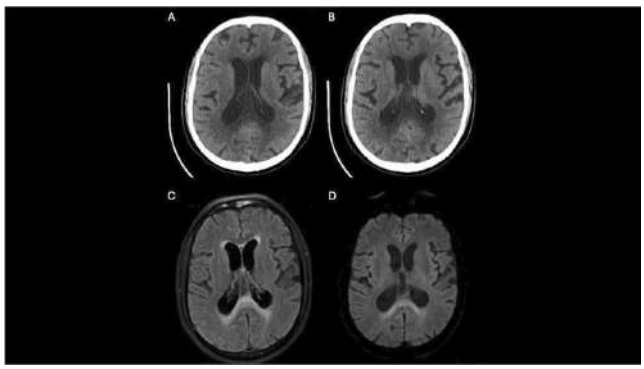
Contrast magnetic resonance imaging of brain showing leptomeningeal enhancement and basal exudates on T1W (2A) and hydrocephalus on T2W with periventricular ooze (2B) suggestive of tuberculous meningitis. Contrast magnetic resonance imaging of lumbosacral.

Conclusion: This is the first case report of coexistent neuroleptospirosis and disseminated tuberculosis creating diagnostic dilemma. One should revise his/her own diagnosis and work up plan once the anticipated therapeutic response is inadequate.
Disclosure: Nothing to disclose.

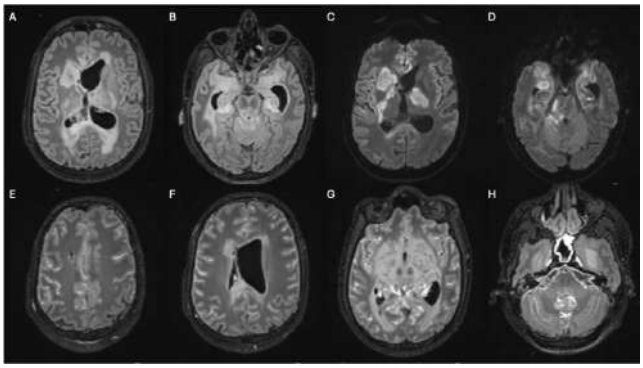
EPO-470 | Linking the unseen: Marchiafava-Bignami disease and tuberculous meningo-myelitis

M. Creta[1]; E. Ballabio[2]; G. Nuzzaco[2]; K. Khouri Chalouhi[3]; S. Tonietti[2]; F. Frediani[2]
[1]Department of Health Sciences, University of Milan, Milan, Italy; [2]Neurological and Stroke Unit Department, San Carlo Bartolomeo Hospital, ASST Santi Paolo e Carlo, Milan, Italy; [3]Neuroradiology Department, San Carlo Bartolomeo Hospital, ASST Santi Paolo e Carlo, Milan, Italy

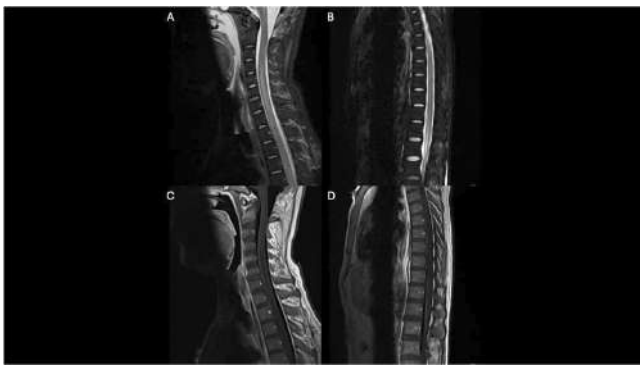
Background and Aims: This work reports the first-ever described case of tuberculous meningo-myelitis (TBMM) associated with Marchiafava-Bignami disease (MBD), complicated by communicating hydrocephalus, multiple acute ischemic strokes, and diabetes insipidus.
Methods: We present the case of a 33-year-old homeless Afghan male with a significant history of alcohol abuse, who presented to the Emergency Room with a recent-onset fever and a sudden and rapidly progressive impaired level of consciousness. Clinical manifestations included focal neurological deficits such as left motor facial and brachial sparing, flaccid paraplegia, sphincter release, and jerking movements.
Results: CT-scan and MRI revealed severe generalized cerebral atrophy with symmetrical hypodensity of the hemispheric white matter and splenium of the corpus callosum. EEG showed widespread slowing without epileptiform abnormalities. Laboratory results indicated electrolyte imbalances and diluted urine. Supportive therapy and vitaminic supplementation were initiated. A second CT-scan revealed communicating hydrocephalus with initial decompensation, necessitating immediate external ventricular drain insertion. CSF analysis showed lymphocytosis, elevated protein levels, decreased glucose levels, and positive cultures for Mycobacterium tuberculosis. A



CT scan: Splenium hypodensity in corpus callosum, suggestive of Marchiafava-Bignami; mild age-related ventricular and cerebral sulci enlargement (A,B). MRI FLAIR: Signal hyperintensity in splenium, supporting suspected Marchiafava-Bignami diagnosis (C,D).



MRI FLAIR: Hydrocephalus, periventricular hyperintensity (A). Mesencephalic and interpeduncular cistern hyperintensity suggests leptomeningitis (B). DWI: acute ischemia (C,D). Contrast-enhanced FLAIR: diffuse leptomeningeal enhancement (E,F,G,H).



MRI sagittal STIR: Hyperintensity in the spinal cord from C4 to C7 (A) and into the upper thoracic tract (B). Post-contrast T1-weighted sequences: Subtle enhancement along spinal cord margins (C,D). Findings suggest suspected myelitis.

second MRI with gadolinium unveiled multiple acute ischemic strokes and diffuse meningeal enhancement and a cervical-dorsal lesion consistent with TBMM. Despite antituberculous chemotherapy, the patient's condition deteriorated, culminating in coma and death.
Conclusion: Establishing a clear link between TBMM and MBD remains challenging. Speculation suggests a potential nutritional imbalance induced by TBMM's high metabolic demand in a multi-system disease, resembling a toxic-like state that can precipitate MBD. Both conditions require a high level of suspicion and prompt empiric treatment initiation in patients with behavioral and socioeconomic risk factors.
Disclosure: Nothing to disclose.

EPO-471 | Horner syndrome besides the obvious – *Pantoea* spp. as a rare cause of cervical spinal epidural abscess

J. Neiva Correia; M. Saianda Duarte; V. Fonseca; A. Arraiolos; J. Morgado; J. Vale
Neurology Department, Hospital Beatriz Ângelo, Loures, Portugal

Background and Aims: Cervical spinal epidural abscess (CSEA) is an uncommon disease, associated with significant morbidity. Diagnosis can be elusive, especially if the classic triad of back pain, fever, and neurological deficit is not present. Horner syndrome (HS) is a rare but possible presentation. MRI with gadolinium is crucial for swift diagnosis and timely initiation of antimicrobial therapy. We present a case linked to the rare Pantoea spp, a group of plant pathogens that can cause human disease.
Methods: Case report.
Results: 53-year-old male, without relevant past medical history, was admitted to the ER after the acute onset of right eye ptosis and gait unsteadiness after osteopathic manipulation for neck and shoulder pain. Physical examination showed marked cervical neck tenderness. Neurological examination revealed a right HS and mild ataxia of the right leg. Brain CT angiography and cervical spine CT scans were normal. Markedly increased inflammatory markers in the workup prompted a lumbar puncture. CSF analysis revealed pleocytosis and hyperproteinorrachia. Empirical ceftriaxone IV 2g q12h was initiated. Spine MRI revealed septic arthritis at C7-D1 with an associated CSEA. Subsequent blood culture identified Pantoea spp, sensitive to ceftriaxone. After six weeks of treatment, there was clinical and radiological improvement.
Conclusion: We report an uncommon presentation of a rare entity caused by a very rare pathogen. This case is also unique because there was no direct inoculation or haematogenous spread, and the few cases of infection reported in the literature were on pediatric or immunocompromised adults. A prompt diagnosis and treatment is needed to achieve a good outcome.
Disclosure: Nothing to disclose.

Neuroimmunology 3

EPO-472 | Plasma proteomics and autoantibody screening: A tool for patient stratification and monitoring CIDP treatment responses

A. Casano[1]; M. Castillo-Dreyfuss[2]; L. Shen[2]; J. Vowinckel[3]; B. Gangadharan[1]; I. Bilic[1]
[1]*Baxalta Innovations GmbH, a Takeda Company, Vienna, Austria;*
[2]*Takeda Development Center Americas, Inc., Cambridge, MA, USA;*
[3]*Biognosys AG, Schlieren, Zürich, Switzerland*

Background and Aims: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is an inflammatory neuropathy with heterogeneous presentation. Precise diagnosis and patient-tailored treatment decisions are hindered by lack of unbiased, quantifiable molecular markers. Although aberrant immune cell-mediated responses and circulating autoantibodies may accompany CIDP, underlying pathomechanisms remain elusive. We investigated correlation of clinically defined disease states with changes in plasma homeostasis in patients receiving immunoglobulin/placebo during remission versus relapse.
Methods: Plasma samples from patients with CIDP receiving hyaluronidase-facilitated subcutaneous immunoglobulin 10% (fSCIG 10%) or placebo during ADVANCE-CIDP 1 (NCT02549170) were analysed. Proteomic analysis (data-independent acquisition liquid

chromatography-mass spectrometry and Olink®) compared longitudinal samples from patients experiencing remission/relapse. A novel multiplex in-solution method to simultaneously detect autoantibodies against 32 CIDP-relevant antigens was also developed, potentially alleviating current technical hurdles associated with autoantibody detection in CIDP.

Results: For >1500 plasma proteins, concentration profiles differed significantly in patients with CIDP versus healthy controls. Identified CIDP profiles emphasized natural killer- and B-cell-mediated immune pathway involvement. When comparing remitting and relapsing patients, differences in profiles involved in extracellular matrix homeostasis, microtubule organization, tight junction assembly, and cytokine production were observed. fSCIG 10% progressively lowered proinflammatory cytokine levels versus placebo. Autoantibody profiling uncovered a CIDP signature for evaluation in larger cohorts.

Conclusion: Versus healthy controls, pronounced plasma protein dynamics were identified in patients with CIDP, providing a broad base for biomarker discovery. Combining plasma proteomics and autoantibody screening may identify unbiased, quantifiable biomarkers for patient stratification and/or monitoring pharmacodynamics following high-dose immunoglobulin administration. Study/writing support funders: Takeda Development Center Americas, Inc./Takeda Pharmaceuticals International AG.

Disclosure: AMC, IB, BG*: employees of Baxalta Innovations GmbH, a Takeda Company; IB: Takeda shareholder; MJC-D, LS: employees of Takeda Development Center Americas, Inc., and Takeda shareholders; JV: employee of Biognosys AG. *At the time of the study.

EPO-473 | The wide spectrum of Anti-Hu Paraneoplastic Neurological Syndromes (PNS): Case-series and review of the literature

K. Rizonaki*; P. Stamatelos*; A. Antoniou; E. Kinnis; E. Petrou; A. Gamvroula; V. Gourbali; G. Kolovos; M. Lentza; E. Alexiou
Neurology Department, Evaggelismos General Hospital, Athens, Greece

Background and Aims: PNS are autoimmune disorders arising from immune response to tumor antigens and they may precede cancer diagnosis for years. Anti-Hu neuronal autoantibodies are related to a wide and heterogeneous range of both Central and Peripheral Nervous System presentations.

Methods: We present four cases of Anti-Hu PNS, along with a systematic review of the literature. We searched MEDLINE for Anti-Hu case-series or case-reports, initially identifying 588 articles. Finally, 181 articles were included.

Results: Our case-series consists of 4 patients (1 Female, Mean Age 69 years). Two patients presented with Subacute Sensory Neuronopathy (SSN) and pronounced autonomic involvement, one patient with Limbic Encephalitis (LE) and one with Encephalomyelitis. Three patients had a concomitant small-cell lung cancer (SCLC), diagnosed after the PNS in two of them. Two patients died after 1 and 11 months, respectively. In our review, we found 1424 anti-Hu cases (Mean age: 63 years, 42% Women). The most common presentations were SSN (49%), LE (16%) and Encephalomyelitis (15%). In 1193 (84%) patients, a neoplasm (most commonly SCLC-84%) was identified and in 79% of them, PNS preceded cancer diagnosis. Immunosuppression along with neoplasm treatment were the preferable approaches in 52% and 51% of patients, respectively. 660 (55%) patients died during follow-up (Mean time to death: 13 months).

Conclusion: Anti-Hu PNS are rare but potentially treatable. They should always be included in the differential diagnosis of patients with compatible neurological syndromes, even without history of cancer. Thorough investigation to identify and treat an underlying neoplasm along with immunosuppressive agents may improve prognosis of these patients.

Disclosure: Nothing to disclose.

EPO-474 | Neurofilament light chain: The importance of plasma biomarkers in therapeutic decision-making in multiple sclerosis

L. Araujo Duarte[1]; A. Salvio Lemos[2]; R. Amphilophio Fernandes[2]; M. Ataíde Teixeira[2]; H. França Alcarraz Ferreira[1]; E. Gutman Gouvea[2]; V. Coutinho Costa[1]; J. Dib Farinhas[2]; V. Coelho Santa Rita Pereira[1]; S. Vieira Alves-Leon[1]
[1]Universidade Federal do Rio de Janeiro; [2]Universidade Federal do Estado do Rio de Janeiro

Background and Aims: Relapsing remitting Multiple Sclerosis (RRMS) is a subtype of MS, an autoimmune chronic inflammatory neurodegenerative disease. During the last decades MS has been remarkably impacted by the advances in knowledge on the pathophysiology, new therapeutic targets, early diagnosis criteria and monitoring of treatment response. Disease follow-up biomarkers as Neurofilament Light Chain (NfL) are not yet available in most locations, but since non-invasive techniques as SiMoA technique have been used to monitor progression and therapeutic response in RRMS, therapeutic decision making has been reviewed.

Methods: In this prospective study, SiMoA technique was used to assess NfL levels in RRMS classified as EDA, NEDA, naïve and patients that switched from first line therapy to moderate-high efficacy DMD.

Results: Sixty-six RRMS patients and 24 age-matched health controls were included. In EDA group, NfL mean level was 30.25 pg/mL, and 6.65 pg/mL for NEDA patients. Among patients without DMD and under first line therapy, NfL mean level were 13.98 pg/mL and 12.94 pg/mL, respectively. After therapy switch, or under moderate-high DMD, NfL levels significantly decreased (6.96 pg/mL; $p < 0.05$), similar to NEDA patients and healthy control (6.7 pg/mL).

Conclusion: The significant difference in NfL levels before and after moderate-high efficacy DMD showed the impact of new drugs in both efficacy and control of NFL levels. The role of NFL can contribute on treatment management, especially in the monitoring of the therapeutic failure beyond the usual outcomes as clinical relapsing and new lesions in MRI, aiming to early impact on the course of MS disability.

Disclosure: Nothing to disclose.

EPO-475 | Immune checkpoint inhibitor-related cerebellar toxicity and comparison with paraneoplastic cerebellar ataxia

M. Dentoni[1]; I. Florean[1]; A. Farina[2]; B. Joubert[2]; J. Honnorat[2]; V. Damato[3]; M. Fabris[4]; G. Gigli[1]; M. Valente[1]; A. Vogrig[1]
[1]*Clinical Neurology, Department of Medicine (DMED), University of Udine, Udine, Italy*; [2]*French Reference Centre for Paraneoplastic Neurological Syndromes and Autoimmune Encephalitis, Hospices Civils de Lyon, Lyon, France*; [3]*Department of Neurosciences, Drugs and Child Health, University of Florence, Firenze, Italy*; [4]*Laboratory of Immunopathology, Institute of Clinical Pathology, Department of Laboratory Medicine, University Hospital of Udine, Udine, Italy*

Background and Aims: Immune checkpoint inhibitors (ICIs) have revolutionized cancer therapy, and the association with immune-related adverse events (irAEs) is well-established. Our aim was (i) to characterize ICI-related cerebellar toxicity; (ii) to compare ICI-related cerebellar toxicity to paraneoplastic cerebellar ataxia (PCA).
Methods: Systematic review of the literature following PRISMA guidelines, with the addition of 8 original cases. We included adult patients developing new-onset, isolated or predominant cerebellar dysfunction within 12 months from the last ICI infusion. Such cases were compared with a consecutive cohort of patients with PCA.
Results: Thirty-five patients were included (males: 25/35 (71%), median age: 65 [range: 20-82]). The most frequent tumour was non-small cell lung cancer (12/35, 34%). Anti-PD1 were adopted in most cases (19/35, 54%). Symptoms developed a median of 11 weeks (range: 0.1-82) after ICI initiation; "isolated cerebellar ataxia" (gait and/or limb and/or trunk ataxia) prevailed at disease peak (13/35, 37%). Antibody positivity was detected in 15/31 patients tested (48%). Cerebrospinal fluid was inflammatory in 26/30 (87%). Magnetic resonance imaging showed cerebellar hyperintensities in 8/35 (23%). Immune-modulating therapy was applied in 33/35 cases (94%), and most patients showed neurological improvement with residual disability (17/35, 49%). When compared with PCA ($n = 15$), the ICI group was significantly associated with NSCLC, isolated ataxia, and a better neurological outcome.
Conclusion: We provided a characterization of ICI-related cerebellar toxicity. Compared to PCA, differences exist in terms of tumour association, clinical features, and outcome. Clinical presentation-antibody-tumor triad in the ICI group poorly reflects the typical associations of paraneoplastic disorders.
Disclosure: Nothing to disclose.

EPO-476 | Abstract withdrawn

EPO-477 | Novel approaches for immune-mediated chronic intestinal pseudo-obstruction: A case series

A. Vilaseca[1]; P. Arranz[1]; A. Zabalza[1]; M. Sanz-Martínez[2]; L. Viñas[2]; L. Alcala-González[3]; H. Ariño[1]; X. Montalban[1]; X. Montalban[4]; X. Montalban[5]; C. Malagelada[3]; C. Malagelada[4]
[1]*Department of Neurology and MS Centre of Catalonia (Cemcat), Vall d'Hebron University Hospital, Barcelona, Spain*; [2]*Immunology Department, Vall d'Hebron University Hospital, Barcelona, Spain*; [3]*Gastroenterology Department, Vall d'Hebron University Hospital, Barcelona, Spain*; [4]*Universitat Autònoma de Barcelona (UAB), Barcelona, Spain*; [5]*Universitat de Vic-Central de Catalunya (UVic-UCC)*

Background and Aims: Neurologic autoimmune gastrointestinal dysmotility (nAGID) represents a significant contributor to gastrointestinal motility disorders, often leading to chronic intestinal pseudo-obstruction (CIPO). The response to immunotherapy varies based on the specific autoimmune disorder. Our goal is to describe the treatment responses of various drugs in 3 patients with CIPO.
Methods: Three consecutive cases diagnosed at a referral center for CIPO during 2023 are described. We collected baseline characteristics, clinical symptoms, radiologic tests, and histopathologic examination. The clinical and radiological response to treatment was used to measure outcome.
Results: All 3 patients had severe CIPO, refractory to previous treatments. Two patients underwent a full-thickness intestinal biopsy that detected lymphocytic myenteric ganglionitis. The first patient was a 35-year-old-male with myasthenia gravis associated to thymoma, who developed a nAGID without any serological marker of autoimmunity. He received vedolizumab with improvement of his digestive symptoms and nutritional status. The second patient was an 18 year old woman who had a non-paraneoplastic anti-Hu associated nAGID. She achieved clinical remission after rituximab. The third patient was a 60-year-old woman, with small cell lung cancer, who developed a paraneoplastic anti-Hu associated nAGID. She received cyclophosphamide, but did not improve and eventually died.
Conclusion: Our findings underscore the potential efficacy of rituximab and vedolizumab in the management of neurologic autoimmune gastrointestinal dysmotility with chronic intestinal pseudo-obstruction, particularly in refractory cases. Although a larger sample is needed, these interventions should be considered valuable options in the therapeutic landscape for such patients.
Disclosure: Nothing to disclose.

EPO-478 | Single fiber EMG in the diagnostic workup of diplopia and ptosis

S. Cornacchini[1]; M. Verza[1]; A. Farina[1]; M. Bastianelli[2]; A. Cassardo[2]; C. Mei[2]; A. Barilaro[3]; L. Massacesi[1]; A. Grippo[2]; V. Damato[1]
[1]*Department of Neurosciences Drugs and Child Health, University of Florence, Florence, Italy*; [3]*Department of Neurology 2, Careggi University Hospital, Florence, Italy*; [2]*Department of Neurophysiology, Careggi University Hospital, Florence, Italy*

Background and Aims: Diplopia and ptosis are common neuro-ophthalmologic signs. Yet identifying the specific aetiology can be challenging due to the different possible causes. In this prospective study, we evaluated the reliability of the stimulated single fiber electromyography (SFEMG) in supporting the diagnosis of myasthenia gravis (MG) presenting with diplopia and ptosis.

Methods: We included 80 patients who presented with diplopia ($n=34$), ptosis ($n=16$), or both ($n=30$), and underwent SFEMG. Patients received a comprehensive diagnostic workup involving detailed history investigation, physical examination, orbital and brain imaging, thyroid function, antibody screening, orthoptic evaluation, ice pack test (when applicable) and repetitive nerve stimulation test (RNS).

Results: SFEMG yielded positive results in 29 of 80 (36.3%) patients of the cohort. Among the patients diagnosed with MG ($n=35$), SFEMG showed a sensitivity of 71.4% (95% CI: 0.55 – 0.84) and specificity of 91.1% (95% CI: 0.79 – 0.96) with a positive predictive value of 86.2% (95% CI: 0.69 – 0.95) and a negative predictive value of 80.3% (95% CI: 0.68 – 0.89). Notably, SFEMG was positive in 6 seronegative MG cases and in 14 cases with negative RNS. In the non-MG group (45/80 patients), SFEMG was negative in the majority (41 patients, 91.1%) of cases, further supporting its value in ruling out MG. A relevant proportion (21/45) of these cases remained undiagnosed.

Conclusion: Our findings suggest that SFEMG is a valuable tool in the diagnostic workup of diplopia and ptosis and in the differential diagnosis of MG, especially in seronegative MG cases and in those with negative RNS results.

Disclosure: Nothing to disclose.

EPO-479 | Difference between high-dose and moderate-dose vitamin D supplement in an animal model of progressive multiple sclerosis

M. Haindl[1]; M. Ücal[2]; M. Nowakowska[2]; W. Wonisch[3]; C. Enzinger[1]; S. Hochmeister[1]

[1]Department of Neurology, Medical University of Graz, Graz, Austria; [2]Department of Neurosurgery, Medical University of Graz, Graz, Austria; [3]Department of Physiological Medicine, Medical University of Graz, Graz, Austria

Background and Aims: Although many studies have found correlations between low vitamin D (VD) serum levels and the onset/progression of Multiple Sclerosis (MS), negative effects of VD supplementation are also reported. Uncritical intake of excessively high VD doses can lead to hypercalcemia and kidney damage. However, little is known about high dose effects on the central nervous system in neuroimmunological diseases. We developed an animal model that represents the cellular characteristics of progressive MS very well. In previous experiments we detected positive effects of moderate doses of VD in terms of alleviating brain pathology.

Methods: This work investigates whether high-dose VD (400IU/day; VD++) leads to histopathological differences compared to moderate doses (400IU/week; VD+) in our animal model. For this purpose, female rats ($n=20$) received VD (Fresenius-Kabi, Graz, Austria) accordingly from age 3 weeks on and underwent the standard procedure of our animal model (Ücal et al., 2017). Tissue was harvested on peak disease, and immunohistochemical evaluation was performed.

Results: Overall, there was no significant difference detectable between VD+ and VD++ with respect to preservation of myelin structures. However, microglial activation was significantly increased in the VD++ group on day 15 ($p=0.003$) and 30 ($p=0.002$). Furthermore, our preliminary data showed a lower number of apoptotic cells in the VD++ group, but at the same time increased neuronal cell loss.

Conclusion: We found no significant difference between VD+ and VD++ doses in preventing myelin damage but an increased microglial activation and neuronal loss in the VD++ group. Our data highlight the need for medically controlled VD supplementation.

Disclosure: This study was partially funded by Fresenius-Kabi (to Hochmeister S).

EPO-480 | Clinical impact of high dose corticosteroids on hospitalisations and complications in patients with Myasthenia Gravis

N. Numajiri[1]; M. Takahashi[2]; M. Waratani[3]; T. Kobayashi[4]; T. Yamamoto[1]; T. Yajima[1]

[1]Medical Affairs Division, Alexion Pharma GK, Tokyo, Japan; [2]Department of Clinical Laboratory and Biomedical Sciences, Osaka University Graduate School of Medicine, Osaka, Japan; [3]Medical and Payer Evidence Strategy, AstraZeneca UK, Ltd, Cambridge, UK; [4]Evidence Observational Research, Data Science, AstraZeneca KK, Osaka, Japan

Background and Aims: Oral corticosteroids (OCS) are medications for controlling symptoms in patients with Myasthenia Gravis (MG). While long-term use of high dose OCS is associated with serious side effects, the real-world clinical impact of high-dose OCS in patients with MG is not well understood.

Methods: A retrospective cohort study was performed using JMDC, a Japanese claims database. Patients with newly diagnosed MG were identified by standard disease codes and the first diagnosis date of MG was defined as the index date. Patients were stratified into two groups by OCS dose level (high OCS ≥7.5 mg/day; low OCS < 7.5mg/day). Patient characteristics, treatment patterns, long-term hospitalization (≥10 days), and clinical complications were compared between the two groups.

Results: We identified total 2,107 patients with a diagnosis of MG, 576 of whom were on OCS (high OCS, $n=210$; low OCS, $n=366$) during the follow-up period. There were no obvious differences in baseline comorbidities between high and low OCS groups. Intravenous immunoglobulin therapy was more frequent in the high OCS group versus the low OCS group (1.72 vs 1.30 courses/year). A significant increase in long-term hospitalization was observed in the high OCS group versus the low OCS group (odds ratio; 1.832, $p=0.007$). The

incidence of new complications such as diabetes, fracture or osteoporosis, neuropsychiatric disease, and sepsis was significantly higher with high OCS versus low OCS ($p=0.0015$, 0.0000, 0.0001 and 0.0022, respectively).

Conclusion: Use of high-dose OCS in patients with MG was associated with adverse outcomes including increased rates of long-term hospitalizations and clinical complications.

Disclosure: This study was funded by Alexion Pharma GK of which NN, TY and TY are employees. MW and TK are employees of AstraZeneca.

EPO-481 | Bio-markers profile in different types of encephalitis: Evidences from cerebrospinal fluid analyses

V. Cristillo[1]; A. Pilotto[1]; D. Arici[1]; I. Volonghi[1]; E. Magni[2]; M. Turla[3]; S. Mariotto[4]; S. Ferrari[4]; A. Ciccone[5]; M. Sessa[6]; U. Balducci[7]; V. De Giuli[8]; F. Castelli[9]; N. J Ashton[10]; K. Blennov[10]; H. Zetterberg[10]; A. Padovani[1]

[1]Neurology Unit, Department odf Clinical and Experimental Sciences, University of Brescia, Italy; [2]Neurology Unit, Poliambulanza Hospital, Brescia, Italy; [3]Neurology Unit, ASST Valcamonica, Esine, Brescia, Italy; [4]Neurology Unit, Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona, Verona, Italy; [5]Department of Neurology and Stroke Unit, Carlo Poma Hospital, ASST Mantova, Mantova, Italy; [6]Department of Neurology, Papa Giovanni XXIII Hospital, ASST Papa Giovanni XXII, Bergamo, Italy; [7]Neurology Unit, ASST Chiari, Chiari, Italy; [8]Neurology Unit, Istituti Ospedalieri, ASST Cremona, Cremona, Italy; [9]University Division of Infectious and Tropical Diseases, University of Brescia and ASST Spedali Civili Hospital, Brescia, Italy; [10]Department of Psychiatry and Neurochemistry, Institute of Neuroscience & Physiology, The Sahlgrenska Academy at the University of Gothenburg, Mölndal, Sweden

Background and Aims: Encephalitis is defined by the presence of brain inflammation. This study was conducted to determine whether neuroinflammation, neuronal and neuroaxonal injury biomarkers could help to differentiate encephalitis and to improve diagnostic approach.

Methods: In this observational multicenter study, adult inpatients, with diagnosis of encephalitis were recruited. Clinical and laboratory features, inclusive of CSF inflammatory (IL-1β, IL-6, Il-8, TNF- α, CXCL-13), neuronal (NfL, p-Tau, aβ40, aβ42) and glial (GFAP, sTREM-2, YKL-40) damage biomarkers, were compared among the 4 groups through ANOVA and k2 test, were appropriate. Post-hoc analyses were performed using Bonferroni correction at $p=0.05$.

Results: One-hundred-fifty-eight encephalitis patients, namely 45 immune-mediated, 38 infectious, 69 not otherwise specified encephalitis (ENOS) and 63 HC entered the study. CSF cell count and protein levels were higher in the infectious group, compared to IE and ENOS. Infectious encephalitis showed higher inflammation parameters (IL-6, IL-8, TNF-α,) compared to HC and ENOS patients; whereas the chemokine CXCL13 was significant higher in both infectious ($p=0.012$) and immune-mediated ($p=0.013$) groups. Glial damage biomarkers were higher in the three different types of encephalitis compared to HC, excepted for sTREM-2, which showed higher values in both infectious ($p<0.001$) and immune-mediated ($p=0.004$) groups, compared to ENOS and HC.

Conclusion: This study indicates a different signature of encephalitis based on different etiologies. Inflammatory alteration was prominent in infectious encephalitis, whereas the B-cell–attracting CXCL13 was overexpressed in both infectious and immune-mediated patients, as for axonal damage biomarkers. Further studies are warranted to confirm and improve the diagnostic value of these biomarkers.

Disclosure: Nothing to disclose.

EPO-482 | Evaluating the effect of efgartigimod in myasthenia gravis crisis

W. Haiyan; S. Fangyi; C. Jiaxin; H. Xin; F. Huiyu

Department of Neurology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background and Aims: In myasthenia gravis (MG) crisis, plasma exchange and immunoglobulin infusion are confirmed effective treatment options, but plasma exchange may not always be available in time, and the response rate to immunoglobulin is not always satisfactory. This study aims to investigate whether the addition of efgartigimod gain benefits for patients with MG crisis.

Methods: We enrolled MG crisis patients who were followed for one year in the NICU and were categorized into two groups: the traditional immunotherapy group and the additional efgartigimod treatment group. The efgartigimod treatment group received a regimen of 20mg/kg, administered on the first and fifth day. The primary endpoints were the duration of mechanical ventilation and the time of discharge.

Results: 19 patients were recruited. The median age at MG onset was 40.89 years. Plasma exchange was performed in 9/19 (47.3%) cases and intravenous immunoglobulin was performed in 15/19 (78.9%) cases. Six patients in the efgartigimod group had shorter hospital stays (16.8 ±8.7 days vs. 27.41 ±21.33 days, $p=0.03$) and mechanical ventilation durations (17.0 ±12.71 days vs. 18.25 ±15.17 days) compared to 13 patients in the conventional treatment group. Additionally, in the efgartigimod group, 66.7% of patients showed a 50% reduction in ADL score from baseline, compared to 38.46% in the conventional treatment group.

Conclusion: The efgartigimod group shows shorter hospital stays and mechanical ventilation durations and the potential to improve muscle weakness in the short term. The trend suggests that efgartigimod could potentially offer advantages in managing the MG crisis.

Disclosure: Nothing to disclose.

EPO-483 | Efgartigimod therapies in N-methyl-D-aspartate receptor encephalitis

D. Wu; B. Luo
Department of Neurology, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China

Background and Aims: N-methyl-D-aspartate receptor (NMDAR) encephalitis is the most common subtype of autoimmune encephalitis. Patients with NMDAR encephalitis develop an intrathecal immune response against NMDARs with antibodies. The therapeutic response to immunotherapy is often delayed and some patients develop complex neurologic and/or neuropsychiatric syndromes with prolonged course.
Methods: Efgartigimod, a human IgG1 antibody Fc fragment engineered to reduce pathogenic IgG autoantibody levels, was used in 5 patients with NMDAR encephalitis. The mean length of stay in these patients was more than 6 months before the use of efgartigimod.
Results: The patients had all used high-dose methylprednisolone, immunoglobulin, and rituximab, but they had not improved. Four of 5 patients showed a significant improvement in symptoms within a week after the use of efgartigimod. At the 3-month follow-up, they continued to improve without the addition of other medication.
Conclusion: Efgartigimod showed improvement in patient with NMDAR encephalitis with prolonged course.
Disclosure: Our study suggests that efgartigimod may have some potential in the treatment of long-standing autoimmune encephalitis.

EPO-484 | The therapeutic effect of efgartigimod in autoimmune encephalitis

Q. Zhou[1]; H. Meng[1]; Q. Lin[2]; S. Chen[1]
[1]*Department of Neurology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China;* [2]*Department of Neurology, Fuzhou Second Hospital, Fuzhou, China*

Background and Aims: In some cases of autoimmune encephalitis, patients may not respond to first-line treatments or may experience intolerable side effects of high-dose steroids or certain immunosuppressive agents, thereby limiting available treatment options. This study explores the therapeutic potential of efgartigimod, a fully humanized FcRn antagonist approved for generalized myasthenia gravis, for the treatment of anti-LGI1 encephalitis.
Methods: Two patients diagnosed with anti-LGI1 encephalitis were enrolled, who presenting seizures, cognitive impairment, and psychiatric disorders. Initial treatments with high-dose steroids and intravenous immunoglobulin showed no significant improvement. Efgartigimod was administered at 10mg/kg once a week for four doses.
Results: In the first 1-2 weeks of efgartigimod treatment, both patients exhibited notable alleviation of clinical symptoms. Antibody titers decreased, and no severe adverse reactions were observed. A 30-day follow-up indicated stable symptoms.
Conclusion: This study is the first to document the application of efgartigimod in treating autoimmune encephalitis. Efgartigimod shows promise as a safe and effective treatment for autoimmune encephalitis. This pioneering report highlights its potential as an innovative therapeutic option for this condition.
Disclosure: Nothing to disclose.

Sleep-wake disorders 1

EPO-485 | Sleep disorders in children with myotonic dystrophy type 1

E. Erokhina[1]; K. Shamtieva[2]; E. Melnik[3]; D. Vlodavets[1]
[1]*Pirogov Russian National Research Medical University, Russian Federation;* [2]*Lomonosov Medical Scientific and Educational Center of Moscow State University, Moscow, Russian Federation;* [3]*Russian Federation Research Centre for Medical Genetics, Moscow, Russian Federation*

Background and Aims: Sleep disturbances are common in myotonic dystrophy type 1 (DM1), but most studies have focused on the prevalence of this symptomatology among adults. The purpose of the study was to evaluate the presence and nature of sleep disorders in children with DM1.
Methods: 9 children were examined: 5 girls, 4 boys, average age 11.7+2.7 years. Three patients (33%) had congenital DM1, six (67%) had childhood DM1. Patients underwent polysomnography (PSG) using a portable Somnolab2 PSG device (Loewenstein Medical (Weinmann), Germany).
Results: Changes in sleep architecture among children were similar to those previously described in adults: increased duration of stage 1 sleep, decreased stage 2 sleep, decreased sleep efficiency index. In 7 children (78%), according to PSG results, mild OSA was registered, in 3 (33%) - in combination with REM-dependent apnea, in 2 (22%) - with central apnea. No sleep disturbances were detected in 2 children (22%). In 87.5% of children, obstructive sleep apnea syndrome was observed in the absence of muscle weakness (8 children (89%) had 2 points on the MIRS scale, which corresponds to the presence of minimal muscle symptoms, 1 patient (11%) had 4 points).
Conclusion: The high incidence of obstructive sleep apnea syndrome in children with DM1 has been confirmed, which occurs even in the absence of significant muscle weakness. So it is advisable to conduct PSG in all patients for earlier diagnosis and treatment of breathing disorders during sleep.
Disclosure: Nothing to disclose.

EPO-486 | Dream experiences during intensive care unit stay: Prevalence, content, vividness, and associated factors

A. van der Hoeven[1]; R. Fronczek[1]; D. Bijlenga[1]; S. Hadra[1]; C. Ridder[1]; M. Henneman[2]; J. Maas[2]; S. Goedemans-de Graaf[2]; G. Lammers[1]; D. van Westerloo[2]; M. Schinkelshoek[1]
[1]Neurology Department, Leiden University Medical Center, Leiden, The Netherlands; [2]Intensive Care department, Leiden University Medical Center, Leiden, The Netherlands

Background and Aims: Vivid dream experiences in the Intensive Care Unit (ICU) are common, but poorly understood. We investigated the prevalence, vividness, content, emotional impact, and associated factors of dream experiences in the ICU.
Methods: Retrospective qualitative study with subjects ≥18 years, previously admitted to the ICU for ≥4 days and/or due to COVID-19, who were not sedated for ≥24 hours during their stay ($n=80$). Participants were interviewed by telephone. Clinical data were collected from patient files.
Results: Interviews were conducted a median of 9 months post-discharge. At the time of the interview, dream experiences were reported by 79%. Of patients with dream experiences, 73% reported "life-like" dreams, and 49% associated their dreams with negative emotions. Some participants (28.6%) continued to have similar dreams at home. The dream content was often related to the ICU admission. Younger age and longer length of stay were related to vivid dream experiences. Of participants with dream experiences 62.5% had experienced delirium during their ICU stay. Perceptual disturbances were also frequently reported by patients (50%) and only 45% could clearly distinguish them from dream experiences. There was an overlap between participants reporting perceptual disturbances and confirmed delirium (70%).
Conclusion: Life-like dream experiences are common in patients in the ICU and often have a negative emotional impact. To mitigate this impact, some participants suggest receiving information during their hospital stay about the potential for vivid dream experiences could be beneficial. Future studies should explore effective ways to distinguish dreams, delirium, and perceptual disturbances and how to reduce their impact.
Disclosure: Nothing to disclose.

EPO-487 | The burden of gender and depression on sleep inertia in central hypersomnias

A. Pagano; F. Placidi; A. Castelli; G. Di Mauro; C. Ferrazzoli; C. Liguori; N. Mercuri; F. Izzi
Sleep Medicine Center, Department of Systems Medicine, Policlinico Tor Vergata – University of Rome "Tor Vergata", Rome, Italy

Background and Aims: Sleep inertia (SI) can be defined as difficulty becoming fully awake after sleep. We aimed to evaluate SI in patients affected by hypersomnias of central origin, including narcolepsy type 1 (NT1), narcolepsy type 2 (NT2) and idiopathic hypersomnia (IH) and to study possible association with sex, age, depression, daytime somnolence and polysomnographic (PSG) parameters.
Methods: Patients with NT1, NT2 and IH underwent to nocturnal PSG recording, 5 naps Multi-sleep latency test (MSLT), Epworth Sleepiness Scale (ESS), Sleep Inertia Questionnaire (SIQ) and Beck Depression Inventory (BDI-II). SIQ total score and four SIQ subdomains (physiological, SIQ-P cognitive, SIQ-C, emotional, SIQ-E and responses to SI, SIQ-R) were assessed.
Results: 45 patients (27 females, 18 males, mean age 39.4±15 years) with diagnosis of NT1 ($n=11$), NT2 ($n=15$), IH ($n=19$). Mean SIQ total score didn't show differences among the three groups (NT1 53±21 vs NT2 56.9±21.4 vs IH 53.6±21.6, $p>0.05$), whereas was significantly higher in female (62.7±19.6 vs 42.3±16.9, $p<0.005$). Age, BDI, BMI, ESS were comparable in males and females. Strong positive correlation was observed between SIQ (total score and all SIQ subdomains) and BDI-II ($p<0.01$). SIQ-R negatively correlated with N3 ($p<0.01$), whereas was positively associated with Sleep Period Time and Total Sleep Time ($p<0.05$). Finally, SIQ does not correlate with age and ESS.
Conclusion: SI assessed by SIQ does not help in the differential diagnosis among hypersomnias of central origin, but appears to be strongly associated with female sex, depression and some polysomnographic parameters.
Disclosure: Nothing to disclose.

EPO-488 | Obstructive Sleep Apnea before and after CPAP titration: Can real-life data detect gender differences?

A. Pascazio; F. Buracchi Torresi; M. Maestri Tassoni; M. Fabbrini; D. Hoxhaj; M. Barsotti; A. Morana; A. Colitta; G. Siciliano; E. Bonanni
Neurology Unit, Department of Neuroscience, Azienda Ospedaliero Universitaria Pisana, University of Pisa, Pisa, Italy

Background and Aims: Since Obstructive Sleep Apnea (OSA) can have atypical features in women, our aim was to assess gender differences in OSA patients with an indication to use Continuous Positive Airway Pressure (CPAP) before and after treatment.
Methods: In this monocentric retrospective study, we recruited 199 OSA patients with an indication to use CPAP. We assessed gender differences in demographic, polygraphic and clinical features, and CPAP adherence.
Results: Median age was 59.5 (51.0-69.2) years, with 47 (23.6%) female patients. Median BMI was 31.0 (27.1-35.6) and apnea hypopnea index (AHI) 45.9 (31.9-66.0), indicating severe OSA. Twenty-seven patients (13.6%) suffered from insomnia. Thirty-eight patients (12.0%) refused CPAP treatment. After 6 (4-10) months, 85 patients underwent a follow-up visit showing a residual AHI of 3.3 (1.3-8.1) and 5.3 (4.4-6.3) hours of CPAP use. These variables did not show any gender differences. While snoring was the most reported symptom in both women and men (95.8%), women reported more nonrestorative sleep

(72.0% vs 55.9%, 0.046), less witnessed apneas (64.0% vs 73.1%, *p* 0.047) more insomnia (25.5% vs 9.9%, *p* 0.006) and hypothyroidism (15.0% vs 3.3.% *p* 0.005). Women with insomnia were older than those without (71 (64-72) vs 59 (51-67), *p* 0.012) and tended to use CPAP for less hours (5.4 (4.4-5.5) vs 6 (5.5-6.1), $p=0.072$).

Conclusion: In our sample women shared most of clinical features with men, probably due to the severity of OSA. However, women had more nonrestorative sleep and/or insomnia, possibly affecting CPAP adherence, showing it is crucial to take gender into account in clinical practice.

EPO-489 | Heart rate response in spontaneous microarousals uncovers an autonomous nervous dysfunction in narcolepsy type 1

C. Bernardes[1]; P. Correia[2]; M. Ferreira[2]; J. Moita[2]; I. Luzeiro[1]; A. Brás[1]
[1]*Neurology Department, Coimbra University Hospital Centre, Coimbra, Portugal*; [2]*Sleep Medicine Centre, Coimbra University Hospital Centre, Coimbra, Portugal*

Background and Aims: Narcolepsy type 1 (NT1) is characterized by the loss of hypothalamic orexin neurons important in the regulation of sleep-wake transitions. These cells have also been implicated in autonomous nervous system regulation and its disturbance has been recently suggested in NT1, although still unclear. This study aimed to assess heart rate (HR) response associated with spontaneous microarousals across sleep stages in NT1 compared to healthy controls.

Methods: Ten NT1 patients and 10 age-matched controls polysomnograpies were examined. Three to seven spontaneous microarousals in each sleep stage preceded by at least 30 seconds of stable sleep were randomly selected and analysed. The HR response was calculated based on the difference between the maximal and average HR during microarousal and average basal HR 10 seconds before the microarousal, and compared between groups.

Results: A total of 428 spontaneous microarousals were analysed (214 NT1 and 214 controls). The duration of spontaneous microarousals was significantly higher in NT1 for N1 (7.6 ±3.2vs5.8 ±1.6), N2 (7.0 ±2.2vs5.8 ±1.9) and N3 (7.1 ±2.6vs5.4 ±1.6). The difference between the average HR during and before microarousals was significantly higher in NT1 across all stages (N1 3.8 ±5vs0.5 ±4.3, N2 4 ±4.5vs0.5 ±3.9, N3 5.3 ±6.4vs2.3 ±4.3 and REM 3.9 ±6.1vs1 ±3.3). Considering the difference between maximal HR during and average basal HR before microarousals, a significantly higher variation was verified in N2 (11.5 ±6.9vs8.9 ±5.4) and REM (13.4 ±8.4vs9.2 ±6.7) for NT1.

Conclusion: The higher HR response in spontaneous microarousals during sleep points toward an enhanced sympathetic activity in the context of possible autonomic dysfunction. This reinforces the importance of looking for dysautonomia in NT1, given the associated morbimortality.

Disclosure: Nothing to disclose.

EPO-490 | REM without atonia index is inversely correlated with asymmetric nigrostriatal denervation in Dementia with Lewy Body

A. Castelli[1]; C. Bonomi[2]; C. Motta[2]; F. Placidi[1]; F. Izzi[1]; N. Mercuri[3]; A. Martorana[2]
[1]*Sleep Center, University of Rome Tor Vergata*; [2]*Memory Clinic, University of Rome Tor Vergata*; [3]*Neurology Unit, University of Rome Tor Vergata*

Background and Aims: The clinical heterogeneity of alpha-synucleinopathies is supported by different pathways of Lewy body accumulation. REM sleep behavioural disorder (RBD) is held as clinical marker of "body-first" phenotype, while nigrostriatal denervation is thought to reflect a "brain-first" involvement in the context of Parkinson's disease. We investigated the associations between polysomnographic features and DAT-SPECT findings in a cohort of patients with Dementia with Lewy Bodies (DLB).

Methods: We enrolled 13 patients with DLB (69.71±8.39 years old) diagnosed according to McKeith 2017 criteria, who underwent clinical examination, polysomnography (PSG) - with evaluation of REM without atonia (RWA) index (%) (AASM criteria) - and DAT-SPECT. Quantitative analyses were performed with the DaT-QUANT software. We evaluated sleep features in DLB patients and used Pearson's analysis to correlate PSG findings with DaT-QUANT measures.

Results: In our cohort, 11/13 patients showed PSG-RWA, 11/13 had altered DAT-SPECT. We observed a positive correlation between sleep efficiency and Striatal Asymmetry ($r=0.866$, $p=0.001$) and a negative correlation between sleep latency and Putamen Asymmetry ($r=-0.608$. $p=0.036$). Moreover, Caudate Asymmetry correlated inversely with RWA index ($r=-0.690$, $p=0.019$) and positively with extrapyramidal motor symptoms measured with UPDRS ($r=-0.697$, $p=0.025$).

Conclusion: Asymmetry in nigrostriatal denervation points to brain-first involvement, due to prevalent ipsilateral connections in the connectome. Our results suggests that in DLB a higher RWA index is linked with more symmetric nigrostriatal impairment (body-first phenotype), while lower RWA is found in patients with more prominent motor symptoms and asymmetric DAT-SPECT alterations (brain-first), supporting the existence of two distinct phenotypes in the disease.

Disclosure: Nothing to disclose.

EPO-491 | Bright light therapy in myalgic encephalomyelitis/ chronic fatigue syndrome patients

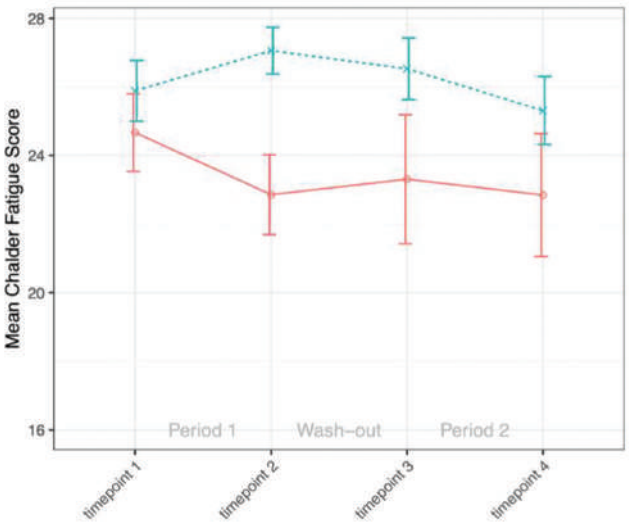
B. Ludwig; D. Moser; L. Hauer; K. Trimmel; S. Seidel
Department of Neurology, Medical University of Vienna, Vienna, Austria

Background and Aims: Chronic Fatigue Syndrome (CFS), also referred to as Myalgic Encephalomyelitis (ME), is a chronic, debilitating

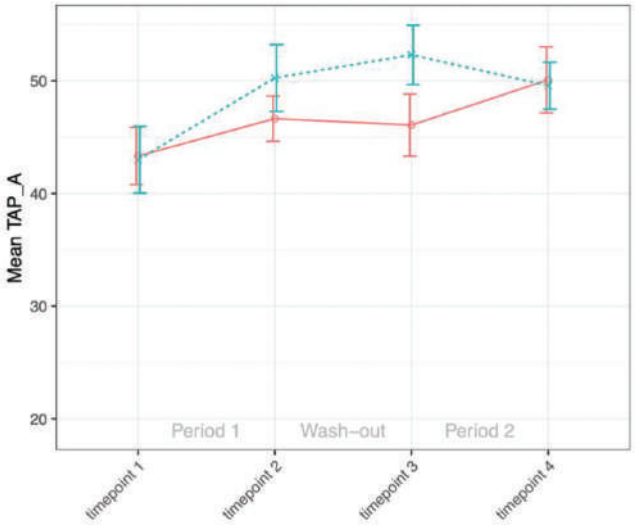
condition of unknown etiology and limited treatment options. Bright light therapy (BLT) has shown controversial results in studies with neurological patients experiencing fatigue symptoms. The aim of the current study was to test the effectiveness of BLT treatment on fatigue and cognitive function in patients with ME/CFS.

Methods: A randomized-controlled cross-over study design was chosen in order to provide all patients access to BLT treatment. 33 outpatients who met the diagnostic criteria according to the Institute of Medicine (2015) were randomly assigned to either start out with BLT or waitlist for the course of 2 weeks. After a 2-week wash-out phase, the assignment was reversed. Primary outcomes of the study were the Chalder Fatigue Score (CFQ) and the Test of Attentional Performance (TAP). A repeated measures ANOVA was performed to compare the effect of BLT on fatigue and cognitive function at baseline and the end of study.

Results: A statistically significant effect of BLT on subjective fatigue levels ($F(1,27) = 6.12$, $p = 0.02$) was found, irrespective of sequence of treatment/waitlist ($F(1,27) = 0.587$, $p = 0.45$). There was also a statistically significant effect of BLT on the domains Attention, ($F(1,26) = 11.96$, $p = 0.002$), irrespective of sequence of treatment/waitlist ($F(1,26) = 0.447$, $p = 0.51$). There was no statistically significant effect of BLT on the domains Divided Attention ($F(1,26) = 1.487$, $p = 0.23$) and Go-No Go ($F(1,27) = 1.93$, $p = 0.18$).



Rating of subjective fatigue with the Chalder Fatigue Score. Red line: group started with bright light therapy. Blue line: group started with waitlist.



Performance in the subdomain Attention of the standardized Test of Attentional Performance. Red line: group started with bright light therapy. Blue line: group started with waitlist.

Conclusion: These preliminary results suggest moderate effects of BLT on fatigue and cognition. Additional analyses accounting for possible placebo effects need to be considered.

Disclosure: Nothing to disclose.

EPO-492 | Periodic SREDA (subclinical rhythmic electrographic discharges of adults): A case report

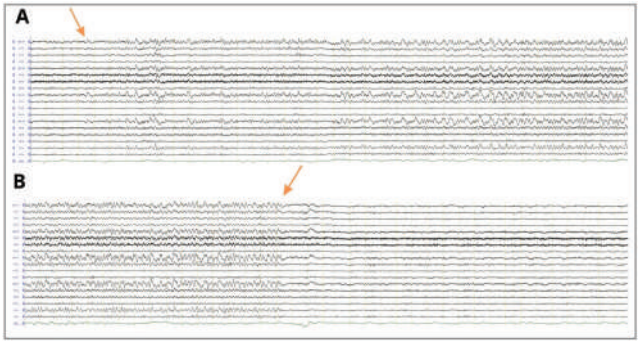
C. Brenlla; G. Mayà; A. Muñoz-Lopetegi; O. Brengaret; C. Gaig; A. Iranzo; J. Santamaría

Neurology Department, Hospital Clínic Barcelona, Barcelona

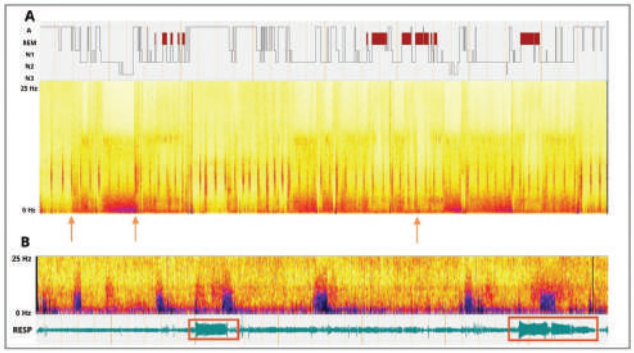
Background and Aims: SREDA (subclinical rhythmic electrographic discharges of adults) is a benign electroencephalographic (EEG) pattern, consisting of episodes during wakefulness of rhythmic theta activity in the frontoparietotemporal regions, without associated clinical findings. Atypical presentations with focal predominance, delta activity, or appearance during sleep have rarely been reported. It is important to recognize atypical SREDA patterns because they can mimic electrographic seizures.

Methods: We report a patient with atypical SREDA with a high number of episodes occurring periodically during sleep and wakefulness.

Results: A 70-year-old woman without past clinical history consulted because of chronic insomnia and nightmares. A nocturnal polysomnogram revealed a moderately reduced sleep efficiency with normal sleep architecture and 67 episodes of SREDA characterized by trains of moderate-high amplitude, diffuse theta-delta activity of anterior predominance, at 3-7 Hz, lasting 1-2 minutes, recurring every 8-9 minutes (range 2-15) throughout all phases of sleep and easily visible in the spectrogram (Figure 2A). A video-EEG during wakefulness revealed 7 episodes of SREDA (2 of them induced by hyperventilation which also increased their duration, figure 2B). The patient was able to talk, calculate, and perform simple and complex commands correctly.



An episode of SREDA starts in A (arrow) consisting of trains of theta-delta activity at 3-7 Hz, lasting 1-2 minutes, with an abrupt ending (arrow in B) and an immediate normalization of the record.



A) Hypnogram of 8 hr sleep recording and B) Daytime wake EEG showing more than 60 episodes of SREDA, indicated by the vertical red lines, appear periodically throughout all stages.

Conclusion: To our knowledge, this is the first report of a SREDA occurring periodically with a high frequency during wakefulness and all stages of sleep. Failure to recognize SREDA can lead to misdiagnoses and unnecessary and potentially harmful use of medication.
Disclosure: Nothing to disclose.

EPO-493 | The role of astrocytes in sleep and memory consolidation

C. Nome; A. Witoelar; P. Qanbari; L. Roth; L. Bojarskaite; L. Bordoni; R. Enger
GliaLab and The Letten Centre, Division of Anatomy, Department of Molecular Medicine, Institute of Basic Medical Sciences, University of Oslo, Oslo, Norway

Background and Aims: Astrocytes are known to participate in homeostatic functions, such as the regulation of extracellular ions, stabilization of the environment surrounding synapses, and regulation of blood flow. Some studies have also indicated that astrocytes might play a role in the regulation of sleep and transitions between sleep states. In this study, our aim is to investigate the role of astrocytes in sleep and memory consolidation in the hippocampus.
Methods: We conducted experiments on 5 BL6 mice, in which we expressed genetically encoded calcium indicators (GCaMP6f) to monitor intracellular calcium levels in astrocytes. Additionally, we surgically inserted a window to the hippocampal CA1 region, as well as LFP and ECoG electrodes. Two-photon microscopy and electrophysiology recordings were utilized to examine astrocytic calcium signals throughout the sleep-wake cycle.
Results: Our findings revealed a reduction in astrocytic calcium signaling during sleep, with an increase shortly before awakening. Currently, we are analyzing the relationship between astrocytic calcium signals and various electrophysiological oscillations linked to memory consolidation. We hope to present these results at the conference this year.
Conclusion: Our findings support the hypothesis that astrocytes might be involved in regulation of the different sleep states, and potentially can facilitate EEG oscillations involved in memory consolidation.
Disclosure: None.

EPO-494 | Assessing Obstructive Sleep Apnoea Syndrome risk in Behçet Syndrome patients: An actigraphic approach

A. Colitta[1]; S. Bruno[2]; F. Cruz-Sanabria[2]; A. Bazzani[3]; F. Starace[2]; E. Bonanni[1]; G. Siciliano[1]; M. Mosca[4]; R. Talarico[4]; U. Faraguna[2]
[1]Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa, Pisa, Italy; [2]Department of Translational Research and of New Surgical and Medical Technologies, University of Pisa, Pisa, Italy; [3]Institute of Management, Scuola Superiore Sant'Anna, Pisa, Italy; [4]Department of Clinical and Experimental Medicine, Rheumatology Unit, University of Pisa, Pisa, Italy

Background and Aims: Previous studies found a higher risk of Obstructive Sleep Apnoea Syndrome (OSAS) in Behçet Syndrome (BS) patients compared to healthy controls (HCs). However, limited research with proper matching criteria assessed differences in OSAS risk between these populations. Furthermore, actigraphy has recently emerged as a valuable screening tool to estimate OSAS risk, with no studies used actigraphy to characterize BS patients' sleep. This cross-sectional study aimed at testing possible differences in both sleep parameters and actigraphic OSAS risk among BS patients and age-, BMI-, sex-, smoking habits-matched HCs.
Methods: Sleep parameters were evaluated through the Pittsburgh Sleep Quality Index and a 7-day actigraphic continuous monitoring. Actigraphic OSAS risk was estimated through a validated machine-learning algorithm, dividing participants into two classes of OSAS risk, i.e., high and non-high OSAS risk. Possible differences in sleep parameters and actigraphic OSAS risk were tested through nonparametric tests. A binomial logistic regression model with Firth bias reduction method was estimated to test possible predictors of high OSAS risk among participants, i.e., HCs group, age, sex, BMI, being a smoker and smoking intensity.

Results: 45 BS patients (Table 1) and 60 HCs were included in the study. Compared to HCs, BS patients showed significantly lower perceived sleep quality ($p < 0.001$), actigraphic sleep efficiency ($p < 0.044$), and OSAS risk ($p < 0.010$)(Table 2). In the regression model, high OSAS risk was significantly predicted only by the HCs group (beta = 3.16; $p < 0.025$).

TABLE 1: Behçet Syndrome patients' clinical data

Clinical Data[1]	N = 45[2]
Age	48 (42, 54)
BMI	23.9 (22.2, 27.6)
Sex	
Female	30 (67%)
Male	15 (33%)
Disease Duration	5 (4, 13)
BDCAF	0 (0, 2)
Active Disease	8 (18%)
Clinical Manifestations at the time of recruitment	
Mouth ulcers	13 (29%)
Genital ulcers	3 (6.7%)
Erythema nodosum	3 (6.7%)
Pseudofolliculitis	5 (11%)
Arthralgia	8 (18%)
Arthritis	2 (4.4%)
Uveitis	2 (4.4%)
Headache	1 (2.2%)
Diarrhea	5 (11%)
Superficial vein thrombosis	1 (2.2%)
Fibromyalgia	23 (51%)
HLAB*51 mutation	27 (60%)
Immunomodulatory and immunosuppressive treatment	
GC Treatment	18 (40%)
dGC	5.0 (5.0, 8.8)
One-year cumulative GC dose	104 (0, 1,400)
Colchicine	14 (33%)
Methotrexate	1 (2.3%)
Cyclosporine	1 (2.3%)
Azathioprine	9 (21%)
Biologic Agents	34 (76%)
Mood Disorders and Insomnia Treatment	
Mood Disorders and/or Insomnia Treatment	12 (27%)
Trazodone	3 (6.7%)
Zolpidem	1 (2.2%)
SSRIs	5 (11%)
SNRIs	1 (2.2%)
TCAs	2 (4.4%)
Mood stabilizers	3 (6.7%)
Gabapentinoids	4 (8.9%)

[1] BDCAF: Behcet Disease Current Activity Form - Interval Scale. Active Disease: BDCAF ≥ 3. HLAB*51: Human Leukocyte Antigens B51. GC: glucocorticoids. dGC: daily glucocorticoid dose (prednisone equivalents, mg). One-year cumulative GC dose: the sum of the total amount of GCs administered to a patient over the year before the recruitment (prednisone equivalents, mg). SSRIs: Selective Serotonine Reuptake Inhibitors. SNRIs: Serotonine and Noradrenaline Reuptake Inhibitors. TCAs: Tricyclic Antidepressants.
[2] Median (IQR); n (%)

TABLE 2: differences in matching variables, sleep parameters and actigraphic OSAS risk between BS patients and healthy controls

Variable[1]	BS Patients, N = 45[2]	Healthy Controls, N = 60[2]	p-value
Age	48 (42, 54)	49 (36, 58)	0.9[3]
BMI	23.9 (22.2, 27.6)	23.8 (22.3, 27.2)	0.9[3]
Sex			0.4[4]
Female	30 (67%)	35 (58%)	
Male	15 (33%)	25 (42%)	
Smoking intensity	0 (0, 0)	0 (0, 0)	0.2[3]
Smokers	4 (8.9%)	11 (18%)	0.4[4]
TST	6.88 (6.30, 7.63)	7.19 (6.51, 7.72)	0.4[3]
SE	92.4 (88.8, 94.8)	94.1 (90.5, 96.1)	**0.044**[3]
WASO	33 (24, 46)	28 (19, 45)	0.2[3]
SFI	6.7 (4.8, 9.8)	6.6 (5.1, 9.5)	>0.9[3]
SRI	77 (72, 83)	77 (66, 85)	0.9[3]
High actigraphic OSAS risk	0 (0%)	9 (15%)	**0.010**[4]
PSQI	8 (6, 11)	6 (3, 7)	**<0.001**[3]

[1] BS: Behçet Syndrome. BMI: Bodi Mass Index (kg/m^2). Smoking intensity: number of cigarettes per week. SE (Sleep Efficiency, %): the ratio of total sleep time to time in bed. TST: Total Sleep Time (hours). WASO (Wake After Sleep Onset, minutes): the period of wakefulness that occurs after a defined sleep onset. SFI (Sleep Fragmentation Index): the total number of awakenings divided by the total sleep time. SRI (Sleep Regularity Index, %): the likelihood of the same sleep-wake state occurring in epochs that are 24 hours apart. OSAS: Obstructive Sleep Apnea Syndrome. PSQI: Pittsburgh Sleep Quality Index.
[2] Median (IQR); n (%)
[3] Wilcoxon rank sum test
[4] Fisher's exact test

Conclusion: Compared to HCs, BS patients show lower perceived sleep quality, actigraphic sleep efficiency, and OSAS risk, irrespective of age, BMI, sex, and smoking habits.

Disclosure: Ugo Faraguna is President and co-founder of Sleepacta s.r.l., a University of Pisa spin-off private company, focused on sleep diagnostics.

EPO-495 | Utilizing transcranial direct current stimulation (tDCS) for insomnia

P. Yi[1]; Y. Su[2]; F. Chang[2]
[1]*Department of Sport Management/Aletheia University*; [2]*Graduate Institute of Veterinary Medicine/National Taiwan University*

Background and Aims: Transcranial direct current stimulation (tDCS) is acknowledged for its non-invasive modulation of neuronal activity in psychiatric disorders, with varied outcomes observed in insomnia research based on different tDCS types and patient conditions. Our primary goal is to elucidate the effectiveness of tDCS and reveal the underlying mechanisms in treating insomnia. We hypothesize that anodal prefrontal cortex stimulation activates glutamatergic projections from the infralimbic cortex (IL) to the ventrolateral preoptic area (VLPO), promoting sleep.

Methods: Electroencephalogram (EEG) electrodes were surgically implanted for sleep-wake data capture. The tDCS electrode was positioned over the infralimbic cortex on the skull, with the reference electrode using the EEG reference electrode. Designer receptors exclusively activated by designer drugs (DREADDs) selectively inhibited the IL-VLPO pathway, aiming to unveil its contribution to tDCS effects.

Results: Administering 0.06 mA of electrical currents for 8 minutes led to a significant increase in non-rapid eye movement (NREM) sleep in naive mice during the initial 3 hours post-stimulation, persisting up to 16-24 hours. In the insomnia group, tDCS enhanced NREM sleep bouts during acute stress response and improved both NREM and REM sleep duration in subsequent acute insomnia. NREM delta powers, assessing sleep quality, remained unchanged. Intervention in the IL-VLPO pathway using DREADDs with the cre-DIO system partially inhibited tDCS efficacy in improving sleep in stress-induced insomnia.

Conclusion: This research clarified that the activation of the IL-VLPO pathway mediates tDCS's impact on stress-induced insomnia, providing valuable insights for future investigations and clinical applications in sleep therapy.

Disclosure: Nothing to disclose.

EPO-496 | Screening restless leg syndrome in neuromyelitis optica and myelin oligodendrocyte glycoprotein-IgG associated disorder

I. Albajar; P. Iruzubieta; J. Equiza; D. Campo-Caballero; G. Nuñez; N. Andres; M. Arruti; T. Castillo; A. Muñoz-Lopetegi
Neurology, Donostia University Hospital, Spain

Background and Aims: Restless legs syndrome (RLS) is a sleep disorder which is diagnosed clinically, affecting 5.6% of Spanish population. Neuromyelitis optica spectrum disorder (NMOSD) and Myelin oligodendrocyte glycoprotein-IgG associated disorder (MOGAD) are immune-mediated inflammatory conditions of the central nervous system. To our knowledge, RLS in NMOSD or MOGAD had not been studied.

Methods: We designed an observational retrospective study. We reviewed data from 151 patients coded as "NMO", "MOGAD", "optic neuritis", "mielitis" or "isolated clinical syndrome". 12 met 2015 criteria for NMOSD and 11 met 2023 criteria for MOGAD. 1 met exclusion criteria and we were unable to contact 2. We administered the Cambridge–Hopkins RLS questionnaire by phone, with follow up open ended questions.

Results: In the NMOSD group, median age was 56 (39-80 y.o.), all female, median EDSS of 4 (0-8), 9/10 suffered spinal cord lesions. In the MOGAD group, median age was 46 (19-61 y.o.), 5 female, 5 male, median EDSS of 0 (0-2), 5/10 suffered spinal cord lesions. 7/10 NMOSD and 3/10 MOGAD had paresthesia, 4/10 NMOSD and 2/10 MOGAD had chronic neuropathic pain and 5/10 NMOSD and 2/10 MOGAD had leg cramps. 4/10 NMOSD and 1/10 MOGAD questionnaires were compatible with definite RLS. However, when asked open-ended questions 4 patients presented RLS-mimicks. Only 1 NMOSD patient was diagnosed with mild RLS.

Conclusion: Our work highlights the importance of validating RLS questionnaires in NMOSD and MOGAD patients, as RLS mimics are common. We did not find a higher-than-expected prevalence of RLS in these patients.

Disclosure: No disclosures.

EPO-497 | Prevalence of sleep disorders in the elderly: A questionnaire-based study

S. Maio[1]; M. Fernandes[2]; M. Antonucci[2]; F. Capecci[2]; N. Mercuri[2]; D. Della Morte[2]; C. Liguori[1]
[1]*Sleep Medicine Center, Neurology Unit, University Hospital of Rome "Tor Vergata", Rome, Italy;* [2]*Department of Systems Medicine, University of Rome "Tor Vergata", Rome, Italy*

Background and Aims: Several studies highlighted a high prevalence of sleep disorders in the elderly population: this could depend on different factors including neuropsychiatric comorbidities, medication use or circadian sleep-wake cycle alterations. The aim of the present study is to assess the prevalence of sleep disorders in geriatrics patients, according to sex and age, through validated screening questionnaires for sleep disorders, global cognition and depression.

Methods: This study included 58 subjects (58.6% women) with a mean age of 77.36 (SD = 6.07) admitted to the geriatrics clinic of the University Hospital of Rome "Tor Vergata". All participants were clinically evaluated and answered different questionnaires assessing sleep quality (Pittsburgh Sleep Quality Index-PSQI), insomnia (Insomnia Severity Index-ISI), sleep apnea risk (Berlin Questionnaire), excessive daytime sleepiness (Epworth sleepiness scale-ESS), restless legs syndrome (International RLS Study Group Scale-IRLSS), chronotype (Morningness-Eveningness Questionnaire-MEQ), depression (Geriatric Depression Scale-GDS) and global cognition (Mini-Mental Examination State-MMSE).

Results: We observed that the most frequent sleep-related complaint was worse quality of sleep measured through the PSQI (36.2%; $n = 21$), followed by sleep apnea risk (34.5%, $n = 20$), insomnia symptoms (25.9%, $n = 15$), EDS (15.5%, $n = 9$) and RLS (12.1%, $n = 7$). Insomnia symptoms, depression and worse sleep quality were more common in women than in men, while older patients (≥ 75 years) had more comorbidities and higher sleep apnea risk than the younger ones (<75 years).

Conclusion: Sleep disorders are frequent in the elderly and the screening through suitable questionnaires may facilitate their recognition and timely treatment.

Disclosure: Nothing to disclose.

EPO-498 | Nocturnal hypokinesia and sleep in Parkinson's disease

S. Diaconu[1]; I. Murasan[2]; D. Rusu[1]; B. Opritoiu[1]; L. Ungureanu[1]; C. Kakucs[3]; C. Falup-Pecurariu[1]
[1]*Department of Neurology, County Clinic Hospital, Brasov, Romania; Faculty of Medicine, Transilvania University, Brasov, Romania;* [2]*Department of Neurology, County Clinic Hospital, Brasov, Romania;* [3]*Faculty of Medicine, Transilvania University, Brasov, Romania*

Background and Aims: Bradykinesia is one of the main pillars in establishing the diagnosis of Parkinson's disease (PD). In addition to

affecting diurnal movement, hypokinesia can also occur during the night, affecting the quality of patients' sleep. Objective: Establishing the degree to which nocturnal hypokinesia impacts the sleep of PD patients.

Methods: The sleep of 131 PD patients was analysed using the Parkinson's Disease Sleep Scale (PDSS-2), Pittsburgh Sleep Quality Index (PSQI), Insomnia Severity Index (ISI) and Athens Insomnia Scale (AIS).

Results: Based on the response to item 9 of the PDSS-2 ("Did you feel uncomfortable at night because you were unable to turn around in bed or move due to immobility?"), PD patients were grouped into two categories: with nocturnal hypokinesia (PD + hypokinesia), which included 97 (74.04%) participants and no nocturnal hypokinesia (PD – hypokinesia), which included 34 (25.95%) participants. PD + hypokinesia patients showed statistically significantly higher scores than PD - hypokinesia patients for the PSQI scales (10.42 $\pm$4.84 vs. 6.50 $\pm$4.22, $p<0.001$), PDSS-2 (27.14 $\pm$9.61 vs. 13.76 $\pm$8.44, $p<0.001$), ISI (12.23 $\pm$5.58 vs. 6.21 $\pm$4.73, $p<0.001$) and AIS (9.64 $\pm$4.59 vs. 4.68 $\pm$4.48, $p<0.001$).

Conclusion: The prevalence of nocturnal hypokinesia among PD patients is high, and the sleep quality of these patients is significantly lower, compared to those with normal mobility during the night. A higher degree of insomnia was also identified among this category.

Disclosure: Nothing to disclose.

EPO-499 | Self-reported sleep difficulties and potentially inappropriate z-hypnotic use among older adults in primary care

T. Siddiqui[1]; T. Simonsen[1]; M. Bjelkarøy[2]; C. Lundqvist[2]
[1]*Health Services Research Unit, Akershus University Hospital, Lørenskog, Norway;* [2]*Health Services Research, Akershus University Hospital and Inst.Clin.Med, University of Oslo, Norway*

Background and Aims: This study aims to assess prevalence and severity of sleep difficulties and potentially inappropriate z-hypnotic use in a General Practitioner (GP) population, and further to examine the association between potentially inappropriate z-hypnotics and self-reported sleep difficulties.

Methods: A cross-sectional study, including 687 older adults recruited through 31 GPs in south-east Norway. We defined z-hypnotics inappropriate use as use over four weeks, three times or more per week. Sleep difficulties were reported as yes/no/sometimes, type, and reasons. Descriptive statistics and logistic regression mixed effect models were conducted.

Results: Out of 687 patients included, 10% had potentially inappropriate z-hypnotic use. Among all the participants, 22% reported difficulty sleeping. The participants reported trouble falling asleep (12%), trouble staying asleep (24%), and 29% experienced both. They reported various reasons for sleep difficulties, including pain (9%), overthinking at bedtime (27%), and 20 % experienced both, including bereavement in close relations. Patients experiencing difficulty sleeping, problems with falling asleep and staying asleep, and experiencing pain and overthinking at bedtime, had higher odds of being users of potentially inappropriate z-hypnotics, than patients without these experiences.

Conclusion: Older adults in primary care have a high prevalence of self-reported sleeping problems and a high proportion of potentially inappropriate z-hypnotics use. GPs need to be aware of patients sleeping problems and their appropriate treatments.

Disclosure: C.L had support for clinical studies (Lundbeck pharma) and received lecture honoraria. All other authors have nothing to disclose.

EPO-500 | Evidence for hypometabolism in epileptic focus and GABA alterations in drug-resistant MRI-negative TLE

S. Wu[1]; G. Yan[2]; R. Wu[1]
[1]*Department of Radiology, Second Affiliated Hospital of Shantou University Medical College, Shantou, China;* [2]*Department of Radiology, Second Affiliated Hospital of Xiamen Medical College, Xiamen, China*

Background and Aims: Increasing evidence suggests that the hypometabolism of the epileptogenic focus affects the treatment prognosis of temporal lobe epilepsy (TLE). Epileptic seizures involve neurotransmitter synthesis and consumption, accompanied by central nervous system energy substance depletion. Therefore, we attempted to investigate the metabolic levels of the epileptogenic focus through single-voxel MRS to provide more evidence for the correlation between hypometabolism of the epileptogenic focus and drug-resistant epilepsy in MRI-negative TLE.

Methods: 47 patients of MRI-negative TLE were divided into a drug-resistant group ($n=9$) and a drug-responsive group ($n=38$) based on their response to medication. Brain metabolite concentrations were quantitatively analyzed by using LCModel. MRS data were compared with those of 20 age- and gender-matched healthy controls, analyzing differences in epileptic focus indicated by video-EEG metabolite changes among different groups.

Results: GABA (gamma-aminobutyric acid) ($p=0.048$), Glu ($p=0.039$), NAA ($p=0.002$), NAAG ($p<0.001$), Cho ($p=0.004$), Cr ($p=0.046$) concentrations on the epileptic side were significantly lower than contralateral in patients. Interestingly, the difference was most evident in patients with drug-resistant epilepsy. GABA was significantly different between the drug-resistant, drug-responsive, and healthy controls group ($p=0.019$).

Conclusion: GABA and Glu levels are significantly reduced on the epileptic side. These metabolite levels were even lower in drug-resistant epilepsy. Cho and Cr are important substances for brain energy regulation and supply, the reduction of them also affects neurotransmitter synthesis, thereby influencing neuronal excitability. This study supports the correlation between hypometabolism of the epileptic focus and poor prognosis in drug-resistant MRI-negative TLE.

Disclosure: The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

EPO-501 | Before and after: Favorable radiological evolution in a pseudotumoral form of multiple sclerosis treated with rituximab

B. Rodríguez García[1]; M. Ravelo León[1]; A. González García[1]; D. Gómez de la Torre Morales[1]; J. Rodríguez Carrillo[1]; J. Aguilera Aguilera[1]; J. Morán Sánchez[1]; G. Carvalho Monteiro[1]; J. Velázquez Pérez[1]; J. Paniagua Escudero[2]; A. Hernández Lain[3]; Y. el Berdei Montero[1]

[1]Neurology Department, Hospital Universitario de Salamanca, Salamanca, Spain; [2]Radiology Department, Hospital Universitario de Salamanca, Salamanca, Spain; [3]Pathological Anatomy Department, Hospital Universitario 12 de Octubre, Madrid, Spain

Background and Aims: Pseudotumoral lesions are an unusual demyelinating disease that could be related to multiple sclerosis and may simulate brain tumors, being necessary an appropriate differential diagnosis, even including brain biopsy. We report a case of a relapsing and progressive pseudotumoral form of multiple sclerosis (PFMS) in a patient controlled due to Rituximab.

Methods: Medical history review of a previously healthy 31-year-old man who developed ten days of progressive left hemiparesis.

Results: A brain magnetic resonance imaging (MRI) verified a T1 hypointense, T2/FLAIR hyperintense right centrum semiovale lesion with restricted diffusion and incomplete ring enhancement, and another similar left parietooccipital lesion (Fig.1). Cerebrospinal fluid (CSF) analysis showed hyperproteinorrachia, absence of IgG oligoclonal bands, negative anti-AQP4 and anti-MOG antibodies and positive HHV-6 PCR. He was treated with dexamethasone and ganciclovir with full recovery. Nine months later he presented a sudden right homonymous hemianopsia. A brain MRI revealed a new occipitotemporal lesion with the same radiological behaviour (Fig.1). CFS analysis without changes except negativization of HHV-6. He received five days of intravenous methylprednisolone with full recovery in the visual field. A new control brain MRI few months later manifested an asymptomatic left frontal injury and consequently a brain biopsy was performed. Pathological findings confirmed demyelination and the diagnosis of PFMS (Fig.2). He started biannual rituximab with good tolerability, remaining clinically stable and next brain MRIs didn't manifest progression (Fig.3).

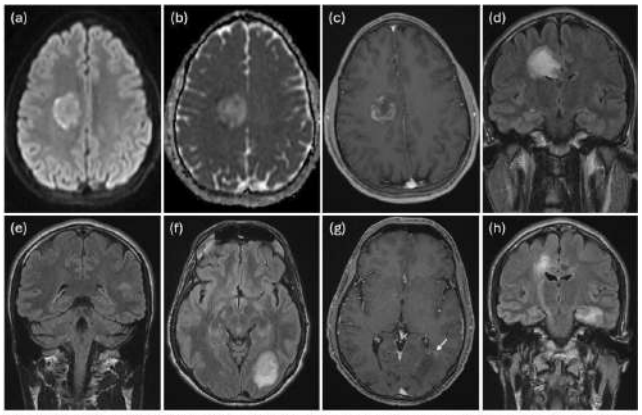

Fig. 1: In (a) and (b) restricted pattern in diffusion and in (c) an incomplete ring enhancement of right centrum semiovale lesion. In (d) hyperintense right centrum semiovale lesion. In (e) hyperintense left parietooccipital lesion. In (f) hyperintense left occipital lesion. In (g) incomplete ring enhancement of left occipital lesion. In (h) hyperintense Wallerian degeneration of the right corticospinal tract, right centrum semiovale and left temporal lesions.

EPO-502 | Unveiling the hippocampal subfield changes across the Alzheimer's disease continuum: a systematic review

B. Pancaldi[1]; A. Zilioli[1]; G. Busi[1]; F. Misirocchi[1]; I. Florindo[1]; D. Berron[2]; E. Westman[3]; M. Spallazzi[1]
[1]Department of Medicine and Surgery, Unit of Neurology, University-Hospital of Parma, Parma, Italy; [2]German Center for Neurodegenerative Diseases (DZNE), Magdeburg, Germany; [3]Division of Clinical Geriatrics; Center for Alzheimer Research; Department of Neurobiology, Care Sciences and Society, Karolinska Institute, Huddinge, Stockholm, Sweden

Background and aims: Studies exploring the hippocampal subregional changes in Alzheimer's disease (AD) have shown contradictory results. This review aims to disentangle such heterogeneity by systematically investigating the dynamic changes of hippocampal subfields across the AD continuum, from the asymptomatic to the dementia stage.
Methods: We systematically searched the PubMed and EMBASE databases for case-control studies. Selected studies included investigations of biomarker-based amyloid status and reported data on hippocampal subfield atrophy using advanced neuroimaging techniques. We assessed the quality of the studies using the Joanna Briggs Institute (JBI) Collaboration's ten-item checklist for case-control studies.
Results: We systematically searched the PubMed and EMBASE databases for case-control studies. Selected studies included investigations of biomarker-based amyloid status and reported data on hippocampal subfield atrophy using advanced neuroimaging techniques. We assessed the quality of the studies using the Joanna Briggs Institute (JBI) Collaboration's ten-item checklist for case-control studies.

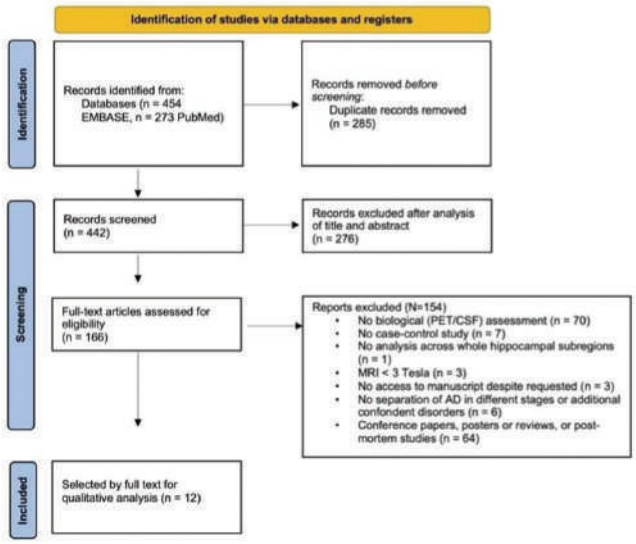

TABLE 1 Modified version of the PRISMA flow chart (Page et al., 2021).

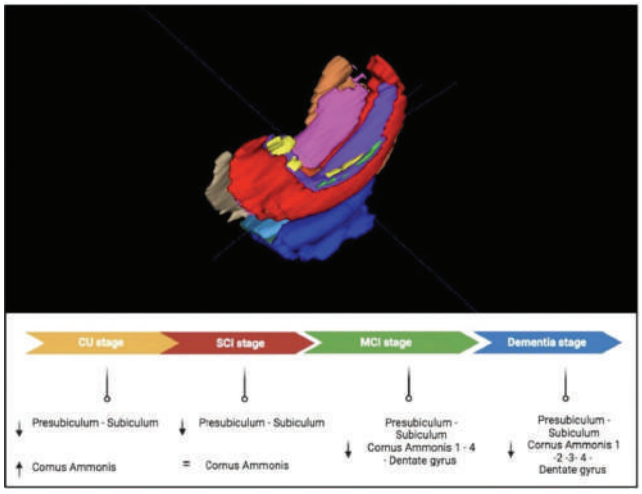

FIGURE 1 An example of hippocampal subfield segmentation with 3D reconstruction obtained using the Automated Segmentation of Hippocampal Subfields software on a high-resolution T2 coronal sequence, along with an exploration of the dynamic changes in hippoca.

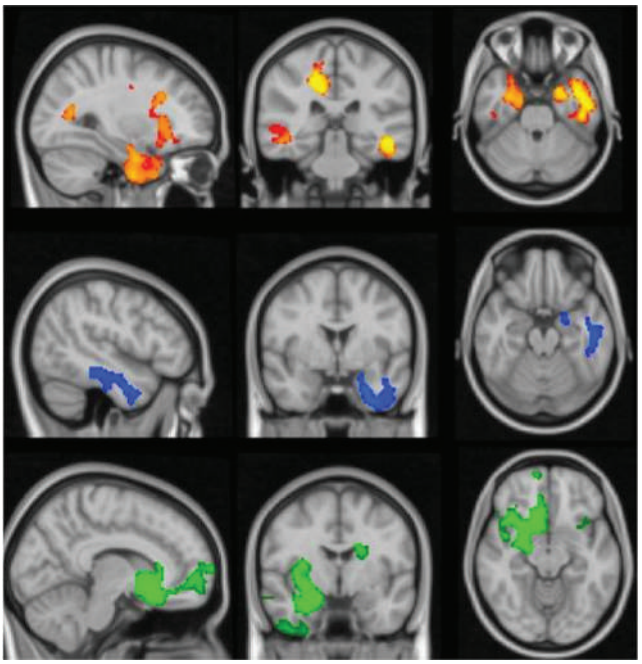
Conclusion: A distinguishable pattern of involvement of hippocampal subfields can be recognized from the cognitively unimpaired phase to the dementia stage, shedding light on hippocampal changes with disease progression, as well as the functional role of hippocampal subregions.
Disclosure: Nothing to disclose.

EPO-503 | Right temporal variant frontotemporal dementia: A multimodal MRI analysis of a new emerging syndrome

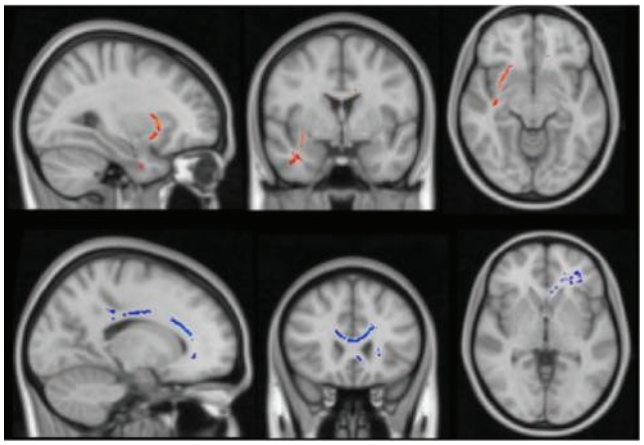
D. Salvatori[1]; C. Gallingani[1]; C. Carbone[1]; M. Tondelli[1]; R. Bedin[2]; G. Vinceti[2]; A. Chiari[2]; G. Zamboni[1]
[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Italy; [2]Neurology Clinic, Azienda Ospedaliero Universitaria of Modena, Italy

Background and Aims: Right-temporal-variant frontotemporal dementia (rtvFTD) is characterized by right anterior temporal lobe (rATL) atrophy and peculiar clinical presentation. Clinical diagnosis is challenging since rtvFTD shares features with both behavioral-variant FTD (bvFTD) and semantic-variant primary progressive aphasia (svPPA). Few studies investigated patterns of gray matter (GM) atrophy. Even less is known about white matter (WM) involvement. We conducted a preliminary-MRI-study on the rtvFTD neuroimaging features.
Methods: We compared GM volume and WM microstructural integrity in rtvFTD and svPPA patients and healthy controls, using voxel-based morphometry (VBM) and tract-based spatial statistics (TBSS), considering age and disease duration as covariates of no interest.
Results: SvPPA patients showed GM atrophy in the left temporal structures relative to HC. rtvFTD patients compared to HC showed GM atrophy in the right fronto-temporal structures, but also in insula

bilaterally and in left temporal and orbitofrontal cortices. RtvFTD were more atrophic than svPPA patients in fronto-temporal regions bilaterally. Moreover, rtvFTD patients had less WM integrity than controls in corpus callosum, right inferior fronto-occipital, inferior longitudinal and uncinate fasciculi. SvPPA patients had decreased WM integrity in corpus callosum and left inferior fronto-occipital fasciculus.



Results of VBM analysis. In red-yellow, regions of rtvFTD patients' GM atrophy compared to controls. In blue svPPA patients' GM atrophy compared to controls. In green regions of rtvFTD patients' GM volume greater reduction in comparison to svPPA patients.



Results of TBSS analysis. In red-yellow, regions of rtvFTD patients' decreased WM integrity compared to controls. In blue-light blue regions of svPPA patients' decreased WM integrity compared to controls.

Conclusion: RtvFTD patients show greater atrophy compared to svPPA patients in both hemisphere, independently of disease duration, suggesting that rtvFTD and svPPA do not mirror each other in GM loss and that a neurodegenerative process starting in the right hemisphere must be more widespread to become clinically evident. Moreover rtvFTD patients show WM disruption in fasciculi which have been implicated in face recognition, emotion processing and language functions.

Disclosure: Nothing to disclose.

EPO-504 | In-vivo PET study of mitochondrial complex 1, sigma-1, & synaptic vesicle 2A in amyotrophic lateral sclerosis patients

E. de Natale[1] ; J. Verghese[1]; A. Terry[1]; H. Wilson[1]; P. Khosropanah[1]; H. Wright[1]; L. Passamonti[2]; K. Evans[2]; R. Comley[3]; H. Tsukada[4]; J. Passchie[5]; G. Searle[5]; E. Pererva[5]; R. Gunn[5]; E. Rabiner[5]; M. Politis[1]; MIND-MAPS Consortium

[1]Neurodegeneration Imaging Group, University of Exeter Medical School, London, UK; [2]Biogen, Cambridge, MA, USA; [3]AbbVie, North Chicago, IL, USA; [4]Hamamatsu Photonics, Hamakita, Hamamatsu, Shizuoka, Japan; [5]Invicro Centre for Imaging Sciences, Hammersmith Hospital, London UK

Background and Aims: This study investigates the potential link between mitochondrial energy dysfunction and synaptic impairment that may contribute to neurodegeneration in Amyotrophic Lateral Sclerosis (ALS). We present preliminary findings from an ongoing longitudinal in-vivo imaging study of mitochondrial complex-1 (MC1), synaptic vesicle protein-2A (SV2A), and sigma-1 receptor (S1R), in ALS patients.

Methods: Nine patients with sporadic ALS (mean age: 59.1±9.7 years, King's staging: 2.42±1.08), and nine matched healthy controls (HC, mean age: 54.2±13.7 years), underwent clinical evaluation, a 3T MRI, and PET/CT scans using [18F]BCPP-EF for MC1, [11C]UCB-J for SV2A, and [11C]SA-4503 for S1R. Analysis deployed the Clinical Imaging Centre atlas for cortical and subcortical Region of Interest (ROI). Volume of distribution (VT) was the primary outcome measure for each tracer. Additional measures included VT corrected for plasma free fraction (VT/fp), and Distribution Volume Ratio minus 1 (DVR-1), using the Centrum Semiovale as reference. Due to notable volumetric differences between ALS and HC in cortical and subcortical ROIs, partial volume correction was applied.

Results: The ALS cohort had a mean ALSFRS of 41.44±4.5. Trends of lower [18F]BCPP-EF VT was observed in ALS patients, with significant difference in the amygdala (-16.4%, $p=0.026$). Conversely, [11C]UCB-J VT was significantly greater in the posterior cingulate (+11.2%, $p=0.036$) in ALS. No significant differences were detected in [11C]SA-4503 binding.

Conclusion: These preliminary, cross-sectional findings, provide initial evidence of altered MC1 and SV2A expression in ALS patients, compared with healthy controls. Collection of clinical and imaging data for up to 16 ALS patients, at baseline and at follow-up, is ongoing.

EAR is an employee of Invicro, KCE was an employee and stock-holder of Biogen at the time the study was conducted. RAC is an employee and shareholder of AbbVie Inc.

EPO-505 | Synaptic density loss in patients with multiple system atrophy: An in-vivo [11C]UCB-J PET molecular imaging study

H. Wilson[1]; E. de Natale[1]; A. Terry[1]; J. Verghese[1]; G. Pagano[1]; P. Khosropanah[1]; L. Passamonti[2]; R. Hutchison[2]; K. Evans[2]; H. Wright[1]; M. Howard[1]; L. Cashmore[1]; Y. Lewis[3]; E. Rabiner[3]; M. Politis[1]

[1]Neurodegeneration Imaging Group, University of Exeter Medical School, UK; [2]Biogen, Cambridge, MA, USA; [3]Invicro Centre for Imaging Sciences, Hammersmith Hospital, London UK

Background and Aims: This study represents an initial in-vivo investigation of pre-synaptic terminal density in patients with Multiple System Atrophy (MSA), using the synaptic vesicle glycoprotein 2A (SV2A) selective PET radioligand [11C]UCB-J.

Methods: Ten MSA patients classified according to the 2022 Movement Disorders Society diagnostic criteria ($n=5$ MSA-P; $n=5$ MSA-C, age: 61.6±5.7), underwent a [11C]UCB-J PET scan with arterial blood collection. For comparison, [11C]UCB-J PET previously acquired from 11 Parkinson's disease (PD, age: 59.0±9.0) and 16 healthy controls (HCs, age: 61.4±12.5). We employed a one tissue-compartment model to calculate total volumes of distribution (VT) for each a priori defined region-of-interest, and subsequently calculated a regional distribution volume ratio parameter (VTROI/ VTCSO=DVR-1) using the centrum semiovale (CSO) as a pseudo-reference region.

Results: [11C]UCB-J DVR-1 was significantly decreased in MSA compared to HCs in the putamen (-17%; $p=0.001$), brainstem (-39%; $p=0.022$) and cerebellum (-22%; $p=0.003$). MSA-P exhibited a reduction in [11C]UCB-J DVR-1 in the putamen compared with HCs (-27%; $p<0.001$) and PD (-20%; $p=0.05$), and additionally in the brainstem (-42%; $p=0.03$) and cerebellum (-26%; $p<0.001$) compared to HCs. MSA-C showed decreased [11C]UCB-J DVR-1 in the cerebellum (-18%; $p=0.053$) compared to HCs. [11C]UCB-J DVR-1 in the putamen was lower in MSA-P compared to MSA-C (-28%; $p=0.014$). Alternative outcome parameters (VT and VT/plasma free fraction) showed similar patterns of reduction.

Conclusion: Our initial findings show evidence of reduced SV2A density in brain regions known to be affected by MSA pathology. Baseline and longitudinal follow-up data collection is ongoing to assess if [11C]UCB-J PET can effectively track disease progression.

Disclosure: This research was conducted with support from Invicro, a Konica Minolta Company and the MIND-MAPS Consortium, incorporating AbbVie, Inc., Biogen, Inc., Celgene, Inc., Pfizer, Inc., and Takeda, Inc. EPO-506 | Abstract withdrawn

EPO-507 | Functional connectivity and microstructural integrity changes in Amyotrophic Lateral Sclerosis

P. Khosropanah[1]; H. Wilson[1]; E. Rosario de Natale[1]; J. Verghese[1]; A. Terry[1]; L. Passamonti[2]; K. Evans[2]; C. Bishop[3]; J. O'Callaghan[3]; E. Rabiner[3]; M. Politis[1]

[1]Neurodegeneration Imaging Group, University of Exeter Medical School, UK; [2]Biogen, Cambridge, MA, USA; [3]Invicro Centre for Imaging Sciences, Hammersmith Hospital, London UK

Background and aims: This study aims to provide a comprehensive analysis, integrating structural, microstructural, and functional aspects, to understand brain changes and functional reorganization in Amyotrophic Lateral Sclerosis (ALS) through Magnetic Resonance Imaging (MRI). This differs from prior research focusing on individual MRI aspects.

Methods: We conducted 3-Tesla MRI scan on twelve ALS patients (age=56±12.3) and sixteen healthy (age=56±15.8) individuals. The sequences included diffusion tensor imaging, resting-state functional MRI, and structural-MRI. We analysed fractional anisotropy (FA), local functional connectivity, and cortical thickness using Tract-Based Spatial Statistics, Regional Homogeneity (ReHo), and surface-based methodologies, respectively.

Results: ALS patients exhibited significant atrophy in the bilateral precentral gyrus, left temporal pole, right-caudal-middle frontal gyrus, and pars-opercularis ($p<0.01$). Left precentral atrophy correlated with King's scale-staging (r=-0.67, $p=0.022$). Compared to controls, ALS showed altered local signal coherence (ReHo) in multiple regions (pAlphaSim<0.05, cluster-size >45 voxels), including frontal lobes, occipital, hippocampal areas, fusiform gyrus, and cingulum. ReHo was decreased in regions displaying significant atrophy ($p<0.05$), except for increased coherence in the right precentral. Reduced ReHo in the right middle frontal gyrus correlated with worse executive function on ECAS (r=0.73, $p=0.009$). FA was reduced in ALS in the bilateral posterior thalamic radiation, superior longitudinal fasciculus, posterior and anterior limb of internal capsule, corona radiata, cerebral peduncle, corpus callosum (body and splenium), motor fibers, fornix, and sagittal stratum ($p<0.05$).

Conclusion: Our multiparametric MRI study highlights complex compensatory mechanisms in ALS brain. Cortical atrophic areas, especially precentral, showed increased local functional connectivity. This underscores the intricate interplay between structural and functional changes in ALS.

Disclosure: This research was conducted with support from Invicro, a Konica Minolta Company and the MIND-MAPS Consortium, incorporating AbbVie, Inc., Biogen, Inc., Celgene, Inc., Pfizer, Inc., and Takeda, Inc. EAR is an employee of Invicro, KCE was an employee and stock-holder of Biogen at the time the study was conducted.

EPO-508 | Lipopolysaccharide induced microglial activation in Parkinson's disease patients: An in vivo PET study

E. de Natale[1]; J. Verghese[1]; A. Terry[1]; H. Wilson[1]; S. Antoniadis[1]; P. Khosropanah[1]; M. Howard[1]; H. Wright[1]; L. Cashmore[1]; A. Thomann[2]; V. Machado[2]; B. Zinnhardt[2]; G. Pagano[2]; M. Politis[1]
[1]*Neurodegeneration Imaging Group, University of Exeter Medical School, UK;* [2]*Roche Pharma Research and Early Development, Neuroscience and Rare Diseases Discovery and Translational Area, Roche Innovation Center Basel, Switzerland*

Background and Aims: Neuroinflammation plays a critical role in Parkinson's disease (PD) pathophysiology, but the exact underlying mechanisms are still unclear. We present preliminary data of an in vivo Positron Emission Tomography (PET) study with [11C]PBR28 and a pharmacological challenge with Lipopolysaccharide (LPS), aiming to visualise acute translocator protein (TSPO) changes reflecting microglial activation in PD.
Methods: Four people with Parkinson's (PwP), three with early disease (mean age 63.3±15 years) and one with MCI (age 61 years), and three healthy controls (mean age 61.33±10.41 years), underwent a PET/MR scan with [11C]PBR28 before, and four hours after intravenous injection of LPS (dose: 1ng/Kg). Percentage change of volume distribution (VT) in cortical and subcortical regions of interest was calculated with the formula %ΔVT = [(VTpostLPS/VTpreLPS) −1] x 100.
Results: PwP with early disease showed higher post-LPS TSPO levels compared to controls, more marked in frontal cortex (42.6% vs 32.1%), temporal cortex (45.4% vs 34.0%), hippocampus (34.3% vs 21.8%), amygdala (48.1% vs 13.6%), thalamus (48.8% vs 32.9%) and midbrain (38.8% vs 18.7%). The PwP with MCI showed smaller change of TSPO levels after LPS challenge in frontal cortex (15.2%), temporal cortex (13.4%), hippocampus (13.5%), amygdala (8.6%), thalamus (15.1%), and midbrain (15.0%).
Conclusion: These preliminary data show a trend for the differential widespread expression of microglial activation of PwP and healthy controls following a challenge with LPS which may provide valuable insights in the understanding of innate immune response. The process of gathering more data from additional PwP and healthy control subjects is currently in progress.
Disclosure: G.P., A.E.T., B.Z., and V.M. are full-time employees and shareholders of F.Hoffmann-La Roche Ltd.

EPO-509 | MRI–based radiomics features to predict post-stroke cognitive impairment: A pilot study

H. Dragoș[1]; A. Stan[1]; D. Muresanu[2]
[1]*Department of Neurosciences, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania;* [2]*RoNeuro Institute for Neurological Research and Diagnostic, Cluj-Napoca, Cluj, Romania*

Background and Aims: Post-stroke cognitive impairment (PSCI) occurs in about 20% of acute ischemic stroke (AIS) patients within the first months and is associated with poor long-term prognosis. MRI radiomics surpasses standard MRI in assessing the heterogeneity of AIS lesions and the subtle regional changes. This study aimed to develop a predictive model incorporating MRI radiomics features and clinical factors to accurately predict PSCI six months after AIS.
Methods: Data were collected from 40 patients with first-ever symptomatic supratentorial AIS confirmed by brain MRI without a history of cognitive impairment or dementia. AIS lesions were segmented using ADC and FLAIR images. First- and second-order statistics radiomics features were extracted using PyRadiomics software. Neuropsychological assessments consisting of the Montreal Cognitive Assessment test, Digit Symbol, Digit Backward, Stroop Color-Word Test, and Rey Auditory Verbal Learning test were performed one and six months after AIS.
Results: Baseline modified Rankin scale, National Institutes of Health Stroke Scale (NIHSS) score and radiomics score were independent predictors of PSCI. The area under the ROC curve of the clinical-radiomics model was 0.84 in the training cohort and 0.87 in the validation cohort.
Conclusion: The clinical-radiomics models outperformed individual clinical or radiomics models and seem to be a useful tool in predicting PSCI.
Disclosure: Nothing to disclose.

EPO-510 | New Year, new headache: A case report of spontaneous intracranial hypotension following a fall on New Year's Eve

I. Pueschel[1]; J. Gerber[2]; J. Schaefer[1]
[1]*Department of Neurology, University Hospital Carl Gustav Carus, Technische Universität Dresden;* [2]*Department of Diagnostic and Interventional Neuroradiology, University Hospital Carl Gustav Carus, Technische Universität Dresden*

Background and Aims: Spontaneous intracranial hypotension (SIH) is characterised by postural headache and is usually associated with cerebrospinal fluid (CSF) leaks. The main reasons for CSF leaks include dural tears and meningeal diverticula [1]. Tarlov cysts, CSF filled perineural cysts, constitute a very cause of SIH.
Methods: A 26-year-old female presented to the emergency department with postural headaches following a fall on New Year's Eve. Spinal magnetic resonance imaging (MRI) revealed a large sacral Tarlov cyst, as well as fluid accumulation along the S1 nerve root and free fluid in the presacral area. Cerebral MRI disclosed bilateral subdural hygromas. Digital subtraction myelography (DSM) and postmyelographic CT revealed a communication between the Tarlov cyst, the epidural and intrathecal spaces as well as a pathologic contrast distribution pattern beyond the cyst. Conservative management, encompassing bed rest, analgesics, caffeine, and intravenous fluids, was initiated.
Results: After ten days of conservative treatment, the patient achieved sufficient symptom control, even after discontinuation of all analgesics. Gradual mobilization was successful, leading to discharge after a total of 14 days.

Conclusion: Clinical and imaging findings indicated spontaneous intracranial hypotension, triggered by a traumatic rupture of an unusually large Tarlov cyst. The success of conservative management in this case suggests that, even with traumatic dural tears, a watchful waiting strategy may be considered before opting for more invasive interventions such as autologous blood patch or surgical treatment.
Disclosure: Nothing to disclose.

EPO-511 | Nerve ultrasound versus MR-Neurography monitoring disease course in chronic inflammatory demyelinating polyneuropathy

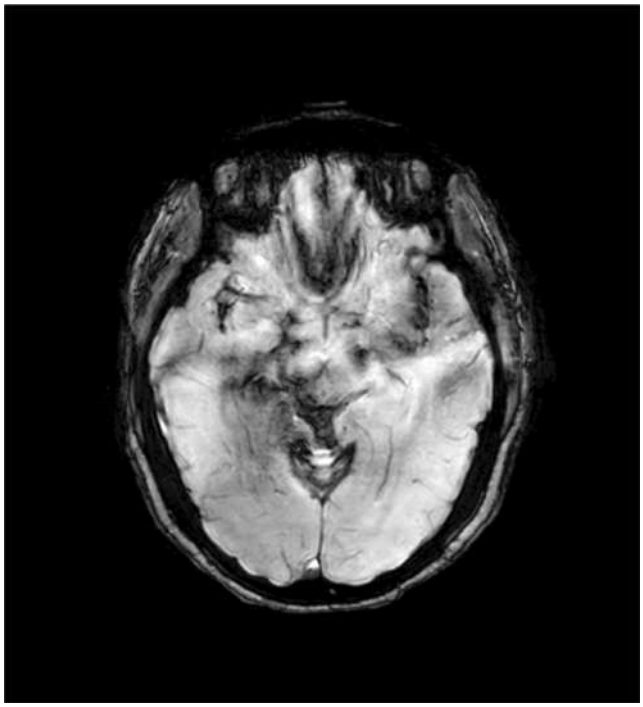
B. Lüling[1]; F. Preisner[2]; J. Motte[1]; A. Fisse[1]; T. Grüter[3]; T. Godel[2]; D. Schwarz[2]; S. Heiland[2]; M. Yoon[4]; R. Gold[1]; M. Bendszus[2]; M. Kronlage[2]; K. Pitarokoili[1]
[1]*Department of Neurology, St. Josef Hospital, Ruhr University of Bochum, Bochum, Germany*; [2]*Department of Neuroradiology, Neurological Clinic, Heidelberg University Hospital, Heidelberg, Germany*; [3]*Department of Neurology, Evangelical Hospital Lippstadt, Lippstadt, Germany*; [4]*Department of Neurology, Evangelical Hospital, Hattingen, Germany*

Background and Aims: We evaluated nerve ultrasound (NUS) and magnetic resonance neurography (MRN) for the longitudinal assessment of patients with chronic inflammatory demyelinating polyradiculoneuropathy (CIDP).
Methods: Twelve CIDP patients, who had received an initial MRN and NUS examination in 2016, were re-examined six years later in 2022. The cross-sectional area (CSA) of all peripheral nerves were evaluated with NUS bilaterally. The lumbosacral plexus, and sciatic, tibial and fibular nerves were evaluated using MRN (T2 weighted imaging and diffusion tensor imaging (DTI)). Imaging parameters were compared between time-points in correlation to clinical assessment.
Results: Over six years, nerve CSA of CIDP patients decreased at the lumbosacral plexus in MRN ($p = 0.015$) and remained stable in NUS. Comparison of the MRN values of the tibial nerve and fibular nerve at the popliteal fossa with a Bland-Altman analysis showed of bias of 2.195 and − 1.903 respectively. Longitudinally, changes in CSA of the lumbosacral plexus (MRN) and tibial nerve (MRN and NUS) correlated with changes in the inflammatory neuropathy cause and treatment validated overall disability sum score (INCAT/ODSS) ($p = 0.006$). Nerve CSA in the initial scan in MRN and nerve ultrasound were inversely correlated with changes in the INCAT/ODSS over six years ($p < 0.05$).
Conclusion: This study confirms the relevance of imaging studies for treatment monitoring in CIDP showing that nerve ultrasound and magnetic resonance neurography can provide reliably CSA values of proximal nerve segments and that changes in nerve CSA for proximal nerve segments reflects the clinical course of CIDP patients.
Disclosure: Nothing to disclose.

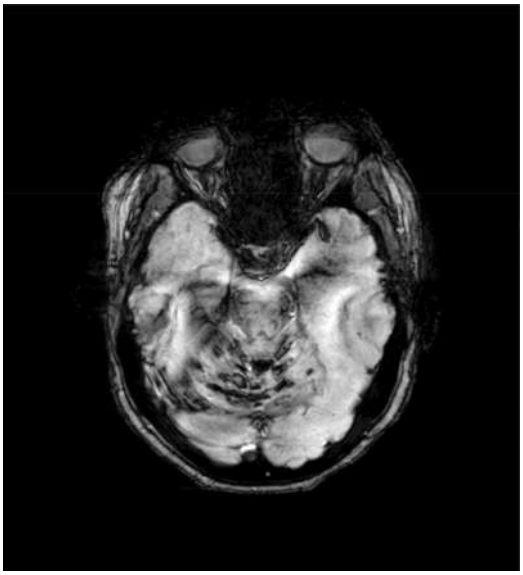
EPO-512 | Drop attacks as a presenting form of superficial central nervous system siderosis

D. Cerdán Santacruz[1]; C. Gómez López de San Román[1]; M. Capra[1]; M. Vargas Cobos[1]; L. Caballero Sánchez[1]; I. Bermejo Casado[1]; M. Álvarez de Eulate[2]; A. Castrillo Sanz[1]; P. Guerrero Becerra[1]; A. Mendoza Rodríguez[1]
[1]*General Hospital of Segovia, Neurology*; [2]*General Hospital of Segovia, Radiology*

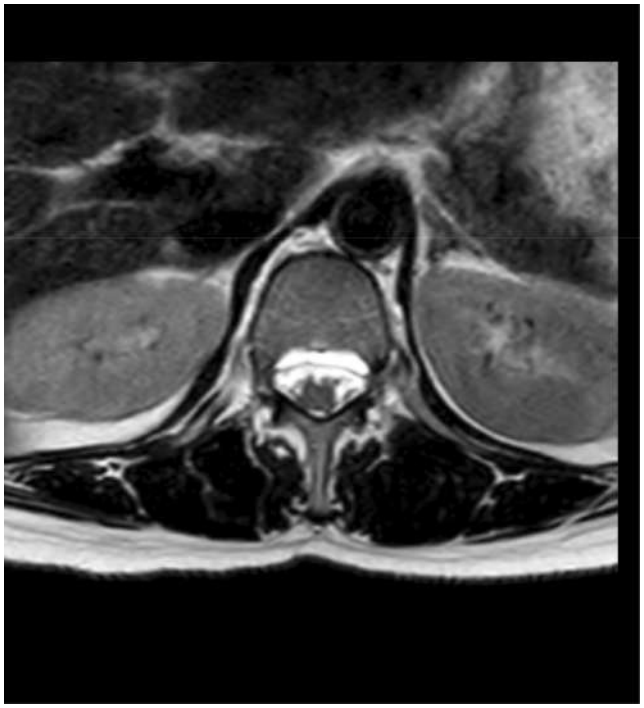
Background and Aims: Superficial siderosis of the CNS is a chronic condition with a broad differential diagnosis consisting of hemosiderin deposition in the subpial layers of the brain and spinal cord due to chronic bleeding into the subarachnoid space.
Methods: A 41-year-old female patient attended at neurology clinic for 4 months history of episodes consisting in sudden falls without warning. The patient's gaze remained fixed, with no speech, no sphincter relaxation or other abnormal movements with recovery in a few minutes but with a feeling of "slowness". The neurological examination is normal. In view of the suspicion of possible complex focal seizures, an EEG study was requested, as well as cranial and spinal MRI.
Results: EEG showed only isolated theta wave bursts of sharp morphology in the right temporal region. Axial T2-weighted brain MR images show hemosiderin deposition along the cerebellar folia, vermis and around the midbrain, pons and Sylvian fissures. Lumbar cord MRI T2-weighted image showed a fluid-filled epidural collection anterior to the spinal cord.



Axial T2_Sylvian fissures



Axial T2_cerebellar folia, midbrain, pons



Lumbar cord

Conclusion: Superficial central nervous system siderosis has a myriad of underlying aetiologies, which vary according to the age of presentation. The clinical picture is varied, depending on where the haemosiderin deposits are located, ranging from asymptomatic cases to frequent symptoms such as gait ataxia, hearing loss or myelopathy. Seizures may occur in less than 5% of patients.
Disclosure: Nothing to disclose.

EPO-513 | Neuroimaging of the brain in children with myotonic dystrophy type 1

E. Erokhina[1]; K. Shamtieva[2]; E. Melnik[3]; D. Kazakov[1]; D. Vlodavets[1]
[1]*Pirogov Russian National Research Medical University, Moscow, Russian Federation;* [2]*Lomonosov Medical Scientific and Educational Center of Moscow State University, Moscow, Russian Federation;* [3]*Research Centre for Medical Genetics, Moscow, Russian Federation*

Background and Aims: Myotonic dystrophy type 1 (DM1) is characterized by multisystem symptoms, in particular damage of the central nervous system. The purpose of the study was to evaluate changes in brain in children with different forms of DM1.
Methods: 13 children underwent magnetic resonance imaging (MRI) on a Magnetom Avanto Siemens Healthineers (Germany) with a magnetic induction value of 1.5 Tesla using a head coil. The MRI protocol included T1, T2 and T2 FLAIR weighted sequences (WI).
Results: All children with congenital DM1 had changes in the brain based on MRI. Lesions in the white matter were identified in 66.7%, including periventricular localization (50%), frontal and temporal (33.3%), parietal and occipital (16.7%). A third of patients with congenital DM1 have ventriculomegaly. Only two patients (28.6%) with the childhood form had hyperintense foci in the periventricular region and frontal regions of the brain on MRI. The pattern of lesions in the white matter of the temporal regions characteristic of DM1 was not detected in any patient, either with congenital or childhood forms. Signs of atrophy of the gray matter of the brain when assessed on the GCA scale were detected in 66.7% of patients with the congenital form. Patients with the childhood form were not characterized by gray matter damage.
Conclusion: The congenital form of DM1 is characterized by more pronounced damage white and gray matter of the brain compared to the childhood form. Children are not characterized by a specific pattern of hyperintensity of the temporal poles, which apparently appears at a later age.
Disclosure: Nothing to disclose.

Epilepsy 3

EPO-514 | Abstract withdrawn

EPO-515 | Epileptic seizures and cardiac disturbances: Expanding the brain-heart connection

L. Fernández Llarena[1]; A. Marinas Alejo[2]; P. De Ceballos Cerrajería[2]; I. Garamendi Ruiz[2]; A. Moreno Estébanez[1]; S. Ontiveros Navarro[3]; M. Sánchez Horvath[3]; C. Santos Sánchez[3]; C. Valido Reyes[1]; A. Rebollo Pérez[1]; V. Fernández Rodríguez[1]; A. Lagüela Alonso[1]; V. Anciones Martín[1]; Á. López Prado[1]; M. Martínez Seijas[1]; A. Rodríguez-Antigüedad Zarrantz[1]

[1]Neurology Department, Cruces University Hospital, Osakidetza Basque Health Service, Barakaldo, Spain; [2]Epilepsy Monitoring Unit, Neurology Department, Cruces University Hospital, Osakidetza Basque Health Service, Barakaldo, Spain; Epilepsy Group, Biocruces Bizkaia Health Research Institute, Osakidetza Basque Health Service, Barakaldo, Spain; [3]Epilepsy Monitoring Unit, Neurophysiology Department, Cruces University Hospital, Osakidetza Basque Health Service, Barakaldo, Spain; Epilepsy Group, Biocruces Bizkaia Health Research Institute, Osakidetza Basque Health Service, Barakaldo, Spain

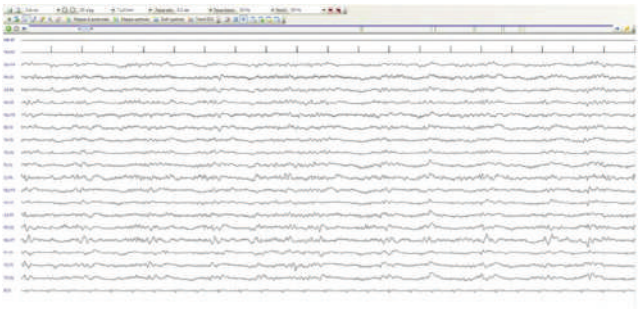
Background and Aims: The objective of this work is to analyse cardiac rhythm disorders induced by epileptic seizures registered in a long-term video-electroencephalography (v-EEG) monitoring unit.
Methods: Single-centre retrospective study of cases of ictal bradycardia, atrioventricular block (AVB), asystole and atrial fibrillation (AF) in patients admitted to the long-term v-EEG monitoring unit of our hospital, between 2012 and 2023. We excluded cases with ictal tachycardia due to its high frequency and those with cardiac arrhythmia.
Results: Cardiac rhythm disorders produced by a concomitant ictal discharge were documented in 30 patients (3'3%) out of 908 monitoring conducted over the 12 years of the study. Ictal bradycardia was detected in 19 patients (2.1%), 7 of them occurring in the postictal phase; 9 patients (1%) presented ictal asystole, with the lengthiest episode lasting 31 seconds; 1 patient (0.1%) had ictal AVB, and 1 patient (0.1%) experienced ictal AF. Long-term v-EEG monitoring revealed a temporal onset in 21 patients and an extratemporal onset in 9 patients, which usually were frontal or fronto-central. Among the recorded cases of ictal asystole, 2 patients required pacemaker placement. No patient experienced Sudden Unexpected Death in Epilepsy (SUDEP).
Conclusion: Ictal cardiac rhythm disturbances are an uncommon, poorly known, and underdiagnosed entity that have prognostic implications due to their association with increased morbidity and mortality. In our series, they were mostly related to epilepsies with temporal onset or involvement. The role of combined long-term v-EEG and electrocardiographic (ECG) monitoring is essential for their diagnosis, particularly in patients who exhibit sudden generalized hypotonia during epileptic seizures.
Disclosure: No disclosure to declare.

EPO-516 | Status epilepticus and acute cauda equina syndrome following intrathecal lidocaine administration: A case series

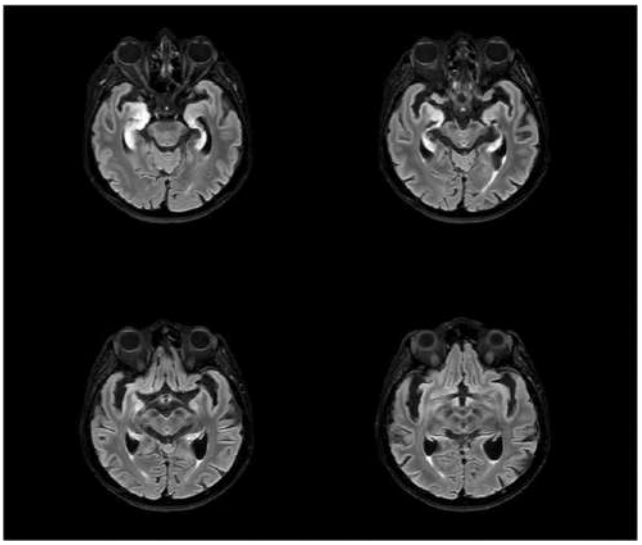
L. Pellegrino; G. Bruschi; D. Seppi; S. Favaretto; F. Dainese

Department of Neuroscience, Neurophysiopathology Unit, Neurology Clinic, Azienda Ospedale Università Padova, Padua (PD)

Background and Aims: Lidocaine (LA) is a widely used local anesthetic and analgesic, and a potential therapeutic option for status epilepticus; however, due to its neurotoxicity, it carries an associated risk of inducing life-threatening seizures and other neurological condition. The semiology and the treatment of these induced seizures remain poorly understood.
Methods: To describe the seizure-related behavior, clinical presentation, electroencephalographic patterns, and management strategies associated with incidental intrathecal LA administration.
Results: We present the three cases of two female of 80- and 42-year-old and a 39-year-old man who developed sudden cauda equina syndrome, bilateral mydriasis, altered state of consciousness, trismus, and clonic movements in the limbs after incidental paravertebral LA injection for chronic lumbar back pain. All patients were admitted to Intensive Care Unit. Blood and CFS tests were unremarkable. In two cases EEG showed generalized and lateralized periodic pattern. In one case, brain MRI showed bilateral hippocampal cytotoxic edema. Outcomes were various, one patient died and another developed mild cognitive impairment.



EEG_second_patient



RM_assial_FLAIR

EEG_first_patient

Conclusion: To this day, toxicity of intrathecal lidocaine administration is not clearly defined. This work can help healthcare personnel to provide accurate management of this rare iatrogenic condition.

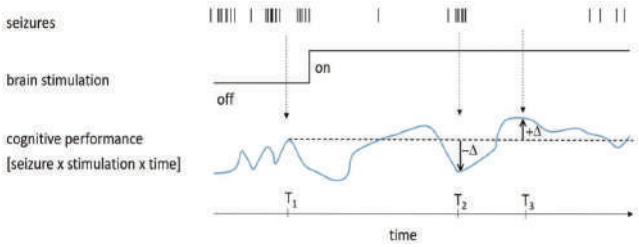
EPO-517 | Digital biomarkers and cognitive proxies for personalized care in epilepsy

L. Imbach; H. Jokeit
Swiss Epilepsy Center, Zurich, Switzerland

Background and Aims: Patients with epilepsy often suffer from cognitive impairments, including psychomotor speed, memory, attention, and executive function. The severity of these cognitive impairments may vary over time depending on seizure burden, interictal epileptic activity, medication and neuromodulation. In particular, intermittent deep brain stimulation may affect an individual's typical cognitive processing at short and intermediate time intervals. However, the severity and time course of these putative cognitive changes at the individual level cannot be adequately assessed by traditional neuropsychological tests.
Methods: Here we present pilot data from serial neuropsychological assessments in a cohort of pharmaco-resistant epilepsy patients in a controlled ANT-DBS ON/OFF/ON paradigm over several days ($n = 10$).
Results: We observed recognizable but partly inconsistent DBS effects on cognitive test performance, mainly in verbal and non-verbal memory domains, associated with active ANT-DBS. These results suggest that immediate (<24 h) and intermediate (>24h) patterns of DBS-induced cognitive effects may act independently. However, the time course of these dynamic changes is currently difficult to monitor using repeated point measures of neuropsychological test performance.
Conclusion: These partly inconsistent results favor a novel diagnostic approach: The widespread accessibility of smart devices offers new opportunities to use passively accessible biomarkers (heart rate, movement, written communication) as proxies for cognitive function in a continuous manner. We propose to use ecological "digital cognitive proxies" from smart devices that infer mental capacity from the speed, results and errors in cognitive tasks such as navigation, memory (codes, names, shortcuts), reading speed and writing errors to guide optimal personalized treatment while monitoring cognitive side effects.
Disclosure: None.



Cognitive performance in a particular domain (e.g. memory) fluctuates over time and is influenced by the interaction of seizure burden, pharmacotherapy, or neuromodulation. Point measurements over long periods of time (T1-T3) do not reveal the true fluctu.

EPO-518 | First seizure clinic: Experience at a tertiary hospital in Madrid

M. Arias Villaran; A. Suárez Plaza; M. Machío Castelló; E. González Villar; B. González Giraldez; J. Serratosa Fernández; L. Olivié García
Neurology, Fundación Jiménez Díaz Hospital, Madrid, Spain

Background and Aims: The diagnosis of epilepsy after a first seizure can be a challenge in clinical practice. The aim of this study was to analyze the diagnostic yield of a First Seizure Clinic (FSC) and describe the determining factors to establish a diagnosis of epilepsy.
Methods: Retrospective chart review for all patients referred to our FSC between June 2019 and December 2023. Our protocol includes a clinical evaluation within 1-6 days by an epilepsy specialist, a 1-hour sleep video-EEG and a brain-MRI.
Results: Ninety-five patients were included, 49/95 (51.6%) were diagnosed at the first visit: 28/95 (29.5%) were diagnosed of epilepsy and 21/95 (22.1%) with non-epileptic events. The diagnosis of epilepsy was based on the presence of previous unrecognized seizures in

11/28 patients (39.3%), on an abnormal EEG in 10/28 patients (35.7%), and on an abnormal MRI in 1/28 (3.6%). Eight patients lost follow-up after the first visit. During follow up, another 8 patients were diagnosed with epilepsy: 5/8 based on overnight video-EEG abnormalities and 1/8 on an abnormal MRI. Only in 2 patients the diagnosis remained unclear after follow-up. In the non-epileptic events group the diagnoses were convulsive syncope, anxiety, acute symptomatic seizures and TIAs.

Conclusion: In the setting of the FSC in our center, the diagnosis of epilepsy was mainly reached after a comprehensive clinical history and a 1 hour video-EEG. When the diagnosis of epilepsy remains unclear after a first seizure, an overnight video-EEG should be prioritized over brain MRI.

Disclosure: Nothing to disclosure.

EPO-519 | The impact of drug-resistant epilepsy in an outpatient clinic of a tertiary hospital

M. Grávalos[1]; J. Mayol[1]; E. Fonseca[2]; M. Quintana[2]; S. López-Maza[2]; D. Campos-Fernández[2]; L. Abraira[2]; E. Santamarina[2]; M. Toledo[2]

[1]Epilepsy Unit, Neurology Department, Medicine Department, Universitat Autònoma de Barcelona, Vall d'Hebron University Hospital, Barcelona, Spain; [2]Research group on Status Epilepticus and Acute Seizures, Vall d'Hebron Research Institute (VHIR), Vall d'Hebron University Hospital, Vall d'Hebron Hospital Campus, Barcelona, Spain

Background and Aims: We aimed to describe the differences in medical management and complications between refractory and non-refractory epilepsy patients.

Methods: Longitudinal prospective study including adult patients with epilepsy (PWE) evaluated at least once in an outpatient clinic of a tertiary hospital during 2023. Demographic and clinical data were collected, and emergency department consultations (ED) and antiseizure medications (ASM) were documented at each visit. Patients were categorized into non-resistant or drug-resistant epilepsy (DRE) according to the ILAE criteria.

Results: 2835 PWE (4935 visits; 51.1% men) were included, of which 785 (27.7%) had DRE. Drug-resistance was more common in focal epilepsy (29.7% vs. 19.6% in generalized epilepsy; $p<0.001$), in younger patients (44.1±17.8 vs. 51.1±20.7 years; $p<0.001$), and in patients with an earlier onset (24.3±22.4 vs. 42.4±26 years; $p<0.001$). DRE rate was significantly higher ($p<0.001$) in mesial temporal sclerosis (69.9%), malformations of cortical development (54.4%), genetic (46.1%) and perinatal hypoxia (44.4%). Patients with DRE accounted for a higher rate of outpatient consultations [median per patient/year: 2 (1-3) vs. 1 (1-2), $p<0.001$], ED consultations (25.5% vs. 16.9%; $p<0.001$) and traumatic injury resulting from seizures (2.1% vs. 0.8%; $p=0.014$). ASM changes were also higher in DRE patients (43.7% vs. 20.2%, $p<0.001$), especially in patients with mesial temporal sclerosis (49.5% vs 28%; $p<0.001$).

Conclusion: In our cohort, DRE patients exhibit a younger age, an earlier onset, and a higher prevalence of focal-related etiologies. They generate more outpatient and ED consultations and more changes in ASM regimen. These results reflect the challenge of managing these cases in clinical practice.

Disclosure: Nothing to disclose.

EPO-520 | Towards therapeutic innovation in temporal lobe epilepsy: Focal adenosinergic modulation of hippocampal excitability

M. Vergaelen[1]; J. Spanoghe[1]; J. Missinne[2]; S. Van Calenbergh[3]; K. Vonck[1]; P. Boon[1]; R. Raedt[1]

[1]4BRAIN, Department of Head and Skin, Ghent University, Belgium; [2]Center for Microsystems Technology, Imec and Ghent University, Ghent, Belgium; [3]Laboratory of Medicinal Chemistry, Department of Pharmaceutics, Ghent University, Ghent, Belgium

Background and Aims: The adenosine A1 receptor (A1R) is a promising therapeutic target in epilepsy by mediating neuronal inhibition. In this study, we investigated whether A1R signaling is still functional in the intrahippocampal kainic acid (IHKA) mouse model for temporal lobe epilepsy (TLE). The feasibility of spatial selective inhibition was evaluated by illumination of specific hippocampal subregions for optical uncaging of CPA from coumarin-caged CPA (cCPA).

Methods: In the CA1 and DG of acute hippocampal slices, the effect of adding 40 nM of the A1R agonist N6cyclopentyladenosine (CPA) on population spike (PS) amplitude to field postsynaptic potential (fPSP) slope, an index of excitability, was evaluated in epileptic IHKA versus healthy mice. Subregion selective inhibition of fPSPs was evaluated through application of 405nm light pulses (10 pulses of 100ms at 0.1Hz) spatially restricted to CA1 or DG of healthy slices incubated with 3μM cCPA.

Results: Administration of CPA resulted in a similar decrease in PS amplitude to fPSP slope ratio in epileptic versus healthy mice for the CA1 and DG ($n=19$, Figure1). In a slice incubated with cCPA, the excitability decreased selectively in the illuminated hippocampal subregion ($n=1$, Figure 2).

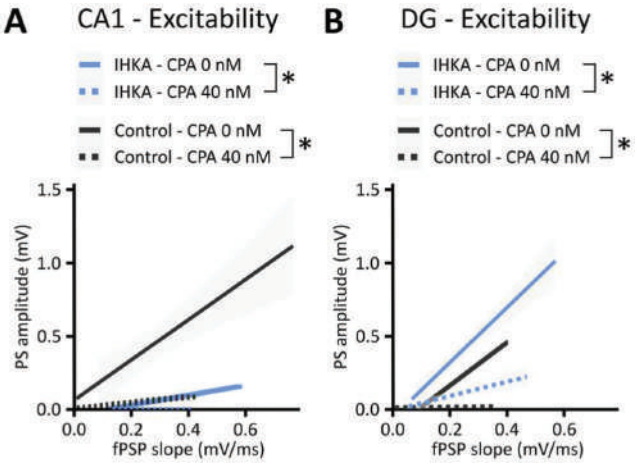


FIGURE 1 Similar decrease in CA1 and DG excitability (PS amplitude in function of fPSP slope) in epileptic IHKA versus healthy mice after administration of 40nM CPA. Data are shown as mean ± SEM. *$p<0.01$.

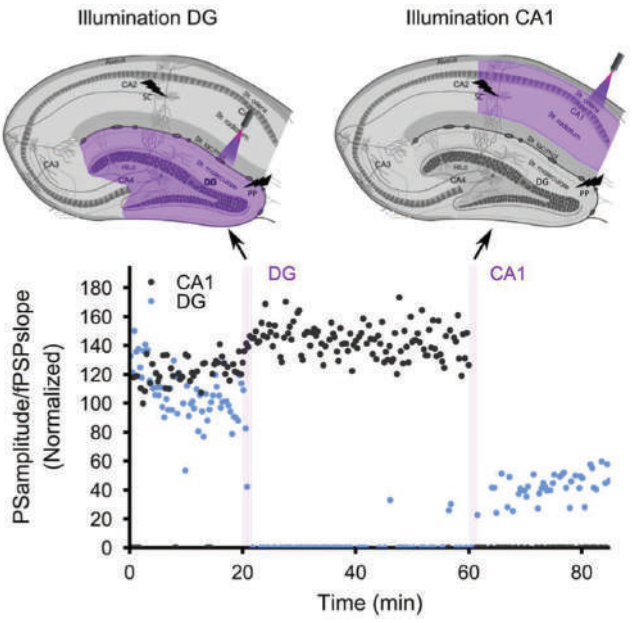

FIGURE 2 cCPA and focal illumination of DG or CA1 results in a decreased excitability (PS amplitude to fPSP slope) selectively in the illuminated region ($n = 1$).

Conclusion: The decrease in excitability is comparable in hippocampal slices of IHKA versus healthy mice upon exposure to CPA, indicating preserved A1R signaling in IHKA mice. The use of cCPA allows modulation of hippocampal subregions through localized illumination. These results indicate that photopharmacology has the potential to become a targeted therapy for TLE.

EPO-521 | Is the salivary concentration of lamotrigine and levetiracetam associated with clinical outcome and side effects?

P. Vassallo[1,2]; E. Choong[3]; I. Aícua-Rapún[1]; C. Stampfli[3]; P. André[2]; A. Rossetti[1]; T. Buclin[3]; L. Decosterd[3]; J. Novy[1]

[1]*Department of Clinical Neurosciences, Neurology Service, University Hospital (CHUV) and Faculty of Biology and Medicine of Lausanne, Switzerland;* [2]*Department of Clinical and Experimental Epilepsy, UCL Queen Square Institute of Neurology, London, UK;* [3]*Service and Laboratory of Clinical Pharmacology, University Hospital (CHUV) and Faculty of Biology and Medicine, Lausanne, Switzerland*

Background and Aims: The correlation between plasma and saliva concentration of anti-seizure medication (ASM) is well established. However, clinical acceptance of saliva therapeutic drug monitoring (TDM) is constrained by significant variability and limited sensitivity. We analysed the correlation between salivary levetiracetam and lamotrigine levels, and clinical efficacy and tolerance.

Methods: We collected blood and saliva samples over two years. Seizure freedom, defined as three times the longest pre-treatment inter-seizure interval or one year seizure-free without treatment changes, and adverse effects were assessed during programmed visits. Predictors of treatment response and adverse events were adjusted in a binary logistic regression model. Lamotrigine and levetiracetam median salivary and plasmatic concentrations were compared between groups categorised by treatment response and adverse effects.

Results: Among 296 adults with epilepsy, 84 (28%) achieving seizure freedom, were older, predominantly on monotherapy, and underwent fewer past ASM trials. 27 (9%), reporting adverse effects, had an older age at epilepsy onset. Seizure-free individuals on lamotrigine had a lower medication dosage (median 2.03 vs 3.26 mg/kg, $p = 0.07$) and salivary concentrations (median 1.39 vs 2.4 mg/L, $p = 0.11$). For levetiracetam, seizure-free individuals displayed lower plasma levels and medication dosage (median dosage 10.87 vs 19.23 mg/kg, $p < 0.000$), while those reporting side effects showed higher salivary concentrations (median 20 vs 14.40 mg/L, $p = 0.04$).

	TOTAL	ADV. EVENTS N= 27	NO ADV. EVENTS N= 269	P-VALUE	TEST USED	SEIZURE-FREE N= 84	ONGOING SEIZURES N= 190	P-VALUE	TEST USED

PV received personal funding for research from Ancrage Foundation and Novartis Stiftung für medizinisch-biologische Forschung unrelated to the current project. This external support played no role in the design, execution, or analysis of the present study.

EPO-522 | Abstract withdrawn

EPO-523 | Neuroimaging as a SUDEP predictor: what is known and what still needs to be uncovered? A systematic review

P. Quintieri; F. Dono; G. Evangelista; S. Consoli; S. De Angelis; C. Corniello; D. Liviello; S. Cipollone; F. Anzellotti; S. Sensi
Department of Neuroscience, Imaging and Clinical Science, "G. D'Annunzio" University of Chieti-Pescara, Chieti, Italy

Background and Aims: Sudden Unexpected Death in Epilepsy (SUDEP) is the most common cause of death in patients with poorly controlled epilepsy. To date, a higher risk of developing SUDEP is mainly identified by clinical factors, among which generalized tonic-clonic seizures and their frequency stand out. This review investigates the role of neuroimaging-based approaches as a tool to help predicting SUDEP.
Methods: We reviewed twelve articles investigating 62 SUDEP cases assessed with a variety of neuroimaging techniques. We set to compare these 62 cases with 469 epileptic patients and 132 non-epileptic controls (overall mean age 31.5 ±7.7). MRI, fMRI, PET and SPECT were carried out in all these groups.
Results: SUDEP and non-SUDEP cases differ anatomically and functionally. MRI data indicate differences in gray matter volumes in the hippocampal and cerebellar cortex. In addition, functional imaging revealed discrepancies in terms of network modulation within the brainstem, whose metabolism and perfusion deviate from physiological values assessed by PET and SPECT scans.
Conclusion: Correlations between the occurrence of SUDEP and neuroimaging alterations are emerging, but their predictive significance must be the object of further intensive investigation.
Disclosure: Nothing to disclose.

EPO-524 | Identification of risk factors for drug resistant epilepsy

R. Coa[1]; R. Lecca[2]; F. Arippa[3]; D. Fonti[4]; L. Polizzi[1]; A. Muroni[1]; M. Melis[1]; M. Figorilli[1]; M. Puligheddu[5]
[1]Epilepsy Centre, AOU Cagliari, Cagliari; [2]S.C Neurorehabilitation Po SS Trinità ASL Cagliari, Cagliari; [3]Department of Mechanical, Chemical engineering, University of Cagliari; [4]U.O. Neurology, P.O. Sirai, ASL Sulcis, Carbonia; [5]Department of Medical Sciences and Public Health, University of Cagliari

Background and Aims: Drug-resistant epilepsy (DRE) represents a significant challenge for epileptologists, affecting approximately 30% of their patients. Early identification of people at risk for DRE is crucial for optimizing both pharmacological and non-pharmacological management strategies. Our study aims to pinpoint the risk factors associated with DRE within the patient population at the Epilepsy Centre of the University of Cagliari.
Methods: Data were retrieved from the medical records of people treated at our Epilepsy Centre. To identify predictive risk factors for DRE, we employed a combination of univariate analysis and logistic regression to assess the collective impact of various factors. We investigated different conditions linked to DRE, including gender, age of onset, etiology (structural, genetic), history of status epilepticus, type of seizures (focal, generalized, combined), learning disabilities, comorbidities, illness duration, and family history of epilepsy.
Results: Out of a total of 804 subjects, 201 were identified as having DRE (26%). Univariate analysis revealed a significant association between DRE and age of onset, structural etiology, presence of status epilepticus, type of seizure, presence of psychiatric and neurological comorbidities, learning disability, and family history of epilepsy. Subsequent multiple regression analysis identified several factors significantly associated with DRE, including age of onset, structural etiology, psychiatric and neurological comorbidities, and learning disability.

Risk factor	OR	95%CI	p value
Age	1.00	0.99 -1.01	0.955
Gender	0.97	0.69-1.36	0.863
Status epilepticus	3.71	1.20-11.45	**0.022**
Combined epilepsy	14.40	3.09-67.11	**0.001**
Structural etiology	1.63	1.12-2.37	**0.011**
Genetic etiology	1.27	0.61-2.67	0.524
Infectious etiology	1.99	0.87-4.55	0.102
Neurological comorbidities	0.92	0.63-1.33	0.643
Psychiatric comorbidities	1.72	1.17-2.52	**0.006**
Learning disability	2.87	1.87-4.42	**0.001**
Family history of epilepsy	1.94	1.13-3.33	**0.016**

OR: odds ratio; **CI:** confidence interval

Statistical analysis of risk factors.

Conclusion: The presence of a structural etiology, psychiatric and neurological comorbidities, learning disability, and early age of onset were identified as significant risk factors for DRE. Early identification of these factors holds promise for improving the management of affected people and refining clinical strategies.
Disclosure: Nothing to disclose.

EPO-525 | Late seizure relapse after anterior temporal lobectomy: The prevalence and its prognostic factors

S. Lee[1]; T. Kim[1]; B. Kim[1]; J. Kang[1]; Y. Koo[1]; J. Lee[2]; S. Hong[2]
[1]Department of Neurology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea; [2]Department of Neurosurgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea

Background and Aims: We investigated the proportion of late seizure relapse (LSR) and its prognostic factors after epilepsy surgery in patients with drug-resistant temporal lobe epilepsy (TLE).
Methods: This retrospective study recruited 178 adults who underwent anterior temporal lobectomy (ATL). We excluded if they had seizure recurrence in the first two years after surgery and if they had less than 3 years of follow-up. Finally, 99 patients were included. Seizure freedom was defined as ILAE outcome class 1 and 2. LSR

was defined as seizure relapse after initial 2-year seizure freedom. The Cox regression analysis was performed. Age, sex, and the potential variables exhibiting a p-value of <0.2 in the univariate analysis were entered in the initial model.

Results: The follow-up period after surgery ranged 36 to 191 months. Hippocampal sclerosis was the most common pathology (71.7%). The rate of LSR was 29.3% and its timing was mean 44.0±16.2 months after surgery. Univariate analyses showed that the presence of seizure risk factor, extratemporal interictal epileptiform discharges (IEDs) during video-EEG monitoring, ATL without hippocampectomy, weekly seizure recurrence before surgery, and vascular etiology had a p-value of <0.2 in association with LSR. The Cox regression showed that LSR was independently predicted by the presence of extratemporal IEDs (odds ratio 4.597, $p=0.002$) and ATL without hippocampectomy (odds ratio 2.679, $p=0.027$).

Conclusion: About one third of TLE patients with initial 2-year seizure freedom after ATL may have LSR. TLE patients with extratemporal IEDs or ATL without hippocampectomy may be at high risk for LSR.

Disclosure: Nothing.

EPO-526 | Cognitive symptoms in autoimmune limbic encephalitis: Long term follow up

S. Corsi; G. Tognoni; F. Iannaccone; F. Baldacci; L. Tommasini; L. Giampietri; S. Gabriele; C. Pizzanelli
Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

Background and Aims: Cognitive impairment is one of the cardinal symptoms of autoimmune limbic encephalitis. This study aims to describe long-term cognitive profile in a group of 9 patients diagnosed with autoimmune limbic encephalitis.

Methods: Clinical data and detailed neuropsychological assessment were collected from 9 patients one year after the acute phase of encephalitis. The average age of the patients was 62 years. Seven patients were males. Neuropsychological battery explored verbal and visuo-spatial memory, language, attentive and executive functions. Cerebrospinal fluid analysis (CSF), brain magnetic resonance imaging, brain 18-fluorodeoxyglucose positron emission tomographic imaging were performed. In 89% of CSF analysis autoantibodies were found (LG1 50%; CASPR2 38%; Glu3 peptide A e B 12%).

Results: All the patients showed severe cognitive deficits in the acute phase. In the long-term follow up only 2 patients showed a full neuropsychological recovery. 56% of the 9 subjects had verbal memory deficits, while visual memory impairment was observed in 33% of patients. Attention was affected in 44% of patients, while executive functions were impacted in 22% of cases, respectively. No language domain impairment was observed in any patients. Only 33% of patients have resumed their previous work activity

Conclusion: Verbal memory emerged as the most frequently impaired cognitive domain in long-term follow up of autoimmune limbic encephalitis. However, other cognitive domains were also affected. Despite being considered a form of encephalitis with a benign prognosis, in our case series, patients exhibited long-term cognitive deficits with an impact on social and occupational functioning.

Disclosure: Nothing to disclose.

EPO-527 | Effectiveness and tolerability of cenobamate as add-on therapy: A historical monocentric comparative study

T. Intravooth; D. Georgiou; A. Barbu; A. Staack; B. Steinhoff
Kork Epilepsy Center, Kehl-Kork, Germany

Background and Aims: Cenobamate is a novel antiseizure medication approved in Europe for adjunctive therapy in adults with drug-resistant focal seizures. However, there are limited data from clinical practice. In this study, our new data on cenobamate were compared with our historical data on lacosamide, perampanel, and brivaracetam.

Methods: Data were collected from our three studies conducted between 2016 and 2023. The retention rate, 50% response rate, and seizure freedom rate at 6 months, as well as the frequency of adverse events, were evaluated. Cenobamate was compared with the three antiseizure medications. Using Bonferroni correction, a result was considered statistically significant at a p-value <0.017.

Results: A total of 391 patients were included. In terms of retention rate, cenobamate was superior to other antiseizure medications ($p<0.001$). There was no significant difference in the 50% response rates and seizure freedom rates between patients treated with cenobamate, lacosamide, brivaracetam, and perampanel. The frequency of adverse events was higher with perampanel than with cenobamate ($p<0.001$).

Conclusion: The results of this study show that cenobamate was a superior option for adjunctive therapy in refractory epilepsies in terms of retention rate in our patients. Significantly more adverse events occurred with perampanel. The higher retention rate under cenobamate therapy compared to other antiseizure medications can most likely be explained by the high efficacy of cenobamate with a more favorable side effect profile. Due to a possible bias of the results, further prospective randomized controlled trials are needed to confirm these results.

Disclosure: Bernhard J Steinhoff has served as a paid consultant for Angelini Pharma, B. Braun Melsungen, Eisai, GW Pharmaceuticals, and UCB. Other authors have nothing to disclose.

EPO-528 | Attributional bias – Misinterpretation of social behaviour in people with epilepsy

V. Ogurcakova[1]; J. Zalud[2]; P. Marusic[1]; J. Amlerova[1]
[1]*Department of Neurology, Second Faculty of Medicine, ERN EpiCARE, Charles University and Motol University Hospital, Prague, Czechia;* [2]*Department of Clinical Psychology, University Motol Hospital, Prague, Czechia*

Background and Aims: Attributional bias is characterised by an impaired ability to predict behaviour of our environment based on social cues. As a consequence, we judge intentions of others as hostile and harmful rather than the result of chance or external factors. People with epilepsy (PWE) find it challenging to engage in social activities or maintain stable employment. Misinterpreting social situations can contribute to their social maladaptation and lower quality of life.

Methods: We examined 53 PWE, 26 with idiopathic generalised epilepsy (IGE), 27 with temporal lobe epilepsy (TLE) from Motol Epilepsy Centre in Prague, and 43 healthy controls (HC). We used the Ambiguous Intentions Hostility Questionnaire (AIHQ) to assess attributional bias (social misinterpretation). It yields 3 scores - aggression bias (AB), hostility bias (HB) and blame score (BS) in different types of situations in terms of intentionality - accidental, ambiguous and intentional. The higher the score in AIHQ, the more impaired the social judgement. We measured depression by Neurological Disorders Depression Inventory in Epilepsy (NDDI-E).

Results: PWE scored higher than HC in AB in ambiguous situations. Both IGE and TLE groups demonstrated HB in ambiguous situations, but TLE group also in accidental situations and IGE group in intentional situations. Duration of the disease or antiseizure medication did not correlate with scores in AIHQ. NDDI-E scores correlated with HB in TLE group.

Conclusion: Attributional bias is an unexplored area of social cognition in PWE. This study suggests an impairment of social judgement which may contribute to social dysfunction and affect quality of life in PWE.

Headache 3

EPO-529 | Efficacy of mindfulness added to treatment as usual in patients with chronic migraine and medication overuse headache

L. Grazzi[1]; D. Montisano[1]; E. Guastafierro[2]; D. D'Amico[1]; B. Del Corso[3]; A. Raggi[2]
[1]*Headache Center, Neuroalgology Dapartment – Neurological Institute Carlo Besta IRCCS Foundation, Milan, Italy;* [2]*Neurology, Public Health and Disability Unit – Neurological Institute Carlo Besta IRCCS Foundation, Milan, Italy;* [3]*Neuroscience Institute – National Research Council, Padova, Italy;*

Background and Aims: To assess the efficacy of a six-session mindfulness-based treatment added to treatment as usual (TaU) on headache frequency and medication intake.

Methods: This is a phase-III single blind RCT single-center study. Patients were enrolled between November 2018 and December 2021, and followed-up for 12 months. 177 patients with Chronic Migraine and Medication Overuse Headache (CM and MOH) were randomized 1:1 to either TaU or mindfulness added to TaU (TaU+MIND). Exclusion criteria were: psychiatric comorbidities; pregnancy; secondary headaches; withdrawal from MOH at least twice in the previous two years; previous experience with mindfulness. TaU consisted of withdrawal from overused drugs, patients' education, and prescription of prophylaxis. Patients attending mindfulness sessions were taught on tackling the pain-pill automatism, and were encouraged to engage in a 7-10 minute/day self-practice. The primary endpoint was the achievement, at 12 months of ≥50% headache frequency reduction compared to baseline. Secondary endpoints included medication intake.

Results: Out or the 177 participants (median age 47.9 years [Q1-Q3: 40.1-54.2]; 19 [11.3%] males; median CM duration 14.6 years [Q1-Q3: 4.9-22.2]) 89 were randomized to TaU and 88 to TaU+MIND. Patients in the TaU+MIND group outperformed those in TaU for the primary endpoint, achievement of ≥50% headache frequency reduction (78.4% vs 48.3%; $p < 0.0001$). They also showed superiority in some secondary endpoints, namely headache frequency and medication intake.

Conclusion: : These findings show that a six-week mindfulness-based treatment as add on to TaU is superior to TaU for the treatment of patient with CM and MOH

Disclosure: Nothing to disclose.

EPO-530 | Cerebral compliance in pseudotumor cerebri and transversus sinus stenosis undergoing venoplasty or CSF puncture

L. Souza Viana[1]; F. Moulin de Moraes[2]; S. De Andrade Matas[2]; G. Sampaio Silva[2]

[1]*Department of Neurology, Hospital Israelita Albert Einstein, Sao Paulo, Brazil*; [2]*Department of Neurology, Hospital Sao Paulo/Federal University of Sao Paulo, Sao Paulo, Brazil*

Background and Aims: Pseudotumor cerebri (PTC) has a high prevalence among women, and 30% to 93% of patients have transverse sinus stenosis (TSS). In addition, venoplasty improves symptoms in up to 87% of patients. Intracranial complacency (IC) can be a surrogate marker for intracranial hypertension. The FDA approved a non-invasive Brazilian method for monitoring intracranial pressure waves, Brain4care (B4C), in 2021. We aimed to compare the IC in patients with PTC and TSS only with lumbar punctures (LP) versus venoplasty.

Methods: This is an observational and single-centered study from 2020 to 2022. Inclusion criteria: ≥18 years with PTC; with presence of TSS. Data were reported as mean (± SD) or median (± IQR). Categorical variables were reported as percentage and compared using the X2 test or Fisher's test. *p*-Values were considered significant when <0.05, using SPSS.

Results: We enrolled 158 patients, among whom nine were excluded due to age: 12 without PTC, 13 without stenosis, 22 with CVT and 35 with missing data. We analyzed 67 patients: In the LP group (50), we found 100% female, mean age 37.6 (SD: 11.6), B4C mean TTP 0.24 (SD: 0.07) in lay-position and 0.23 (SD: 0.06) in sit-position. In the venoplasty group (17), we noticed 88.2% females, with a mean age of 45.6. (SD: 12.6), B4C mean TTP 0.24 (SD: 0.07), and 0.23 (SD: 0.06) in positions. There were no differences in IC between the two groups.

Variable	Lumbar puncture	Venoplasty	Total	P-Value[1]
Age, mean ±SD	37.6 ± 11.6	45.6 ± 12.6	39.6 ± 12.3	0.029
Gender - Male	0/50 (0.0%)	2/17 (11.8%)	2/67 (3.0%)	0.062
Time of symptoms, mean ±SD	8.8 ± 12.4	10.0 ± 17.0	9.1 ± 13.6	0.794

(1) T-student or Qui-square.
(2) Linear effect of the Lumbar Puncture Group vs Stent evaluated by linear model adjusted for age, sex and hypertension.
(3) Odds Ratio of the Lumbar Puncture vs Stent Group evaluated by logistic regression model adjusted for age, sex and hypertension.

Primary outcomes

Conclusion: We demonstrated no significant difference in IC between patients with PTC associated with TSS submitted only to LP vs venoplasty.

Disclosure: Nothing to disclose.

EPO-531 | Underdiagnosis and impact of menstrual migraine in real-world clinical practice

G. Terwindt[1]; J. Ailani[2]; B. Galabova[3]; J. Cirillo[4]; A. Jenkins[3]; L. Abraham[3]; J. Brown[4]; K. Hygge Blakeman[4]; J. Jackson[5]; W. Whitton[5]; L. Hancock[5]

[1]*Department of Neurology, Leiden University Medical Center, Leiden, The Netherlands*; [2]*MedStar Georgetown University Hospital, Washington DC USA*; [3]*Pfizer, Ltd., Tadworth, Surrey*; [4]*Pfizer, Inc., New York, NY USA*; [5]*Adelphi Real World, Bollington, UK*

Background and Aims: Patients with menstrual migraine (MM) experience more severe, disabling and prolonged attacks than non-MM patients. Research indicates that approximately 2/3 of female migraine sufferers may experience MM and diagnoses are often unreliable without a validated monitoring tool. This cross-sectional study aimed to assess how often MM is reported in clinical practice.

Methods: Data were drawn from the 2022/23 Adelphi Migraine Disease Specific Programme™, a real-world cross-sectional survey across France, Germany, Italy, Spain, the UK, and the USA. The cross-sectional study involved retrospective data collection from physicians and their female patients providing data on migraine diagnosis, including MM, and attack severity. Analyses were descriptive.

Results: There were 264 primary care practitioners (PCPs) and 340 neurologists who provided data on 3,049 female patients aged ≤55 years, with 32% ($n = 986$) diagnosed with MM. Physicians estimated that 38% of their patients had diagnosis of MM, with an additional 20% of patients without a physician-confirmed MM diagnosis who reported menstruation as a trigger for their migraines. Patients with MM experienced more severe migraine attacks than those without MM. Physicians tended to underestimate the severity, particularly for MM patients compared to those without MM. The reporting disparity in attack severity was more

pronounced in MM patients when managed by a PCP. (Table 1). Treatment prescribed to both patient groups were similar, but MM patients reported less satisfaction with their preventive treatment, than those without MM.

	Patients with Menstrual Migraine		Patients without Menstrual Migraine	
	Managed by Primary Care Practitioner	Managed by Neurologist	Managed by Primary Care Practitioner	Managed by Neurologist
Patient-reported overall migraine attack severity [n (%)]				
n	**179**	**138**	**285**	**261**
Very mild	10 (6)	5 (4)	29 (10)	22 (8)
Mild	61 (34)	49 (36)	105 (37)	82 (31)
Moderate	74 (41)	56 (41)	103 (36)	111 (43)
Severe	32 (18)	23 (17)	44 (15)	38 (15)
Very Severe	2 (1)	5 (4)	4 (1)	8 (3)
Physician-reported overall migraine attack severity [n (%)]				
n	**179**	**138**	**285**	**261**
Very mild	11 (6)	3 (2)	38 (13)	39 (15)
Mild	63 (35)	52 (38)	124 (44)	99 (38)
Moderate	96 (54)	67 (49)	103 (36)	98 (38)
Severe	9 (5)	15 (11)	20 (7)	23 (9)
Very Severe	0 (0)	1 (1)	0 (0)	2 (1)

TABLE 1 Patient and physician reported overall migraine attack severity. Note- data reported on patient/physician pairs, where patients had fully completed the patient-reported questionnaire and full physician-reported data were concurrently available.

Conclusion: Optimal treatment for MM requires heightened physician awareness, recognition, and understanding of its implications, aiming to alleviate additional burdens for affected females.

EPO-532 | A machine-learning-based algorithm to predict response to anti-CGRP monoclonal antibodies in patients with migraine

M. Romozzi[1]; A. Lokhandwala[2]; C. Vollono[1]; G. Vigani[3]; A. Burgalassi[3]; D. García-Azorín[4]; P. Calabresi[1]; P. Geppetti[3]; L. Iannone[3]

[1]Dipartimento Universitario di Neuroscienze, Università Cattolica del Sacro Cuore, Rome, Italy; [2]YPrime, Philadelphia, PA, USA; [3]Section of Clinical Pharmacology and Oncology, Department of Health Sciences, University of Florence, Florence, Italy; [4]Hospital Clinico Universitario de Valladolid, Headache Unit, Department of Neurology, Valladolid, Spain

Background and Aims: The study aimed to determine whether machine-learning (ML)-based models can predict responses to monoclonal antibodies (mAbs) against the calcitonin gene-related peptide (CGRP) in patients with migraine using early predictors and to create a prediction tool.

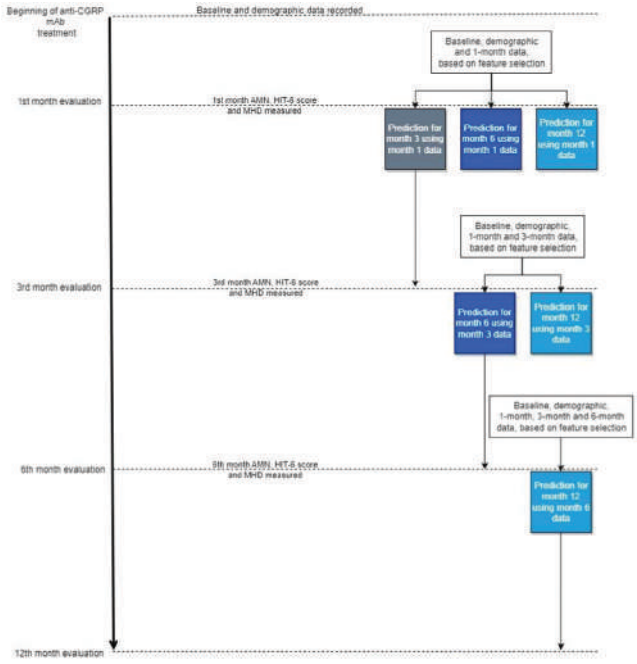
Methods: We collected data from patients receiving anti-CGRP mAbs for 12 months. Demographic and monthly clinical variables were collected, including monthly headache days (MHD), monthly days with acute medication use (AMD), number of analgesics, Headache Impact Test-6 (HIT-6). Response rates were categorized as <25%, 25-50%, 50-75%, and >75% reduction in MHD. ML models were trained using random forest algorithm. ML models were optimized to maximize the F1 score, and their performance was evaluated using standard evaluation metrics, including accuracy, precision, and area under the receiver operating characteristic curve (AUC-ROC). Sequential backward feature selection was employed to identify the most relevant predictors. Each model was given 11 baseline data inputs (type of mAb, age, gender, migraine diagnosis, disease duration, aura, MHD, AMD, HIT-6, number of analgesics) and month-based predictors for months 1, 3, 6.

Results: We included 336 patients treated with anti-CGRP mAbs. We developed 6 models to predict 3-,6-,and 12-month responses using early predictors. ML-based models yielded predictions with F1 score of 0.42-0.71 and AUC-ROC score of 0.44-0.72. Shapley Additive explanations summary plots were generated to interpret the contribution of each feature for each model. Based on these findings, a response prediction tool was developed.

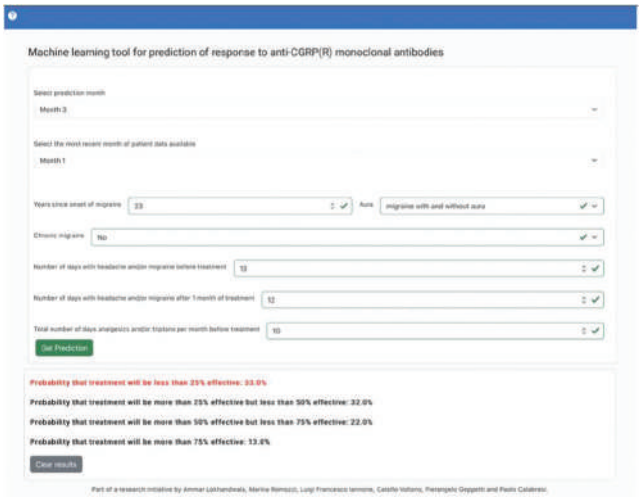
Table 1. Patients demographic and clinical features at baseline.	Overall population (n =336)
Demographics	
Age [years], mean ± SD	48.2±13.0
Sex female, n (%)	269 (80.1)
Migraine features	
Chronic migraine, n (%)	302 (89.9)
Medication overuse, n (%)	259 (77.1)
Aura, n (%)	28 (8.3)
Migraine duration [years], mean ± SD[a]	38.1±15.7
Chronicization duration [years], mean ± SD[b]	18.0±15.4
Monthly headache days, mean (SD)	22.9±6.9
Days with at least one analgesic use, mean ± SD	19.6±8.8
Analgesics number, mean (95%CI)	33.4 (30.1-36.8)
MIDAS score, mean ± SD	88.1±61.7
HIT-6 score, mean ± SD	67.8±6.4

Abbreviations: HIT-6, Headache Impact Test 6; MIDAS, Migraine Disability Assessment; SD, standard deviation. Percentages are expressed on column total. [a]Calculated on 317 patients. [b]Calculated on 293 patients.

Patients' demographic and clinical features at baseline.



Flow chart of the anti-calcitonin gene-related peptide (CGRP) monoclonal antibodies calculator tool at 3, 6 and 12 months. AMNs, absolute number of analgesics; Headache Impact Test-6 (HIT-6); MHDs, monthly headache days.



Demo of the Machine-learning (ML)-based tool to predict anti-calcitonin gene-related peptide (CGRP) monoclonal antibodies response at 3, 6 and 12 months.

Conclusion: The ML-based response prediction tool holds promise in predicting treatment outcomes for patients with migraine undergoing anti-CGRP mAbs treatment, potentially aiding in clinical decision-making and cost-optimization.

Disclosure: Nothing to disclose.

EPO-533 | Functional neurological symptoms in headache disorders: A case-series retrospective study

M. Gonçalves; I. Pinto; G. Cabral

Neurology Department, Hospital de Egas Moniz, ULS Lisboa Ocidental, Lisbon, Portugal

Background and Aims: To evaluate functional neurological symptoms (FNS) within a population diagnosed with headache disorders and to investigate the influence of preventive headache treatments on FNS.

Methods: We conducted a retrospective study involving patients diagnosed with headache disorders according to the ICHD-3, presenting with FNS at an outpatient clinic from 2020 to 2022.

Results: We identified 23 patients (82.6% female, mean age 40 years) diagnosed with headache disorders, with episodic or chronic migraine being the most prevalent ($n = 17$, 73.9%), all without aura who presented with FNS. Most patients (60.9%) presented with multiple FNS (sensorimotor, visual, or related to speech); these were followed by sensory symptoms (30.4%), impaired gait, and non-epileptic seizures (4.3% each). FNS were mostly paroxysmal (65.2%) and occurred between and during headache crises, with a notable exacerbation of FNS during heightened headache episodes (65.2%). Neurological examinations revealed at least one positive sign of functionality in 69.6% of cases. Preventive treatment for headaches was started in 20 patients, predominantly antidepressant drugs (47.8%). Eight patients (34.8%) failed at least one preventive. During the follow-up period, 50% reported an improvement in headache frequency

(≥50%) and 75% patients had an improvement of their FNS. Patients with better control of headache frequency had higher rates of improvement of FNS (70% versus 30%).

Conclusion: In our study, the predominant presentation of FNS was characterized by its multiplicity, often displaying a paroxysmal nature and exacerbations during concurrent headache crises. The effectiveness of preventive treatment, aimed at reducing headaches, translated into improvement in FNS.

Disclosure: None.

EPO-534 | Efficacy of anti-CGRP mAbs in migraine: A comparative analysis between overweight and normal-weight populations

G. Cretella; R. De Simone; S. Braca; A. Miele; A. Stornaiuolo; C. Giannini; C. Russo

Neurology Department, University of Naples Federico II, Naples, Italy

Background and Aims: Migraine and excess weight share a relationship not yet fully understood. Moreover, the Body Mass Index (BMI) has been positively correlated with the frequency of migraine attacks. Anti-CGRP monoclonal antibodies (mABs) hold a pivotal role in targeting peripheral mediators in migraine treatments. Consequently, this study endeavors to assess the efficacy of mABs in a population characterized by excess weight compared to a normal weight control group

Methods: We enrolled 120 chronic migraine patients treated with anti-CGRP mAbs divided into two groups according to BMI (BMI > 25 and <25). Over a time period of 12 months, we recorded mean monthly headache, BMI, midas, headache intensity and acute medication intake every three months

Results: A monthly migraine frequency of 22+-7 days was found in the control group and 20+-7 days in the group of overweight patients before starting treatment. At month 12, an average of 9.5+-8.6 and 8.8+-7.0 days were found, respectively. Preliminary analysis of the data reveals a decrease in the monthly frequency of migraine in both the overweight patient group and the control group ($p < 0.001$). When comparing the difference in the decrease, it does not appear statistically significant ($p = 0.6$). Further analyses are still in progress

Conclusion: The current analysis reveals that antibody treatment retains efficacy in the overweight population in the same way as in the normal-weight group. There are limited data in literature on the use of CGRP inhibitor monoclonal antibodies in individuals who are overweight/obese and further studies are needed to better understand efficacy in this patient population

Disclosure: Nothing to disclose.

EPO-535 | The stigma of cluster headache and its comparison with migraine

J. Membrilla[1]; S. Quintas[2]; E. Caronna[3]; A. Alpuente[3]; A. Muñoz-Vendrell[4]; S. Campoy[4]; C. Morales[5]; L. Sevillano Orte[6]; M. Castro Sánchez[7]; A. Layos[8]; A. Andrés López[8]; A. Sánchez Soblechero[9]; A. Lozano Ros[9]; J. Garcia Ull[10]; S. Pérez Pereda[11]; A. González Martínez[2]; M. Cordova Infantes[12]; M. Fernández Recio[12]; C. Nieves Castellanos[13]; M. Álvarez Álvarez[14]; C. Moreno Rodrígez[3]; A. López Bravo[6]

[1]Neurology, Hospital Universitari Francesc de Borja, Gandia, Spain; [2]Neurology, Hospital Universitario La Princesa, Madrid, Spain; [3]Neurology, Hospital Universitari Vall d'Hebron, Barcelona, Spain; [4]Neurology, Hospital Universitari de Bellvitge-Viladecans, L'Hospitalet de Llobgregat, Spain; [5]Neurology, Hospital Universitario de Canarias, La Laguna, Spain; [6]Neurology, Hospital Reina Sofía, Tudela; [7]Neurology, Hospital Regional Universitario, Málaga, Spain; [8]Neurology, Hospital General Universitario, Albacete, Spain; [9]Neurology, Hospital General Universitario Gregorio Marañón, Madrid, Spain; [10]Neurology, Hospital Clínico Universitario, València; [11]Neurology, Hospital Universitario Marqués de Valdecilla, Santander, Spain; [12]Neurology, Hospital Universitario Virgen de Valme, Sevilla, Spain; [13]Neurology, Hospital Universitario y Politécnico La Fe, València, Spain; [14]Hospital Universitario de Cabueñes, Gijón, Spain

Background and Aims: Stigma refers to the situation in which an individual is disqualified from full social acceptance, manifesting itself in the form of stereotypes, prejudice and discrimination. There are validated measures to measure the stigma associated with neurological diseases, but cluster headache (CH) has not been investigated so far. Our aim is to study the stigma of CH and compare it with that of migraine.

Methods: This is a multicenter cross-sectional study conducted by junior members of the Spanish Headache Study Group. Migraine and CH patients were recruited. Stigma was assessed with the SSCI (Stigma Scale for Chronic Illness). Other psychosocial aspects (cognitive reserve, self-esteem, anxiety, depression, stress and catastrophizing) were evaluated by specific scores. Migraine cases were classified into refractory/refractory migraine (RRM) or non-refractory/refractory migraine (non-RRM) according to the EHF criteria. CR patients were classified into episodic (ECH) or chronic (CCH).

Results: Ninety-six patients were enrolled: 37 ECH, 19 CCH, 17 non-RRM and 23 RRM. SSCI score was higher in CCH and RRM, 56.0 (34.0-77.0) and 59.0 (39.0-71.0) respectively; in ECH it was scored 42.0 (30.5-64.0) and in non-RRM, 37.0 (30.0-52.5). The difference between non-RRM and CCH ($p = 0.038$), between non-RRM and RRM ($p = 0.006$) and between ECH and RRM ($p = 0.019$) was statistically significant. CCH and RRM also showed higher scores in the depression assessment with respect to non-RRM. No statistically significant differences were found in the rest of the assessments.

Conclusion: Chronic cluster headache patients, like resistant or refractory migraine patients, show a higher degree of stigma relative to non-resistant and non-refractory migraine.
Disclosure: Nothing to disclose.

EPO-536 | Impact of migraine preventive treatment on interictal burden

M. Lorenzo Diéguez; A. Sánchez Huertas; M. Aledo Serrano; J. Díaz de Terán
Department of Neurology, La Paz University Hospital

Background and Aims: To analyze the impact of migraine preventive treatment on interictal burden (IB) and interictal predictors of response to preventive treatment.
Methods: Prospective cohort study in a headache unit. Patients with migraine who started treatment between January-February 2023 and followed up for 3 months were included. Epidemiological and clinical variables such as monthly migraine days (MMD), monthly consumption of NSAIDs and triptans, and IB (determined by the Migraine Interictal Burden Scale-4 and an ad-hoc questionnaire, including interictal symptoms) were collected at the beginning of treatment and at 3 months.
Results: 100 patients; 90 women (90%) (age mean 48.5 ± 10.9 years) 11% low-frequency episodic migraine; 20% high-frequency; 69% chronic. Of these last two groups, 54% started treatment with monoclonal anti-CGRP (Mab), 31% with botulinum toxin type A (OnabotA) and 8% with oral preventives. At similar reduction of MMD (61% vs. 58%), a greater decrease of IB (57% vs. 41%), consumption of NSAIDs (68% vs. 50%) and triptans (64% vs. 41%) with higher improvement index in response to symptomatic treatment (68.5% vs 46%) was observed in those patients treated with anti-CGRP compared to OnabotA.
Conclusion: In addition to reducing MMD, preventive treatment significantly reduces IB, being this reduction greater in patients treated with MaB. We also identified IA as a possible predictive factor of non-response to preventive treatment.
Disclosure: Nothing to disclose.

EPO-537 | Role of dexamethasone as a possible protective factor against long-COVID headache

O. Duraníková[1]; S. Horváthová[1]; P. Sabaka[2]; M. Minár[1]; I. Straka[1]; P. Valkovič[1]
[1]*2nd Department of Neurology, Comenius University, Faculty of Medicine and University Hospital in Bratislava, Slovakia;* [2]*Department of Infectology and Geographical Medicine, Comenius University, Faculty of Medicine and University Hospital in Bratislava, Slovakia*

Background and Aims: Although respiratory symptoms prevail in COVID-19 infection, headache is one of the most common symptoms that may persist for months in the form of long-COVID headache. The aim of our study was to evaluate long-COVID headache characteristics and search for possible biomarkers.
Methods: We conducted retrospective analysis of 295 (126 women) hospitalized patients with COVID-19 infection in Slovakia after 12-15 months. Retrospectively we contacted patients via video call with self-administered questionnaire. In headache patients we searched for participants with persisting headache up to 15 months. Subsequently we evaluated persisting headache's phenotype and its possible biomarkers.
Results: 34.6% ($n = 102$) of patients had COVID-19 associated headache, with 41.2% ($n = 42$) reporting persisting headache. It was unilateral in 40%, pulsating in 38% and accompanied by nausea and phonophobia in 60% and 74% respectively. While no specific laboratory marker was associated with persisting headache, we found a significant association between persisting headache and treatment with dexamethasone. Patients treated with dexamethasone during hospitalization had lower chance of developing persisting headache (52% vs. 73% $p = 0.029$).
Conclusion: We confirmed persisting headache for 12-15 months in almost half of our patients with predominance of migraine-like characteristics. Patients with administered dexamethasone had a statistically lower probability of developing long-COVID headache. This has relevant implications into clinical practice, as long-COVID headache remains a therapeutic challenge worldwide with specific recommendations and a tailored approach needed.
Disclosure: Nothing to disclose.

EPO-538 | Anti-CGRP monoclonal antibodies effectiveness among men and women: Are there differences?

P. Gallego Fuentes; L. Rodríguez Jiménez; M. Castro Sánchez; L. García Trujillo
Neurology, Hospital Regional Universitario, Málaga, Spain

Background and Aims: Migraine affects more women and there is evidence that supports the influence of female sex hormones on its pathophysiology. CGRP is the main neuropeptide that causes pain during migraine attacks and its blood levels can be modified by those hormones.
Methods: We reviewed 225 patients that started anti-CGRP monoclonal antibodies (mAbs) between 2019 and 2022, in order to ensure a long follow-up. 14 were excluded for lost to follow-up. Our objective is to assess if there are differences in the response to this treatment in males versus women.
Results: There were 189 women and 31 men with an average age of 45 years old. 77% of men and 79% of women had chronic migraine with an average of 5 preventive medications failed. The average reduction of monthly migraine days was 4 for women and 6 for men, while the average reduction of monthly headache days was 7 for women and 11 for men. 58% of men and 66 % of women achieved a reduction of 50% of monthly headache or migraine days.

Constipation was the main adverse effect for women (17%), but no men had it. There were not statistically significant differences between groups except from the response to an antibody switch that was higher in men (50% vs 22%)

Conclusion: In our series, response to anti-CGRP mAbs was similar in women and men, what suggests a significant role of CGRP in migraine pathophysiology in both sexes. Gastrointestinal adverse effects were not reported by men, so this should be assessed in future studies.

Disclosure: Nothing to disclose.

EPO-539 | Sleep quality assessment in resistant migraine

R. Cagigal; S. Casanova; A. Rocha; M. Branco
Neurology Department, Unidade de Saúde Local Gaia/Espinho

Background and Aims: Resistant migraine is defined by having failed at least 3 classes of migraine preventatives and suffer from at least 8 debilitating headache days per month for at least 3 consecutive months without improvement. Sleep disorders are known contributors for resistant migraine. Pittsburgh Sleep Quality Index (PSQI) is a validated self-report questionnaire that assesses sleep quality. If higher than 5, it is considered pathological. We report a series of patients with resistant migraine in whom sleep quality was assessed.

Methods: We included patients suffering from migraine followed in Neurology appointments that fulfilled the European Headache Federation criteria for resistant migraine and were waiting to start anti-CGRP (calcitonin gene-related peptide) monoclonal antibody treatment and. PSQI was assessed.

Results: We included 34 patients, 91.2% female, mean age of 44.7 years. 61.8% had chronic migraine, 85.3% without aura. Only 29.4% were formally diagnosed with sleep pathology (26.5% insomnia, 2.9% obstructive sleep apnea) and 26.5% were medicated (17.6% trazodone, 11.8% benzodiazepine). Patients were medicated with a mean of 1.15 migraine preventatives, haven previously tried a mean of 3.32 preventatives. The mean number of monthly debilitating headache days was 12.03. 82.4% of patients had a pathological PSQI, with a mean score of 10.56. The most impaired component score was subjective sleep quality.

Conclusion: Our series' results suggest that sleep disorders could be underassessed in Neurology appointments and, therefore undertreated. Strengthening PSQI assessment in migraine patients could be of value in preventing resistant migraine, allowing therapeutic optimization.

Disclosure: Nothing to disclosure.

EPO-540 | Effectiveness and tolerability of lasmiditan as acute migraine treatment (DART): A real-world multicentric Italian study

R. De Icco[1]; G. Vaghi[1]; L. Iannone[2]; M. Corrado[1]; A. Burgalassi[2]; E. De Matteis[3]; F. De Santis[3]; C. Fasano[2]; E. Piella[4]; M. Romozzi[5]; G. Sebastianelli[6]; G. Avino[7]; S. Background and Aims: Lasmiditan, a serotonin 5-HT1F receptor agonist, has been recently approved in Italy for the acute migraine treatment. We designed a prospective multicentric study to evaluate lasmiditan effectiveness and tolerability in the real-world setting (NCT05903040).

Methods: We enrolled 55 patients (87.3% females, 45.4 + 14.4 years, 21.8% – $n = 12$ with chronic migraine-CM, baseline monthly migraine days 9.1 + 7.2) from 13 Italian headache centers. Patients were instructed to treat up to four migraine attacks with lasmiditan 50 mg (20.4%) or 100 mg (79.6%). Using an ad hoc diary, we prospectively collected migraine-attack features every 30 minutes after lasmiditan administration, up to 2 hours (2 h).

Results: Preliminary analyses were conducted on 28 first-treated attacks (1/28 in a CM patient) and 49 total attacks. At lasmiditan intake, 42.9% patients rated migraine intensity as severe (0–3 rating scale). Pain freedom 2 h post-dose was reported in 35.7% (10/28) of first-treated attacks, and in 36.7% (18/49) of total attacks. The rate of pain freedom was not influenced by timing of lasmiditan intake ($p = 0.145$), baseline pain severity ($p = 0.262$) and presence of chronic vs episodic migraine ($p = 0.683$). Freedom from the most bothersome symptom 2 h post-dose was reported in 47.7% of attacks. Adverse events were reported in 26 of total attacks treated (53.1%),

predominantly as dizziness ($n=11$), fatigue ($n=8$) and paraesthesia ($n=6$). Tolerability was rated as good-to-excellent in 50% of cases.

Conclusion: Our real-world data support lasmiditan effectiveness in the acute treatment of migraine. Adverse events were reported in 53.1% of attacks.

Disclosure: CT has participated in advisory boards for AbbVie, Dompé, Eli Lilly, Lundbeck, Novartis, Pfizer, and Teva; lectured at symposia and is a principal investigator or collaborator in clinical trials sponsored by AbbVie, Eli Lilly, Lundbeck, Novartis, and Teva; received research grants from the European Commission, the Italian Ministry of Health, the Italian Multiple Sclerosis Foundation, and the Migraine Research Foundation; and serves as an associate editor for Cephalalgia and The Journal of Headache and Pain. R.D.I received speaker honoraria for scientific presentations from Eli-Lilly, and Teva, and has participated as advisory board for Pfizer. GV reports consultant fees from Lundbeck.

EPO-541 | The relationship of medication overuse to vertigo, sleep, anxiety, depression and comorbidities in migraine patients

R. Wilcha; P. Amarasena; L. Villar Martinez; J. Hoffmann; P. Goadsby

NIHR King's Clinical Research Facility, SLaM Biomedical Research Centre, and Wolfson Sensory, Pain and Regeneration Centre, King's College London, UK

Background and Aims: The global prevalence of medication overuse headache (MOH) is 1–2%. Migraine is the predominant risk factor, impacting 78% of individuals with MOH. Despite well-established evidence that MO can contribute to the deterioration and chronification of a pre-existing headache syndrome, little is known about its role in relation to existing comorbidities and other disabling symptoms of migraine. We sought to examine the relationship between medication overuse and the total number of comorbidities and the symptoms of vertigo, sleep disturbance, anxiety and depression.

Methods: Data were collected ($n=192$) through the use of patient self-completed health questionnaires utilising a variety of standardised tools including the Dizziness Handicap Inventory (DHI), Subjective Vertigo Questionnaire (SVQ), Epworth Sleepiness Scale (ESS), Pittsburgh Sleep Quality Index (PSQI), Generalized Anxiety Disorder 7 (GAD-7), and Patient Health Questionnaire 8 (PHQ-8). Binomial logistic regression was applied to examine the predictive role of medication overuse in relation to symptoms of vertigo, poor sleep, anxiety, and depression and the total number of comorbidities.

Results: The model demonstrated that medication overuse was associated with an increased total number of comorbidities ($\chi^2(4)=6.978$, $p=0.008$). There was no statistically significant difference observed in scores related to the symptoms of vertigo, sleep disturbance, anxiety and depression.

Conclusion: This data shows medication overuse is associated with an increased total number of comorbidities in migraine patients. Moving forward, physicians must recognise the impact of other comorbidities, not only headache that may contribute to medication overuse.

Disclosure: Nothing to disclose.

EPO-542 | An interdisciplinary integrated one-stop-shop special outpatient clinic for idiopathic intracranial hypertension

G. Bsteh[1]; S. Macher[1]; N. Krajnc[2]; W. Marik[3]; M. Michl[4]; N. Müller[1]; S. Zaic[1]; J. Harreiter[5]; K. Novak[6]; C. Wöber[1]; B. Pemp[4]

[1]Department of Neurology, Medical University of Vienna, Vienna, Austria; [2]Comprehensive Center for Clinical Neurosciences & Mental Health, Medical University of Vienna, Vienna, Austria; [3]Department of Neuroradiology, Medical University of Vienna, Vienna, Austria; [4]Department of Ophthalmology, Medical University of Vienna, Vienna, Austria; [5]Department of Neurosurgery, Medical University of Vienna, Vienna, Austria; [6]Division of Endocrinology, Department of Internal Medicine, Medical University of Vienna, Vienna, Austria

Background and Aims: Management of idiopathic intracranial hypertension (IIH) is complex requiring contributions from multiple specialized disciplines. In practice, this creates considerable organizational and communicational challenges for health care professionals and patients. To meet those challenges, we established an interdisciplinary integrated outpatient clinic for IIH (comprising neurology, neuroophthalmology, neuroradiology, neurosurgery and endocrinology) with a central coordination and a one-stop-shop concept. Here, we aimed to evaluate effects of this one-stop-shop concept on objective clinical outcome of patients with IIH.

Methods: Using the Vienna-IIH database, we compared the one-stop-shop era (1-JUL-2021 to 31-DEC-2022) to a reference group receiving standard care (1-JUL-2018 to 31-DEC-2019) regarding clinical outcome parameters (visual impairment/worsening, headache improvement/freedom) assessed 6 months after diagnosis. Multivariate binary logistic regression models were used to adjust for confounders (age, body mass index [BMI], CSF opening pressure, visual impairment and chronic headache at diagnosis).

Results: Baseline characteristics of the one-stop-shop group ($n=85$) and standard care group ($n=81$) were comparable (female: 90.6% vs. 90.1%; mean age: 33.6 vs. 32.8 years, median BMI: 31.8 vs. 33.0, median CSF opening pressure: 320 vs. 341 mmH_2O, visual impairment at diagnosis: 71.8% vs. 69.1%, chronic headache at diagnosis: 55.3% vs. 56.8%). Compared to standard care, the one-stop-shop concept was associated with a significantly higher likelihood of achieving both headache improvement (odds ratio [OR] 2.24, $p<0.001$) and headache freedom (OR 1.75, $p=0.031$), whereas the risk for visual impairment (OR 0.87, $p=0.231$) and visual worsening (OR 0.67, $p=0.354$) was not significantly reduced.

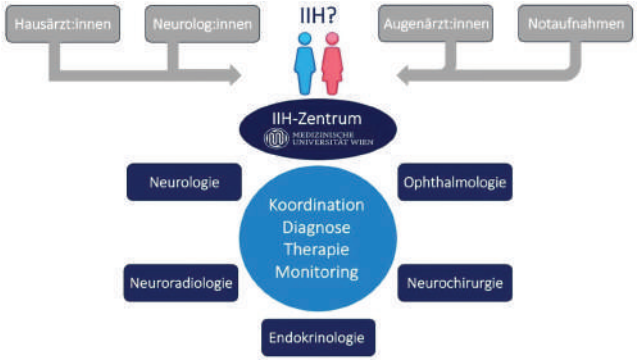

FIGURE 1 IIH one-stop-shop concept.

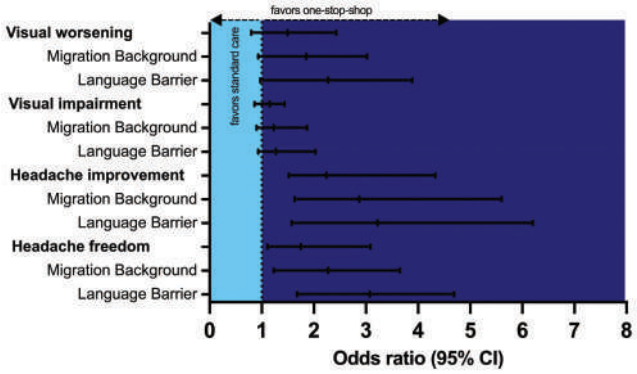

FIGURE 2 Outcome in the one-stop-shop concept compared to standard management.

Conclusion: Interdisciplinary integrated management of IIH significantly improves headache outcome and potentially also visual outcome.

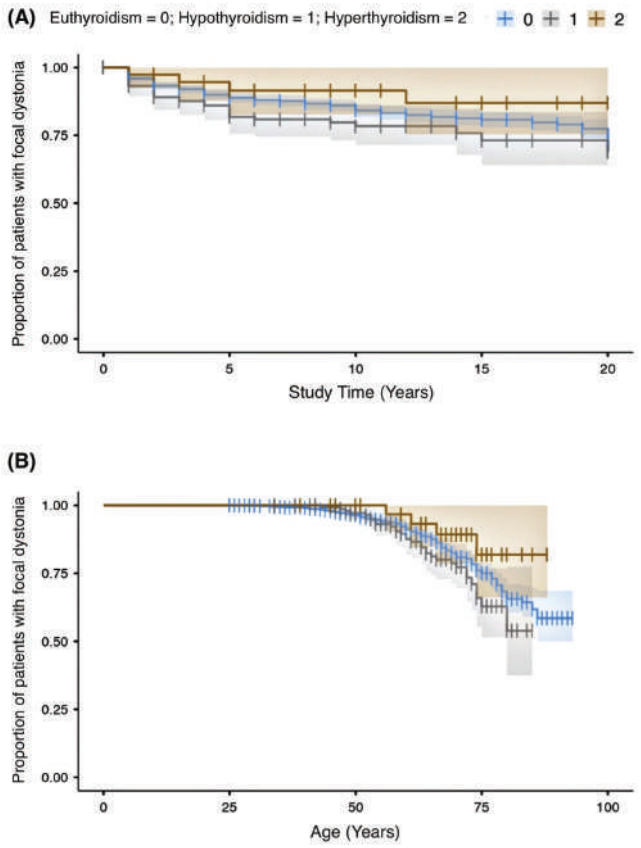
Background and Aims: A few earlier observations and recent controlled studies pointed to the possible contribution of thyroid diseases in idiopathic adult-onset dystonia (IAOD).

Methods: To investigate the association between thyroid status and clinical characteristics of IAOD, focusing on dystonia localization, spread, and associated features such as tremors and sensory tricks. Patients were identified from the Italian Dystonia Registry, a multicentre dataset of patients with adult-onset dystonia. The study population included 1518 IAOD patients. Patients with hypothyroidism and hyperthyroidism were compared with those without any thyroid disease.

Results: In the 1518 IAOD patients, 167 patients (11%; 95% CI, 9.5%–12.6%) were diagnosed with hypothyroidism and 42 (2.8 %;

95% CI, 1.99–3.74) with hyperthyroidism. The three groups were comparable in age at dystonia onset, but there were more women than men in groups with thyroid disease. We found more patients with blepharospasm in the hyperthyroidism group, but the difference lacked significance after the Bonferroni correction. The remaining dystonia-affected body sites were similarly distributed in the three groups, as did dystonia-associated features and spread.



Kaplan–Meier's survival analysis of the spread of dystonia in patients with focal onset. (A) Study time was represented by the time elapsed between dystonia onset and spread. (B) Study time was represented by age at spread.

Conclusion: Even if the frequency of patients with thyroid disease is higher than the general European population, we cannot discuss the results in terms of risk factors due to the different ascertainment methodology. However, our findings provided novel information indicating that the high rate of thyroid diseases is not specific for any distinct dystonia subpopulation and does not appear to influence the natural history of IAOD.

Disclosure: Nothing to disclose.

EPO-544 | Neuropathological characteristics of the patients with old-onset Parkinson's disease

K. Inoue[1]; H. Fujimura[1]; T. Saito[1]; K. Toyooka[1]; M. Yamadera[1]; C. Mori[1]; M. Sudo[1]; Y. Izumi[2]

[1]Department of Neurology, NHO Osaka Toneyama Medical Center, Toyonaka, Japan; [2]Department of Neurology, Tokushima University Faculty of Medicine

Background and Aims: The clinical features of the patients with old-onset Parkinson's disease (PD) are characterized by postural areflexia, frozen gait, hallucinations, cognitive impairment, and autonomic failure.

Methods: From a consecutive autopsy series of 187 patients, 25 patients, pathologically confirmed Parkinson's disease and aged 50 years or older at onset, were selected. Their median age at onset was 72 years, median age at death: 83 years and 18 males (72%). We compared the age of onset, sex, duration of disease, presence or absence of dementia, Lewy body (LB) score, and lesions of Alzheimer's disease (AD) in the group with onset under 75 (normal) and after 75 years of age (elderly).

Results: In PD cases that developed after the age of 75 years, the duration of the disease was significantly shorter, and many cases were clinically diagnosed with dementia. In the elderly group, LB scores tended to be smaller in the brainstem and larger in the limbic system and neocortex than in the normal group, but there was no significant difference. Many of the cases in both groups were accompanied by mild to moderate AD lesions, but only a small number were diagnosed with pathological AD.

Conclusion: In elderly PD, LB lesions to the limbic ~ neocortex may expand prematurely.

Disclosure: Nothing to disclose.

EPO-545 | MRI volumetric assessment of neuropsychiatric symptoms in multiple system atrophy

I. Ruiz Barrio; A. Horta Barba; A. Puig Davi; S. Martinez Horta; J. Kulisevsky; J. Pagonabarraga

Movement Disorders Unit, Neurology Department, Hospital de Sant Pau, Barcelona, Spain

Background and Aims: Multiple system atrophy (MSA) presents diverse motor and non-motor symptoms, with growing recognition of cognitive and neuropsychiatric manifestations. This study aims to address this gap by investigating neuropsychiatric symptoms and their neuroanatomical correlations in MSA.

Methods: Ten consecutive patients diagnosed with MSA based on current clinical criteria were included. Frontal Behavioral Inventory (FBI) and Neuropsychiatric Inventory (NPI) were administered to all patients. T1-weighted scans were obtained using a 3 Tesla Philips Achieva station, and structural image processing was conducted with FreeSurfer (v.7.4.1). Volumetric analysis, involving the correlation of

volumetric data with neuropsychiatric scales, was performed using R statistical software (v.4.3.0). Multiple comparisons were corrected using False Discovery Rate.

Results: High prevalence of neuropsychiatric symptoms was observed in MSA (44.4% with ≥3 points in FBI, mean NPI score 6.8 ± 3.9). Demographics are summarised in table 1. There were no significant differences among clinical subtypes in analyzed variables. Linear modeling revealed significant amygdala atrophy across higher scores of FBI and NPI ($p = 0.025$ and 0.014, respectively), independent of clinical subtype (Figures 1 and 2).

Conclusion: Neuropsychiatric symptoms, prevalent in both parkinsonian and cerebellar subtypes of MSA, may be associated with amygdala atrophy. Further studies exploring the pathophysiology of neuropsychiatric alterations in MSA are essential, considering the significant impact on daily activities.

Disclosure: Nothing to disclose.

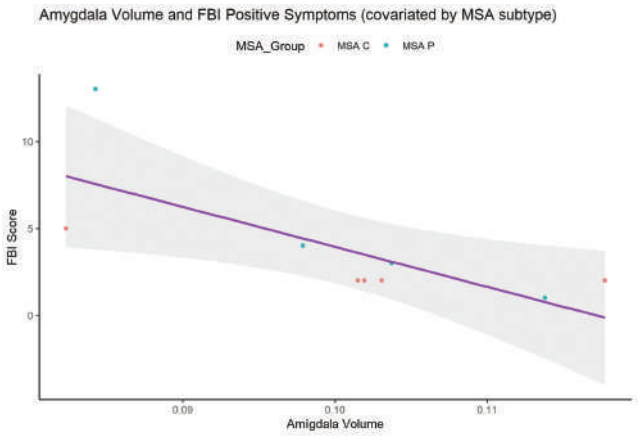


FIGURE 1 Correlation between amygdala volume and FBI positive symptoms.

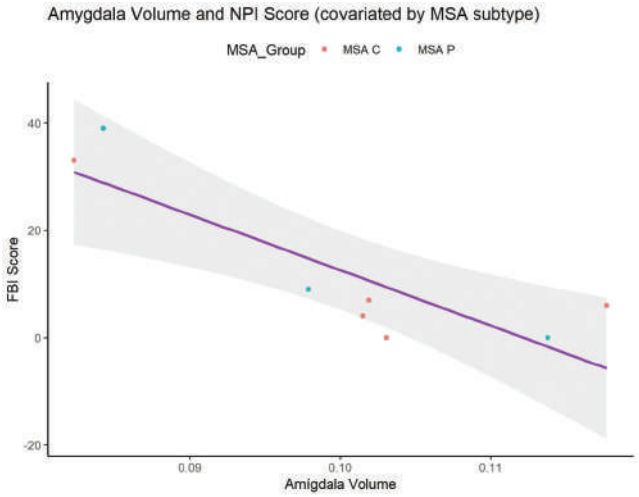

FIGURE 2 Correlation between amygdala volume and NPI score.

EPO-547 | **A randomized, double-blinded, placebo-controlled QTc study to evaluate BIA 286156 effect on cardiac repolarization**

I. Peixoto[1]; D. Hilt[2]; H. Gama[1]; J. Holenz[1]

[1]*Research & Development Division, BIAL-Portela & C[a], S.A., S. Mamede do Coronado, Portugal;* [2]*BIAL BioTech Investments, Inc.*

Background and Aims: Betaglucocerebrosidase (GCase) is encoded by the GBA1 gene. Its mutations are the most common genetic risk factor for Parkinson's disease (PD). BIA 286156 is an allosteric activator of GCase developed to treat the causative processes in GBA-PD. This study primarily aimed to evaluate the effect of BIA 286156 on QT interval corrected (QTc) for heart rate (HR) based on the Fridericia correction (QTcF) in healthy subjects.

Methods: Phase 1, randomized, double-blinded, placebo-controlled, 4-period crossover study. Subjects received 1 of 12 treatment sequences. A single dose of 60 mg or 150 mg BIA 28-6156, 400 mg moxifloxacin or placebo was administered in fed state (Table 1). Relationship between BIA 28-6156 plasma concentrations and change-from-baseline QTcF (ΔQTcF) was analyzed to exclude an effect of ΔΔQTcF >10 msec at clinically relevant plasma levels. HR, PR, and QRS intervals, and electrocardiogram (ECG) waveform morphology were evaluated. Incidence and severity of treatment emergent adverse events (TEAEs) were analyzed.

Results: A total of 37 subjects were enrolled, with 33 completing the study. Based on the concentration-QTc analysis, an effect on ΔΔQTcF exceeding 10 msec can be excluded within the full observed range of plasma concentrations of BIA 28-6156 up to ~7150 ng/mL. No clinically relevant effects on studied ECG parameters were found. No deaths or other serious AEs were reported. 2 subjects withdrew due to AEs.

Table 1: Overview of Study Treatment Periods and Treatment Sequences

Treatment Sequence (n)	Period 1	Period 2	Period 3	Period 4
1 (n=3)	B	C	A	D
2 (n=3)	C	D	B	A
3 (n=3)	A	B	D	C
4 (n=3)	D	A	C	B
5 (n=4*)	C	A	B	D
6 (n=3)	A	D	C	B
7 (n=3)	B	C	D	A
8 (n=3)	D	B	A	C
9 (n=3)	A	B	C	D
10 (n=3)	B	D	A	C
11 (n=3)	C	A	D	B
12 (n=3)	D	C	B	A

n = number of subjects

Notes: A, B, C and D = 1 of 4 possible study drug treatments:

- **Treatment A:** *Therapeutic dose:* 60 mg of BIA 28-6156 (1×60-mg BIA 28-6156 capsule+2 placebo capsules) in the fed state
- **Treatment B:** *Supratherapeutic dose:* 150 mg of BIA 28-6156 (2×60-mg BIA 28-6156 capsules+1×30-mg BIA 286156 capsule) in the fed state
- **Treatment C:** *Placebo control:* BIA 28-6156 matching placebo (3 placebo capsules) in the fed state
- **Treatment D:** *Positive control:* 400 mg of moxifloxacin (1×400-mg moxifloxacin capsule + 2 placebo capsules) in the fed state

* One subject was withdrawn from the study and only received the placebo treatment in Period 1. This subject was replaced and the replacement subject received all planned treatments according to the treatment sequence.

Conclusion: BIA-28-6156 doses were well tolerated, with a favorable safety profile. These results showed no clinically relevant effects on ECG parameters, constituting a negative thorough QT/QTc study.

Disclosure: Supported by Bial-Portela & C[a], S.A.

EPO-548 | Baseline variables associated with apomorphine sublingual film retention

J. Kassubek[1,2]; J. Schwarz[3]; L. López Manzanares[4]; M. Fonseca[5]; C. Denecke Muhr[5]
[1]*Department of Neurology, University Hospital Ulm, Ulm, Germany;* [2]*German Centre for Neurodegenerative Diseases, Ulm, Germany;* [3]*Department of Geriatrics, Kreisklinik Ebersberg, Ebersberg, Germany;* [4]*La Princesa University Hospital, Madrid, Spain;* [5]*Bial – Portela & Ca, S.A., Coronado, Portugal*

Background and Aims: The Phase 3 Study CTH-301 evaluated the long-term safety/tolerability and efficacy of apomorphine sublingual film (SL-APO) for treating OFF-episodes in Parkinson's disease patients with motor fluctuations. Data from this study were used to build a model to identify baseline variables that differ between patients who completed the study and those who discontinued during the dose optimisation or long-term maintenance phase due to either lack of efficacy or adverse events (AEs), therefore influencing retention.

Methods: Baseline variables were ranked based on their correlation (Chi-square) with the discrete target variable (completers vs non-completers due to lack of efficacy or AEs). A logistic regression classification algorithm with LASSO regularisation was used to select the final variables.

Results: Of 496 patients, 120 completed the study, 26 discontinued due to lack of efficacy, 167 due to AEs, and 183 due to other reasons. Median time on SL-APO was 204 days. Compared to completers, non-completers due to lack of efficacy demonstrated a higher levodopa total daily dose ($p<0.001$), lower rate of morning akinesia ($p=0.036$), higher rate of de novo enrolment (no previous SL-APO exposure; $p=0.048$) and higher number of levodopa intakes ($p=0.027$) (Figure 1). Compared to completers, non-completers due to AEs had a lower rate of concomitant dopamine agonists use ($p<0.001$) and higher rate of de novo enrolment ($p=0.019$) (Figure 2).

Figure 1. Key baseline variables identified for comparison between subgroups of patients who completed the study and those who discontinued due to lack of efficacy: (A) total daily levodopa dose at baseline; (B) presence of morning akinesia; (C) enrolment group (*de novo* vs roll-over*); (D) number of daily levodopa intakes. **De novo* patients were defined as those who started SL-APO treatment *de novo*, while roll-over patients were defined as those who had completed previous SL-APO studies (CTH-201, CTH-203, CTH-300, or CTH-302). SD, standard deviation; SL-APO, apomorphine sublingual film

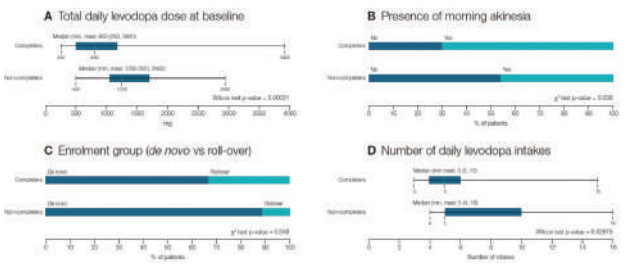

Figure 2. Key baseline variables identified for comparison between subgroups of patients who completed the study and those who discontinued due to adverse events: (A) dopamine agonists use; (B) age; (C) enrolment group (*de novo* vs roll-over*). **De novo* patients were defined as those who started SL-APO treatment *de novo*, while roll-over patients were defined as those who had completed previous SL-APO studies (CTH-201, CTH-203, CTH-300, or CTH-302). SD, standard deviation; SL-APO, apomorphine sublingual film

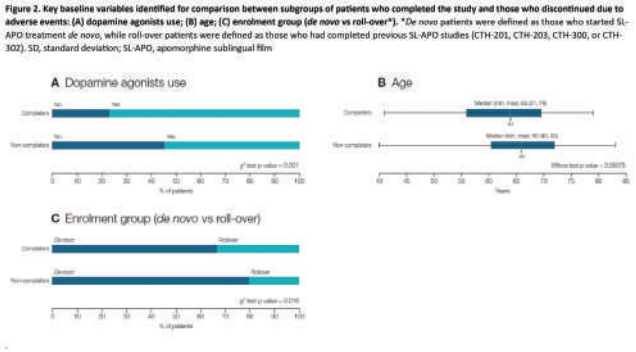

Conclusion: Levodopa dose and intakes, morning akinesia, previous SL-APO exposure and concomitant dopamine agonist use might influence retention. These results may help identify patients more likely to remain on SL-APO over the long term.

Disclosure: Supported by Bial.

EPO-549 | Efficacy and safety of levodopa in dystonia in Wilson disease (LIDWID): A randomized placebo-controlled trial

P. Kalita; D. Ahmed; D. Mahajan
Sanjay Gandhi Post Graduate Institute of Medical Sciences

Background and Aims: Dystonia is the commonest movement disorder in neurologic Wilson disease (NWD). Levodopa is used in primary dystonia, but has not been systematically evaluated in NWD. We report the efficacy and safety of levodopa compared to placebo in NWD patients with dystonia.

Methods: NWD patients having a Fahn-Marsden Dystonia Rating (FMDR) score of >20 were included in whom other possible causes were ruled out. Patients were randomized to levodopa-carbidopa (LCD) or placebo using 1:1 randomization. LCD (100 mg + 10 mg) was started in a dose of half tab thrice daily, and increased every week to 2 tablets thrice daily. Placebo group received saccharine tablet. Outcome was defined at 3 months. The primary outcome was improvement in FMDR score by >50%, and secondary outcomes were Neurological Severity score (NSS), Dysphagia Outcome and Severity Scale (DOSS) score and side effects.

Results: 13 patients each were randomized to LCD and placebo. Their baseline characteristics were comparable. Only one patient in each group achieved primary outcome. At 3 months, both LCD and placebo groups had significant improvement in FMRD score, NSS and DOSS score. The improvement in FMRD (55.00 ± 35.35 vs 45.92 ± 41.40; $p=0.55$), NSS (7.61 ± 4.61 vs 5.77 ± 3.37; $p=0.25$) and DOSS score (4.92 ± 1.70 vs 4.77 ± 2.16; $p=0.84$) however were not significantly different between LCD and placebo groups. Four patients had minor side effects (3 LCD and 1 placebo).

Conclusion: LCD is safe in NWD and well tolerated. Patients in both LCD and placebo group improved at 3 months, but LCD did not have advantage over placebo in reducing dystonia.

Disclosure: Nothing to disclose.

EPO-550 | Foslevodopa/foscarbidopa in advanced Parkinson's disease: Demonstration of savings from a societal perspective in the UK

K. Chaudhuri[1]; L. Bergmann[2]; J. Belsey[3]; T. Boodhna[4]; E. Leoncini[4]; J. Zamudio[5]
[1]*Institute of Psychiatry, Psychology & Neuroscience, King's College London, UK;* [2]*AbbVie, Ludwigshafen, Germany;* [3]*JB Medical Ltd, London, UK;* [4]*AbbVie, Marlow, UK;* [5]*AbbVie, North Chicago IL, USA*

Background and Aims: In patients with advanced Parkinson's disease (aPD), adequate control of OFF time may not be achievable using oral/transdermal therapies. Clinical trials of Foslevodopa/foscarbidopa (LDp/CDP) have shown meaningful reductions in OFF-time and sleep disturbance – both strong predictors of healthcare resource use. Previous analyses have only considered direct medical costs: this analysis considers a broader societal perspective.
Methods: Clinical trial and real-world evidence were used to drive a cost-utility model comparing LDp/CDp with best medical treatment (BMT), which was accepted by the UK National Institute of Health and Care Excellence. Using outputs from this analysis, a societal impact model was developed. Quintiles of normalised OFF-time across a 16-hour waking day in each treatment group were applied to literature-based estimates for direct medical, non-medical and indirect costs. The resulting state-specific cost estimates were applied to the modelled aPD patient population.
Results: The mean overall cost of care per patient on BMT was estimated as £115,667 in year 1, rising to £123,943 in year 5 (2022 GBP). For LDp/CDp, the corresponding costs were £111,491 and £118,495 respectively. Savings were approximately evenly split across the three cost categories. If applied to all 17,500 aPD patients in the UK, this would amount to a net saving in LDp/CDp-treated patients of £73.1 million in year 1, rising to £95.4 million in year 5.
Conclusion: The use of LDp/CDp in aPD patients inadequately controlled on oral therapy, is associated with net annual savings of over £73 million compared to BMT, when considered from a societal perspective.

EPO-551 | Fractures and emergency department contacts among patients with Parkinson's disease in denmark

T. Henriksen[1]; U. Lønberg[2]; J. Samuelsson[3]; P. Schwarz[4]
[1]*Movement Disorder Unit, University Hospital of Bispebjerg, Copenhagen, Denmark;* [2]*Formerly AbbVie Denmark, København, Denmark;* [3]*AbbVie Sweden, Solna, Stockholm, Sweden;* [4]*Department of Endocrinology, Bone-metabolic Research Unit, Rigshospitalet, København Ø, Denmark*

Background and Aims: Parkinson's Disease (PD) patients often experience symptoms like freezing of gait, axial rigidity, and postural instability, increasing their risk of falls. Osteoporosis in PD is common, which increases the risk of fractures if falling. Falls resulting in fractures could require surgical intervention, significantly contributing to morbidity and mortality. However, there is currently no data on fracture rates within the Danish PD population. This study aimed to analyze fracture rates and other fall-related injuries among Danish PD patients.
Methods: This study is a retrospective, nationwide analysis that used data from the National Patient Registry, Danish National Prescription Registry, and Statistic Denmark. We evaluated the standardized incidence ratio (SIR) of hip fractures, major osteoporotic fractures (MOF, including hip, vertebral, humerus, and forearm fractures), and traumatic emergency department (ED) visits in PD patients compared to the general population.
Results: The analysis incorporated 7,242 patients with PD and 2,851,000 matched controls. Hip fracture rates in patients with PD were four times higher compared to the general population, when standardised by sex and age. Additionally, the incidence rates of major osteoporotic fractures (MOF) and traumatic emergency department visits were three times and two times higher, respectively. When considering multiple fractures, the incidence rate of traumatic emergency department visits is 2.6 times higher in Parkinson's patients.
Conclusion: Our study shows a significantly increased risk of fractures for PD patients compared to the general population, indicating a need for optimal medical treatment, fall-prevention, and potential use of anti-resorptive medication in PD patient care.
Disclosure: Tove Henriksen (TH) has received honorary for talks from AbbVie, Britannia, Nordic Infucare, NeuroDerm, Convatec. TH has been a principal investigator for a study sponsored by AbbVie. EPO-552 | Cognitive phenotyping of GBA-Parkinson's disease: A study on deep brain stimulation outcomes

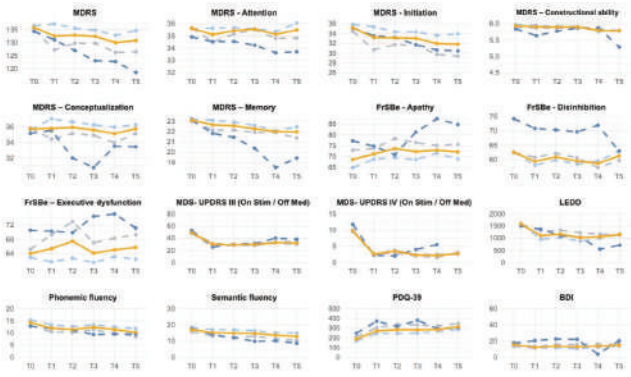
J. Fernández-Vidal; I. Aracil-Bolaños; C. García; J. Kulisevsky; B. Pascual-Sedano
Movement Disorders Unit, Department of Neurology, Hospital de la Santa Creu i Sant Pau

Background and Aims: Glucocerebrosidase (GBA) gene in Parkinson's disease (PD) associates earlier onset and worse cognitive decline. Deep Brain Stimulation (DBS) in GBA-PD effectively treats motor symptoms but long-term cognitive effects are unclear. Our study investigated 5-year outcomes in GBA-PD-DBS.
Methods: Retrospective cohort at H.Sant Pau (Barcelona, Spain) of DBS-PD with pre/postDBS assessments: cognitive (MDRS), frontal behavior (FrSBe), verbal fluencies, motor (MDS-UPDRS), L-dopa (LEDD), life quality (PDQ-39), and depression (BDI). Non-GBA-PD cluster analysis was conducted based on first-year cognitive impairment (CI).
Results: Out of 96 PD patients, 13 (13.5%) were GBA-PD. Cluster analysis identified progressors//non-progressors. Progressors' trajectory showed similarities to GBA-PD in cognition, FrSBe and PDQ-39, whereas non-progressors remained stable. In 56 PD-patients with 5-year cognitive follow-up, 8 were gene-carriers. GBA-PD showed faster CI to dementia ($p=0.05$), especially in attention ($p=0.015$), conceptualization ($p=0.004$) memory ($p=0.05$), with no age or education baseline differences. Regarding FrSBe, GBA-PD exhibited worse baseline disinhibition ($p=0.03$) with progressive improvement, while apathy and executive dysfunction deteriorated like non-GBA-PD. Depression scales showed higher values during the first two years in GBA-PD ($p=0.04$). Motor outcomes, LEDD, and phonetic fluency showed no differences, while GBA-PD-semantic-fluency worsened over time ($p=0.02$). No long-term differences were found in GBA-PD-PDQ-39.



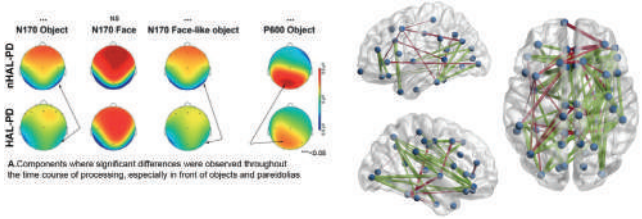
Evolution of studied variables. Groups: GBA-PD (dark blue), non-GBA-PD (orange), non-GBA-progressors (grey), non-GBA-non-progressors (light blue).

Conclusion: GBA-PD-CI was centered on attention, conceptualization, and memory; similar profile as progressors. Semantic fluency correlates with cognitive worsening in GBA-PD. From onset, GBA-PD-FrSBe was poorer and fluctuating but stable; also as progressors. Motor outcomes and quality of life were similar between GBA-PD, non-GBA-PD, and clusters, unaffected by CI. Previous surgery, FrSBe and fluencies, rather than MDRS/subscales, predict CI in non-GBA-PD-clusters.
Disclosure: Nothing to disclose.

EPO-553 | Neurophysiological architecture of visual categorization in Parkinson's disease with minor visual hallucinations

L. Perez-Carasol; S. Martinez-Horta; A. Horta-Barba; A. Puig-Davi; J. Kulisevsk; J. Pagonabarraga
Movement Disorders Unit, Department of Neurology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background and Aims: Although minor hallucinations are common in Parkinson's disease (PD, its precise neural mechanisms remain partially understood. Here, we addressed behavioral and neurophysiological anomalies accompanying visual categorization in patients with minor hallucinations.
Methods: We performed task-related EEG on 23 patients with (HAL-PD) and 23 without (nHAL-PD) minor hallucinations during a visual-categorization task based on objects, faces and facial-pareidolias. We identified the main neurophysiological components along the time course of processing and we studied its spectral characteristics to build functional connectivity models based on the signal sources.
Results: No differences were found in any of the clinical/sociodemographic parameters. HAL-PD showed difficulties identifying the most ambiguous stimuli. The neurophysiological components along visual processing showed abnormalities in HAL-PD in: (1) early visual categorization processes (N170) for stimuli requiring less specialized analysis (objects [$t(23)=1.9$; $p<0.05$]; pareidolias [$t(23)=2.23$; $p<0.05$]) and (2), in the late processes of semantic attribution (P600) [$t=(23)=2.2$; $p<0.05$]. Time-frequency analysis showed a main slow-wave component (3 Hz–8 Hz) decreased in HAL-PD along the time interval of interest. The HAL-PD group showed an overall decreased connectivity between different areas of the brain (green), accompanied by an increased connectivity between left-sided inferior/anterior nodes of the semantic system and posterior nodes of the default-mode network.



Task-related components and connectivity analysis.

Conclusion: Minor hallucinations are associated with a combined impairment of early visual recognition (N170) and later semantic attribution (P600). This is accompanied by several differences in the neural architecture subserving these processes. Our results emphasize the use of inadequate semantic information to confer meaning to the deficiently processed stimulus as the central mechanism for minor hallucinations.
Disclosure: Nothing to disclose.

EPO-554 | Mixed brain pathology in neurodegenerative parkinsonism and dementia

K. Mensikova[1]; L. Tuckova[2]; D. Hrabos[2]; J. Bouchal[2]; J. Ehrmann[2]; P. Kanovsky[1]
[1]Department of Neurology and Clinical Neuroscience Center, Faculty of Medicine and Dentistry, Palacky University and University Hospital Olomouc, Olomouc, Czechia; [2]Department of Clinical and Molecular Pathology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czechia

Background and Aims: The aim of the study was to assess the presence and proportion of mixed neurodegenerative pathology in a prospective cohort of patients treated for any phenotype of neurodegenerative parkinsonism and its impact on the accuracy of clinical diagnosis.
Methods: A total of 49 brains of patients who were diagnosed with neurodegenerative parkinsonism or dementia and who consented to join the donor programme were autopsied; neuropathological examinations were performed according to the standard protocol.
Results: There were 25 patients, in whom the pathological examination confirmed the presence of single pathology: 13 patients suffered from alfa-synucleinopathy (syn), 5 patients suffered from tauopathy (tau), 1 patient suffered from TDP-34-pathology (TDP-43) and 6 suffered from AD-related proteinopathy (AD). In 21 patient examinations revealed the presence of double pathology (4 syn/tau, 7 syn/AD, 6 tau/AD, 4 AD/TDP-43), and in 3 patients examination revealed the presence of triple pathology (syn/tau/AD). The correct clinical diagnosis was confirmed in 26 cases, the incorrect clinical diagnosis was done in 23 cases; 13 of them suffered from the mixed brain pathology.
Conclusion: The mixed brain pathology is relatively common finding at brain autopsy in patients who suffered from neurodegenerative parkinsonism, even when the recent and validated clinical diagnostic criteria were used during the diagnostic process. This fact should serve as a basis for the further discussion about their usefulness. These findings also point to the need of intensive research aimed at identifying biomarkers capable of predicting the corresponding types of pathological processes.

EPO-555 | Impact of ADORA2A gene polymorphism on Dyskinesia in Parkinson's disease

S. Kuzieva; S. Shokhimardonov
Neurology Department, Tashkent Medical Academy, Tashkent, Uzbekistan

Background and Aims: Parkinson's progression leads to motor complications and dyskinesias with levodopa use. This study investigates the link between ADORA2A gene polymorphisms (rs2298383, rs35060421, and rs5751876) and dyskinesia in Parkinson's patients, inspired by the positive effects of ADORA2A receptor antagonism on motor symptoms and dyskinesias.
Methods: A cohort of 200 Parkinson's disease (PD) patients, aged 25 and above, with a minimum of one year of levodopa treatment, participated in the study. Among them, 70 patients exhibiting dyskinesia were designated as cases, while 130 patients without dyskinesia comprised the control group. Genetic evaluations were conducted on both groups, utilizing DNA extracted from peripheral venous blood. The genetic analysis involved high-resolution melting analyses to assess and compare genetic profiles.
Results: While no significant association was observed between the investigated polymorphisms of rs5751876 and rs2298383 alleles and dyskinesia, the rs35060421 allele showed a notably higher frequency in the patient group (odds ratio: 1.39). In regression analysis, considering factors such as gender, age of disease onset, duration of levodopa treatment, and total drug dosage, the odds ratio for rs35060421 increased to 1.608. This suggests that the presence of this allele, in conjunction with other factors, elevates the risk of developing dyskinesia.
Conclusion: Patients with Parkinson's disease (PD) experiencing dyskinesia exhibited longer disease duration, more severe symptoms, and a higher dosage of levodopa. Although no statistically significant difference was identified between dyskinesia and the studied polymorphisms, there is a potential association suggesting that individuals with the rs35060421 polymorphism may face an increased risk of developing dyskinesia.
Disclosure: Nothing to disclose.

EPO-556 | Oropharyngeal adverse events in Parkinson's patients with motor fluctuations treated with apomorphine sublingual film

L. Wojtecki[1,2]; F. Moreira[3]; E. Cubo[4]; M. Fonseca[5]; G. Harrison-Jones[5]; C. Denecke Muhr[5]
[1]Department of Neurology & Institute of Clinical Neuroscience and Medical Psychology, University Clinic Duesseldorf, Duesseldorf, Germany; [2]Department of Neurology and Neurorehabilitation, Hospital Zum Heiligen Geist, Duesseldorf, Kempen, Germany; [3]Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [4]Department of Geriatrics, Hospital Universitario de Burgos, Burgos, Spain; [5]Bial – Portela & Ca, S.A., Coronado, Portugal

Background and Aims: Study CTH-301 demonstrated that apomorphine sublingual film (SL-APO) was well-tolerated and efficacious for treating OFF-episodes in Parkinson's disease patients with motor fluctuations. This post-hoc analysis explored the occurrence of oropharyngeal treatment-emergent adverse events (TEAEs) in patients included in this study.

Methods: Study CTH-301 was a Phase 3, multicentre, open-label trial composed of a dose-optimisation (DO) and long-term safety (LTS) phase. Incidence, severity and time to onset of oropharyngeal TEAEs and discontinuations due to oropharyngeal TEAEs were evaluated. Baseline characteristics that differed between patients who developed oropharyngeal TEAEs and those who did not and between patients who discontinued due to oropharyngeal TEAEs and those who did not were also identified.

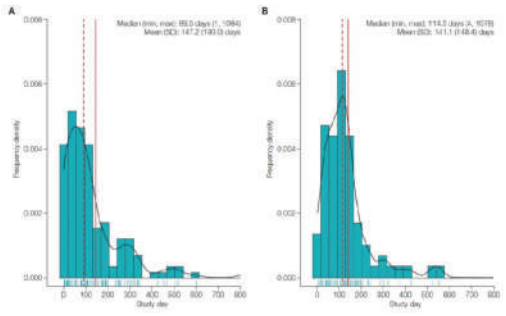
Results: Of 496 patients, 206 (41.5%) experienced oropharyngeal TEAEs and 81 (16.3%) discontinued due to oropharyngeal TEAEs (both DO + LTS) (Table 1). The majority of oropharyngeal TEAEs overall and those leading to discontinuation were mild or moderate (Table 1), with more severe TEAEs being associated with higher discontinuation rates. Median time to onset for oropharyngeal TEAEs and oropharyngeal TEAEs leading to discontinuation was 89.5 and 114.5 days from study initiation, respectively (Figure 1). Baseline characteristics significantly associated with the occurrence of oropharyngeal TEAEs were dopamine agonists use ($p < 0.001$), older age ($p < 0.01$) and other dopaminergic medications use ($p < 0.01$). Baseline characteristics significantly associated with occurrence of oropharyngeal TEAEs leading to discontinuation were older age ($p < 0.01$) and dopamine agonists use ($p = 0.042$).

Table 1. Summary of oropharyngeal TEAEs during the dose-optimisation phase and the long-term safety phase of Study CTH-301

	Dose-optimisation phase n=449	Long-term safety phase n=426	Dose-optimisation and long-term safety phase N=496
All TEAEs			
Any TEAEs, n (%); number of events	232 (51.7); 657	365 (85.7); 1966	446 (89.9); 2623
Oropharyngeal TEAEs			
Any oropharyngeal TEAEs n (%); number of events	53 (11.8); 78	178 (41.8); 475	206 (41.5); 553
Drug-related TEAEs, n (%); number of events	25 (5.6); 36	145 (34.0); 394	160 (32.3); 430
Mild*	20 (4.5); 30	67 (15.7); 141	79 (15.9); 168
Moderate*	5 (1.1); 5	72 (16.9); 148	75 (15.1); 152
Severe*	0	6 (1.4); 8	6 (1.2); 8
TEAEs leading to drug reduction, n (%); number of events	1 (0.2); 1	7 (1.6); 13	8 (1.6); 14
TEAEs leading to drug interruption, n (%); number of events	0	45 (10.6); 72	45 (9.1); 72
TEAEs leading to drug discontinuation, n (%); number of events	1 (0.2); 1	80.0 (18.8); 137	81 (16.3); 138
Mild*	1 (0.2);1	24 (5.6); 31	25 (5.0); 32
Moderate*	0	52 (12.2); 81	52 (10.5); 81
Severe*	0	4 (0.9); 5	4 (0.8); 5
TEAEs leading to death, n (%); number of events	0	0	0

*Based on the highest severity level for each subject, TEAE, treatment-emergent adverse events

Figure 1. Distribution of days to onset of oropharyngeal TEAEs during the dose-optimisation phase and the long-term safety phase of Study CTH-301: (A) any oropharyngeal TEAEs; (B) oropharyngeal TEAEs leading to discontinuation. Black lines indicate smoothed density estimate of the histograms; turquoise vertical lines on x-axes indicate days to onset of oropharyngeal TEAEs or discontinuation due to oropharyngeal TEAEs for each individual patient; dashed red lines indicate the median; continuous red lines indicate the mean. SD, standard deviation; TEAEs, treatment-emergent adverse events



Conclusion: Oropharyngeal TEAEs, including those leading to discontinuation, were mostly mild or moderate and predominantly occurred within the first few months of SL-APO initiation.

Disclosure: Supported by Bial.

EPO-557 | Remote monitoring of symptoms helps to maintain the quality of life in Parkinson's disease

L. Mäkitie[1]; J. Niskala[1]; K. Redecop[2]; W. van Deen[2]; C. Godoy junior[2]; H. Mueller[3]; B. Tas[3]; E. Fiorenzato[4]; L. Weis[4]; A. Antonini[4]; M. Koivu[1]

[1]Department of Neurology, Brain Center, Helsinki University Hospital and Department of Clinical Neurosciences, University of Helsinki, Helsinki, Finland; [2]Erasmus School of Health Policy and Management, Section Health Technology Assessment, Erasmus University, Rotterdam, The Netherlands; [3]NeuroPath SRL/BV, Engheim, Belgium; [4]Parkinson's Disease & Movement Disorders Unit, Department of Neuroscience (DNS), University of Padua, Italy

Background and Aims: Remote monitoring of patients provides objective information for the healthcare to adjust the treatment. Simultaneously the patient has a better insight into the disease giving opportunity for improvements in self-care and lifestyle. In AICCELERATE-project, we develop remote monitoring of persons with Parkinson's disease (pwp).

Methods: 26 pwps were randomized either to an intervention group ($N = 14$) provided with a wrist-worn wellness wearable (Polar Ignite 2), a videomonitoring solution (NeuroPath), and a mobile symptom diary (Health Village, HUS) or to a control group ($N = 12$). Patients were asked to use the devices monthly. All patients were clinically evaluated twice in 6 months by validated scores (MDS-UPDRS, NMSS and PDQ39). Adherence was evaluated by the number of measurements taken. Quality of life, Parkinson-symptoms and levodopa equivalent daily doses were compared between groups with statistical tests (Wilcoxon for pre-post comparisons and Mann-Whitney *U* for between group comparisons).

Results: During 6 months, patients had performed median of 4.8 video-monitoring sessions (12 motor tasks/session), reported symptoms 2.4 times with the diary, and used the wellness wearable for median of 103 days. Three patients wished to discontinue in the study during the follow-up. Quality of life (PDQ39) had improved after remote monitoring period compared to control group (the changes in PDQ-4.5 and 3.5, respectively, $p = 0.017$). There was no statistical difference between baseline demographics or the progression of symptoms between groups.

Device	Manufacturer	Data collected	Number of measurements, median (range)
	Polar, Kempele, Finland	Sleep duration and interruptions Steps/day	103 days (40-183)
	NeuroPath, Enghien, Belgium	Metrics and videos of 12 motor tasks	4,8 sessions, 58 videos (20-77 videos)
	Helsinki University Hospital, Helsinki, Finland	Questionnaire for motor and non-motor symptoms and disability	2 (0-7)

TABLE 1 Median number of remote measurements taken in 6 months at home by intervention group.

	Age (range)	Disease duration, years (IQR)	LEDD, (IQR)	PDQ39, baseline (IQR)	Change of PDQ39 (IRQ; p-value)	MDS-UPDRS, baseline (IQR)	NMSS, baseline (IQR)
Intervention group	68 (46-82)	4,6 (7,8)	475 (312)	23,5 (17)	-4,5 (7,8; 0,059)	33,5 (18)	18,5 (21)
Control group	69 (50-76)	4,0 (8,5)	425 (513)	29,5 (30)	13,5 (11,3; 0,107)	41,5 (37)	38,5 (32)

TABLE 2 Demographics at baseline and validated scores as median values in intervention and control groups. Interquartile range (IQR), range and *p*-values in parentheses. LEDD, levodopa equivalent daily dose.

Conclusion: Patients are motivated to use technology for months to acquire detailed information on their disease. The quality of life is not affected by monitoring, rather promotes better well-being.

Disclosure: The project has been funded by EU's Horizon2020.

EPO-558 | Home-based non-invasive brain stimulation in combination with speech therapy in Parkinson's disease – Preliminary data

L. Brabenec[1]; D. Kovac[2]; J. Mekyska[2]; P. Klobusiakova[1]; L. Rehulkova[3]; V. Kabrtova[3]; I. Rektorova[1]

[1]Central European Institute of Technology – CEITEC, Masaryk University, Applied Neuroscience Research Group, Brno, Czechia; [2]Brno University of Technology, Department of Telecommunications, Brno, Czechia; [3]Faculty of Medicine and St. Anne's University Hospital, First Department of Neurology, Brno, Czechia

Background and Aims: Hypokinetic dysarthria (HD) affects up to 90 % of Parkinson's disease (PD) patients, manifesting as reduced loudness, imprecise articulation, and impaired speech prosody. This ongoing study aims to investigate the effects of home-based transcranial direct-current stimulation (tDCS) as an add-on to the remote Lee-Silverman Voice Treatment (LSVT), compared to LSVT alone (coupled with sham stimulation), in PD patients.

Methods: Using a double-blinded, randomized design, PD patients are divided into two groups, receiving either real or sham anodal tDCS (2 mA, 20 min) of the right superior temporal gyrus (rSTG – auditory-feedback area) over 20 sessions in four weeks. Concurrently, both groups undergo remote LSVT. All participants undergo MRI scanning (fMRI-reading task and resting state) and evaluation by speech therapists, at baseline and after the treatment.

Results: Analysis of the first 12 subjects (6 sham, 6 real stimulation) revealed significant improvements for all participants in the Dysarthric profile scale Total score (median relative change = 5.87, $p = 0.005$) and Phonetics score (median relative change = 4.0, $p = 0.038$). Changes in Phonetics score correlated with changes in left supplementary motor area (lSMA) activations ($R = 0.678$, $p = 0.045$). Interestingly, changes in resting state connectivity between rSTG and lSMA were higher after real stimulation (median = 63.8) than after sham (median = −100.4), though not statistically significant ($p = 0.114$).

Conclusion: Preliminary data suggest that the remote LSVT is beneficial for PD patients and combination with home-based stimulation is feasible. We also observed neural correlates of induced speech improvements.

Disclosure: Nothing to disclose.

EPO-559 | Levodopa-induced dyskinesias impact on quality of life in Parkinson's disease: A 5-year follow-up study

Background and Aims: Levodopa-induced dyskinesias (LID) are frequent in Parkinson´s disease (PD). Our aim was to analyze the change in the frequency of LID over time and identify LID related factors and know how LID impact on patients´ quality of life (QoL).

Methods: PD patients from the COPPADIS cohort were included. LID was defined as a non-zero score in the item "Time spent with dyskinesia" of the UPDRS-IV. It was applied at baseline (V0) and annually for 5 years. The 39-item Parkinson's disease Questionnaire Summary Index (PQ-39SI) was used to asses health-related QoL.

Results: The frequency of LID at V0 in 672 PD patients (62.4 ± 8.9 years old; 60.1% males) with a mean disease duration of 5.5 ± 4.3 years was 18.9% (127/672) and increased progressively to 42.6% (185/434) at 5-year follow-up (V5y) (Figure 1A). LID was associated with disease duration and time under levodopa therapy (Figure 1A-1D). Significant Independent factors associated with LID ($p < 0.005$) were a longer time under levodopa treatment and disease duration, a higher dose of levodopa, a lower dose of dopamine agonist and weight, and the presence of motor fluctuations and pain (Table 1). Patients with LID had a higher score on the PDQ-39SI in all visits ($p < 0.005$) and at V0 LID was independently associated with a greater score on the PDQ-39SI ($\beta = 0.073$; 95% CI, 0.274–4.534, $p = 0.027$; $R^2 = 0.62$) (Table 2).

Variables at baseline (V0)	Adjusted R-squared	OR	CI 95%	p
	0.52			
To have motor fluctuations		4.966	2.687 – 9.176	<0.0001
Levodopa daily dose		1.002	1.001 – 1.003	<0.0001
VAS-PAIN		1.156	1.060 – 1.261	0.001
Disease duration		1.013	1.004 – 1.022	0.005
DA equivalent daily dose		0.998	0.996 – 0.999	0.025
Weight		0.979	0.959 – 0.999	0.041
Time under levodopa therapy		1.105	1.003 – 1.219	0.044

Dependent variable: LID at baseline. Covariates were included in the multivariate analyzes using sequential logistic regression methods and only significant variables (p<0.005) were kept in the model. Hosmer and Lemeshow test = 0.576.

DA, dopamine agonist; VAS, Visual Analogue Scale.

TABLE 1 Factors associated with the presence of LID at baseline (V0) in the COPPADIS cohort ($N = 672$).

Variables at baseline (V0)	Adjusted R-squared	β	CI 95%	p
	0.62			
NMSS		0.441	0.129 – 0.178	<0.0001
FOGQ		0.222	0.407 – 0.826	<0.0001
VAFS		0.118	0.256 – 0.894	<0.0001
BDI-II		0.099	0.065 – 0.282	0.002
PDSS		-0.093	-0.088 – -0.015	0.005
Age		-0.075	-0.208 – -0.227	0.011
UPDRS-III		0.084	0.019 – 0.191	0.016
Levodopa-induced dyskinesia		0.073	0.274 – 4.534	0.027

Dependent variable: PDQ-39SI at baseline. Covariates were included in the multivariate analyzes using sequential logistic regression methods and only significant variables (p<0.005) were kept in the model. Durbin-Watson test = 1.81.

BDI-II, Beck Depression Inventory-II; FOGQ, Freezing of Gait Questionnaire; NMSS, Non-Motor Symptoms Scale; PDSS, Parkinson's Disease Sleep Scale; UPDRS, Unified Parkinson's Disease Rating Scale; VAFS, Visual Analog Fatigue Scale.

TABLE 2 Effect of LID (levodopa-induced dyskinesia) on quality of life after adjustment to other covariates at baseline (V0) in the COPPADIS cohort ($N = 672$).

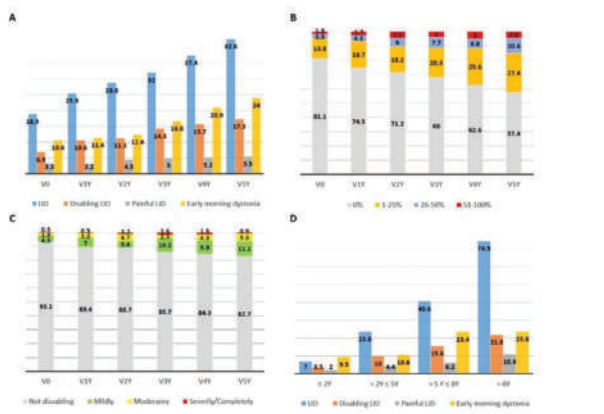

Figure 1. A. Frequency of LID, disabling LID, painful LID and early morning dystonia at baseline (V0; N=672) and annually for 5 years. V1y (12 months ± 1 month; N=604); V2y (24 months ± 1 month; N=517); V3y (36 months ± 2 months; N=482); V4y (48 months ± 3 months; N=465); V5y (60 months ± 3 months; N=434). B. Frequency of awake time with LID according to the UPDRS-IV-item 32 at V0, V1y, V2y, V3y, V4y and V5y. C. Degree of severity of LID according to the UPDRS-IV-item 33 at V0, V1y, V2y, V3y, V4y and V5y. D. Frequency of LID, disabling LID, painful LID and early morning dystonia at V0 regarding the time under levodopa therapy in the group of patients receiving levodopa at V0 (N=490). P value < 0.0001 for all analysis except for early morning dystonia (p=0.032). LID, levodopa-induced dyskinesias; UPDRS, Unified Parkinson's Disease Rating Scale.

Conclusion: LID are frequent in PD patients. A higher dose of levodopa and lower weight were factors associated to LID. LID impact on QoL.

Disclosure: The authors report no conflict of interest.

EPO-560 | Effects of sensory modulation on balance control, a preliminary study with healthy individuals and chronic stroke

R. Chang; L. Chou

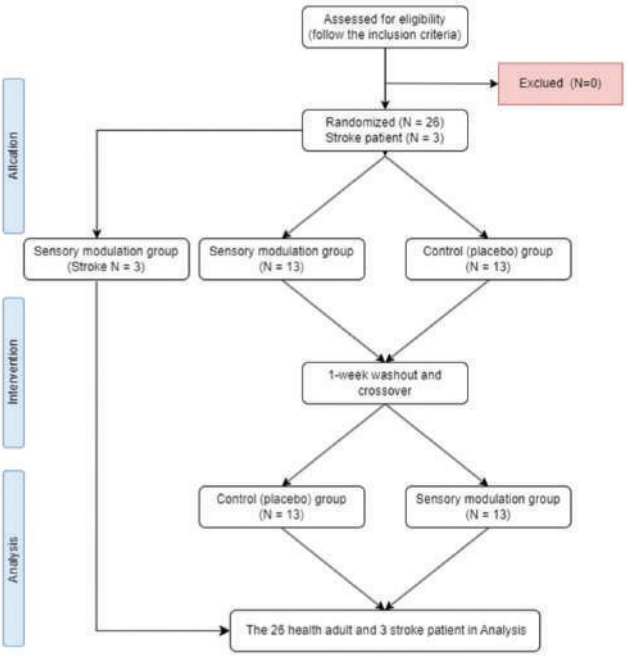
National Yang Ming Chiao Tung University

Background and Aims: Individuals with sensory deficits rely on feedforward control for better motor performance. Additional sensory afferent input can induce feedforward control. EEG event-related synchronization/desynchronization (ERD/ERS) and theta-gamma

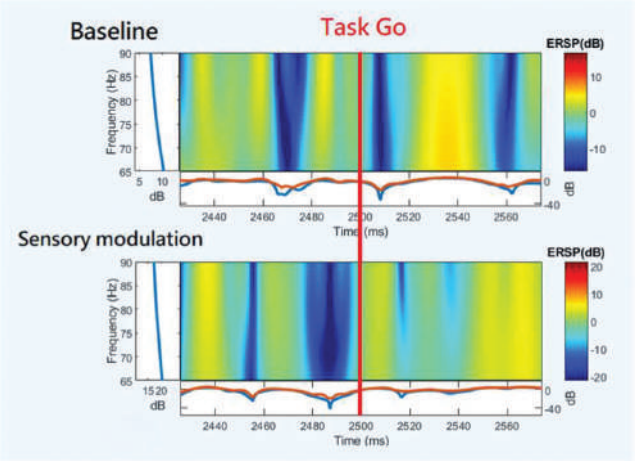
coupling are thought to be related to feedforward control. This study aims to determine if sensory afferent input induced by local vibration (sensory modulation) induces feedforward control.

Methods: Participants underwent a sensory modulation experiment and placebo experiment in random order. Participants first received 30 s of high-frequency vibration stimulation on the dominant foot's tibialis anterior muscle, then received balance assessment and training (five rounds total). The placebo condition used sham vibration. The Balance Index (Biodex balance system) and EEG (TMSi-64 channel system) were collected before and after sensory modulation. The EEG data were processed with time-frequency analysis and the frequency-profile of theta and gamma bands and ERD/ERS peak values were calculated. Pearson's correlations determined theta-gamma coupling and two-way repeated measures ANOVA was used to compare the ERD/ERS between the two conditions. The statistical significant level was set to <0.05.

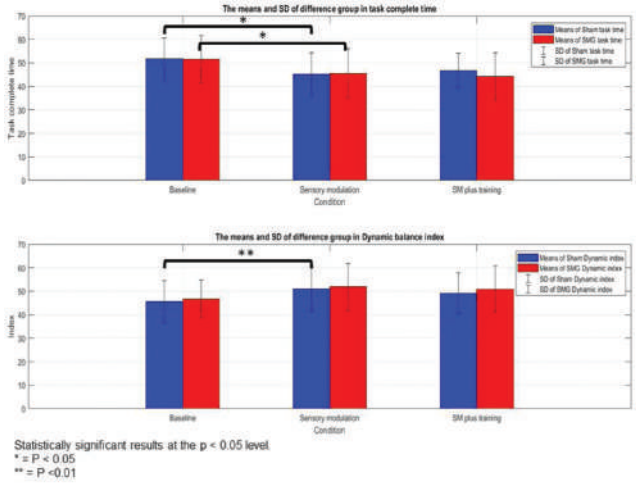
Results: Our study with 26 healthy adults found that sensory modulation significantly improved the dynamic balance index ($p=0.004$) and induced greater theta gamma phase-amplitude coupling in the motor cortex ($r=0.9$; $p<0.001$). Our results also found that the gamma ERD in the sensory modulation condition was significantly lower, but earlier than the placebo condition ($p=0.013$).



The study flowchart.



With the intervention of sensory modulation, the sensory modulation group showed greater and earlier event-relative desynchronization peaks in the time-frequency analysis of EEG measurements.



The sensory modulation group and the Sham group showed a significant reduction in task completion time at baseline and after sensory modulation. The sensory modulation group showed a significant increase in balance dynamic index at baseline and after sensitivity.

Conclusion: Our study found that sensory modulation with local vibration can induce feedforward control, and a similar trend was also observed in stroke patients.

Disclosure: Nothing to disclose.

EPO-561 | The use of opicapone for motor fluctuations in Parkinson: Real-life experience of two Italian Movement Disorders Centers

M. Liccari[1]; R. Bacchin[2]; M. Catalan[1]; M. Malaguti[2]; L. Antonutti[1]; B. Giometto[2]; P. Manganotti[1]

[1]*Clinical Unit of Neurology, Department of Medicine, Surgery and Health Sciences, University Hospital of Trieste ASUGI, University of Trieste, Trieste, Italy;* [2]*Clinical Unit of Neurology, Department of Emergency, Santa Chiara Hospital, Azienda Provinciale per i Servizi Sanitari (APSS), Trento, Italy*

Background and Aims: Opicapone (OPC) is used as add-on to L-Dopa (LD) therapy for management of motor fluctuations (MFs) in Parkinson's disease (PD). Its benefit on PD population has been established by different clinical trials, and a recent post-hoc analysis has demonstrated its better tolerability when used early in iPD. Data are missing about the use of OPC on Italian population of PD patients, so the aim of this paper is to report the real-life experience of the two Centers of Trieste and Trento.

Methods: Retrospective data have been gathered of Italian PD patients followed for at least two years after OPC introduction for MFs.

Results: 152 patients have been enrolled, 35% reported adverse events (AEs) on the two-year follow-up. 27% discontinued OPC because of a severe AE, which in 76% of cases was a dopamine-related AE. Univariate analysis recognized as clinical predictors of treatment discontinuation because of any AE were age, disease duration, MFs duration, Hoehn-Yahr stage, past history of hallucinations or addictive behaviour, mild cognitive complaint, falls, and for treatment discontinuation due to dopamine-related AE were age, MFs duration, Hoehn-Yahr, previous addictive behaviour, MCI, and falls. Predictors of OPC withdrawn accordingly to multivariate were MFs duration and Hoehn-Yahr.

Conclusion: Real-life data on Italian PD population confirm good tolerability and safety of OPC for the treatment of MFs, moreover when introduced early according to disease course and LD treatment pathway. MFs duration and Hoehn-Yahr stage have been shown to be important predictors of OPC therapy maintenance over a follow-up of at least 2 years.

Disclosure: Nothing to disclose.

EPO-562 | Clinical correlates of iron deposition within subcortical nuclei in early drug-naïve Parkinson's disease patients

M. D'Anna[1]; R. De Micco[1]; N. Piramide[1]; F. Di Nardo[1]; M. Pirozzi[1]; M. Siciliano[2]; G. Tedeschi[1]; F. Esposito[1]; A. Tessitore[1]

[1]*Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Napoli, Italy;* [2]*Neuropsychology Laboratory, Department of Psychology, University of Campania "Luigi Vanvitelli", Caserta, Italy*

Background and Aims: Iron deposition using Quantitative Susceptibility Mapping (QSM) has been reported in patients with Parkinson's disease (PD)1. We explored the association between 3TMRI-derived iron deposition content within 12 bilateral subcortical nuclei and several motor, nonmotor and neuropsychological features in a cohort of 58 early drug-naïve PD patients.

Methods: Disease severity was assessed by UPDRS-III, nonmotor symptoms by Nonmotor symptoms scale (NMSS), autonomic dysfunction by Scale for Outcomes in Parkinson's disease for Autonomic symptoms (SCOPA-AUT), behavioral symptoms by Beck Depression Inventory (BDI-II), Parkinson Anxiety Scale (PAS) and Apathy Evaluation scale (AES). An extensive neuropsychological assessment was acquired and a *z*-score for each cognitive domain was calculated. QSM values were extracted from 12 bilateral subcortical nuclei by applying the HybraPD atlas2. A partial correlation analysis was run between MRI and clinical data.

Results: We found significant correlations between the iron content within bilateral dentate nuclei and UPDRS-III scores; left externus globus pallidus/right red nucleus and AES scores; left subthalamic nucleus/externus globus pallidus and *z*-score executive; bilateral putamina/right externus globus pallidus and *z*-score attention; left substantia nigra (pars reticulate) and PAS scores; right substantia nigra (pars compacta) and BDI-II scores; right red nucleus and several thalamic subregions and SCOPA-AUT scores.

Conclusion: The presence of specific clinical features is associated with increased iron deposition within different subcortical nuclei in PD patients in the early stages. These findings may be associated with a more severe clinical picture at baseline and may potentially lead to more rapid worsening over time.

EPO-563 | Subacute cerebellar ataxia: Always look for malignancy: A case report

C. Martin de la Morena[1]; M. Gómez Dunlop[1]; E. Gamo González[1]; R. Martín García[1]; S. Novo Ponte[1]; P. Sánchez Alonso[1]; P. Rábano Suárez[2]

[1]*Hospital Puerta de Hierro de Majadahonda, Madrid, Spain;* [2]*Hospital Doce de Octubre, Madrid, Spain*

Background and Aims: Intracellular anti-SOX1 antibodies are associated with several neurological síndromes. Lambert-Eaton syndrome and subacute cerebellar degeneration (CD) are the most frequent. Almost all cases are paraneoplastic, and small cell lung carcinoma (SCLC) is the most frequently detected malignancy.

Methods: Case description.

Results: We present the case of a 62-year-old male patient, exsmoker, with mild active alcohol intake, who seeked neurology consultation for a 9-month progressive gait and speech disorder. On neurological examination, he had moderate dysarthria, hypermetric saccades on horizontal plane, mild bilateral dysmetria, and severe gait ataxia, requiring constant bilateral support. There was no cognitive impairment. On further questioning, he had lost 10 kg during that period. He was diagnosed with subacute cerebellar

degeneration. Brain magnetic resonance showed mild cerebellar atrophy, possibly related to chronic alcohol intake. Focusing on treatable causes, lumbar puncture revealed normal CSF cell count, glucose and proteins, but positive anti-SOX1 antibodies were found in serum and CSF (confirmed with indirect immunofluorescence and Western Blot). Electromiography showed no evidence of Lambert-Eaton. Seeking for occult malignancy, a carinal adenopathy was found on PET-CT scan and a biopsy revealed a SCLC stage III. Three months after chemotherapy and 2 cycles of immunoglobulins, his neurological condition has mildly improved, now being able to walk with one support.

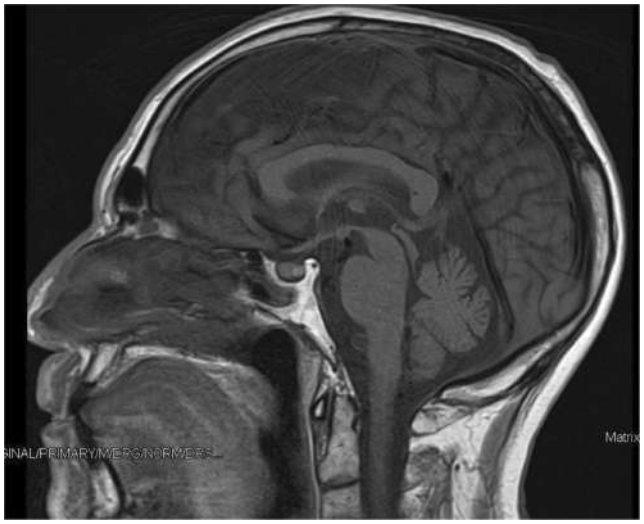

IMAGE 1 Mild cerebellar atrophy in MRI.

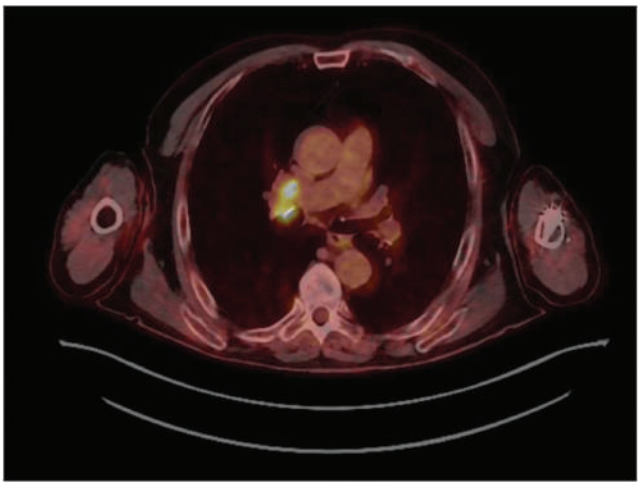

IMAGE 2 A pathological carinal adenopathy is found in PET-CT scan.

Conclusion: Subacute cerebellar degeneration has some treatable causes. When anti-SOX1 antibodies are found, search for malignancy is a must. Knowledge of paraneoplastic neurological syndromes can improve cancer detection and treatment.

Disclosure: None.

EPO-564 | Effectiveness of a multidisciplinary approach to prevent falls and gait impairment in patients with Parkinson's disease

E. Cubo[1]; A. Garcia-Bustillo[2]; J. Ramirez-Sanz[2]; J. Garrido-Labrador[2]; A. Olivares-Gil[2]; F. valiñas-Sieiro[1]; M. Allende-Rio[1]; J. Trejo[1]; s. calvo[1]; J. Diez-Pastor[2]; D. Garcia-Garcia[2]; A. Arnaiz Gonzalez[2]

[1]*Neurology Department, Hospital Universitario Burgos, Spain;* [2]*University of Burgos*

Background and Aims: Managing Parkinson's disease (PD) requires a multidisciplinary approach to address the diverse needs of patients. We aimed to study the short and long-term effectiveness of a multidisciplinary telemedicine program in addition to in-office usual care in non-demented patients with PD at risk for falling.

Methods: Longitudinal, randomized, case-control study. All participants in the office were evaluated at baseline, four, and eight months (V0, V1, and V2). Patients included in the telemedicine program received additional multidisciplinary care with nurse, neurologist, and occupational therapist interventions from V0 to V1. The severity of motor, non-motor symptoms, and quality of life were compared at each visit.

Results: Fifty patients were included, 25 patients [telemedicine program, 48% males, mean age of 71.1 ± 9.0 years, median number of falls (last month) of 1.0 (IQR: 0.0; 1.5)] and 25 patients [control group, 52% males, mean age of 69.2 ± 9.4 years, median number of falls (last month) of 1.0 (IQR: 0.0; 2.0)]. When both groups were compared, in the telemedicine group, apathy, and depression symptomatology, freezing of gait and balance were improved at V1 compared to V0 (all p values < 0.0001), and freezing of gait and balance at V2. In post-hoc analyses, quality of life improvement was correlated with improvement in depression in the telemedicine group.

Conclusion: By leveraging multidisciplinary telemedicine interventions in addition to in-office visits, healthcare providers can deliver patient-centric care, improving non-motor symptoms and gait impairment in PD. These hybrid interventions could solve current barriers to health systems with limited capacity.

EPO-565 | Reduced glucocerebrosidase activity in patients with sporadic Parkinson's disease

A. Mili; S. Naija; A. Rekik; E. Jarrar; K. Jemai; A. Hassine; S. Ben Amor

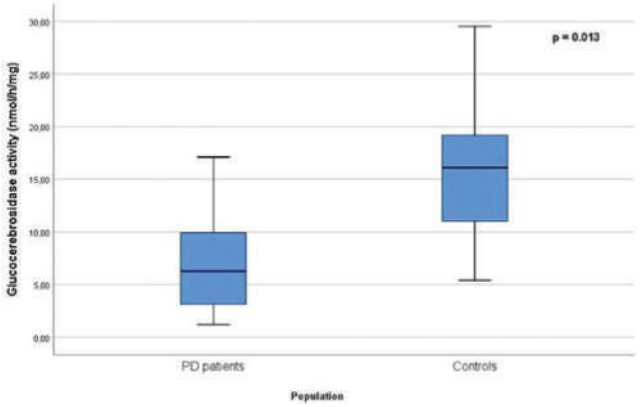
Department of Neurology, Sahloul Hospital, Sousse, Tunisia

Background and Aims: The pathogenesis of sporadic Parkinson's disease (PD) is thought to be resulting from a complex interplay between genetic and environmental factors. While GBA1 mutation is a

confirmed risk factor of PD, little is known about glucocerebrosidase (Gcase) activity in sporadic PD. Our work aims to measure the Gcase activity in sporadic PD patients and matched healthy controls and identify any clinical or biological correlation with disease severity.

Methods: Flow cytometry was used to measure lysosomal Gcase activity in lymphocytes from 50 sporadic PD patients and 50 age/gender-matched healthy controls. All participants underwent a neurological examination, including a motor severity assessment by MDS-UPDRS score and modified Hoehn and Yahr scale (H&Y), along with a measure of blood glucose and lipids.

Results: Gcase activity was significantly reduced in PD group (6.84 nmol/h/mg ± 4.16 vs 16.06 ± 5.9; $p = 0.013$; OR = 2.13). Within PD group, lower Gcase activity was correlated with age >65 ($p = 0.049$; OR = 1.27) and PD onset before 50 ($p = 0.046$; OR = 1.49). Enzymatic activity was not correlated to the other studied variables: Sex, BMI, PD duration, MDS-UPDRS score, H&Y stage, glucose and lipids levels ($p > 0.05$).



Glucocerebrosidase activity in PD patients and controls.

Conclusion: Our study revealed a reduced glucocerebrosidase activity in patients with sporadic PD but did not find a correlation with its severity. Larger sample studies are needed to corroborate these findings. If confirmed, it could be a step towards the first biomarker for PD.

Disclosure: Nothing to disclose.

EPO-566 | Effect of fecal microbiota transplantation on clinical symptoms of Parkinson disease – A pilot study

M. Figura[1]; Ł. Milanowski[1]; J. Nowak[2]; A. Antoniak[2]; M. Kopczyński[2]; K. Sadowski[2]; W. Zając[2]; D. Koziorowski[1]
[1]*Department of Neurology, Faculty of Health Science, Medical University of Warsaw, Warsaw, Poland;* [2]*Student Scientific Group "Nekon" by the Department of Neurology, Faculty of Health Science, Medical University of Warsaw, Warsaw, Poland*

Background and Aims: The gastroenteric tract is involved in the pathogenesis of Parkinson's disease (PD) from its early, premotor stage. Gut bacteria may play a role in the pathogenesis and progression of PD. The aim of the study is to assess the impact of Fecal Microbiota Transplantation (FMT) on clinical symptoms of PD.

Methods: 25 patients with a diagnosis of PD were included in the analysis. Patients were randomly assigned to two groups: FMT from healthy donor or identically looking placebo produced from the patients' stool. Patients and clinicians were blinded to group allocation. FMT/placebo were administered into the distal part of the small intestine via colonoscopy. Patients underwent clinical assessments before and 1, 3, 6 and 12 months after the procedure (v0, v1, v3, v6 and v12 respectively). UPDRS I-IV, EQ5D, Constipation Assessment Scale (CAS), PDQ-39, NMSS, Gastrointestinal Dysfunction Scale for PD (GIDS-PD) were performed. Levodopa equivalent daily dose (LEDD) was calculated for each visit. Statistical analysis was performed with R version 4.1.2.

Results: Significant differences in LEDD between visits v1-3 after the procedure ($p = 0.003$) and difference in EQ5D between v1-3, v1-12 and v0-12 ($p < 0.05$) were observed. CAS and GIDS-constipation subscale varied significantly between v0-12 ($p < 0.05$). Significant differences were observed between V1 and 3 in several subscales of NMSS, particularly assessing psychiatric symptoms. No significant change in UPDRS III in the "off" state was observed.

Conclusion: FMT may influence clinical picture of PD, especially regarding its non-motor symptoms. Results suggest that the impact of the procedure diminishes with time, so repeated interventions could be considered.

Disclosure: Nothing to disclose.

EPO-567 | Long-term monitoring of copper metabolism parameters during treatment in patients with Wilson's disease

M. Misztal[1]; A. Członkowska[1]; A. Wiśniewska[2]
[1]*Second Department of Neurology, Institute of Psychiatry and Neurology, Warsaw, Poland;* [2]*Department of Genetics, Institute of Psychiatry and Neurology, Warsaw, Poland*

Background and Aims: In Wilson's disease (WD), therapy aims to achieve homeostasis of copper metabolism and prevent excessive copper accumulation and deficiency. WD patients require lifelong treatment and regular monitoring of copper metabolism parameters.

Methods: This retrospective study is based on medical records collected from patients diagnosed with WD from the 1970s to 2022. The study groups included compliant patients, 237 treated with D-penicillamine (DPA) (89 hepatic, 120 neurological, 28 asymptomatic) and 228 with zinc sulfate (ZS) (94 hepatic, 70 neurological and 64 asymptomatic). The daily urinary copper excretion (UCE), serum copper and ceruloplasmin concentrations were analysed before and during long-term treatment.

Results: A significant decrease in serum copper and ceruloplasmin is observed during the first year of therapy, regardless of medication type. These parameters stabilise in the following years, but a slight increase occurs after ten years. A greater decline is obtained in the neurological form than in the hepatic and asymptomatic. The

pattern of UCE differs in the DPA group, with a significant increase within half a year of starting treatment. In the ZS group, the trend is similar to the other copper metabolism parameters.

Conclusion: The copper metabolism parameters reach optimal values in the first year of treatment and then stabilise. The decrease in serum copper leads to decreased ceruloplasmin, which can increase during long-term therapy improving liver functions. Patients with a neurological form are more prone to excessive decopperization. The obtained ranges of copper metabolism results may contribute to developing optimal long-term monitoring of WD patients.

Disclosure: Nothing to disclose.

EPO-568 | Correlations between CSF biomarkers of AD, neuropsychological tests and UPDRS-III in a cohort of PD patients

F. Musso[1]; A. Cimmino[1]; A. Scalese[1]; G. Giuffrè[2]; M. Petracca[2]; A. Bentivoglio[2]; P. Calabresi[2]; G. Di Lazzaro[2]

[1]*Sezione di Neurologia, Dipartimento di Neuroscienze, Facoltà di Medicina e Chirurgia, Università Cattolica del Sacro Cuore, Roma, Italy;* [2]*Neurologia, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Roma, Italy*

Background and Aims: Cerebrospinal fluid (CSF) biomarkers for biological diagnosis of Parkinson's Disease (PD) are lacking a wide clinical application. CSF biomarkers of amyloidopathy, tauopathy and neurodegeneration have been used in the last decades to measure Alzheimer's disease (AD) pathology in vivo and as a predictor of cognitive impairment in AD and have been proven to predict cognitive decline in PD as well. The objective is to assess the correlations between CSF biomarkers of AD pathology and cognitive/motor impairment in a cohort of PD patients.

Methods: We recruited 89 subjects with a diagnosis of PD. A lumbar puncture was performed and AD CSF biomarkers were quantified. When lumbar puncture was done, neuropsychological battery and UPDRS-III were performed. Correlations between CSF biomarkers, neuropsychological tests and UPDRS-III at the time of lumbar puncture and at last follow-up were carried out.

Results: Our results revealed a statistically significant correlation between biomarkers of amyloidopathy (Aβ42 and Aβ42/40) and poorer performances in MMSE, RAVLT delayed recall, Spatial Span, Raven matrices, MFTC, semantic verbal fluency, ROCF delayed recall. Interestingly, *t*-tau and *p*-tau levels were found to predict the % change between the UPDRS-III score at the baseline and follow-up, also when corrected with follow-up duration, LEDD and baseline UPDRS score.

Conclusion: This study highlighted how biomarkers of amyloidopathy can predict worse performances in some common neuropsychological tests. Furthermore, tau species showed potential in identifying PD patients at risk of accelerated motor decline, suggesting a possible synergistic role of tau with alpha-synuclein in the clinical progression of Parkinson's disease.

Disclosure: Nothing to disclose.

EPO-569 | Contribution to efficacy by active metabolites of suvecaltamide in a preclinical rat model of essential tremor

N. Shanks[1]; S. Markova[1]; R. Mukkavilli[2]; L. Tan[1]; M. Lee[1]; E. Brigham[1]

[1]*Jazz Pharmaceuticals, Palo Alto, CA, USA;* [2]*Jazz Pharmaceuticals, Philadelphia, PA, USA*

Background and Aims: Suvecaltamide (JZP385), a potent, selective T-type calcium channel modulator, reduced the functional impact of essential tremor (ET) in a phase 2 trial (NCT03101241). We present the pharmacokinetic/pharmacodynamic (PK/PD) relationship and contribution to anti-tremor efficacy in a harmaline-induced rat ET model for suvecaltamide and its active metabolites (JZZ05000034 = M01, JZZ05000035 = M02).

Methods: Tremor was quantified using piezoelectric signals in rats receiving harmaline (15 mg/kg, intraperitoneal) 1 hour before single oral doses of suvecaltamide or its metabolites (analytes). Plasma and brain analyte concentrations were measured in satellite experiments following harmaline and analyte administration.

Results: Suvecaltamide dose-dependently suppressed existing tremor when administered post-harmaline, with significant effects at ≥1 mg/kg. Tremor reduction was rapid and sustained during 4-hour recordings. All analytes were measurable in plasma and brain. While suvecaltamide concentrations peaked early and then decreased, active metabolite concentrations were more sustained over the experimental period. When dosed directly, both metabolites reduced tremor at plasma concentrations consistent with those achieved after suvecaltamide administration. Plasma suvecaltamide, M01, and M02 concentrations at 1 mg/kg were consistent with those achieved at steady state in humans at projected therapeutic doses. We characterized the PK/PD relationship of the suvecaltamide total active moiety in rats and utilized CaV3 potency and unbound plasma concentrations to translate to humans.

Conclusion: These results illustrate contributions to efficacy by active suvecaltamide metabolites in rats, which must be considered clinically given they are predicted to translate to human efficacy. These data support continued clinical development of suvecaltamide for adults with moderate-to-severe ET (NCT05122650) or residual Parkinson's disease tremor (NCT05642442).

EPO-570 | Cerebellar ataxia in mitochondrial pathology: Review based on a case series

N. Blanco Sanromán[1]; G. Olmedo Saura[2]; M. Domine[1]; M. Coronel Coronel[1]; L. Querol Gutierrez[3]; I. Ruiz Barrio[2]; S. Bernal Nogueral[4]; J. Kulisevsky[2]; M. Olivé[3]; J. Pérez Pérez[2]

[1]Neurology Department, Hospital de la Santa Creu i Sant Pau, Barcelona; [2]Movement Disorders Unit, Neurology Department, Hospital de la Santa Creu i Sant Pau, Barcelona; [3]Neuromuscular Diseases Unit, Neurology Department, Hospital de la Santa Creu i Sant Pau; [4]Genetics Department, Hospital de la Santa Creu i Sant Pau

Background and Aims: Cerebellar involvement in mitochondrial pathology is under-recognized, especially when it manifests as the initial symptom without a family history of such conditions. This study aimed to characterize the casuistry and clinical features of patients presenting with cerebellar ataxia due to mitochondrial pathology.

Methods: A descriptive, retrospective, single-center study was conducted on patients assessed in the ataxia unit of a tertiary hospital over five years. Patients diagnosed with mitochondrial cerebellar ataxia (CAM) were included, and demographic, clinical, and neuroimaging data were examined.

Results: Out of 221 patients, six were diagnosed with CAM (prevalence 2.7%). The average onset age was 48.3 years, with a diagnostic delay of 11.7 years. None had a family history of mitochondrial pathology, although two had history of deafness and diabetes. All patients presented with ataxia, scanning dysarthria and oculomotor impairment: ophthalmoparesis (cases 1, 2, 3, 5), gaze-evoked nystagmus (4). Other common clinical features included reduced visual acuity due to optic atrophy (4, 5, 6), sensory-motor polyneuropathy (2, 3, 4, 5, 6), myopathy (1, 2, 3) and spasticity (4), alongside other neurological manifestations such as stroke-like episodes (1), generalized epilepsy (1, 3, 5), chorea (3) and pes cavus (5, 6). Systemic symptoms included diabetes, early-onset hearing loss, and dilated cardiomyopathy. MRI findings reflected predominantly cerebellar atrophy or vermian volume loss. Genetic mutations were identified in genes including MT-TL1 (cases 1, 2), POLG (3) OPA1 (4), and TSFM (5, 6).

Symptoms		Mutation
Neurological		
Ataxia	6/6 (100%)	MELAS, POLG, OPA1, TSFM
Dysarthria	6/6 (100%)	MELAS, POLG OPA1, TSFM
Chorea	1/6 (16,6%)	POLG
Epilepsy	4/6 (66,6%)	MELAS, POLG, TSFM (5)
Stroke-like episodes	1/6 (16,6%)	MELAS (1)
Polyneuropathy	5/6 (83,3%)	MELAS (2), POLG, OPA-1
Spasticity	1/6 (16,6%)	OPA-1
Myopathy	3/6 (75%)	MELAS (1,2) ,POLG
Cognitive impairment	3/6 (50%)	MELAS (1) , POLG, TSFM (1)
Pes cavus	2/6 (33,3%)	TSFM
Ocular		
Ophtalmoparesis	4/6 (66,6%)	MELAS (1,2), POLG, OPA1
Ptosis	1/6 (16,6%)	MELAS (2)
Optic atrophy	3/5 (50%)	OPA1, TSFM
Gaze evoked nystagmus	1/6 (33,3%)	OPA1

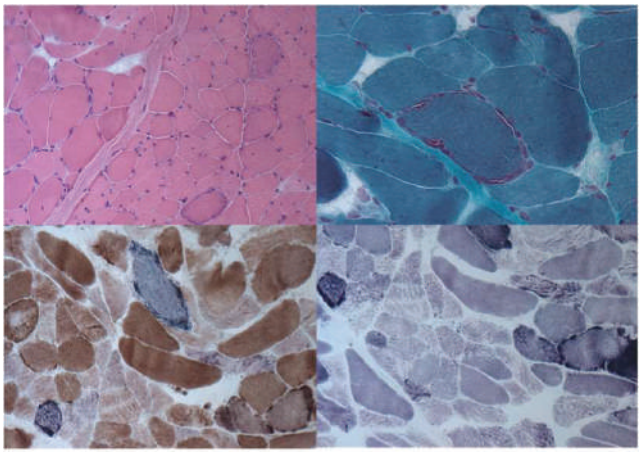
MRI- (A) T1-sagittal (B) T2- axial.



Muscle biopsy- (A) Hematoxylin-eosin (B) Gomori trichrome stain (C) COX (D) SDH.

Conclusion: Mitochondrial etiology should be considered in the differential diagnosis of late-onset cerebellar ataxias, even in the absence of family history. Recognizing associated symptoms could aid the diagnosis, with implications for prognosis, therapy, and genetic counseling.

Disclosure: Nothing to disclose.

EPO-571 | Wearable sensor detects early morning bradykinesia (EMB): From Parkinson's watch to bedside

P. Gómez López[1]; L. Neumaier[2]; M. Qamar[3]; L. Batzu[3]; K. Ray Chaudhuri[3]

[1]Neurology Department, Hospital Universitario Virgen del Rocio, Sevilla, Spain; [2]Parkinson-Klinik Ortenau, Wolfach, Germany; [3]Institute of Psychiatry, Psychology & Neuroscience at King's College and Parkinson Foundation International Centre of Excellence at King's College Hospital, London, UK

Background and Aims: Early Morning Bradykinesia (EMB) is clinically noted as early morning off (EMO) period which presents with motor and a range of non-motor symptoms (Rizos et al 2014) often undetected in clinical practice with a negative effect on quality of life in Parkinson's disease (PD). Continuous objective monitoring using the PD validated Personal KinetiGraph (PKG) can detect EMB in clinically unrecognized cases.

Methods: We report interrater reliability of detecting EMB using PKG criteria from two blinded who visually identify EMB from PKG reports and commented on severity (moderate or severe).
Results: A total of 100 PKG reports of PwP were analyzed (63% female and 37% male, median Hoehn and Yahr (HY) score 2–3), mean disease duration 9.4 years (±7.1), mean levodopa equivalent daily dose 633.98 mg (±558.24). EMB was observed in 73% PD and was reported as moderate in 64.3%, severe in 35.6%. Cohen's Kappa Interrater reliability score was 0.71 (substantial) for EMB diagnosis and 0.51 (moderate) for severity. No statistical significant correlations were found between EMB and motor scales.
Conclusion: PKG is an objective measurement device with a good interrater reliability for the identification of EMB and its severity. Our findings provide important evidence of the use of PKG for nocturnal monitoring in PD.
Disclosure: All authors report no conflict of interest.

EPO-572 | Elevation of alpha-fetoprotein in patients with dystonia

P. Havrankova[1]; L. Kunc[1]; J. Roth[1]; J. Rajmonová[1]; M. Zech[2]; R. Jech[1]
[1]Department of Neurology and Centre of Clinical Neuroscience, First Faculty of Medicine and General University Hospital in Prague, Charles University in Prague, Prague, Czechia; [2]Institute of Neurogenomics, Helmholtz Zentrum München, Munich, Germany Institute of Human Genetics, Technical University of Munich, Munich, Germany Institute for Advanced Study, Technical University of Munich, Garching, Germany

Background and Aims: Alpha-fetoprotein (AFP) is a glycoprotein produced by the liver, and it is a tumor marker. Elevated levels are nevertheless associated with ataxia telangiectasia (AT), caused by a mutation in the ATM gene. The variant form of AT usually manifests in adolescence or adulthood, dystonia may be the only symptom. Telangiectasia and other symptoms of classic AT may be absent. Therefore, AFP seems to be an important biomarker in patients with dystonia. A screening study was conducted to determine the incidence of alpha-fetoprotein elevation in patients with dystonia.
Methods: Patients with dystonia occurred before the age of 50 years, were included. Alpha-fetoprotein levels were examined on an Atellica IM analyzer, with normal levels in the range of 0–8 ng/ml. Whole exome sequencing (WES) was performed in patients with elevated AFP levels.
Results: A total of 167 patients (48 men) were included, mean age of 56.5 years (±10 years). Elevated AFP levels (8.1–96.7 ng/ml) were detected in 14 (8.3%) patients (2 men), mean age 61.8 years (±12 years). In patients with elevated AFP levels, neither ATM nor any other mutation was detected in WES. The incidence of elevated AFP levels for the Atellica IM analyzer is 1.6% in the healthy population.
Conclusion: Elevated AFP levels with negative results in WES were present in a higher number of patients than it corresponds to the healthy population. This is a result that should be confirmed/refuted by further studies. AFP should be considered as a new biomarker in dystonia patients.
Disclosure: Nothing to disclose.

EPO-573 | Benefits of early highly effective vs escalation treatment in relapsing MS estimated using a treatment-sequence model

I. Smets[1]; M. Versteegh[2]; S. Huygens[2]; B. Wokke[1]; J. Smolders[1]
[1]MS Centre ErasMS, Department of Neurology, Erasmus Medical Center, Rotterdam, The Netherlands; [2]Huygens & Versteegh, Zwijndrecht, The Netherlands

Background and Aims: Uncertainty about disproportionate impact on healthcare budgets limits implementation of early highly effective treatment (EHT) in multiple sclerosis (MS). Therefore, it is necessary to estimate cost-effectiveness of escalation vs. EHT disease-modifying treatment (DMT) sequences.
Methods: Using a health-economic approach, we analyzed health benefits (relapse rate reduction, disability prevention), direct/indirect DMT and societal costs of escalation vs. EHT DMT sequences. In scenario analyses, we allowed (1) earlier use of alemtuzumab and (2) a single retreatment with cladribine.
Results: In our model, we showed that the ratio between costs and quality-adjusted life years for the most cost-effective EHT and escalation sequence results into a similar net health benefit with higher costs but also higher QALYs associated with an EHT vs escalation strategy. Earlier use of alemtuzumab is more cost-effective than in later lines, even when aggravating the impact of its side effects tenfold. Retreatment with cladribine was more cost-effective in both escalation and EHT sequences.
Conclusion: Certain EHT sequences are equally cost-effective to escalation sequences and are likely to result in more health at uncertain additional costs. The favourable cost-benefit ratio of cladribine and alemtuzumab suggests that a wider application of affordable highly-effective therapies could promote the cost-effectiveness both EHT and escalation approaches.
Disclosure: I.S. has received honoraria from Merck, Biogen Idec and Sanofi. B.H.A.W. declares no conflict of interest. S.A.H. and M.M.V. are shareholders of Huygens & Versteegh which conducts research for government organizations and pharmaceutical companies, including research in MS. J.S. received lecture and/or consultancy fee from Biogen, Merck, Novartis, and Sanofi Genzyme.

EPO-574 | Choroid plexus volume as proxy of higher cerebrospinal fluid inflammatory activity in multiple sclerosis

I. Addazio[1]; E. Portaccio[1]; C. Ballerini[1]; V. Penati[1]; A. Caporali[1]; C. Fabbiani[2]; E. Fainardi[2]; E. De Meo[1]; M. Amato[1]
[1]*Department Neurofarba, Section of Neurosciences, University of Florence, Florence, Italy;* [2]*Department of Experimental and Clinical Biomedical Sciences, Neuroradiology Unit, University of Firenze, AOU Careggi, Firenze, Italy*

Background and Aims: In our study, we investigate the hypothesis that Choroid Plexus volume (CPv) enlargement serves as a surrogate marker for heightened inflammatory cerebrospinal fluid (CSF) activity. This last, in turn, contribute to damage gradients observed in the normal-appearing white matter (NAWM) near the ventricles of patients with relapsing Multiple Sclerosis (MS) at disease onset.
Methods: Our cross-sectional evaluation involved 108 subjects. Using the nephelometric method and the Reiber formula, we quantified IgM intrathecal synthesis (ITMS) as an inflammatory activity biomarker in CSF. We performed advanced post-processing MRI analysis, encompassing brain, lesion and choroid plexus (CP) volume assessment. Additionally, we used T1/T2 mapping to evaluate the NAWM damage gradient.
Results: Comparing MRI features between the groups and exploring the link between NAWM damage gradient and CPv, we employed multiple linear regression models. Among the 108 patients subjected to MRI analysis, 32 tested positive for ITMS (ITMS+), while 76 were ITMS-negative (ITMS-). Importantly, ITMS+ and ITMS- patients exhibited comparable baseline clinical and demographic characteristics. While no significant differences were found in brain and lesion volumes between the two groups, CPv was notably enlarged in the ITMS+ group (beta 0.57, 95% c.i. 0.35–0.79, $p < 0.001$). Additionally, a significant relationship emerged between the T1/T2 ratio gradient and CPv (beta = 0.46, <0.001).
Conclusion: Our findings suggested a potential role for the CP in influencing NAWM changes. Further research is essential to validate this hypothesis and identify specific CSF biomarkers associated with CPv and NAWM damage.
Disclosure: E.P. received funding from Biogen, Merck, Sanofi, Novartis. M.P.A received funding from Biogen Idec, Merck Serono, Bayer Schering and Sanofi. E.D.M., I.A., C.B., V.P., A.C., C.F., E.F., report no disclosures.

EPO-575 | Demographic, clinical and serum parameters for the prediction of apheresis outcome in the steroid-refractory MS relapse

I. Vardakas; J. Dorst; A. Huss; T. Fangerau; D. Taranu; H. Tumani; M. Senel
Department of Neurology, University of Ulm, Ulm, Germany

Background and Aims: The optimal treatment strategy for steroid-refractory MS relapses remains unclear. We investigated the predictive power of multiple serum parameters, demographic and clinical data on apheresis outcome.
Methods: We examined sera of 38 participants of the IAPEMS-trial (randomized-controlled trial to evaluate the safety and efficacy of immunoadsorption versus therapeutic plasma exchange in steroid refractory MS relapses, NCT02671682) and conducted statistical analysis using serum parameters, demographic and clinical trial data. We classified apheresis outcome assessing the improvement of the affected functional system score four weeks after the procedure.
Results: In binary logistic regression analysis younger age (OR 0.948, 95% CI 0.903–0.995, $p = 0.03$) and lower sGFAP concentrations (RR 0.948, 95% CI 0.903 –0.995, $p = 0.03$) were associated with a favorable relapse outcome. In addition, we observed a strong trend towards a positive apheresis outcome with higher sNfL (RR 1.413, 95% CI 0.965–2.069, $p = 0.08$). Further analysis of our data showed no predictive power for further serum parameters (immunoglobulins, immunoglobulin free light chains, CXCL13, CXCL12, BCMA, BAFF), Symbol Digit Modalities Test (SDMT) and optical coherence tomography (OCT) measures in our study.
Conclusion: In line with published data, our study confirmed that patients with younger age and lower serum GFAP levels are more likely to benefit from apheresis. The potential predictive value of sNfL needs to be investigated in further prospective studies.
Disclosure: None of the authors have any disclosure related to this study.

EPO-576 | Real-life efficacy and safety of ofatumumab for highly active multiple sclerosis: The San Raffaele Hospital experience

I. Gattuso[1]; S. Guerrieri[1]; A. Genchi[1]; A. Nozzolillo[1]; C. Zanetta[1]; T. Zaccone[1]; M. Martire[1]; L. Ferrè[1]; F. Esposito[1]; M. Rocca[2]; M. Filippi[3]; L. Moiola[1]
[1]*Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [2]*Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; Vita-Salute San Raffaele University, Milan, Italy;* [3]*Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; Vita-Salute San Raffaele University, Milan, Italy; Neurophysiology Service*

Background and Aims: Ofatumumab is a highly effective treatment for multiple sclerosis (MS), approved in Europe in April 2021. Post-marketing information is still limited. We report our real-life experience (San Raffaele Hospital MS cohort, Milan, Italy).
Methods: Data from MS patients receiving ofatumumab for at least 1 year were obtained: clinical information, neuroradiological examinations and lymphocyte subsets values were collected.
Results: Among 100 MS patients receiving ofatumumab, 37 were treated for at least 1 year (33 relapsing-remitting-RRMS; 4 relapsing-RMS; mean age 38.42 ± 10.6 years; 27 females, 10 males; mean disease duration 8.77 years – range 0.5–31.9; median EDSS 2.0 – range 0–8.0; 15/37 treatment-naïve; mean follow up 1.16 years – range

1.00–1.78). During the year before treatment start 35/37 patients showed MRI activity (2/37 shifted from Natalizumab for safety reasons), while 27/37 also experienced relapses. While treated with ofatumumab, no patients showed further relapses, while only 3/37 had persistent MRI activity (3/3 at rebaseline examination 6 months after treatment start, none with Gd-enhancing lesions). CD19+ lymphocyte count was available at 3 months in 24/37 participants: all patients showed B cells depletion (i.e. <0.5% – mean 0.09% – range 0.0–0.33%), with persistence at 1 year. Treatment was well tolerated, with no serious adverse event: 31/37 patients reported fever after first injection, while only 3/37 after titration; 5/37 patients presented mild-to-moderate upper respiratory tract infections. No pregnancy occurred.

Conclusion: Our short-term data suggest ofatumumab is effective, safe and well tolerated in MS. Long-term follow-up and larger cohorts are needed to confirm our observations.

EPO-577 | Patient-reported fatigue in patients with relapsing multiple sclerosis receiving ocrelizumab: MoOzaRt interim analysis

I. Penner[1]; J. Leemhuis[2]; T. Maier[2]; E. Weber[2]; H. Schreiber[3]
[1]*Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Switzerland; COGITO Center for Applied Neurocognition and Neuropsychological Research, Düsseldorf, Germany;* [2]*Roche Pharma AG, Grenzach-Wyhlen, Germany;* [3]*Neurological Practice Center, Ulm, Germany*

Background and Aims: Fatigue is considered the most common and one of the most debilitating symptoms in multiple sclerosis (MS). MoOzaRt aims to assess the impact of ocrelizumab on patient-reported long term (trait) and transient (state) fatigue in patients with relapsing forms of MS (RMS) under therapy with ocrelizumab.

Methods: The ongoing non-interventional study MoOzaRt (ISRCTN55332718) aims to recruit ~740 RMS patients initiating therapy with ocrelizumab from Germany and Switzerland. The primary endpoint is the change in the Fatigue Scale for Motor and Cognitive Functions (FSMC) total score from baseline to month 24, evaluating trait fatigue. Secondary endpoints include changes in state fatigue (Visual Analogue Scale, VAS), in Expanded Disability Status Scale (EDSS) and in safety.

Results: The first interim analysis (data cut off Dec 14, 2023) included 80 patients (72.5% female, mean age 37.5 (SD 9.9) years) with a mean EDSS score of 2.31 (SD 1.39) (table 1). Overall, FSMC total scores remained stable over 12 months ($N = 71$), while the proportion of patients with severe fatigue decreased markedly from in this period (table 2). VAS scores and detailed patient reported outcomes will be presented at the EAN.

Baseline characteristics	Total (N=80)
Sex, female, N (%)	58 (72.5)
Age at baseline [years], mean (SD)	37.5 (9.9)
Any medication history, N (%)	55 (68.8)
Number of relapses within 0-12 months prior to study enrolment, N (%)	
0	25 (32.9)
1	39 (51.3)
EDSS score, mean (SD)	2.31 (1.39)
Time since first MS symptoms [years], mean (SD)	8.71 (8.41)
Time since first MS diagnosis [years], mean (SD)	6.77 (6.92)
Previous treatments and therapies, N (%)	59 (73.8)

TABLE 1 Baseline characteristics.

FSMC	Baseline (N=80)	Month 6 (N=71)	Month 12 (N=71)	Month 18 (N=29)
FSMC total score, mean (SD), [95%KI]	51.8 (23.0), [46.7; 56.9]	50.5 (22.8), [45.1; 55.8]	51.1 (22.4), [45.8; 56.5]	48.9 (25.1), [39.3; 58.4]
FSMC total score category, N (%)				
Normal	30 (37.5)	28 (39.4)	27 (38.0)	13 (44.8)
Mild	12 (15.0)	8 (11.3)	9 (12.7)	3 (10.3)
Moderate	7 (8.8)	12 (16.9)	15 (21.1)	3 (10.3)
Severe	31 (38.8)	23 (32.4)	20 (28.2)	10 (34.5)

TABLE 2 FSMC scores at baseline and month 6, 12 and 18.

Conclusion: The first interim analysis of the MoOzaRt study revealed stable FSMC total scores with a trend towards a decline in the proportion of patients with severe trait fatigue already during the early treatment phase. Further results will deepen our insights into the specific impact of ocrelizumab on trait and state fatigue and factors that may influence fatigue in RMS patients.

EPO-578 | Updated real world immunogenicity data on Tysabri S.C. and Tysabri I.V.

J. Lizrova Preiningerova[1]; E. Kubala Havrdova[1]; O. Vencourova[1]; K. White[2]; Z. Benova[3]; A. Drenth[4]

[1]*General University Hospital and First School of Medicine, Charles University, Prague, Czechia;* [2]*Biogen, Cambridge, MA, USA;* [3]*Biogen, Prague, Czechia;* [4]*Biogen, Baar, Switzerland*

Background and Aims: Natalizumab (Biogen), approved for relapsing forms of multiple sclerosis, is available in both subcutaneous (SC) and intravenous (IV) formulations, with administration intervals of every four weeks (Q4W) or every six weeks (Q6W) in off-label use. This study offers a real-world observational analysis of the immunogenicity, tolerability, and effectiveness of Tysabri administered through both SC and IV methods over a 24-month period at a single academic center.

Methods: Anti-natalizumab antibody in serum (NTZ-Ab, Unilabs, Copenhagen, Denmark) are tested at baseline and at every 3rd administration. All subjects are followed with EDSS, relapse rate, JCV index and yearly brain MRI.

Results: There are 242 patients with mean length of follow up: 20.4 months (0.7–26.7) divided into 4 cohorts based on their treatment pattern: (1) Switch from IV-Q6W to SC-Q6W (SC-Q6W), $n=156$; (2) Ongoing IV-Q6W (IV-Q6W), $n=38$; (3) Treatment-naïve to IV-Q4W (IV-N), $n=13$; and (4) Treatment-naïve to SC-Q4W (SC-N), $n=35$. We observed three cases of NTZ-Ab positivity (1.2%). One patient on long term treatment Q6W had NTZ-Ab+ at the time of switch from IV to SC and thereafter (listed in SC-Q6W cohort); the treatment was discontinued. Two patients in the SC-N cohort showed persistent NTZ-Ab from 3 months on treatment. One of them remains on treatment with no clinical or radiological disease activity despite of persistent NTZ-Ab+ and one was switched to a different treatment due to radiological activity. There was no new occurrence of NTZ-Ab later during treatment.

Conclusion: The immunogenic potential of Tysabri is low and NTZ-Ab occur early.

Disclosure: This study is supported by Biogen. EKH received honoraria/research support from Biogen, Merck Serono, Novartis, Roche, and Teva; has been a member of advisory boards for Actelion, Biogen, Celgene, Merck Serono, Novartis, and Sanofi Genzyme. JLP has received research funding from Biogen and honoraria from Merck Serono, Novartis and Roche. OV has nothing to disclose. KW, ZB, AG, and AD are employees of and may hold stock and/or stock options in Biogen.

EPO-579 | Evaluating association of chronic active lesions with disability in multiple sclerosis: A systematic literature review

F. Bagnato[1]; M. Mordin[2]; N. Greene[3]; S. Mahida[2]; K. Higuchi[4]; J. Wingerden[5]

[1]*Neuroimaging Unit, Neuroimmunology Division, Department of Neurology, Vanderbilt University Medical Center, Nashville, TN, USA;* [2]*RTI Health Solutions, Research Triangle Park, NC, USA;* [3]*Sanofi, Cambridge, MA, USA;* [4]*Sanofi, Bridgewater, NJ, USA;* [5]*Sanofi, Amsterdam, The Netherlands*

Background and Aims: Chronic active lesions (CAL) are important component of multiple sclerosis (MS) disease pathology and indicate the presence of a smoldering neuroinflammatory processes. Yet, only recent advances in magnetic resonance imaging (MRI) and positron emission tomography have made it possible to identify CAL in vivo in people with MS (pwMS). Several studies assessed the association between CAL and disability accumulation in pwMS.

Methods: A systematic literature search was conducted following PRISMA guidelines 2020 using PubMed, Embase, and Cochrane Library on April 21, 2023. The review included studies assessing associations between CAL and clinical/radiological outcome of disability accumulation in people with any MS phenotype.

Results: A total of 149 unique studies were identified and 31 met the inclusion criteria. Of these, 21 evaluated paramagnetic rim lesions (PRL) using susceptibility-based MRI, 9 evaluated slow expanding lesions (SEL) on T1-weighted (T1-w)/T2-w MRI, and 1 studied both. The presence of PRL was associated with disability accumulation in 19 studies, with 9 of those studies reporting an association between the number or volume of PRL and disability accumulation. SEL were associated with disability accumulation in 10 studies, with 5 of those studies reporting association between the number or volume of SEL and disability accumulation.

Conclusion: This literature review found significant associations between CAL and disability accumulation that may lead to transitioning to progressive disease in pwMS. This illustrates role of CAL and smoldering disease in MS in driving disability accumulation. CAL remains an important unmet therapeutic target and development of treatments promoting their resolution is crucial.

Disclosure: Nothing to disclose.

EPO-580 | EMbrace the diversity in MS with a Value Based Healthcare (VBHC) implementation model in Portugal

J. Cerqueira[2]; S. Aguiar[3]; A. Fontainhas[4]; A. Pimenta[5]; A. Morganho[3]; C. Domingues[5]; E. Bettencourt[5]; H. Cardoso[4]; J. Soares[6]; L. Leitão[7]; M. Reis[5]; M. Santos[7]; M. [1]NOVA School of Business and Economics, Lisbon, Portugal; [2]School of Health Sciences, University of Minho and Unidade Local de Saúde de Braga, Braga, Portugal; [3]Neurology Department, Health Service of the Autonomous Region of Madeira – SESARAM, EPERAM; [4]Day Hospital Unit, Hospital Prof. Doutor Fernando Fonseca, ULS Amadora/Sintra EPE; [5]Roche Farmacêutica Química, Lda, Portugal; [6]Pharmaceutical Services, Hospital Prof. Doutor Fernando Fonseca, ULS Amadora/Sintra EPE; [7]Neurology Department, Hospital Prof. Doutor Fernando Fonseca, ULS Amadora/Sintra EPE; [8]Pharmaceutical Services, Health Service of the Autonomous Region of Madeira – SESARAM, EPERAM; [9]Unidade Local de Saúde de Braga, Braga, Portugal

Background and Aims: Managing multiple sclerosis (MS) is challenging, due to its chronic degenerative nature, young patient population, and unpredictability and diversity of its symptoms. In such a setting, adoption of a Value-based Healthcare (VBHC) approach can increase efficiency and improve care by incorporating patient values and quality of life considerations. This paper outlines the implementation of a VBHC framework in three Portuguese multiple sclerosis centers, with different multidisciplinary teams, as part of the European consensus "S.O.S. MS Project".

Methods: The Portuguese project (EMbrace), started in March 2021, includes a basic education on VBHC concepts, an analysis and refinement of the patient journey in each center and a prospective longitudinal collection of a standard dataset comprising patient-reported outcomes. Periodic meetings allow the sharing of experiences and practices. Central to this initiative is the application of a process reengineering methodology to healthcare environments, focusing on five pillars: patient-centered value, work rhythm, waste-minimization, definition of value streams, and continuous improvement.

Results: EMBrace resulted in an alignment of clinical pathways, validation of Key Performance Indicators, and benchmarking against international models. Its implementation faced challenges in timing and data collection, highlighting the need for more streamlined processes and the integration of technology. Nevertheless, it demonstrated the feasibility of a VBHC approach in MS care and its potential for more efficient, patient-centric healthcare models.

Conclusion: The EMbrace Project, still in development, has the potential to significantly influence MS care by providing evidence to guide implementation of VHBC projects.

Disclosure: This project has been supported by ROCHE that facilitated the contact between all the centers, coordinated the meetings and provided know-how and technical assistance. The authors have no other disclosures relevant to this work.

EPO-581 | 8-Point change in symbol digit modalities test scores: Findings from the phase 3 SUNBEAM and DAYBREAK ozanimod trials

J. DeLuca[1]; J. Cohen[2]; B. Cree[3]; G. Comi[4]; L. Kappos[5]; C. Cheng[6]; J. Sheffield[6]; J. Riolo[6]; A. Thorpe[6]; R. Benedict[7]

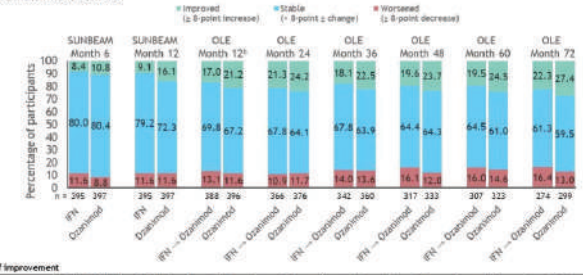
[1]Kessler Foundation, West Orange, NJ, USA and Departments of Physical Medicine and Rehabilitation, and Neurology, Rutgers – New Jersey Medical School, Newark, NJ, USA; [2]Mellen Center for MS Treatment and Research, Cleveland Clinic, Cleveland, OH, USA; [3]Weill Institute for Neurosciences, Department of Neurology, University of California San Francisco, San Francisco, CA, USA; [4]Vita-Salute San Raffaele University and Casa di Cura Igea, Milan, Italy; [5]Research Center for Clinical Neuroimmunology and Neuroscience Basel (RC2NB), Departments of Head, Spine and Neuromedicine, Clinical Research, Biomedicine, and Biomedical Engineering, University Hospital and University of Basel, Basel, Switzerland; [6]Bristol Myers Squibb, Princeton, NJ, USA; [7]Jacobs MS Center, Department of Neurology, Jacobs School of Medicine and Biomedical Sciences, University at Buffalo, State University of New York, Buffalo, NY, USA

Background and Aims: In a post hoc analysis of the phase 3 SUNBEAM trial, more ozanimod-treated participants had clinically meaningful (≥4-point) improvement on the Symbol Digit Modalities Test (SDMT) than those treated with interferon beta-1a (IFN). In this analysis, the long-term effects of ozanimod on cognitive processing speed (CPS) in participants with relapsing multiple sclerosis (RMS) were evaluated using 8-point SDMT change, which may better represent individual-level CPS changes than a 4-point threshold.

Methods: In SUNBEAM (NCT02294058), adults with RMS were randomly assigned oral ozanimod 0.46 or 0.92 mg/d or intramuscular IFN 30 μg/wk for ≥12 months (mean treatment duration 13.5 months); completers were eligible for an ozanimod 0.92 mg open-label extension (OLE) trial (DAYBREAK, NCT02576717; database lock: 7 April 2023). The percentage of participants with 8-point SDMT change relative to SUNBEAM baseline is reported.

Results: SUNBEAM participants entering the OLE were included (ozanimod 0.92 mg, $n = 397$; IFN, $n = 395$). Mean (SE) baseline SDMT scores were 48.0 (0.69) and 47.4 (0.68), respectively. Compared with participants receiving IFN, those in the ozanimod group were more likely to achieve 8-point SDMT improvement at SUNBEAM month 12 (nominal $p = 0.0048$; Figure). After IFN-randomised participants switched to ozanimod, statistical group differences were no longer apparent (Figure). After 6–8 years of ozanimod (end of OLE), the proportion of participants with 8-point improvement was numerically, but not nominally significantly, higher in the continuously ozanimod-treated group compared with those initially randomised to IFN (Figure).

Figure. Categorical analysis of participant-level changes in SDMT relative to SUNBEAM baseline[a]



Odds of Improvement

	SUNBEAM Month 6	SUNBEAM Month 12	OLE Month 12[b]	OLE Month 24	OLE Month 36	OLE Month 48	OLE Month 60	OLE Month 72
OR (95% CI)	1.3 (0.8–2.2)	1.9 (1.2–2.9)	1.3 (0.9–1.8)	1.1 (0.8–1.6)	1.2 (0.8–1.8)	1.1 (0.8–1.7)	1.2 (0.8–1.8)	1.2 (0.8–1.8)
Nominal *P* value	0.2366	0.0048	0.2204	0.5456	0.2933	0.5139	0.3205	0.3378

Intent-to-treat population. Percentages may not add to 100 due to rounding. *P* values are nominal because treatment comparisons in this post hoc, exploratory analysis were not subject to multiplicity adjustment. *P* values were calculated for odds ratio for clinically meaningful SDMT improvement (>=8-point increase) relative to SUNBEAM baseline in continuous ozanimod vs IFN groups using a generalised estimating equation model adjusted by baseline SDMT score; stratification factors (region [Eastern Europe vs rest of the world] and baseline Expanded Disability Status Scale score category [<=3.5 vs > 3.5]), age at baseline, brain volume at baseline, treatment and the interaction between the treatment and time point as fixed effects, assuming unstructured within-subject covariate structure; for the DAYBREAK OLE visits, treatment duration during SUNBEAM was added as a fixed effect in addition to those stated above.
[a]Participants randomised to IFN in SUNBEAM switched to ozanimod 0.92 mg in the DAYBREAK OLE 12–24 months after SUNBEAM baseline.
[b]OLE month 12 visit included data collected after OLE first dose date up to OLE month 12.
IFN, interferon beta-1a; OLE, open-label extension; OR, odds ratio; SDMT, Symbol Digit Modalities Test.

Conclusion: Long-term ozanimod treatment protects from cognitive deterioration. These data support the early use of ozanimod in patients with RMS.

EPO-582 | Real-world data on effectiveness and tolerability of Ofatumumab at short-term follow-up

J. Arzalluz-Luque; A. Torres-Moral; J. Dotor; R. López-Ruiz; M. Ben-Yelun; S. Eichau

Department of Neurology, Hospital Universitario Virgen Macarena (Sevilla)

Background and Aims: Ofatumumab is a highly effective disease-modifying therapy (DMT) for relapsing multiple sclerosis (MS). Real-world outcome data are needed for clinical practice. Our aim was to describe effectiveness and tolerability at 6 and 12-month follow-up.

Methods: Patients diagnosed with MS starting Ofatumumab between December 2022-December 2023 were included. Baseline demographics, disease characteristics and clinical/radiologic features were collected. Effectiveness/tolerability outcomes were assessed after 6 and 12 months.

Results: We included 43 relapsing MS patients; 29 (67.4%) were women. Mean age was 37.2 ± 10.2 years and disease duration was 10.1 ± 7.9 years. Median baseline EDSS was 3 (range: 0–6). The median number of relapses in the two previous years was 1 (range: 0–4). Last MRI before Ofatumumab showed 5–10 lesions in 11 (25.6%) patients, 10–30 in 20 (46.5%) and >30 in 11 (25.6%); 32 (74.4%) had spinal-cord lesions. Prior DMT exposure was reported in 31 (72.1%) vs 12 (27.9%) naive patients. Switch to Ofatumumab was mostly due to ineffectiveness (27/31 [87.1%]) vs lack of tolerability/safety (4/31 [12.9%]). There were no discontinuations during a mean follow-up of 8.6 ± 2.9 months. Only 3 (7%) patients had a relapse, which happened in the first 6 months. At 6-month and 12-month follow-up median EDSS was 2.8 (range: 0–6) and 1.5 (range: 0–6), respectively. Overall, 3/21 (14.3%) had EDSS worsening in the first year and 2/21 (9.5%) had new lesions on rebaseline 6-month MRI. Adverse events occurred in 30/41 (73.2%) patients, mainly at the first injection (21/30 [70%]); the most common was flu-like syndrome in 25/30 (83.3%).

Conclusion: Ofatumumab was effective and well-tolerated in our population. Most patients were stable; few had disease activity early after starting Ofatumumab and were therefore not considered treatment failures. Minor self-limited tolerability issues were reported.

Disclosure: Nothing to disclose.

EPO-583 | Epstein-Barr virus DNA in the cerebrospinal fluid of multiple sclerosis patients and controls

J. Lehikoinen[1]; K. Nurmi[1]; M. Ainola[1]; J. Clancy[2]; J. Nieminen[3]; L. Jansson[1]; H. Vauhkonen[4]; A. Vaheri[4]; T. Smura[4]; S. Laakso[3]; K. Eklund[5]; P. Tienari[3]

Background and Aims: Epstein-Barr virus (EBV) infection is a major risk factor for multiple sclerosis (MS). We examined the presence of EBV DNA in the cerebrospinal fluid (CSF) and blood of MS patients and controls and estimated the proportions of EBV-positive B cells in CSF and blood.

Methods: CSF was collected at diagnostic lumbar punctures from 45 MS patients and 45 HLA-DR15 matched controls; all subjects were EBV seropositive. Cellular DNA was amplified and representative samples were obtained in 28 cases and 28 controls. In a subset of participants, non-amplified DNA from CSF cells and blood B cells were analysed. Multiple droplet digital PCR (ddPCR) runs were performed to assess the cumulative EBV positivity rate.

Results: One of the 45 MS patients and none of the 45 controls was positive for EBV DNA in CSF supernatants. CSF cellular DNA was analysed in eight independent ddPCRs: EBV DNA was detected at least once in 18 (64%) of the 28 MS patients and in 15 (54%) of the 28 controls ($p = 0.59$, Fisher's test). The cumulative EBV positivity increased up to 59%, suggesting that all subjects would have tested EBV positive, had more DNA been analysed. The estimated proportion of EBV positive B cells was >1/10,000 in both CSF and blood.

Conclusion: EBV-DNA is equally detectable in the CSF cells of both MS patients and controls with ddPCR, and the probabilistic approach indicates that the true positivity rate approaches 100% in

EBV-positive individuals. The proportion of EBV positive B cells appears higher than previously estimated.

Background and Aims: We report long-term hepatic safety during an open-label extension study (DAYBREAK) of ozanimod.

Methods: Patients with relapsing multiple sclerosis who completed a phase 1–3 ozanimod trial were eligible for DAYBREAK (NCT02576717), where they received ozanimod 0.92 mg/d. Liver enzymes were measured every 3 months for 3 years, then every 6 months. Database lock: 7 April 2023.

Results: The 2494 patients had a mean (SD) 60.9 (17.9) (range 0.03–81.5) months of ozanimod exposure during DAYBREAK. Alanine aminotransferase (ALT) or aspartate aminotransferase (AST) levels ≥3× upper limit of normal (ULN) or bilirubin >2× ULN were infrequent (<4% each; Table 1); there were no cases of severe drug-induced liver injury (DILI). Mean (SD) time to onset was 27.3 (17.7) and 30.2 (18.9) months for ALT and AST ≥3× ULN, respectively, and 16.4 (15.8) months for bilirubin >2× ULN. First ALT >1×ULN during DAYBREAK primarily occurred during year 1. Consecutive ALT elevations ≥3× ULN were uncommon (Table 1). Hepatobiliary treatment-emergent adverse events (TEAEs) occurred in 104 (4.2%) participants (Table 2) and led to treatment discontinuation in 2 (0.08%); 10 (0.4%) discontinued due to hepatic enzyme elevation–related TEAEs. Fifteen (0.6%) patients had serious hepatobiliary TEAEs (Table 3).

Table 1. Hepatic Laboratory Abnormalities at Any Visit During DAYBREAK Based on Laboratory Testing

	DAYBREAK Participants (N=2494[a])
Maximum ALT, n (%)	
>1xULN	1017 (40.9)
>=3xULN	91 (3.7)
>=5xULN	20 (0.8)
Consecutive ALT abnormalities[b]	
>=3xULN	22 (0.9)
>=5xULN	6 (0.2)
Maximum AST, n (%)	
>1xULN	548 (22.0)
>=3xULN	42 (1.7)
>=5xULN	18 (0.7)
Maximum bilirubin, n (%)	
>1xULN	577 (23.2)
>2xULN	73 (2.9)
>3xULN	9 (0.4)

[a]Of the 2494 participants, 2489 had nonmissing postbaseline assessments on which these analyses are based
[b]Refers to elevations confirmed on >=2 consecutive elevations.
ALT, alanine aminotransferase; AST, aspartate aminotransferase; SD, standard deviation; ULN, upper limit of normal.

Table 2. Hepatobiliary TEAEs During DAYBREAK

	DAYBREAK Participants (N=2494)	
	n (%)	IR/1000 PY[a] (95% CI)
Any hepatobiliary TEAE	104 (4.2)	8.4 (7.0–10.2)
Hepatobiliary TEAEs that occurred in ≥2 participants in the overall DAYBREAK population[b]		
Hyperbilirubinemia	27 (1.1)	2.2 (1.5–3.1)
Cholelithiasis	16 (0.6)	1.3 (0.8–2.1)
Cholecystitis chronic	12 (0.5)	1.0 (0.5–1.7)
Hepatic cyst	8 (0.2)	0.5 (0.2, 1.1)
Hepatic steatosis	5 (0.2)	0.4 (0.2–0.9)
Biliary dyskinesia	4 (0.2)	0.3 (0.1–0.8)
Chronic hepatitis	4 (0.2)	0.3 (0.1–0.8)
Hepatitis	4 (0.2)	0.3 (0.1–0.8)
Cholestasis	3 (0.1)	0.2 (0.1–0.7)
Gallbladder polyp	3 (0.1)	0.2 (0.1–0.7)
Hypertransaminasemia	3 (0.1)	0.2 (0.1–0.7)
Sphincter of Oddi dysfunction	3 (0.1)	0.2 (0.1–0.7)
Steatohepatitis	3 (0.1)	0.2 (0.1–0.7)
Cholecystitis	2 (0.08)	0.2 (0.0–0.6)
Cholecystitis acute	2 (0.08)	0.2 (0.0–0.6)
Hepatic cytolysis	2 (0.08)	0.2 (0.0–0.6)
Hepatic lesion	2 (0.08)	0.2 (0.0–0.6)
Hepatitis toxic	2 (0.08)	0.2 (0.0–0.6)
Hepatomegaly	2 (0.08)	0.2 (0.0–0.6)
Nonalcoholic steatohepatitis	2 (0.08)	0.2 (0.0–0.6)

[a]IR per 1000 person-years is calculated as number of persons/person-years x 1000 for specific system organ class category or preferred term subcategory. Person-years for each category/subcategory: for a person in a particular category/subcategory, the time on study is calculated based on the date the person first has a TEAE within the category/subcategory (date of first TEAE - first dose date of study drug + 1)/365.25; for persons who do not have a TEAE in the category/subcategory, the time on study is the study duration (last dose date of study drug - first dose date of study drug +1)/365.25.
[b]Additional hepatobiliary TEAEs that occurred in a single participant each (0.04%) in the total DAYBREAK population included biliary colic, biliary polyp, biliary tract disorder, cholangitis, drug-induced liver injury, gallbladder disorder, hepatic function abnormal, hepatitis acute, hepatitis chronic active, hepatotoxicity, liver disorder, and liver tenderness.
CI, confidence interval; IR, incidence rate; PY, person-years; TEAE, treatment-emergent adverse event.

Table 3. Serious Hepatobiliary TEAEs

	DAYBREAK Participants (N=2494), n (%)
Any serious hepatobiliary disorder	15 (0.6)
Cholelithiasis	6 (0.2)
Cholecystitis chronic	3 (0.1)
Cholecystitis acute	2 (0.08)
Biliary polyp	1 (0.04)
Cholecystitis	1 (0.04)
Cholestasis	1 (0.04)
Chronic hepatitis	1 (0.04)

TEAEs, treatment-emergent adverse events.

Conclusion: After up to nearly 7 years of ozanimod in DAYBREAK (mean 60.9 months), ALT and AST elevations ≥3× ULN remained infrequent. Severe DILI did not occur in this dataset. Consecutive ALT elevations ≥3× ULN were uncommon. Rates of serious hepatic TEAEs and hepatic TEAEs leading to discontinuation were low. Postmarketing hepatic safety findings are gathered and reported separately.

EPO-585 | Reliability of a digital cohort in multiple sclerosis: The MSCopilot® French patients

L. Carment[1]; P. Drouin[1]; L. Ahamada[1]; L. Pillet[1]; A. Plaud[1]; A. Vives[1]; S. Zinai[1]; A. Tourbah[2]

[1]*Ad Scientiam, Paris, France;* [2]*Université Versailles Saint Quentin en Yvelines, Université Paris Saclay, Service Neurologie, Hôpital Raymond-Poincaré AP-HP, Garches*

Background and Aims: We describe the feasibility of collecting sociodemographic and functional parameters using MSCopilot®, a clinically validated software as a medical device, and the representativeness of this French digital cohort of patients with multiple sclerosis (PwMS).

Methods: Real world data from the MSCopilot® database were collected between October-2017 to September-2023. Adult PwMS who had provided informed consent were included. MSCopilot® was used at home without supervision to collect sociodemographic and treatment self-reported data and perform the digital active tests that evaluate four functional parameters (walking capacity, low contrast visual acuity, cognitive processing and dexterity).

Results: A total of 1755 PwMS were included with a 2:1 female/male ratio (1204/551), consistent with the French MS population albeit slightly younger (41.1 ± 12 years). The majority of patients self-reported an EDSS score < 4 (71.4%, average score = 2.3 ± 2). Among the four digital assessments, three revealed significant group differences between patients with EDSS <4 and ≥4, the latter group showing a decreased performance in walking capacity, cognitive function and hand dexterity ($p < 0.01$).

Conclusion: MSCopilot® enables the characterization of key functional parameters in a real-life digital cohort mirroring the French MS population sociodemographic parameters. This demonstrates the significance of digital cohorts in providing additional insights for a better understanding of the disease through real world evidence.

Disclosure: L. Carment, P. Drouin, L. Ahamada, A. Plaud, LE. Pillet, A. Vives, S. Zinai are employees of Ad Scientiam, A. Tourbah is a member of its scientific committee and received honoraria for lectures, travel grants and research support from Biocara, Hikma, Novartis, Roche.

EPO-586 | Central vein sign analysis in confluent multiple sclerosis lesions separated with an automated algorithm

L. Marchi[1]; M. Pasca[1]; B. Lambert[2]; P. Rubini[2]; S. Doyle[2]; H. Dehaenne[2]; A. Tucholka[2]; P. Roca[2]; E. Fainardi[3]; L. Massacesi[4]

[1]*Department of Neurosciences, Drug and Child Health, University of Florence, Florence, Italy;* [2]*Pixyl Medical, Grenoble, France;* [3]*Neuroradiology Unit, Careggi University Hospital, Florence, Italy;* [4]*Department of Neurology 2 and Tuscan Region Multiple Sclerosis Referral Centre, Careggi University Hospital, Florence, Italy*

Background and Aims: The Central Vein Sign (CVS) is an MRI marker that, among demyelinating syndromes, is pathognomonic of multiple sclerosis (MS). However according to the NAIMS guidelines, confluent white matter lesions (WMLs) must be excluded as in these cases veins cannot be unequivocally assigned to each lesion component. This criterion, limiting number of evaluable WMLs, sometimes prevents reliable evaluation of the CVS. In this study performance of an automated algorithm for confluent WMLs segmentation into each component was explored.

Methods: RRMS patients ($n = 11$; disease duration 17 years; EDSS 4) who had performed standardized 3T MRI scans, including FLAIR* sequences were recruited. Confluent WMLs, usually not eligible for CVS evaluation according to NAIMS criteria, were not excluded and their individual components were identified by LesDiv algorithm developed by Pixyl Medical.

Results: The patients showed 748 lesions. Among the 589 non-confluent lesions, 272 fulfilled the NAIMS criteria for CVS analysis and out of them 206 were perivenular (PVL) (76%). Among the 159 confluent lesions the LesDiv algorithm identified 427 sub-components. Out of them 81 (19%) were eligible for the CVS analysis and of these 78 were PVL, increasing to 353 (30%) the number of WMLs eligible for the CVS analysis and to 80% (284/353) the total PVL proportion observed in these patients. The mean proportion of PVL/ patient increased from 67% to 70%.

n=11	median	(range)
Age, years	38	(27-50)
Disease duration, years	17	(<1-31)
EDSS	4.0	(0-6.0)
Number of DMTs received prior to MRI	3	(1-6)
	n	(%)
Gender, female	9	(81%)
MS phenotype: RR-MS	6	(54%)
Patients treated with AHSCT	6	(54%)
Patients receiving treatments at MRI	5	(46%)

Table 1: Clinical-demographic characteristics of the patient population at the time of the MRI scan.

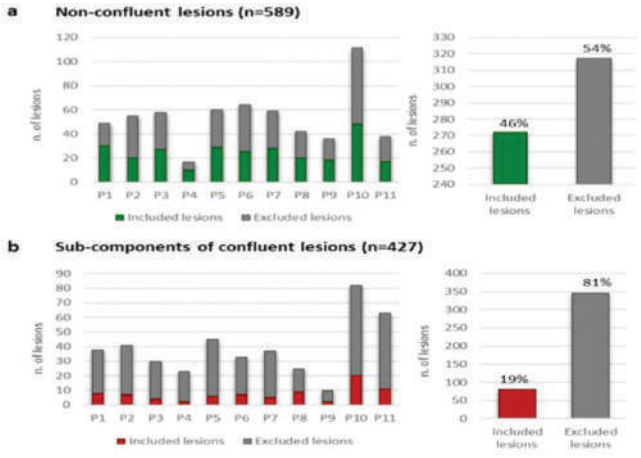

Fig 1: Number of non confluent lesions (a) and sub-components of confluent lesions (b) included and excluded according to NAIMS criteria.

Fig. 2: Comparison between the %PVL obtained from the analysis of non-confluent lesions (green line) and the %PVL after the inclusion of sub-components of confluent lesions (blue line).

Conclusion: Segmentation of confluent WMLs in their individual components increases WMLs number fulfilling the NAIMS criteria for inclusion in CVS analysis and eventually also PVL proportion.

Disclosure: Nothing to disclose.

EPO-587 | **Long-term outcomes with ozanimod in the DAYBREAK extension trial by number of MS relapses during the phase 3 trials**

L. Freeman[1]; A. Okai[2]; L. Kappos[3]; J. Cohen[4]; C. Cheng[5]; J. Riolo[5]; P. Vermersch[6]

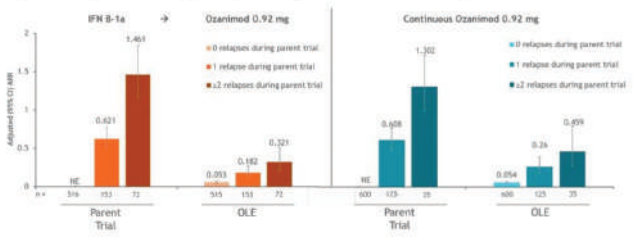
[1]Dell Medical School, The University of Texas at Austin, Austin, TX, USA; [2]North Texas Institute of Neurology & Headache, Plano, TX, USA; [3]Research Center for Clinical Neuroimmunology and Neuroscience Basel (RC2NB), Departments of Head, Spine and Neuromedicine, Clinical Research, Biomedicine, and Biomedical Engineering, University Hospital and University of Basel, Basel, Switzerland; [4]Mellen Center for MS Treatment and Research, Cleveland Clinic, Cleveland, OH, USA; [5]Bristol Myers Squibb, Princeton, NJ, USA; [6]Univ. Lille, Inserm UMR 1172 CHU Lille, FHU Precise, Lille, France

Background and Aims: Early intervention with ozanimod results in control of multiple sclerosis (MS) disease activity that is maintained with long-term use. Whether long-term efficacy differs among patients with varying degrees of disease activity is unknown. Here we examine long-term outcomes (6–7 years) among patients who had 0, 1, or ≥2 relapses during the first 1–2 years of continuous ozanimod 0.92 mg/d or intramuscular interferon (IFN) beta-1a 30 μg/wk followed by ozanimod 0.92 mg/d.

Methods: In phase 3 "parent" trials, adults with relapsing MS were randomised to oral ozanimod 0.46 or 0.92 mg/d or intramuscular IFN 30 μg/wk for ≥12 (SUNBEAM–NCT02294058) or 24 months (RADIANCE–NCT02047734), after which they were eligible for open-label ozanimod 0.92 mg/d in an open-label extension trial (DAYBREAK–NCT02576717). Clinical and radiologic outcomes from parent-trial baseline through DAYBREAK month 60 (database lock: 7 April 2023) were compared among patients who experienced 0, 1, or ≥2 relapses during SUNBEAM/RADIANCE.

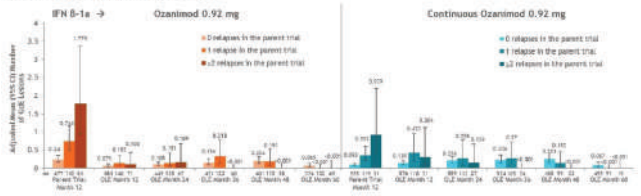
Results: Patients with 1 or ≥2 relapses during SUNBEAM/RADIANCE had numerical decreases in mean annualised relapse rate during DAYBREAK (Figure 1). Patients in all relapse groups who switched from IFN to ozanimod in DAYBREAK had numerical decreases in mean gadolinium-enhancing and new/enlarging T2 lesion counts that were maintained through month 60 (Figures 2–3). Lesion counts in patients treated with continuous ozanimod remained low through OLE month 60 in all relapse groups.

Figure 1. Adjusted ARR by Relapse Group and Treatment during Parent Trial



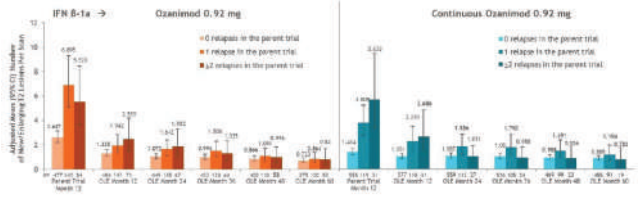
The phase 3 parent trial treatment period includes parent study day 1 through the end of treatment during the parent study; the OLE treatment period is from OLE study day 1 through the last dose date or data-cutoff date, whichever occurred first. Analyses were based on the negative binomial regression model with parent treatment group, adjusted for region (Eastern Europe vs rest of the world), age at parent baseline, and the parent baseline number of gadolinium-enhancing lesions. The natural log transformation of time on treatment is used as an offset term to adjust for patients having different exposure times. ARR, annualised relapse rate; IFN, interferon; NE, not estimated; OLE, open-label extension.

Figure 2. Adjusted Mean Number of GdE Lesions by Relapse Group and Treatment during Parent Trial



The adjusted mean (95% confidence interval) number of GdE lesions was derived using a negative binomial model, adjusted for study, region (Eastern Europe vs rest of the world), age at baseline, and baseline number of GdE lesions. GdE, gadolinium-enhancing; IFN, interferon; OLE, open-label extension.

Figure 3. Adjusted Mean Number of New/Enlarging T2 Lesions per Scan by Relapse Group and Treatment during Parent Trial



The adjusted mean (95% confidence interval) number of new/enlarging T2 lesions per scan relative to baseline (parent baseline for the parent trials; DAYBREAK baseline for DAYBREAK) was derived using a negative binomial model, adjusted for study, region (Eastern Europe vs rest of the world), age at baseline, and baseline number of GdE lesions; the log of the number of postbaseline scans was an offset term in the model. GdE, gadolinium-enhancing; IFN, interferon; OLE, open-label extension.

Conclusion: Regardless of prior relapse trends in phase 3 trials, long-term treatment with ozanimod for up to 60 months in DAYBREAK was associated with clinical and radiologic improvement.

MS and related disorders 6

EPO-588 | Real-world safety and effectiveness of ocrelizumab in different treatment lines in RMS – CONFIDENCE interim analysis

M. Buttmann[1]; M. Weber[2]; S. Meuth[3]; P. Dirks[4]; S. Blümich[5]; S. Hieke-Schulz[5]; J. Leemhuis[5]; T. Ziemssen[6]

[1]Caritas Hospital, Bad Mergentheim, Germany; [2]Institute of Neuropathology, Department of Neurology, University Medicine Göttingen, Germany; [3]Department of Neurology, University Clinic Düsseldorf, Heinrich-Heine-University Düsseldorf, Germany; [4]F. Hoffmann-La Roche Ltd., Basel, Switzerland; [5]Roche Pharma AG, Grenzach-Wyhlen, Germany; [6]Center of Clinical Neuroscience, Neurological Clinic, Carl Gustav Carus University Clinic, University of Technology, Dresden, Germany

Background and Aims: CONFIDENCE (ML39632, EUPAS22951) is a German non-interventional, post-authorization safety study including multiple sclerosis (MS) patients newly treated with ocrelizumab (OCR) and other disease-modifying therapies. This analysis included real-world patients with RMS treated with OCR up to 5.5 years.

Methods: Data cut-off was 11/10/2023. Safety and effectiveness were described for OCR in treatment-naïve patients (TN-patients) and patients with ≥1 prior MS-specific therapies (pwPMST). Safety analysis included OCR patients with ≥1 dose; effectiveness analyses for patients with ≥1 follow-up visit(s) evaluated annual relapse rate (ARR), Kaplan-Meier estimate for 24-week confirmed disability progression (CDP) and 24-week confirmed disability improvement (CDI), as well as Treatment Satisfaction Questionnaire for Medications© (TSQM).

Results: Mean (SD) observation time for safety was 3.21 (1.32) years with 2267 patients equaling 7743.41 patient years (of which 404 TN-patients, 780 pwPMST ≥3). Adverse events (AEs) occurred in 56.7/100 patient years (PY) in TN-patients (88.7/100PY in pwPMST ≥3); 22.9/100PY were classified as System Organ Class (SOC) "Infections and infestations" (32.3/100PY in pwPMST ≥3). Mean (SD) observation time for effectiveness was 3.21 (1.31) years with 2261 patients; overall ARR was 0.11 (SD 0.31). Over 48 months, 78.7% and 75.8% of TN-patients ($n = 326$) and pwPMST ≥3 ($n = 667$), respectively, did not experience CDP; 18.7% of TN-patients vs. 13.7% of pwPMST ≥3 reached CDI; overall population TSQM global satisfaction was 70.57 (20.15) at baseline and 79.39 (19.34) after 48 months.

Conclusion: Here we present real-world safety and effectiveness of OCR in different treatment lines in RMS. No new safety signals with increasing exposure time to OCR were observed.

EPO-589 | Alemtuzumab in relapsing-remitting multiple sclerosis: Navigating efficacy and autoimmune challenges

M. Cazola[1]; C. Guerreiro[1]; M. Soares[2]; P. Faustino[2]; I. Gomes[2]; F. Ladeira[2]; C. Capela[2]; J. Sequeira[2]
[1]*Neurology Department, Saint Joseph's Local Health Unit, Lisbon, Portugal;* [2]*Multiple Sclerosis' Centre of Integrated Responsibility, Saint Joseph's Local Health Unit, Lisbon, Portugal*

Background and Aims: Alemtuzumab effectively addresses highly active relapsing-remitting multiple sclerosis (RRMS). However, it poses potential autoimmune complications, notably thyroid eye disease (16% of cases).

Methods: We describe a case with alemtuzumab-Induced thyroid eye disease.

Results: A 58-year-old non-smoking woman, with no family history, was diagnosed with RRMS in 1996 following symptom onset in 1994. Her clinical course involved recurrent relapses, leading to hospitalizations. Treatment initially comprised interferon beta-1b and intravenous immunoglobulin. Due to inadequate disease control, she transitioned to natalizumab and later fingolimod due to the risk of progressive multifocal leukoencephalopathy. In 2017, with an EDSS of 4 and ongoing activity, alemtuzumab was considered. Meeting prerequisites, she underwent the first alemtuzumab cycle. Six months later, elevated anti-thyroid-stimulating hormone receptor antibodies, painful exophthalmos, decreased visual acuity, along with horizontal ophthalmoparesis emerged, leading to a diagnosis of Graves' disease-related orbitopathy. It was promptly managed with bilateral orbital decompression. Despite treatment (antithyroid medication, mycophenolate mofetil, tocilizumab, and methylprednisolone), progressive visual acuity decline ensued, culminating in thyroidectomy. In the latest evaluation, thyroid function normalized, with a persisting temporal scotoma and limitations in left eye abduction and elevation. Post-thyroidectomy, she underwent a second alemtuzumab cycle without complications. Imaging studies revealed no new lesions, with no reported relapses in the past year, ARR 0.

Conclusion: Despite lacking specific risk factors for alemtuzumab-associated thyroid eye disease, except gender, the patient proved unresponsive to immunosuppression, necessitating thyroidectomy. This case highlights alemtuzumab's efficacy in RRMS while underscoring the need for monitoring due to potential autoimmune complications, with a favorable clinical outcome despite challenges.

Disclosure: Nothing to disclose.

EPO-590 | OzEAN interim analysis: Treatment satisfaction, QoL, and fatigue in RRMS patients after 1-year ozanimod use in Germany

M. Buttmann
Department of Neurology, Caritas Hospital Bad Mergentheim, Bad Mergentheim, Germany

Background and Aims: Ozanimod (OZA) was approved in 2020 for the treatment of adults with relapsing-remitting MS (RRMS) in the EU. Patient-reported outcomes from routine clinical care represent an important data gap.

Methods: OzEAN (NCT05335031) is a prospective, noninterventional study currently enrolling adult RRMS patients across 80 sites in Germany. This interim analysis reports first real-world data on quality of life (QoL), fatigue (FSMC) and treatment satisfaction after 1 year of OZA.

Results: This analysis included 317 patients treated with OZA for an average of 17.7 months. At 6 months, most patients showed either improved or stable physical QoL (PCS) (40.1% each, $n = 39/96$), whereas 18.8% ($n = 18$) showed worsened PCS. At 12 months, most patients showed either stable or improved (39.3% each, $n = 22/56$) PCS, 21.4% ($n = 12$) showed worsened PCS. At 6 months, 46.7% ($n = 49/105$) of patients showed improved, 32.4% stable ($n = 34$) and 21.0% ($n = 22$) worsened mental QoL (MCS). At 12 months, 50.0% ($n = 29/58$), 29.3% ($n = 17$) and 20.7% ($n = 12$) of patients showed improved, stable, and worsened MCS, respectively. 60.9% ($n = 112/184$) of patients suffered from fatigue at baseline. At 12 months, the percentage of patients without fatigue increased from 39.1% to 44.3%; mean baseline and 12-month FSMC was 51.6 (± 20.7; $n = 184$) and 49.4 (± 20.5; $n = 79$), respectively. Treatment satisfaction was high, especially regarding side effects (91.8 ± 18.9; $n = 82$) and convenience (92.6 ± 11.9; $n = 82$), with 67 of 82 patients reporting no side effects after 12 months OZA.

Conclusion: This interim analysis indicates a positive effect of ozanimod on patient QoL and fatigue, along with high treatment satisfaction.

Disclosure: Funding: This study was supported by Bristol Myers Squibb. MB: honoraria for lecturing, consulting, and/or travel expenses for attending meetings from Bayer, Biogen, Boehringer, Bristol

EPO-591 | Cardiovascular disease in patients with multiple sclerosis and their association with course, disability and progression

M. Andolina; S. Iacono; G. Schirò; G. Sorbello; A. Calì; G. Salemi; P. Ragonese

Department of Biomedicine, Neuroscience and Advanced Diagnostics, University of Palermo, Italy

Background and Aims: Comorbidities are thought to be a negative prognostic factor in people with multiple sclerosis (pwMS) although the association between cardiovascular diseases (CVDs) and MS disability severity is conflicting. The aim of this study is to explore the association between CVDs and the risk of disability worsening and secondary MS progression (SPMS).

Methods: frequency and incidence of CVDs were calculated. The independent risk of reaching EDSS 4, EDSS 6 and SPMS conversion was computed for CVDs by using multivariable Cox-regression models.

Results: A total of 622 pwMS were included (72.8% female; age: 51.4 years [42–60]; follow-up: 12.3 years (7–21). CVDs reached a frequency of 40.7% with an incidence of 3 cases every 100 pwMS per year of follow-up and the commonest were hypertension (23.5%) followed by hyperlipidemia (11.7%) and type 2 diabetes mellitus (6.3%). CVDs were common in progressive MS course and the number of incident cases increased with increasing patient's age ($rs = 0.37$; $p < 0.0001$) and MS duration ($rs = 0.32$; $p < 0.0001$). T2DM at diagnosis or at any point before the index condition singled out as independent risk factor of reaching EDSS 4 (HR = 1.99 [95% CI 1.02–3.90], $p = 0.04$), EDSS 6 (HR = 1.61 [95% CI 0.9–2.8], $p = 0.09$) and SPMS conversion (HR = 1.74 [95% CI 0.99–3.1], $p = 0.055$).

Conclusion: CVDs are common in pwMS wherein are mainly associated with disease duration, progressive course and older age. T2DM was the only CVDs associated with higher risk of disability worsening and MS progression despite hypertension classically was also associated with bad MS prognosis.

Disclosure: Nothing to disclose.

EPO-592 | Post SARS-CoV-2 vaccination immune response in patients with MS treated with varying doses of parenteral cladribine

A. Zasybska; A. Pietruczuk; K. Rejdak

Department of Neurology, Medical University of Lublin, Lublin, Poland

Background and Aims: A vaccination against SARS-CoV-2 is recommended in the multiple sclerosis (MS) group of patients. However, the effects of DMTs on the humoral and cell-mediated response after SARS-CoV-2 vaccination in MS patients remain unclear. The aim of this analysis is to compare the immune response to SARS-CoV-2 vaccination in MS patients treated with cladribine and those receiving DMTs.

Methods: The study group consisted of 18 patients diagnosed with progressive multiple sclerosis (PMS) who received different doses of cladribine in parenteral formulation. The antibody titers specific to *N* protein and S1 spike protein were measured in all patients, on average 12 months after the last dose of the vaccine. Then 11 patients were treated with cladribine only, 3 patients treated cladribine with at least one disease modifying drug in the past, 4 patients with at least one disease modifying drug). Patients who qualified for the study had received at least one dose of the vaccine against SARS-CoV-2.

Results: Conducted analysis shows that 91% of patients treated with cladribine showed the presence of vaccination antibodies against the SARS COV-2 virus. One patient, with lymphopenia 0.65×10^9 and an incomplete dose of cladribine, did not obtain a positive antibody titer indicating the acquisition of immunity. No adverse effects on the post-vaccine immune response have been shown in patients treated with at least 2 disease modifying drugs.

Conclusion: Parenteral cladribine treatment with different dosing schemes had no negative significant effect on the generation of the immune response to the SARS-CoV-2 virus post vaccination.

Disclosure: Nothing to disclose.

EPO-593 | Performance of the NMOSDCopilotTM digital tool for unsupervised self-assessment of NMOSD: The OPTIS study design

M. Levy[1]; E. Sotirchos[2]; L. Carment[3]; E. Touré Cuq[3]; S. Fam[4]; D. Case[4]; A. Kielhorn[4]; E. Aras[4]; A. Vivès[3]; J. De Seze[5]
[1]Department of Neurology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA; [2]Department of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD, USA; [3]Ad Scientiam, Paris, France; [4]Alexion Pharmaceuticals Inc., Boston, MA, USA; [5]Department of Neurology, Hôpital Civil, Strasbourg University, Strasbourg, France

Background and Aims: Neuromyelitis Optica Spectrum Disorder (NMOSD) is characterised by unpredictable relapses leading to the accrual of neurological disability. Regular patient assessments help understand disease burden before, during, and after relapses, which supports clinical decision making. NMOSDCopilotTM, a Software as a Medical Device, supports self-assessment by NMOSD patients. It features a smartphone application collecting active digital biomarkers of walking, dexterity, cognitive and vision functions, and e-questionnaires (pain, fatigue, bladder and bowel control and quality of life). A web portal allows clinicians to access patients' data.

Methods: OPTIS is a prospective, open-label, multicenter, single group study enrolling adults with AQP4-IgG+ NMOSD in the United States, France, and Germany. It is designed to validate the clinical performance and the safety of NMOSDCopilotTM and demonstrate its usability. Patients will use NMOSDCopilotTM to complete tests and questionnaires during clinical visits at baseline, 6- and 12-months, as well as standard clinical evaluations (Timed 25-Foot Walk, 9-Hole Peg Test, Symbol Digit Modalities Test, Sloan Low-Contrast Letter Acuity Test). Remote self-assessments will be completed every month for 12 months.

Results: OPTIS will evaluate the correlation between NMOSDCopilotTM digital active tests and standard in-clinic testing in 103 patients with AQP4+ NMOSD. Other objectives include evaluating reliability and reproducibility of tests in NMOSDCopilotTM, as well as the safety, usability, adherence, and satisfaction with the tool.

Conclusion: The OPTIS study will generate evidence on the clinical performance of NMOSDCopilotTM. NMOSDCopilotTM has the potential to enable frequent patient self-assessments of neurological function, characterise burden of disease, and facilitate clinician disease management decisions.

Disclosure: This work was funded by Ad Scientiam (Paris, France) and was supported by a collaborative research agreement from Alexion Pharmaceuticals Inc. (Boston, USA). Michael Levy is an employee of the Massachusetts General Hospital (Boston), one of the OPTIS study sites. Elias Sotirchos is an employee of the Johns Hopkins University School of Medicine (Baltimore), one of the OPTIS study sites. Jerôme De Sèze is an employee of the Hôpital Civil (Strasbourg), one of the OPTIS study sites. Sami Fam, Dan Case, Adrian Kielhorn, Emrah Aras are employees of Alexion Pharmaceuticals Inc. Loïc Carment, Emma Touré Cuq, and Alizé Vives are employees of Ad Scientiam.

EPO-594 | Aquaporin-4 positive NMOSD: An atypical pathology with nerve root enlargements and peripheral nervous system damage

E. Ogawa[1]; M. Otomo[2]; K. Tsukita[1]; G. Watanabe[1]; A. Yasaka[1]; A. Tamagake[1]; Y. Suzuki[1]
[1]Department of Neurology, National Hospital Organization Sendai Medical Center; [2]Department of Neurology, Osaki Citizen Hospital

Background and Aims: Neuromyelitis optica spectrum disorder (NMOSD) is an inflammatory disease of the central nervous system (CNS). Recent studies have reported damage to the peripheral nervous system (PNS) in NMOSD. However, most studies have focused on NMOSD lesions localized in the transitional zone between the CNS and PNS at the root level. The aim of this report is to describe a patient with autoantibodies against aquaporin-4 (AQP4) positive NMOSD, presenting with demonstrated nerve root enlargements and PNS damage in demyelination.

Methods: Conducted a descriptive analysis encompassing clinical, imaging, blood and cerebrospinal fluid (CSF) examination, and electrophysiological assessments.

Results: A 72-year-old woman was admitted to our hospital in March 2023 due to limb weakness. Neurological examination revealed a positive relative afferent pupillary defect, muscle weakness in her limbs, hyporeflexia of the lower extremities and sensory disturbance below Th1 level. An MRI demonstrated a left internal capsule lesion, longitudinal extensive transverse myelitis at the level of C4-Th10, nerve root enlargements, and high-intensity signals in the bilateral cervical/lumbar cord. Positive anti-AQP4 antibodies in both serum and CSF led to the diagnosis of NMOSD. Testing for anti-myelin oligodendrocyte glycoprotein, -neurofascin-155, -Contactin-1, and -ganglioside antibodies returned negative results. Her symptoms significantly improved following six sessions of plasma exchange.

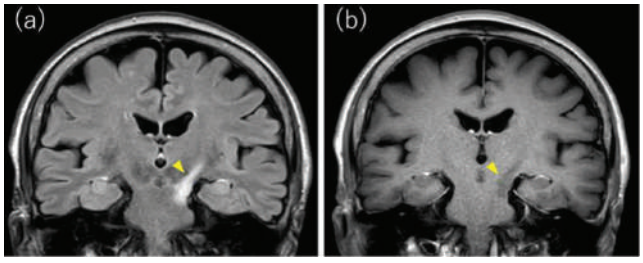

FIGURE 1 Brain MRI: FLAIR image reveals a high signal in the left internal capsule (a), while T1W1 image exhibits a low signal intensity in the same area (b). MRI, magnetic resonance imaging; FLAIR, fluid-attenuated inversion recovery.

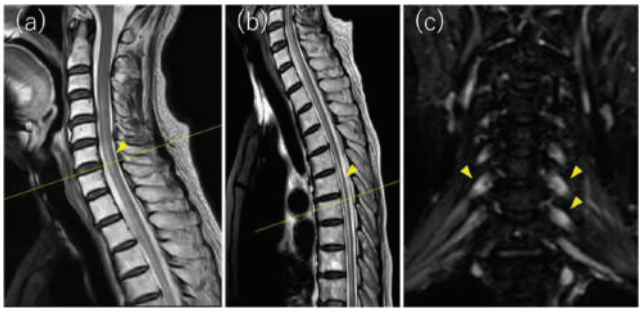

FIGURE 2 Spine MRI: Spinal MRI illustrates longitudinal extensive transverse myelitis at the level of C4-Th10 (a), (b) and associated nerve root enlargements (c).

Conclusion: This report represents one of the few cases of anti-AQP4 antibody-positive NMOSD with demonstrated nerve root enlargements, contributing to an expanded understanding of NMOSD pathology. We discussed the pathomechanisms of the nerve root enlargements in this case.
Disclosure: Nothing to disclose.

EPO-595 | Assessing the clinical value of the central vein sign by MRI for the differential diagnosis of multiple sclerosis

C. Oreja-Guevara[1]; E. Alba Suárez[1]; L. García-Vasco[1]; I. Gómez-Estévez[1]; P. Salgado-Cámara[1]; J. Quezada Sanchez[1]; J. Alvaréz-Linera[2]
[1]*Neurology, Hospital Clínico San Carlos, Idissc, Madrid, Spain;*
[2]*Radiology, Ruber Internacional Hospital, Madrid, Spain*

Background and Aims: Patients with diffuse symptoms often present a few non-specific hyperintense lesions on cranial MRI, raising diagnostic doubts. The central vein sign (CVS), indicative of a vein within a white matter lesion visible on MRI, is considered suggestive of multiple sclerosis. Objective: To study the utility of the central vein sign in differentiating diagnoses in patients with T2 hyperintense lesions, employing the SWI sequence in brain MRI.
Methods: Prospective study. Standard and SWI sequence brain MRIs were performed on Multiple Sclerosis patients and those with uncertain diagnosis who presented hyperintense lesions in T2. Clinical, CSF and OCT data were collected in cases with uncertain diagnoses.
Results: Ten patients were analyzed: 5 with uncertain diagnosis and 5 with MRI-confirmed MS. MS patients showed between 80–100% of T2 hyperintense lesions with CVS on SWI sequence. All five patients with uncertain diagnosis tested negative for CSF IgG OCBs. Among them, two had no CVS lesions: one was later diagnosed with migraine and small vessel disease, and the other tested positive for MOG antibodies. Two others showed up to 20% of lesions with CVS: one has recently diagnosed with double negative NMOSD and the other with MOGAD. One patient, presenting with headache, had 80% of lesions with CVS; however, two performed lumbar punctures were negative for IgG OCBs, and the MRI findings did not meet the MAGNIMS criteria.
Conclusion: The central vein sign could be useful to rule out the diagnosis of MS in patients with uncertain diagnosis.
Disclosure: Nothing to disclose in relation with the abstract.

EPO-596 | BDNF and NTRK2 gene polymorphisms associations with fatigue in a cohort of multiple sclerosis patients

M. Pantuliano; V. Pozzilli; F. Motolese; M. Rossi; A. Cruciani; L. Celani; F. Santoro; V. Di Lazzaro; F. Capone
Neurology, Neurophysiology and Neurobiology Unit, Department of Medicine, Campus Bio-Medico University of Rome, Rome, Italy

Background and Aims: Numerous studies have focused on the role of brain-derived neurotrophic factor (BDNF) and tropomyosin-related kinase B (TrkB) signalling in psychiatric and neurological disorders, including multiple sclerosis. There are conflicting data regarding the effects of BDNF and neurotrophic receptor tyrosine kinase 2 (NTRK2) genetic polymorphisms on brain atrophy, cortical thickness, neuroinflammation, neuroplasticity, as well as cognitive decline in patients with multiple sclerosis (pwMS). This study aimed to explore a possible correlation of BDNF and NTRK2 polymorphisms with cognitive impairment and fatigue in pwMS.
Methods: We enrolled 40 pwMS, who underwent venous sampling to analyse BDNF polymorphism rs6265 and NTRK2 polymorphisms rs1387923, rs1565445, and rs2769605. Subsequently, patients were administered various clinical tests or questionnaires, including Fatigue Severity Scale (FSS). Demographic data were collected retrospectively. We then performed a MANCOVA test and a categorical regression analysis.
Results: We found a statistically significant difference in the means of the groups of NTRK2 rs1387923 regarding FSS scores ($p = 0.022$). Successively, we performed a follow-up categorical regression analysis, which showed a significant correlation between the A/G genotype and higher FSS scores compared to either the A/A genotype or G/G genotype ($p = 0.019$ and $p < 0.001$, respectively) only in patients with BDNF Val/Val or Val/Met genotype.

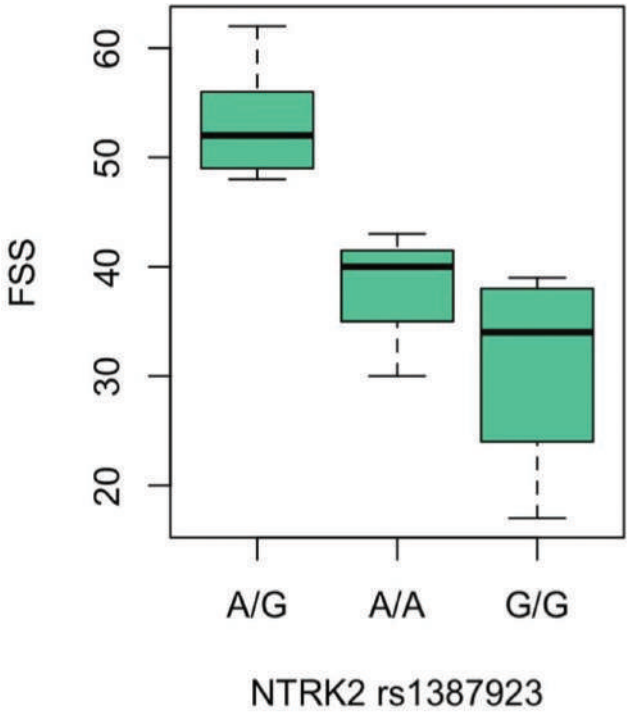

FIGURE 1 Boxplot representing averaged values of Fatigue Severity Scale (FSS) scores corresponding to A/G, A/A, and G/G genotypes of NTRK2 rs1387923 polymorphism in the subgroup of patients with BDNF Val/Val or Val/Met genotype.

Conclusion: BDNF has been linked to fatigue in cancer and chronic fatigue syndrome. To our knowledge, this is the first study to suggest that BDNF and NTRK2 polymorphisms may be associated with an increased susceptibility to fatigue in pwMS. Further studies on a larger number of patients are needed to corroborate this hypothesis.
Disclosure: Nothing to disclose.

EPO-597 | User perspectives on digital health applications for people with multiple sclerosis: A focus group investigation

B. Fasching[1]; R. Stark[1]; N. Krajnc[1]; F. Leutmezer[1]; G. Bsteh[1]; T. Berger[1]; B. Seebacher[2]; P. Altmann[1]
[1]*Department of Neurology, Medical University of Vienna, Austria;* [2]*Clinic for Rehabilitation Muenster, Department of Rehabilitation Research, Muenster, Austria*

Background and Aims: Digital health applications (DHA) are software tools designed to assist in healthcare management. They are particularly relevant for people with chronic diseases such as multiple sclerosis (MS). Despite advances in clinical use, further strategies are needed to facilitate DHA implementation and maintain adherence of its users. This study aimed to analyse patient perspectives on the feasibility of DHA and identify key criteria for potential clinical implementation.
Methods: People with MS (pwMS) with prior DHA interaction were recruited through the Department of Neurology, Medical University of Vienna. Semi-structured interviews, guided by WHO digital health principles, were transcribed from two focus groups and subsequently analysed using reflexive thematic analysis.
Results: Thirteen pwMS (9 female) were interviewed in two focus groups. Participants' median age was 43 years (range 25–60), median disability on the Expanded Disability Status Scale was 1.5 points (1–6). Key findings include the need for a user-centred design of DHA ensuring interfaces are intuitive and tailored to the specific needs of pwMS. The integration of DHA into existing clinical workflows was seen as an opportunity to improve communication on an equal footing between pwMS and neurologists. Robust data protection measures, transparent data policies and autonomous data management were considered essential for a sustained use of DHA.
Conclusion: This study elaborates on attributes of DHA that may enhance their feasibility as an addition to standard care for pwMS. Recognizing individual patient needs and incorporating an intuitive design emerged as critical factors in DHA adherence.
Disclosure: This study was funded by Roche Austria by a research grant awarded to the corresponding author (PA). The form says I have to enter less than 1500 characters but disclosures for all authors make up 2200 characters.

EPO-598 | Autoimmune diseases associated with neuromyelitis optica spectrum disorder: Population-based registry data

T. Pekmezovic[1]; V. Jovicevic[2]; M. Andabaka[2]; N. Momcilovic[2]; N. Veselinovic[2]; O. Tamas[2]; M. Budimkic[2]; S. Todorovic[3]; M. Jeremic[2]; E. Dincic[4]; S. Vojinovic[3]; S. Mesaros[2]; J. Drulovic[2]
[1]*Faculty of Medicine, University of Belgrade, Belgrade, Serbia;* [2]*Clinic of Neurology, University Clinical Center of Serbia, Belgrade, Serbia;* [3]*Clinic of Neurology, University Clinical Center Nis, Nis, Serbia;* [4]*Clinic of Neurology, Military Medical Academy, Belgrade, Serbia*

Background and Aims: The aim of our study was to estimate the frequency of autoimmune comorbidities in NMOSD patients from the national Serbian NMOSD Registry. Additionally, analysis of the frequency of related pathogenic organ-specific and not organ-specific autoantibodies was analyzed.
Methods: Our study comprises 136 patients with NMOSD, diagnosed according to the NMOSD criteria 2015. At the time of the study, in the Registry were collected demographic and clinical data, including those related to the coexisting comorbidities and pathogenic autoantibodies.
Results: Among 136 NMOSD patients, 50 (36.8%) had at least one associated autoimmune disorder. The most frequently reported diseases were autoimmune thyroid disease (15.4%), Sjogren's syndrome (11.0%), systemic lupus erythematosus (5.1%), myasthenia gravis (4.4%), and primary antiphospholipid antibody syndrome (2.9%). Aquaporin (AQP) 4-IgG was present in the sera from 106 patients (77.9%) and in this subgroup, autoimmune comorbidities were statistically significantly more frequent than in the AQP4-IgG negative subjects ($p=0.002$). In the total cohort of our NMOSD patients, out

of 106 tested patients, at least one pathogenic autoantibody was detected in 76 subjects (71.7%). Antinuclear antibodies (ANAs) were the most frequently detected antibodies (54.3%). ANAs and anti-extractable nuclear antigen antibodies were statistically significantly more frequent in AQP4-IgG positive vs. AQP4-IgG negative patients ($p=0.006$, and $p=0.033$, respectively).

Conclusion: NMOSD patients, especially AQP4-IgG seropositive ones, are rather frequently associated with wide spectrum of autoimmune diseases, including both organ-specific and systemic autoimmune disorders, and related pathogenic autoantibodies, in our defined cohort with European ethnical background.

Disclosure: Nothing for disclose.

EPO-599 | Comparison of ocrelizumab and ofatumumab: Examining clinical characteristics within the first year of market availability

M. Peters[1]; D. Ellenberger[2]; F. Fneish[2]; N. Frahm[2]; T. Friede[3]; P. Flachenecker[4]; K. Hellwig[5]; C. Kleinschnitz[6]; A. Stahmann[2]

[1]*German MS-Registry, Gesellschaft für Versorgungsforschung mbH (Society for Health Care Research [GfV]), Hannover, Germany*; [2]*German MS-Registry, MS Forschungs- und Projektentwicklungs- gGmbH (MS Research and Project Development gGmbH [MSFP]), Hannover, Germany*; [3]*Department of Medical Statistics, University Medical Center Göttingen, Göttingen, Germany*; [4]*Neurological Rehabilitation Center Quellenhof, Bad Wildbad, Germany*; [5]*Department of Neurology, St. Joseph and St. Elisabeth Hospital, Ruhr University, Bochum, Germany*; [6]*Department of Neurology and Center of Translational and Behavioral Neurosciences (C-TNBS), University Hospital Essen, Essen, Germany*

Background and Aims: The number of treatment options for relapsing multiple sclerosis (RMS) has considerably increased in recent years. Onlabel anti-CD20 monoclonal antibodies (anti-CD20) ocrelizumab (OCR; introduced: 2018) and ofatumumab (OFA; introduced: 2021) are highly effective disease-modifying therapies (HE-DMTs). This study aims comparing the clinical characteristics of people with MS (pwMS) initiating treatment with OCR/OFA within the first year of German market availability.

Methods: We analysed data from the German MS Registry as of 1-Nov-2023, focusing on OCR/OFA-treated RMS patients. pwMS with DMT initiation within one year of German market availability (observation time: OCR 1-Feb-2018 to 1-Feb-2019; OFA 1-Sep-2021 to 1-Sep-2022) were characterized regarding clinical variables and DMT prescription before OCR/OFA.

Results: 452 pwMS received OCR and 175 OFA (Table 1). Age, disease duration and disability level (expanded disability status scale; EDSS) at OCR/OFA initiation were significantly lower in OFA patients than in OCR patients. Lower EDSS scores were identified to favor OFA initiation (Figure 1). OFA users were more often treatment-naïve than OCR users (29.7% vs. 25.7%; chi-square test $p=0.334$; Figure 2). S1P receptor modulators, natalizumab, and daclizumab were the most used pre-OCR treatments, whereas glatiramer acetate, anti-CD20, and cladribine were more frequently prescribed before OFA.

Table 1. Baseline comparison between initiation with ocrelizumab and ofatumumab patients with MS

Variables	Ocrelizumab (N=452)	Ofatumumab (N=175)	p-value
Female sex, N (%)	324 (71.7)	113 (64.6)	0.101
Age at MS onset [years], mean (± SD)	29.3 (9.7)	29.5 (9.6)	0.871
Time to MS diagnosis [years], median [25%;75%-quantiles]	0.2 [0.0;1.1]	0.1 [0.0;0.6]	0.075
Age at ocrelizumab/ofatumumab initiation [years], mean (± SD)	41.9 (11.0)	39.4 (11.8)	***0.020***
Disease duration at ocrelizumab/ofatumumab initiation [years], mean (± SD)	12.2 (8.8)	10.2 (8.8)	***0.013***
EDSS at ocrelizumab/ofatumumab initiation, median [25%;75%-quantiles]	3.0 [2.0;4.5]	2.0 [1.5;2.9]	***<0.001***
Annualised relapse rate (± SD)	0.28 (0.6)	0.20 (0.5)	0.063
Number of prior therapies, N (%)			0.942
Initial therapy	116 (25.7)	52 (29.7)	
1 prior therapy	1024(27.4)	43 (24.6)	
2 prior therapies	83 (18.4)	31 (17.7)	
≥ 3 prior therapies	129 (28.5)	49 (28.0)	

EDSS - expanded disability status scale; MS – Multiple sclerosis; N – number of patients; SD - standard deviation

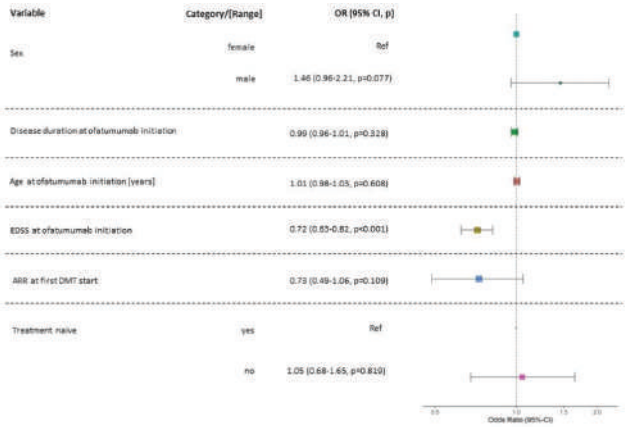

Figure 1 - Predictors for starting treatment with ofatumumab within the first year of market availability. A multivariable logistic regression model was used to identify variables associated with the initiation of ofatumumab among 175 MS patients. The forest plot contains colored boxes indicating the ORs of the variables analyzed for treatment with ofatumumab. Box sizes represent the number of patients included. Whiskers symbolize the 95% CIs of ORs. ARR - annualized relapse rate; CI - confidence interval; EDSS - expanded disability status scale ; MS - multiple sclerosis; OR - odds ratio; p - p-value; Ref - reference

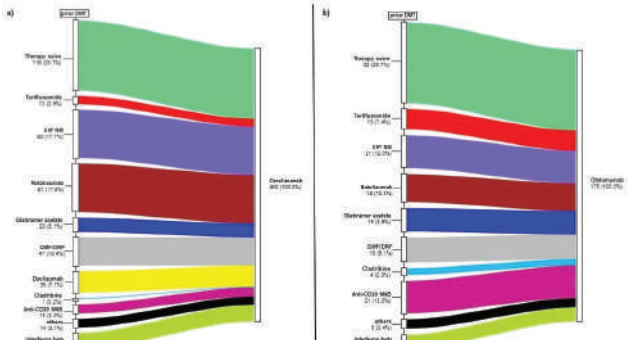

Figure 2. DMTs prescribed prior to patients with ocrelizumab (a) (N=452) and ofatumumab (b) (N=175). The boxes on the left side represent the proportion of patients, stratified by the prior DMT used. On the right side, the immediately following ocrelizumab (a) or ofatumumab (b) treatment is shown. The color line does correspond to the proportions of patients using the respective DMTs. Anti-CD20 MAB – anti-CD20 monoclonal antibodies; ocrelizumab/ofatumumab/rituximab; DMF – dimethyl fumarate; DMT – disease-modifying therapy; DRF – disease-free rate; MS – multiple sclerosis; N – number of patients; S1PRM – sphingosine-1-phosphate-receptor modulators; teriflunomide/leflunomide

Conclusion: Differences in clinical patient characteristics and pre-therapy may be explained by the market availability of additional HE-DMTs. PwMS were more often initiated with OCR as the first in-class medication compared to the subsequent OFA. The administration route of OCR (infusion) and OFA (injection) could also impact patient preferences and physician decisions in the future.

Disclosure: The authors have received speaking fees, travel support, honoraria from advisory boards, and/or financial support for research activities from pharmaceutical companies. None resulted in a conflict of interest.

EPO-600 | A phase 2 trial of tolebrutinib, a Bruton's tyrosine kinase inhibitor, for chronic active lesions in multiple sclerosis

D. Reich[1]; S. Raza[1]; C. Donnay[1]; A. Blazier[2]; S. Sawney[1]; J. Akinsanya[1]; J. Ohayon[1]; A. Fletcher[1]; J. Dwyer[1]; Y. Akahata[1]; G. Wirak[2]; I. Cortese[1]; S. Jacobson[1]; D. Ofengeim[2]; M. Absinta[3]; T. Turner[2]; M. Gaitán[1]

[1]National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD, USA; [2]Sanofi, Cambridge, MA, USA; [3]Translational Neuropathology Unit, San Raffaele Scientific Institute, Milan, Italy

Background and Aims: In paramagnetic rim lesions (PRL), iron accumulates in activated microglia at the edge of chronic active multiple sclerosis (MS) lesions. PRL are associated with smoldering tissue degeneration and aggressive disease and are not resolved by approved disease-modifying therapies. Tolebrutinib, a brain-penetrant Bruton's tyrosine kinase (BTK) inhibitor, modulates B cells and microglia.

Methods: BRaKe-MS (NCT04742400), a single-site, open-label, rater-blinded, Phase 2a trial, assessed whether 48 weeks of tolebrutinib 60 mg resolved PRL on 7-tesla MRI in adults with no new white matter lesions or clinical relapses for ≥6 months, who were on anti-CD20 therapy at baseline. Radiological, clinical, and biological outcomes were measured at 24 and 48 weeks (primary outcome). Secondary outcomes included safety, tolerability, and other radiological outcomes.

Results: We enrolled a preplanned total of 7 participants. At baseline, the median number of PRL per participant was 9 (range: 6–46). The primary outcome (disappearance of ≥1 PRL in at least 2 participants) will be reported, together with changes in the CSF and blood proteome (Olink) and single-cell transcriptome (10×). No participant had a clinical or radiological relapse. The most common adverse events were COVID-19 (4), headache (3), and nausea (3). No safety-related discontinuations or treatment-related deaths occurred.

Conclusion: BRaKe-MS tested whether 48 weeks of BTK inhibition with tolebrutinib reduced radiological and biological markers of inflammation associated with chronic active white matter lesions in MS.

Disclosure: This study was supported and sponsored by the Intramural Research Program of NINDS (NIH), in part via a Cooperative Research and Development Agreement with Sanofi.

Muscle and neuromuscular junction disorder 3

EPO-601 | Comparison between IVIG and plasma exchange in the management of myasthenia crisis

N. Gutti; J. Kalita; F. Ahamed

Department of Neurology, Sanjay Gandhi Postgraduate Institute of Medical Sciences

Background and Aims: Myasthenic crisis (MC) is characterized by type II respiratory failure needing mechanical ventilation (MV). Intravenous immunoglobulin (IVIg) or plasma exchange (PLEX) are used as a rescue treatment although there is paucity of information. We compare the efficacy of IVIg and membrane based PLEX in MC in an open labelled trial.

Methods: Patients with MC were included, and their clinical findings, precipitating causes and laboratory parameters were noted. Patients were either treated with IVIg (400 mg/kg/day for 5 days) or membrane based PLEX (40 ml/kg/alternate day for 5 sessions). Primary outcome was duration of MV, and secondary outcomes were duration of hospital stay, time to reach pre-worsening status, pyridostigmine dose at discharge, and adverse events.

Results: 44 episodes of MC occurred in 17 patients. IVIg was prescribed in 15 (34.1%) and PLEX in 8 (18.18%) episodes. Mean age was higher in IVIg group than the PLEX (49.53 ± 9.93 vs 40.25 ± 7.92; $p = 0.02$). Other baseline characteristics are comparable. Infection was the most frequent cause (61.4%) of MC. IVIg group required longer duration of MV compared to PLEX (17.47 ± 11.32 vs 7.38 ± 7.40 days; $p = 0.018$). However, there was no difference in the duration of hospital stay (30.33 ± 21.39 vs 24.12 ± 7.88 days; $p = 0.33$) and time to reach pre-worsening status (53.33 ± 22.25 vs 48.13 ± 31.27 days; $p = 0.68$). Allergic reaction (6.7%) and raise in creatinine (13.3%) were seen in IVIg group needing withdrawal in one. In PLEX group, 50% episodes were associated with transient fall in blood pressure, not required withdrawal.

Conclusion: Membrane based plasmapheresis reduced the duration of mechanical ventilation in MC compared to IVIg. Blood pressure monitoring is important during plasmapheresis.

Disclosure: Nothing to disclosure.

EPO-602 | Subcutaneous efgartigimod PH20 demonstrates improvements in gMG patients regardless of prior administration route

E. Cortés Vicente[1]; J. Verschuuren[2]; H. Wiendl[3]; L. Liu[4]; F. Gistelinck[4]; S. Steeland[4]; B. Van Hoorick[4]; J. Podhorna[4]; K. Utsugisawa[5]; J. De Bleecker[6]; R. Mantegazza[7]

[1]*Neuromuscular Diseases Unit, Department of Neurology, Hospital de la Santa Creu i Sant Pau, Universitat Autònoma de Barcelona, Barcelona, Spain; Center for Networked Biomedical Research into Rare Diseases (CIBERER), Madrid, Spain;* [2]*Department of Neurology, Leiden University Medical Center, Leiden, Netherlands;* [3]*Department of Neurology, University of Münster, Münster, Germany;* [4]*argenx, Ghent, Belgium;* [5]*Department of Neurology, Hanamaki General Hospital, Hanamaki, Japan;* [6]*Department of Neurology, Ghent University Hospital, Ghent, Belgium;* [7]*Department of Neuroimmunology and Neuromuscular Diseases, Fondazione Istituto Neurologico Carlo Besta, Milan, Italy*

Background and Aims: ADAPT-SC+ is an ongoing, open-label extension trial evaluating long-term efficacy/safety of subcutaneous (SC) efgartigimod PH20 (coformulated with recombinant human hyaluronidase PH20) in generalised myasthenia gravis (gMG). Interim analyses (December 2022) demonstrated efficacy/safety of efgartigimod PH20 SC in gMG participants rolled over from ADAPT+/ADAPT-SC (Fig.1). Here we evaluate efgartigimod PH20 SC in gMG participants who received IV or SC formulations in antecedent studies.

Methods: Efgartigimod PH20 SC 1000 mg was administered in cycles of 4 once-weekly injections. Subsequent cycles were initiated ≥28 days from last dose based on clinical evaluation.

Results: As of December 2022, 179/184 participants received ≥1 efgartigimod PH20 SC dose; participants previously received efgartigimod IV (IV-SC: 127/179 [70.9%]) or efgartigimod PH20 SC (SC-SC: 52/179 [29.1%]). Mean (SD) study duration was 413.9 (107.9) days (136.9 patient-years follow-up) and 410.4 (96.7) days (56.5 patient-years follow-up) in the IV-SC and SC-SC subgroups, respectively. In AChR-Ab+ participants (IV-SC: $n=98$; SC-SC: $n=43$), mean [SE] total MG-ADL score improved from baseline to week 4, cycle 1 (IV-SC: −4.3 [0.33]; SC-SC: −3.6 [0.49]) and was consistent over subsequent cycles in both subgroups (Fig.2). Mean MG-QoL15r/EQ-5D-5L scores improved from baseline over multiple cycles in both subgroups, indicating improved QoL over time. Adverse events were predominantly mild/moderate and consistent between subgroups; most frequent were injection site erythema (IV-SC: 30.7%; SC-SC: 25.0%), COVID-19 (IV-SC: 23.6%; SC-SC: 19.2%), and headache (IV-SC: 17.3%; SC-SC: 26.9%). Four deaths were reported (IV-SC), with none efgartigimod-related, as per investigator.

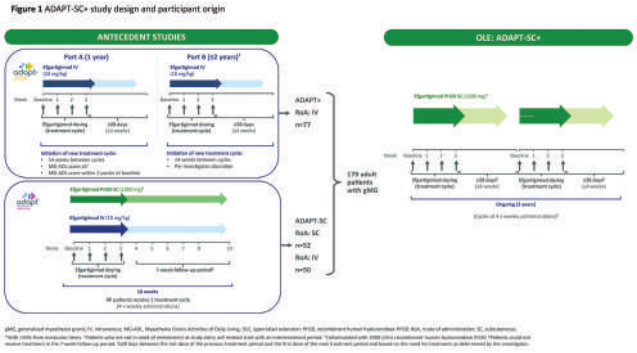

Figure 2 Mean change in MG-ADL total score from baseline (AChR-Ab+ participants)

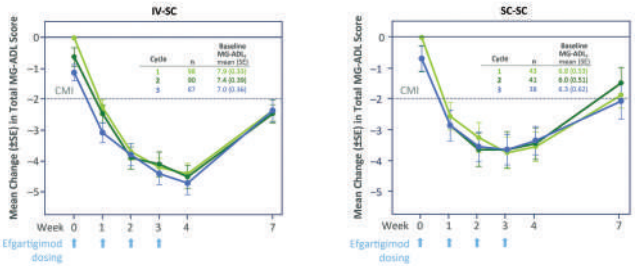

AChR-Ab+, acetylcholine receptor antibody–positive; CMI, clinically meaningful improvement; IV, intravenous; MG-ADL, Myasthenia Gravis Activities of Daily Living; SC, subcutaneous; SE, standard error.

Conclusion: Efgartigimod PH20 SC demonstrated comparable efficacy/safety in gMG participants previously treated with IV or SC formulations.

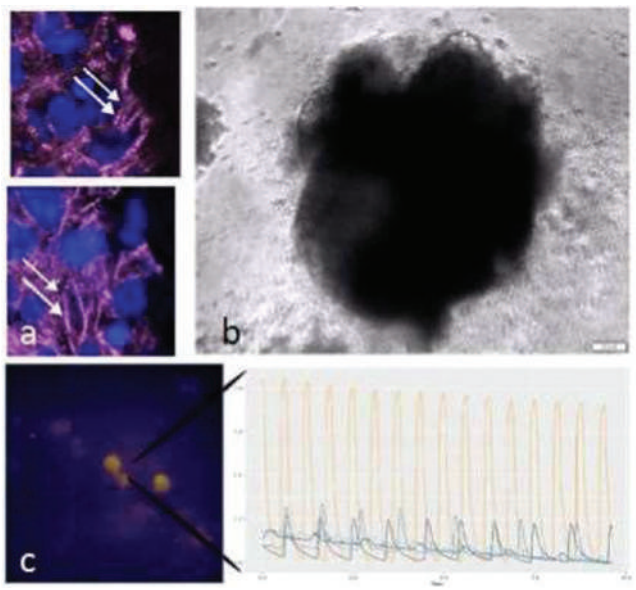
EPO-603 | Cardiac organoids as in vitro model for myotonic dystrophy type 1

L. Fontanelli[1]; A. Kostina[2]; G. Bellini[1]; L. Becattini[1]; G. Vadi[1]; A. Aguirre[2]; G. Siciliano[1]

[1]*Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy;* [2]*Institute for Quantitative Health and Engineering, Michigan State University, East Lansing, MI, USA*

Background and Aims: Current animal models fail to faithful replicate the complexity of Myotonic Dystrophy. Organoids are self-organizing in vitro culture systems that acquire in vivo-like organ complexity, enabling them to recapitulate the architecture and functions of organs. Our aim is to generate cardiac organoids as in vitro model of DM1 to explore pathophysiology of the disease and as a preclinical model for testing candidate drugs.
Methods: Three iPSCs lines from distinct caucasian affected with myotonic dystrophy harbouring different expansion triplet numbers have been used. Cardiac organoids were generated using a published protocol by Lewis-Israeli (2021) and cultured until day 50 (Fig. 1).
Results: Patient-derived organoids (PdOs) showed similar contractile structures to controls (Fig. 1) and manifested different gene expression profiles. PdOs showed increased expression of COL1A1 ($p<0.01$) and calcium channel ($p=0.03$) and a decrease in insulin receptor ($p<0.01$) and IGF receptor ($p=0.03$). Of note, an increase of CACNA1C expression have been found also in vivo (Poulin, 2021), while the reduction in INSR and IGFR expression may, in part, explain the insulin resistance, We observed marked differences in PdOs and control organoids regarding the amplitude of calcium transients and conduction velocities, both reduced in DM1 organoids (Fig. 1).



1A: Both patient-derived and controls organoids shows characteristic contractile structures. 1B: Organoids at 50 days of culture. 1C: calcium analysis.

Conclusion: We generated PdOs that replicate certain features observed in vivo. Given their flexibility, organoids can serve as personalized disease models and may improve our understanding of pathophysiological mechanisms in DM1, as a tool to evaluate DMPK expansion effects in distinct aspects of cell physiology, as well as a test platform for candidate drugs.
Disclosure: Nothing to disclose.

EPO-604 | Safety and efficacy of amifampridine in Lambert-Eaton myasthenic syndrome patients – Real world data

P. Szczudlik[1]; E. Sobieszczuk[1]; M. Walczak[2]; A. Kostera-Pruszczyk[1]
[1]*Department of Neurology, Medical University of Warsaw, Poland, ERN EURO NMD;* [2]*Department of Pediatrics, Endocrinology, Diabetology, Metabolic Disease and Cardiology of the Development Age, Pomeranian Medical University, Poland*

Background and Aims: Lambert-Eaton myasthenic syndrome (LEMS) is an ultrarare neurological disease with triad of symptoms: muscle paresis, dysautonomy and areflexia. Symptomatic treatment with amifampridine is available. Aim: To assess the effectiveness and safety of treatment in real-world.
Methods: 14 patients with non-neoplastic LEMS treated with amifampridine were enrolled in the study (F 42.9%, mean age 48.8 ± 11.4 years). The patients were assessed using Quantitative Myasthenia Gravis (QMG) scale, QMG limb domain (LD) score, spirometry, Hand Grip Strength (GRIP) test and repetitive nerve stimulation study (RNS) at baseline and end of follow-up. Diagnostic delay was 7–260 months. The patients were treated for 21.1 ± 12.0 weeks (13–48 weeks).
Results: All patients improved in QMG score. Mean improvement was 5.1 ± 2.0 (1–8) points ($p<0.001$). Clinically meaningful improvement ≥3 points achieved 85.7% of patients ($N=12$) Improvement in QMG LD was seen in 78.6% of the patients (mean 2.2 ± 1.6 points, $p<0.001$). Also, FVC improved on treatment ($p=0.031$). Mean improvement in GRIP test was 7.0 ± 7.1 kg in right and 5.2 ± 7.5 kg in left hand ($p<0.001$). In RNS before treatment, facilitation (>100%) was observed in 78.6% ($N=11$) of patients and was higher before treatment ($p<0.001$). Mean increase of CMAP amplitude was 2.1 ± 1.6 times. CMAP amplitude increased on treatment ($p<0.001$). In 64.3% ($N=9$) of patients lowering of corticosteroid dose was achieved.
Conclusion: Amifampridine is an effective treatment in non-neoplastic LEMS patients. Treatment is well-tolerated and allows to lower dose of corticosteroids in the majority of patients.
Disclosure: Nothing to disclose.

EPO-605 | From phenotype to genotype: Diagnosis pitfalls in atypical FSHD cases

F. Torri[1]; C. Strafella[2]; L. Vercelli[3]; G. Gadaleta[3]; B. Risi[4]; L. Colantoni[2]; E. Giardina[2]; M. Filosto[4]; T. Mongini[3]; G. Siciliano[1]; G. Ricci[1]
[1]*Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy;* [2]*Genomic Medicine Laboratory-UILDM, Santa Lucia Foundation IRCCS, Rome, Italy;* [3]*Neuromuscular Unit, Department of Neurosciences; Rita Levi Montalcini, University of Turin, Turin, Italy;* [4]*Neuromuscular Omnicenter, NeMO, Fondazione Serena Onlus, Milan, Italy*

Background and Aims: Facioscapulohumeral muscular dystrophy (FSHD) is the third most common dystrophy, in which different

phenotypes can be observed, showing different disease progression and/or implying distinct genetic mechanisms. To date, the diagnostic criteria are based on the detection of the genetic signature (reduced D4Z4 allele, permissive haplotype, hypomethylation, mutations in modifiers genes as SMCHD1, LRF1 or DNMT3B). Still, the interpretation of the genetic test cannot ignore a careful correlation with the phenotype.

Methods: We present data of a cohort of 43 patients from 24 families selected by phenotypic features, characterized by incomplete penetrance/atypical phenotypes according to the Comprehensive Clinical Evaluation Form (CCEF), in which a short D4Z4 allele segregated. The molecular characterization included the assessment of 4q subtype, DNA methylation levels, Whole Exome Sequencing (WES) and segregation analysis.

Results: In our cohort, methylation levels displayed high variability in relation to the disease phenotype. In more than half of the atypical phenotypes, despite the detection of the FSHD genetic signature, WES analysis identified VUS or likely pathogenic/pathogenic variants in other genes associated with neuromuscular disorders, compatible with the observed phenotype, or known FSHD-modifying genes. A definitive alternative diagnosis was obtained in 5 families.

Conclusion: Our results further support the need to perform a detailed phenotypic characterization of patients with a suspect of FSHD, and, in cases of atypical phenotypes, to combine the D4Z4 sizing with other procedures such as WES. In this regard, methylation analysis represents a valuable tool to provide preliminary evidence for FSHD to be confirmed by further testing.

Disclosure: The authors have no conflicts of interest to disclose.

EPO-606 | The METMYD Study: Early results on efficacy and safety of metformin in myotonic dystrophy type 1 (DM1)

E. Frezza[1]; S. Rossi[2]; A. Perna[3]; E. Bucci[4]; G. Greco[1]; M. Goglia[1]; V. Visconti[5]; A. Botta[5]; M. Nuccetelli[6]; G. Antonini[4]; A. Petrucci[3]; G. Silvestri[2]; R. Massa[1]

[1]Department of Systems Medicine, University of Rome "Tor Vergata", Rome, Italy; [2]Institute of Neurology, Department of Neuroscience, Catholic University of Sacred Heart, Rome, Italy; [3]Center for Neuromuscular and Neurological Rare Diseases, San Camillo Forlanini Hospital, Rome, Italy; [4]Unit of Neuromuscular Diseases, Department of Neurology Mental Health and Sensory Organs (NESMOS), Faculty of Medicine and Psychology, 'Sapienza' University of Rome, Sant'Andrea Hospital, Rome, Italy; [5]Department of Biomedicine and Prevention, Genetics Unit, University of Rome "Tor Vergata", Rome, Italy; [6]Department of Laboratory Medicine, Tor Vergata University Hospital, Rome, Italy

Background and Aims: DM1 is still orphan of a cure or disease-modifying treatment. While gene therapy and antisense-oligonucleotide treatments are under investigation, recent studies showed that metformin can modify the aberrant alternative splicing causative of DM1. The aim of this study is to evaluate the superiority of a 24 month-treatment with the biguanide drug metformin over placebo, on mobility and strength parameters in adult DM1 patients.

Methods: METMYD is a multi-center, randomized, triple-blind, two-arm, placebo-controlled, phase III clinical trial. The primary endpoint is a better performance at the 6MWT at the end of study as compared to baseline. Secondary clinical endpoints explore muscle quantitative testing of upper and lower limbs, dexterity, fatigue. In addition, quantitation of circulating alternative splicing products deficient in DM1 and of markers of oxidative stress is performed before and after treatment.

Results: Enrolment started in January 2020 and the study ended in December 2023. One-hundred and forty-nine patients were enrolled and 146 were randomized either to metformin or placebo. The two arms at baseline did not differ for sex, age, BMI, HOMA index and 6MWT. Fifty-four (37%) patients (29 on metformin, 25 on placebo) dropped out for various reasons, mainly non-compliance, consent withdrawal and diarrhea and 92 patients completed the protocol.

Conclusion: The METMYD study shows that a long-term pharmacological intervention is feasible in DM1 patients, even during the COVID-19 pandemics. Metformin showed to be safe when administered in non-diabetic DM1 patients, the only common AE being diarrhea, as in general population. The analysis of clinical and laboratory efficacy measures is underway.

Disclosure: Nothing to disclose.

EPO-607 | Anti-HMGCR necrotizing myopathy: Characterization and therapy management in 17 patients over a 10 years follow-up

G. Brodini[1]; G. Gadaleta[1]; G. Urbano[1]; L. Chiadò-Piat[1]; T. Manetta[2]; G. Mengozzi[2]; T. Mongini[1]; L. Vercelli[1]

[1]S.S. Neuromuscular Unit, Department of Neurosciences "Rita Levi Montalcini", AOU Città della Salute e della Scienza, Molinette Hospital, Turin, Italy; [2]S.C. Biochimica Clinica, AOU Città della Salute e della Scienza, Molinette Hospital, Turin, Italy

Background and Aims: Antibodies against 3-hydroxy-3-methylglutaryl-coenzyme A reductase (HMGCR) myopathy represents an immune-mediated necrotising myopathy (IMNM) typically associated with statin use, with a variable onset. In this retrospective study we examined 17 patients diagnosed with anti-HMGCR IMNM according to 2017 EULAR criteria, followed at our Center in the years 2013–2014.

Methods: Medical records, encompassing clinical, histological, instrumental, and laboratory data (table 1–2), were systematically reviewed.

Results: Clinical onset manifested as a progressive proximal muscle weakness in 70.5% of patients. 29.5% of cases were only mildly symptomatic but 80% of them developed remarkable weakness within two years, before starting IVIg treatment, with only one remaining slightly symptomatic. 88% of patients had prior statin exposure; elevated serum creatine kinase (CK) levels (600–27000 UI/L) and positive anti-HMGCR antibodies were observed in all cases. In 16/17 patients, immunomodulant/suppressive therapy was administered with steroids and/or intravenous immunoglobulin (IVIg); five patients also received azathioprine or methotrexate. IVIg yielded

optimal responses in 88% of patients. Immunotherapy was gradually tapered for all patients throughout the years. Of nine patients ceasing IVIg after achieving clinical-biochemical remission, six of them had to resume treatment, leading to rapid improvement.

Gender		Age at onset

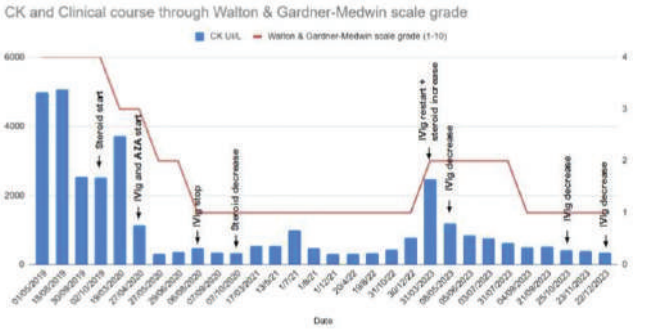
TABLE 2 Ab anti-HMGCR-IMNM. Treatment management.



GRAPHIC 1 Ab anti-HMGCR-IMNM. Clinical course (calculated with Walton and Gardner-Medwin scale grade, y axis on the right), serological course (based on CK levels, y axis on the left) and treatment modifications thorough the years of one patient.

Conclusion: Anti-HMGCR IMNM seems to produce a persistent dysimmune process; chronic immunomodulant treatment appears to be the most suitable to maintain clinical and biochemical remission. In our cohort, 67% of patients relapsed after IVIg treatment suspension, although still well responded to IVIg reintroduction. This highlights the need for recurring treatment cycles and vigilant clinical and serological monitoring.

Disclosure: Nothing to disclose.

EPO-608 | Facioscapulohumeral muscular dystrophy (FSHD) type 1 mimics: Review of 60 cases with normal size D4Z4 alleles

G. Gadaleta[1]; L. Vercelli[1]; G. Urbano[1]; G. Brodini[1]; E. Rolle[1]; R. Tupler[2]; T. Mongini[1]

[1]*Department of Neuroscience "Rita Levi Montalcini", Neuromuscular Unit, University of Turin, Turin, Italy*; [2]*Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy*

Background and Aims: Analysis of D4Z4 alleles is indicated in patients with facial-shoulder girdle weakness and in FSHD1 patients' relatives. Our research focused on carriers of D4Z4 alleles with ≥11 repeats, reviewing their phenotypes according to the Comprehensive Clinical Evaluation Form (CCEF) Clinical Categories, and identifying alternative genetic diagnoses.

Methods: We examined 510 patients referred for 4q35-D4Z4 analysis to the Miogen Laboratory (Modena) in the last 15 years.

Results: Excluding 356 cases (69.8%) showing a D4Z4-reduced allele, 154 (30.2%) carried D4Z4 alleles with ≥11 repeats: 94 (61%) were unaffected relatives (Category C), and 60 (39%) represented sporadic symptomatic patients. Among the latter group, 9 (15%) presented a full phenotype (Category A), 3 (5%) an incomplete one (Category B), and 48 (80%) an atypical involvement (Category D). Subsequent genetic analyses identified damaging variants in the following genes and Clinical Categories: 3 SMCHD1 (FSHD2) and 1 COL6A (Category A); 1 EMD (Category B1); in Category D, 4 CAPN3 (2 recessive and 2 dominant), 2 COL6A, 1 MYH7, 1 DMPK, 1 RYR1, 1 GAA, 1 DMD (Becker phenotype), 1 FKRP, and 1 SGCG. In 1 atypical

case, a variant on PMP22 already described in Charcot-Marie-Tooth (CMT)-like distal weakness was found. In the remaining 41 patients further genetic analyses are ongoing.

Conclusion: The study of 4q35 region is justified in FSHD-like phenotypes and in FSHD1 patients' relatives for segregation. In our cohort, alternative diagnoses were found in 32% of FSHD1-mimicking phenotypes, making it a varied group needing thorough phenotyping and extensive genetic investigations.

Disclosure: Nothing to disclose.

EPO-609 | Safety and efficacy of tofacitinib in patients with refractory myasthenia gravis: A pilot study

R. Zhao; C. Yan; S. Luo; C. Zhao

Department of Neurology, Huashan Hospital Affiliated to Fudan University, National Medical Center for Neurological Diseases, Shanghai, China

Background and Aims: Myasthenia gravis is one of the most common autoimmune neuromuscular disorders. About 10 percent MG patients still are refractory and there still is an unmet need for effective, well tolerated, and convenience treatment options for these patients. We aimed to assess the safety and efficacy of tofacitinib, an inhibitor of JAK kinases with oral administration.

Methods: This registered open-label, single-arm pilot study was conducted from June 2020 through December 2023 (NCT04431895). Refractory gMG patients received tofacitinib (5mg, twice a day) as the only IS in combination with corticosteroids. Clinical scales, including QMG score, MG-ADL, MG-QoL15, and MGC were assessed prospectively from the baseline to 24 weeks after Tofacitinib initiation. The phosphorylation level of STAT3 in peripheral blood CD4+T cells for MG patients were detected by multi-color flow cytometry.

Results: We enrolled 19 anti-AChR antibody-positive gMG cases. By week 24 after tofacitinib administration, a significant reduction was observed in MG-ADL (6.0 vs 1.5 at baseline; $p=0.0004$) and QMG (14 vs 11 at baseline; $p=0.0391$), respectively. Corticosteroids dose were significantly reduced from 20 mg to 15 mg ($p=0.0074$). Tofacitinib induced the elevation of triglycerides in some patients. Phosphorylation flow cytometry revealed that tofacitinib inhibits the phosphorylation levels of STAT3 protein in Th17.1 cells in MG who received tofacitinib.

Conclusion: The study provided preliminary evidence of the safety and efficacy profile of tofacitinib in treating patients with refractory gMG. The therapeutic effect of Tofacitinib was probably associated with the inhibition of pro-inflammatory Th17.1 cells.

Disclosure: Nothing to disclose.

EPO-610 | Germinal centers are associated with the prognosis of thymoma-associated myasthenia gravis

H. Chung[1]; H. Shin[2]; S. Kim[2]

[1]*Department of Neurology, Yongin Severance Hospital, Yonsei University Health System, Yongin, Korea;* [2]*Department of Neurology, Yonsei University College of Medicine, Seoul, Korea*

Background and Aims: Some studies have observed that the presence of germinal centers (GCs) in the non-neoplastic thymic tissues play a part in the pathogenesis of thymoma-associated myasthenia gravis (TAMG). The aim of this study is to analyze whether the presence of GCs in the thymus of patients with TAMG are associated with clinical outcome of myasthenia gravis after removal of thymoma.

Methods: We conducted a retrospective analysis of TAMG patients who underwent surgical removal of the thymoma. Clinical characteristics were collected and thymic tissue slides were rereviewed by a pathologist. Patients were classified into GC-positive and GC-negative groups based on the presence of GC.

Results: Preoperative use of prednisolone is known to reduce the number of GCs, and the proportion of patients who were on preoperative prednisolone treatment was lower in the GC-positive group (Table 1) After excluding the patients with preoperative prednisolone use, a total of 83 patients with 37 (44.6%) in the GC-positive group and 46 (55.4%) in the GC-negative group were analyzed. The clinical differences between the two groups are presented in Table 2. Multivariate analysis using cox regression revealed a negatively significant between minimal manifestation and the presence of GCs (Table 3).

Table 1. Clinical and perioperative data of patients with thymoma associated myasthenia gravis with and without germinal centers in thymic tissue adjacent to the thymoma

Masaoka stage (III, IV)	1.544	0.607-3.924	0.362			
Postoperative therapy	1.023	0.562-1.862	0.941			
Thymoma recurrence	0.433	0.154-1.221	0.113			
Germinal center	0.466	0.265-0.855	0.014*	0.479	0.237-0.968	0.040*

Conclusion: Presence of GCs in the nonthymomatous tissue of TAMG patients was associated with greater disease severity and worse clinical outcome after thymectomy. The presence of thymic GCs could be used as a predictor of clinical outcome in patients with TAMG.
Disclosure: Nothing to disclose.

EPO-611 | Real world experience of Efgartigimod in a single UK centre – A 17 month follow up study

J. Spillane; N. Thambirajah; G. Logou; S. Sumaria; R. Howard; D. Kullmann
National Hospital for Neurology and Neurosurgery, Queen Square, UCLH NHS Foundation Trust, London, UK

Background and Aims: We present our experience of treating patients with generalised Myasthenia Gravis (gMG) with the neonatal Fc receptor (FcRN) antagonist Efgartigimod under the UK Early Access to Medicine Scheme (EAMs) in single centre over a 16 month period.
Methods: Data regarding all patients receiving Efgartigimod in the National Hospital for Neurology and Neurosurgery were collected prospectively. Efgartigimod was given as per the ADAPT protocol. Response to Efgartigimod was measured with MG-ADL scores, change in prednisolone dose and need for rescue therapies.
Results: 18 patients with gMG were treated with Efgartigimod over the 17 month period, 12 were female and the average disease duration was 14.6 years (range 1–40). 66% had required IVIG/PLEX regularly and 22% had required intermittent rescue treatment prior to starting Efgartigimod. All patients had previously received prednisolone and non-steroidal immunosuppressant therapies (NSITs). The average NSITs tried was 2.4. 50% had received Rituximab. The mean MG-ADL at baseline was 11.3. Following the first treatment cycle 89% were defined as MG-ADL responders with an average reduction of 7 points. Two patients stopped taking Efgartigimod due to lack of efficacy. 89% remained on it with a mean inter-cycle interval of 6.5 weeks. 83% of patients reduced their steroid doses. Rescue IVIG and PLEX were required in the two patients that stopped treatment but otherwise no rescue treatments were required Efgartigimod was well tolerated with only minor side effects reported.
Conclusion: Efgartigimod is an effective and well tolerated treatment in patients with refractory gMG.
Disclosure: JS received speakers fees, and travel support from UCB and argenx and has served on UCB advisory boards.

EPO-612 | Cyclic and continuous dosing of intravenous Efgartigimod for generalised myasthenia gravis: Part A of ADAPT NXT

K. Claeys[1,2]; V. Bril[2]; Y. Hussain[3]; K. Gwathmey[4]; G. Sahagian[5]; A. Habib[6]; E. Cortés-Vicente[7]; E. Brauer[8]; D. Gelinas[8]; A. Sumbul[8]; R. Jimenez[8]; D. Hristova[8]; R. Mantegazza[9]; A. Meisel[10]; S. Attarian[11]; ADAPT NXT Study Group[12]

Background and Aims: Individualised cyclic administration of efgartigimod, a human immunoglobulin G1 Fc-fragment that blocks the neonatal Fc receptor, was well tolerated and efficacious in the ADAPT/ADAPT+ phase 3 trials in generalised myasthenia gravis (gMG). In an effort to evaluate additional dosing regimens, the phase 3b ADAPT NXT study (NCT04980495) is investigating the efficacy, safety, and tolerability of 10 mg/kg intravenous efgartigimod administered in a cyclic (4 once-weekly infusions, 4-week intertreatment period) or continuous dosing regimen [every 2 weeks (Q2W)].

Methods: Adult participants with acetylcholine receptor antibody positive gMG who had MG-ADL total score ≥5 (with >50% of the score due to nonocular symptoms), and on a stable dose of ≥1 concomitant gMG treatment were recruited. Sixty-nine participants were randomised 3:1 on Day 1 to either continuous or cyclic dosing regimens for the initial 21-week comparison period (Part A; Figure). In Part B, participants in the cyclic arm received a final cycle before being rolled over to continuous Q2W dosing, while participants in the continuous dosing arm maintained Q2W dosing. Participants were followed for an additional 105-week extension period, and participants who maintained clinical improvement had the option to reduce dosing frequency to every 3 weeks.

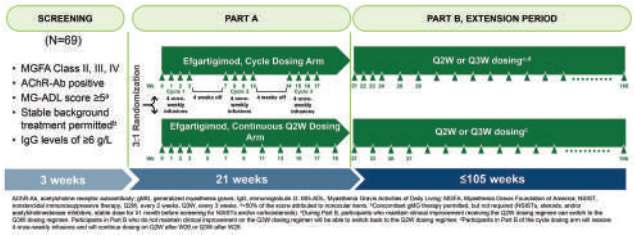

FIGURE ADAPT NXT study design.

Results: The primary endpoint is mean (SD) of the average change in MG-ADL total score from study baseline to Week 21 for each regimen. Safety, tolerability, and pharmacokinetic/pharmacodynamic effects are also being assessed; results will be presented at the congress.

Conclusion: ADAPT NXT will provide important efficacy and safety data on different treatment regimens in patients with gMG.

EPO-613 | Danon disease in Japan: A phenotype-genotype correlation

K. Sugie[1]; A. Uruha[2]; M. Yamaoka[1]; A. Yamanaka[1]; H. Shimizu[1]; Y. Nishimori[1]; T. Shiota[1]; H. Nanaura[1]; N. Eura[1]; I. Nonaka[3]; I. Nishino[3]

[1]Department of Neurology, Nara Medical University; [2]Department of Neurology, Tokyo Metropolitan Neurological Hospital; [3]Department of Neuromuscular Research, National Institute of Neurology, National Center of Neurology and Psychiatry

Background and Aims: Danon disease, an X-linked dominant vacuolar cardiomyopathy and skeletal myopathy, is caused by primary deficiency of lysosome-associated membrane protein-2 (LAMP-2). However, the clinical and genetic characteristics of Danon disease have not been well established.

Methods: We conducted a nationwide, questionnaire-based survey on Danon disease to 2,617 hospitals in Japan. We reviewed clinical histories, muscle specimens, and genetic analyses of the LAMP-2 gene in patients. We added patients newly found and reported since the national survey in Japan.

Results: As a result, we identified 47 Danon disease patients (23 men and 24 women) from 26 families. Hypertrophic cardiomyopathy and ECG abnormalities were documented in most patients with Danon disease. Among the 20 patients who had died, 19 (95%) died of cardiac failure or sudden cardiac arrest. Heart transplantation, the most effective therapy, was performed in only one woman and is just now required by 5 patients. Pathologically, all patients showed autophagic vacuoles with sarcolemmal features in muscles. In this study, 22 different LAMP-2 mutations were identified in 26 families with Danon disease. Half of the probands showed de novo mutations. The distribution of mutations widely ranged from exon 1 to 9. Four families with mutations in exon 9B (c.1097_1098 delAA) that encodes LAMP-2B showed markedly mild or no cardiomyopathy.

Conclusion: Cardiomyopathy is the most important prognostic factor and the main cause of death among Danon disease patients. However, clinical phenotypes of only mutations in exon 9B were markedly mild, suggesting that this particular mutation causes an exceptionally mild phenotype.

Disclosure: Nothing to disclose.

EPO-614 | Ventilatory function and sleep-disordered breathing in patients with facioscapulohumeral muscular dystrophy type 1

M. Lima; R. Rocha; S. Moreira

Serviço de Neurologia, Unidade Local de Saúde de Matosinhos, Matosinhos

Background and Aims: Facioscapulohumeral muscular dystrophy type 1 (FSHD1) is rarely associated with ventilatory dysfunction. The prevalence of sleep-disordered breathing (SDB) is thought to be high but remains poorly characterized and likely underestimated.

Methods: Observational study on demographic and clinical characteristics of adult FSHD1 patients.

Results: Twenty-nine patients were included, 52% males, with a mean current age of 49.6±15.7 years. The mean duration of disease was 26.8±16.4 years, with 5 (17%) patients showing childhood onset. The median Clinical Severity Score (CSS) was 3 (IQR=2.25–3). Twenty-four patients (83%) were able to walk unaided, 2 with unilateral support, 1 with bilateral support, and 2 were wheelchair-bounded. Respiratory function tests were conducted in 28 patients. Spirometric curves were normal in 20 (69%) patients, with a restrictive pattern in 4 (14%), and obstructive in another 4 (2 with a history of asthma). Patients with mild to moderate symptoms (CSS ≤3) showed higher mean forced vital capacity (FVC) than those with severe disease (CSS ≥3.5) ($p=0.01$). No correlation was found between respiratory function parameters (FEV1, FVC) and disease duration. Nine patients underwent maximal respiratory pressure studies, with altered results in 4, showing a tendency for greater compromise in expiratory pressures. Sleep studies were conducted in 27 patients, with 13 (48%) presenting sleep apnea syndrome, 6 of which requiring nocturnal non-invasive ventilation.

Conclusion: Our results support previous studies suggesting a high prevalence of SDB in FSHD1 patients. We would also like to emphasize the importance of an active search for ventilatory dysfunction in these patients, especially in more severe motor presentations.

Disclosure: Nothing to disclose.

EPO-615 | Clinical outcome measures in a prospective cohort of myasthenia gravis patients

M. Verza[1]; G. Spagni[2]; S. Falso[1]; S. Cornacchini[1]; E. Cencini[1]; L. Palazzo[1]; A. Farina[1]; A. Mariottini[1]; A. Barilaro[1]; L. Massacesi[1]; A. Evoli[3]; V. Damato[1]

[1]*Department of Neurosciences, Psychology, Drug Research and Child Health, University of Florence, Florence, Italy;* [2]*German Center for Neurodegenerative Diseases (DZNE) Berlin; Berlin, Germany;* [3]*Department of Neuroscienze, Università Cattolica del Sacro Cuore, Rome, Italy*

Background and Aims: Clinical assessment of myasthenia gravis (MG) relies on validated patient-reported outcome (PRO) and physician reported outcome (PhyRO) measures, coupled with post-intervention status (PIS) or the recently proposed "PASS question". The aim of this study is to validate the PASS question and assess PIS and PASS cut-off values for PRO and PhyRO scales in a prospective cohort.

Methods: The clinical status of AChR-MG patients was assessed with MG-ADL, MG-QOL15r and QMG scores over a 1 year-period. Favourable outcomes were defined by a positive response to the PASS question and a PIS of minimal manifestation (MM)-or-better. ROC curve analysis was used to determine cut-off values of the QMG, MG-ADL and MG-QOL15r in relation to PASS and PIS.

Results: 107 AChR-MG patients were included, of whom 42% females, with a median age at onset of 46 years. Patients with a favourable PASS and in MM-or-better status had a lower median QMG, MG-ADL, MG-QOL15 scores than symptomatic patients ($p<0.0001$). A QMG ≤9, MG-ADL ≤2 and MG-QOL15r ≤6 identified patients with a favourable PASS status. Same cut-offs for the QMG and MG-ADL scores were found to identify patients in MM-or-better, while the cut-off for the MG-QOL15r was much lower (≤4). In the multivariable logistic regression both MG-ADL ($p=0.025$) and MG-QOL15r ($p=0.043$) were independently associated with "PASS=yes", while QMG score was not.

Conclusion: PASS and PIS provide complementary information on the MG clinical status. The PASS cut-off values found for the most common MG scales support the use of the PASS question in clinical practice and clinical trials.

Ageing and dementia 4

EPO-616 | Alzheimer disease prognostic from early clinical assessment: A two-year follow-up study

L. Álvarez-Sánchez[1]; Á. Balaguer[2]; M. Peretó-Pamblanco[1]; C. Peña-Bautista[1]; L. Ferré-González[1]; M. Baquero-Toledo[3]; C. Cháfer-Pericás[1]

[1]*Alzheimer Disease Research Group, Instituto de Investigación Sanitaria La Fe; Valencia; Spain;* [2]*Math Faculty, Universitat de València, Valencia, Spain;* [3]*Division of Neurology; University and Polytechnic Hospital La Fe, Valencia, Spain*

Background and Aims: Alzheimer Disease (AD) evolution is characterized by high heterogenicity. Some patients show fast evolution, and further research is required. The aim of this study is to develop a prognostic model using clinical variables to detect patients at high risk of fast AD progression.

Methods: This observational study has been carried out in the Cognitive Disorders Unit in the Neurology Service of the Hospital Universitari i Politècnic La Fe (HULAFE). Participants were patients diagnosed with mild cognitive impairment (MCI) due to Alzheimer's

disease (AD) at time-1 (T1). For this, CSF biomarkers, and neuropsychological evaluation (CDR sum of boxes, MMSE, and RBANS) were obtained atT1. Two years after diagnosis (T2) the neuropsychological evaluation was repeated. From these data, a prognosis model for the probability of fast AD progression was developed using neuropsychological and CSF variables at T1 as predictor variables; and neuropsychological score (sum of the 3 tests) difference (T2-T1), as response variable.

Results: The developed model predicted the probability of fast progression, with an AUC of 0.79 (sensitivity 63.6% (95% CI 35.4–84.8); specificity 85.4% (95% CI 71.6–93.1); positive predictive value 53.8% (29.1–76.8); negative predictive value 89.7% (95% CI 76.4–95.9). Among the predictor variables, sex, CSF NfL and RBANS (language, immediate memory and visuospatial/constructional) could be relevant.

Conclusion: Some variables obtained from the MCI-AD diagnosis time (neuropsychology, CSF) could be helpful for detecting patients with a high risk of fast AD progression.

Disclosure: Nothing to disclose.

EPO-617 | Role of pro-inflammatory S100A9 protein in amyloid-neuroinflammatory cascade in neurodegenerative diseases

L. Morozova-Roche
Department of Medical Biochemistry and Biophysics, Umeå University

Background and Aims: The amyloid cascade and neuroinflammation are central to onset of Alzheimer's and other neurodegenerative diseases. S100A9 may serve as a critical link in the amyloid-neuroinflammatory cascade in these diseases, as this protein possesses both amyloidogenic properties and acts as alarmin, triggering inflammatory responses.

Methods: The kinetic analysis of amyloid aggregation by thioflavin-T fluorescence, microfluidic analyses, charge-detection mass-spectroscopy, AFM, molecular dynamic simulation and gamma-oscillation were used in synergy. The level of S100A9 in CSF was measured by ELISA and dot-blots.

Results: We found that S1009 is intrinsically amyloidogenic and forms amyloids in vitro, in cells and in the brain tissues during Alzheimer's, Parkinson's and traumatic brain injury. We showed that S100A9 co-assembles with Aβ42 fibrils, forming new type of hetero-amyloid complexes. In these complexes the autocatalytic surfaces of Aβ42 fibrils template S100A9 amyloids. The formation of Aβ42-S100A9 complexes may sequestrate smaller toxic species, which is consistent with finding that their co-aggregation mitigates amyloid cytotoxicity. Small molecules, regulating S100A9 amyloid aggregation, including cell penetrating NCAM1 peptides, oleuropein aglycone, Nb10 and TiNb9 polyoxometalates, cyclin and DOPA derivatives, are viewed in the light of their prospective therapeutic applications in blocking amyloid formation. We have shown also that the levels of S100A9 follow those of Aβ in CSF during the development of Alzheimer's and S100A9 together with Aβ can serve as a biomarker for early stages of Alzheimer's disease.

Conclusion: The finding of S100A9 involvement in neurodegenerative diseases may open a new avenue for therapeutic interventions targeting S100A9 primarily and via this pathway affecting the whole amyloid-neuroinflammatory cascade.

Disclosure: There is no conflict of interest in presented data.

EPO-618 | Effects of frailty on hospital outcomes among patients with neurological disorders: A cohort study

M. Toccaceli Blasi[1]; F. Raffaele[1]; D. Belvisi[1,2]; G. Bruno[1]; M. Canevelli[1,3]; G. Fabbrini[1,2]
[1]*Department of Human Neuroscience, "Sapienza" University, Rome, Italy;* [2]*IRCCS Neuromed, Pozzilli IS, Italy;* [3]*National Center for Disease Prevention and Health Promotion, Italian National Institute of Health, Rome, Italy; Aging Research Center, Karolinska Institutet and Stockholm University*

Background and Aims: Patients acutely presenting with neurological disorders exhibit highly heterogeneous clinical courses. We explored whether baseline frailty predicts adverse hospital outcomes among patients admitted to neurological wards.

Methods: All patients consecutively admitted to the neurology wards of the Policlinico Umberto I University Hospital of Rome (Italy) were considered. A 40-item Frailty Index (FI) was calculated from the emergency department assessment. Hospitalization outcomes were prospectively collected. Linear and logistic regression models were conducted to test the association between FI and adverse hospital outcomes.

Results: Overall, 185 participants (women 50.3%; mean age 68.6, SD 18.6 years) were enrolled. FI scores ranged between 0 and 0.43, with a median value of 0.15 (IQR 0.10–0.20), and were positively correlated with age (Spearman's rho 0.55, $p < 0.001$). In multivariate regression models adjusted by age, sex, and neurological diagnosis, the FI was significantly associated with the number of days spent in the neurological ward (B 2.19, 95% CI 0.36–4.02, per 0.1 increase; $p = 0.02$), with a lower likelihood of being discharged at home (OR 0.38, 95% CI 0.23–0.64, per 0.1 increase; $p < 0.001$), with higher odds of nosocomial infections (OR 1.55, 95% CI 1.00–2.42 per 0.1 increase; $p = 0.05$), prescription of antibiotics (OR 1.74, 95% CI 1.12–2.72, per 0.1 increase; $p = 0.01$) and sedatives (OR 1.84, 95% CI 1.04–3.29 per 0.1 increase; $p = 0.04$).

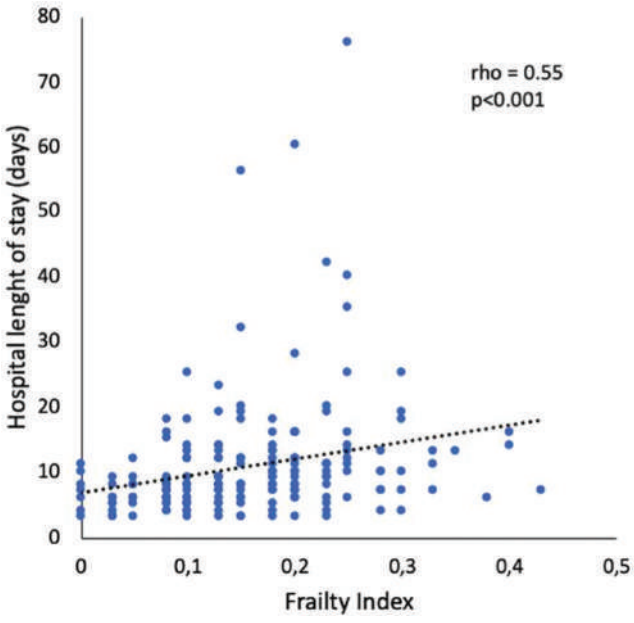
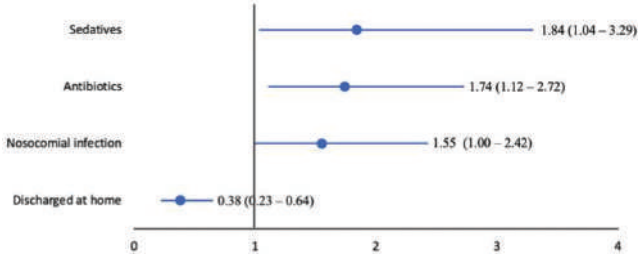
TOTAL			
FRAILTY INDEX (range 0-1)			

40-item Frailty Index.



Correlation between Frailty Index and hospital length of stay (days).



Bivariate logistic regression model adjusted by age, sex, and neurological diagnosis exploring the factors associated with the 40-item Frailty Index (dichotomized dependent variable of interest). Data are shown as odds ratios (95% confidence intervals).

Conclusion: Assessing the frailty status of patients with acute neurological conditions can improve prognostication. This can have relevant implications for care planning and allocation of healthcare resources.

EPO-619 | Cross-sectional and longitudinal associations between sTREM2 and synapses-related biomarkers in healthy individuals

M. Munoz Garcia[1]; Y. Deming[2]; S. Johnson[2]; S. Asthana[2]; C. Carlsson[2]; O. Okonkwo[2]; D. Perez-Martinez[3]; A. Villarejo[3]; K. Blennow[4]; H. Zetterberg[4]; B. Bendlin[2]; E. Morenas-Rodriguez[5]

[1]Group of Neurovascular Investigation, Research institute Hospital 12 de Octubre (imas12), Madrid, Spain; [2]Wisconsin Alzheimer's Disease Research Center, University of Wisconsin School of Medicine and Public Health, Madison, WI, USA; [3]Memory Unit, Department of Neurology, Hospital Universitario 12 de Octubre, Madrid, Spain; [4]Department of Psychiatry and Neurochemistry, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [5]Group of Neurogenerative Diseases, Hospital Universitario 12 de Octubre Research Institute (imas12), Madrid, Spain

Background and Aims: We aimed to study the association between TREM2-dependent microglial activation and synaptic dysfunction, and whether this relationship is influenced by AD core biomarkers in asymptomatic volunteers.

Methods: We studied cross-sectional ($n=239$) and longitudinal ($n=117$) associations between cleaved sTREM2 (cTREM2) and synapse-related biomarkers (neurogranin, alpha-synuclein and s100b) in cerebrospinal fluid (CSF) from asymptomatic volunteers. cTREM2 was measured by an in-house MSD-based immunoassay, while synapse-related and AD core markers were quantified by the Elecsys® platform (Neurotoolkit). We defined subgroups according to the AT classification, and medians of *p*-tau and Aβ42/Aβ40 ratio. We used R program (v-4.3.1) for statistical analysis.

Results: Cross-sectional associations are shown in table 1. Higher s100b levels were associated with higher cTREM2 levels independently of AD core biomarkers in participants with Aβ42/Aβ40 ratio < median, and in participants with *p*-tau levels >median. Higher

cTREM2 levels were also independently associated with higher alpha-synuclein levels in the T+ group, with a trend for an association in A+ participants. Higher baseline s100b levels independently predicted a larger longitudinal increase of cTREM2 (beta = 0.28, *p*-value = 0.03). Baseline cTREM2 levels were not associated with any synaptic biomarker longitudinally.

Model 1 adjusted by age and sex. Model 2 adjusted by age, sex, Aβ42 and PTAU.
Aβ42/Aβ40 median = [illegible]. The cut-off for amyloid (A) positivity according to the Aβ42/Aβ40 ratio is < [illegible].
P-tau median = [illegible] pg/mL. The cut-off for tau (T) positivity according to P-tau is > 24.8 pg/mL.

TABLE 1 Beta-coefficients and *p*-values for cross-sectional associations between synaptic biomarkers and cleaved TREM2 (cTREM2) in linear regression models.

Conclusion: cTREM2 is associated with s100b and alpha-synuclein in asymptomatic participants with a biomarker profile suggestive of first stages of Aβ-aggregation and tau pathology. Higher baseline levels of s100b predicts a larger longitudinal increase of cTREM2 in asymptomatic volunteers. Our findings suggest an early influence of synaptic dysfunction on the TREM2-dependent microglial response in neurodegenerative processes.

Disclosure: Nothing to disclose.

EPO-620 | Association of *Helicobacter pylori* infection and Alzheimer's disease risk – A meta-analysis of case-control studies

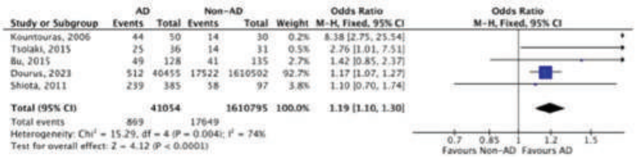
A. Menegaz de Almeida[1]; M. Reis[2]; E. Assis[3]; F. Machado[4]; J. Limongi[5]

[1]Department of Medicine, Federal University of Mato Grosso, Mato Grosso, Brazil; [2]Department of Medicine, National University of Rosario, Rosario, Argentina; [3]Department of Medicine, Baltic Federal University, Kaliningrad, Russian Federation; [4]Department of Medicine, State University of Southwest Bahia, Bahia, Brazil; [5]Department of Neurology, University of São Paulo, São Paulo, Brazil

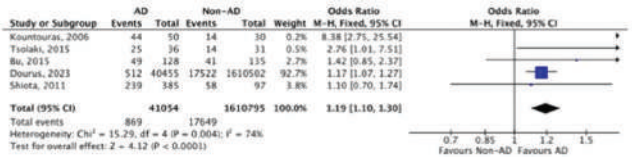
Background and Aims: Alzheimer's disease (AD) remains a challenge in public health due to the aging of the global population. The potential link between bacterial infections, specifically by Helicobacter pylori (HP), and the pathogenesis of AD is still unclear. Hence, we sought to explore the association between HP infection and AD.

Methods: MEDLINE, Embase, and Cochrane databases were systematically searched. Data were examined using the Mantel-Haenszel method, with Odds Ratio (OR) as the primary measure of association and 95% confidence intervals (CI). Heterogeneity was assessed using I^2 statistics. Statistical analysis were performed using Review Manager software, version 5.4.1.

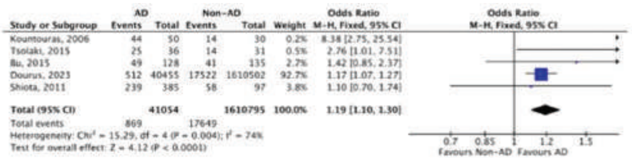
Results: A total of 1,651,849 patients from 5 population-based case-control studies were included in this analysis. Within these patients, 41.054 composed the case group of patients previously diagnosed with AD. In the AD group, 869 individuals were found to be positive for HP infection, meanwhile, in the non-AD group, this number was 17,649 individuals. Comparing the incidence of HP infection between both groups, statistically significant correlation was observed between AD and HP infection (2.11% vs 1.09%, OR. 1.19, 95% CI 1.10–1.30, $p < 0.01$, $I^2 = 74\%$).



Odds Ratio – Forest Plot.



Odds Ratio – Forest Plot.



Odds Ratio – Forest Plot.

Conclusion: In this meta-analysis, consistent results suggest that HP infection is associated with an increased odds for AD.

Disclosure: All authors declare no conflicts of interest and assume responsibility for data reliability and freedom from bias in presentation and interpretation.

EPO-621 | Combining a semantic cued recall paradigm with blood-based biomarkers in the detection of Alzheimer's disease pathology

M. Lima[1]; A. Silva-Spínola[2]; D. Damas[1]; D. Duro[1]; M. Leitão[2]; M. Tábuas-Pereira[1]; J. Durães[1]; I. Santana[3]; I. Baldeiras[3]

[1]Neurology Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [2]Center for Innovative Biomedicine and Biotechnology, University of Coimbra, Coimbra, Portugal; [3]Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background and Aims: Episodic memory impairment defined by the Free and Cued Selective Reminding test (FCSRT) is a reliable marker

of the early involvement of medial temporal structures in AD. Blood-based biomarkers (BBM) (*p*-tau181, NfL and GFAP) were developed for the diagnosis and prognosis of AD. We aim to study the association between FCSRT and BBM in detecting prodromal AD.

Methods: We included 70 non-demented individuals (66 years of median age, 67% female) with memory complaints and available cerebrospinal fluid (CSF)-AD biomarkers. Baseline and longitudinal neuropsychological evaluation were performed. Median follow-up duration was 8 months. BBM were determined using Single Molecule Array (SiMoA). Amyloid pathology was determined by amyloid status (A) using CSF Abeta42/40 ratio.

Results: In the comparison between A+ ($n=28$) and A- individuals ($n=42$), we observed significant differences in all the FCSRT-selected measures ($p<0.05$), except for FCSRT cued-delayed recall. Longitudinally, significant differences in the change of normative *z*-scores for MoCA and MPCR were shown ($p<0.001$). A+ individuals had significantly higher levels of serum GFAP and plasma *p*-Tau181. Additionally, multinomial logistic regression model, adjusted for age, identified blood *p*-Tau181 (B = 1.8, $p=0.002$), GFAP (B = 0.02, $p=0.008$) and NfL (B = −0.2, $p=0.01$) as independent significant predictors of amyloid status, particularly in relation to FCSRT free-delayed recall (B = −0.4, $p=0.006$).

Conclusion: This study shows the utility of a semantic and cued recall paradigm (FCSRT) for detecting AD at its prodromal stage, supporting its use as a valid clinic marker together with BBM. These results can now be used to develop individual predictive models of disease progression.

Disclosure: Nothing to disclose.

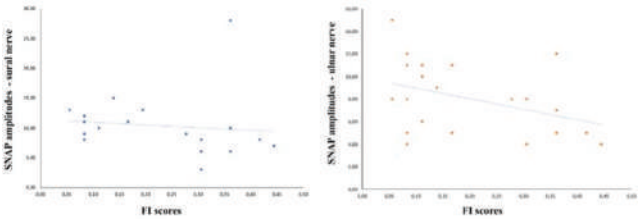
EPO-622 | Association between frailty and neurophysiological measures of peripheral nerve conduction

M. Salzillo; M. Canevelli; G. Di Stefano; G. Bruno; A. Truini
Department of Human Neuroscience, La Sapienza University of Rome

Background and Aims: Frailty is a marker of biological age and has been associated with a higher risk of adverse neurological outcomes. The present study aimed at investigating the association between frailty and neurophysiological measures of nerve conduction.

Methods: Patients with no peripheral nervous system disorders were subjected to a nerve conduction study at the Department of Human Neuroscience, Sapienza University of Rome. Frailty was assessed through a Frailty Index (FI), designed on the model of deficit accumulation and constituted by 36 items including symptoms, signs, disabilities, and laboratory findings. Spearman's correlations were used to conduct the statistical analysis.

Results: Overall, 25 participants (mean age 59.9, standard deviation [SD] 16.1; 64.7 % women) were recruited. SNAP amplitudes were significantly, inversely correlated with age (ulnar: rho = −0.48, $p=0.03$; sural: rho = −0.73, $p<0.001$). A negative correlation was also observed between SNAP amplitudes and FI scores (ulnar: rho = −0.09, $p=0.03$; sural: rho = −0.73, $p=0.06$). In partial correlations adjusted by FI, age was no longer correlated with the SNAP amplitude of the ulnar nerve (rho = −0.35, $p=0.18$); the correlation coefficient between age and the SNAP amplitude of the sural nerve decreased to −0.54, $p=0.03$.



Correlation between SNAP amplitude and sural and ulnar nerve.

Bibliography

Conclusion: The negative correlation between increasing age and measures of SNAP amplitudes seems to be partly moderated by frailty. The FI may be useful to explore the impact of the ageing process on peripheral nerve conduction, beyond chronological age.

Disclosure: Nothing to disclose.

EPO-623 | Quantitative T1-mapping changes in the gray matter of patients with Alzheimer's disease

M. Losa[1]; L. Gualco[1]; E. Peira[2]; B. Orso[1]; L. Argenti[1]; L. Lombardo[1]; D. Arnaldi[1]; N. Montobbio[3]; M. Sormani[3]; F. Massa[1]; A. Chincarini[2]; M. Costagli[1]; L. Roccatagliata[3]; M. Pardini[1]
[1]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DiNOGMI), University of Genoa, Genoa, Italy;* [2]*Istituto Nazionale di Fisica Nucleare (INFN), Genoa, Italy;* [3]*Department of Health Sciences (DISSAL), University of Genoa, Genoa, Italy*

Background and Aims: Structural MRI plays an important role in the diagnosis of Alzheimer's disease (AD) so that it is included in the A/T/N classification. However, structural changes occur late in the course of the disease and lack of a specific correlation with the underlying pathogenetic process. The purpose of our study is to analyze the role of brain quantitative T1-mapping as a possible index of AD pathology.

Methods: 27 AD patients and 22 healthy controls underwent an MR scan on a clinical 3T MR scanner with a protocol including an MP2RAGE sequence whose output include a set of 3D structural T1-weighted images and a coupled quantitative T1 map. 3D T1 images were then segmented using FreeSurfer obtaining segmentation masks of the brain that were used to extract regional quantitative T1 (qT1) values of the subjects' gray matter.

Results: Statistical analysis performed with a volume-corrected model (so corrected for regional atrophy) demonstrated a significant increase in qT1 values in regions known to be involved in AD. For example, hippocampi demonstrated significantly increased qT1 values ($p=0.0055$). Moreover, we found a significant difference in overall cortical values ($p=0.028$) primarily driven by parietal lobe ($p=0.0197$).

Conclusion: Our results demonstrate the presence of alterations in qT1 values in AD that do not seem to be justified by atrophy alone, suggesting in this way that other changes in the microscopic composition of the brain of these subjects can influence this MR-derived metric.

Disclosure: Nothing to disclose.

EPO-624 | Cerebral amyloid angiopathy in the basal ganglia and brainstem in routine autopsies

Okamoto[1]; M. Amari[1]; M. Ikeda[1]; T. Fukuda[2]; K. Suzuki[2]; M. Takatama[3]

[1]Department of Neurology, Geriatrics Research Institute and Hospital, Maebashi, Japan; [2]Department of Pathology, Geriatrics Research Institute and Hospital, Maebashi, Japan; [3]Department of Internal Medicine, Geriatrics Research Institute and Hospital, Maebashi, Japan

Background and Aims: Previously, we confirmed that cerebellar CAA was observed in 29 cases (48.3%), and the severity of cerebellar CAA was relatively mild compared with 60 cases with CAA-positive occipital lobe. On the other hand, CAA are said a few in the basal ganglia and brainstem, but the frequency and severity of CAA in the basal ganglia and brainstem are obscure.

Methods: We selected 54 cases with CAA observed in the occipital lobe. Analyses were performed on the occipital lobe, cerebellum, basal ganglia, and brainstem. Brain sections were mainly immunostained with monoclonal amyloid β (Aβ) peptides 17–24 (4G8) and monoclonal anti-phosphorylated tau (AT8) antibodies.

Results: Of the 54 cases, CAA was observed in the basal ganglia and brainstem in 13 cases (24.1%). In the basal ganglia, CAA was rarely or slightly observed in the claustrum, putamen, and thalamus in 10 cases, with no evidence of CAA in the pallidum. In the putamen and thalamus, Aβ deposits were mainly located in the abdominal portions of the tunica media and adventitia of the vessels. In the brainstem, two cases showed rare CAA in the midbrain. In five cases, CAA was only rarely observed in the meningeal vessels of the brainstem.

Conclusion: These findings suggest that CAA initially develops in the leptomeningeal and cortical vessels of the neocortex, followed by the vessels of cerebellum, and then vessels of the putamen, thalamus, and brainstem.

Disclosure: Nothing to disclose.

EPO-625 | Performance and concordance of plasma versus CSF biomarkers of Alzheimer's disease: A single center Memory Clinic cohort

M. Poli[1]; C. Bonomi[1]; M. Nuccetelli[2]; S. Bernardini[2]; C. Motta[1]; A. Martorana[1]

[1]UOSD Centro Demenze, Department of Systems Medicine, University of Rome "Tor Vergata", Rome, Italy; [2]Department of Experimental Medicine, University of Rome "Tor Vergata", Rome, Italy

Background and Aims: Cerebrospinal fluid (CSF) for Alzheimer's disease (AD) comes with several limitations, namely relative invasiveness, restricted access and high costs, hence the recent focus on plasma biomarkers. Previous studies identified a good accuracy of plasma phosphorylated-tau181 (plasma/*p*-tau181) and plasma amyloid ratio (plasma/amyR, Aβ42/Aβ40) to identify patients with biologically-defined AD. We addressed their use in clinical practice, verifying their performance accounting for possible confounders, such as renal function (serum creatinine) and blood-brain barrier permeability (Albumin Quotient), and concordance with CSF biomarkers.

Methods: We enrolled 99 patients with CSF and plasma AD biomarkers, measured using fully-automized CLEIA (Fujirebio LUMIPULSE® G1200). Patients were stratified into CSF/A+T+ ($n=45$, CSF Aβ42/Aβ40 < 0.06, CSF/*p*-tau181 > 55 pg/ml) or CSF/non-A+T+ ($n=54$). We evaluated accuracy, sensitivity and specificity of pathological plasma/*p*-tau181 (>2.01 pg/ml), plasma/amyR (<0.083) and these combined (plasma/A+T+) in differentiating CSF/A+T+ vs CSF/non-A+T+, as well as inter-test reliability (Cohen's K).

Results: Plasma/*p*-tau181 showed good sensitivity (82.22%), specificity (87.041%) and agreement with CSF/A+T+ status ($K=0.694$); plasma/amyR had lower sensitivity (57.78%), good specificity (81.48%) and modest agreement ($K=0.399$); plasma/A+T+ had the overall best sensitivity (94.44%), but low specificity (51.11%) and moderate agreement ($K=0.472$). The multivariate logistic regression highlighted that both pathological plasma/*p*-tau181 and plasma/amyR are strongly associated with CSF/A+T+ (respectively OR = 31 and OR = 6; $p<0.001$), additionally when adjusting plasma/*p*-tau181 for creatinine levels (OR = 32) and amyR for Albumin Quotient (OR = 7.7).

Conclusion: Our findings confirm plasma/*p*-tau181 as the most reliable stand-alone predictor of AD. Moreover, renal function and measures of blood-brain barrier permeability should be considered in order to improve the consistency of plasma biomarkers in clinical practice.

Disclosure: Nothing to disclose.

EPO-626 | Synthesis and evaluation of ketoamide derivatives in modulating amyloid beta aggregation for Alzheimer's disease therapy

R. Kumar[1]; B. Das[2]; A. Baidya[2]; L. Wang[1]; B. Winblad[1,3]
[1]*Department of Pharmaceutical Engineering & Technology, Indian Institute of Technology (BHU), Varanasi, India and Department of Neurobiology, Care Sciences and Society, Division of Neurogeriatrics, Karolinska Institutet, Solna, Sweden;* [2]*Department of Pharmaceutical Engineering & Technology, Indian Institute of Technology (BHU), Varanasi, India;* [4]*Theme Inflammation and Aging, Karolinska University Hospital, Huddinge, Sweden*

Background and Aims: The prevalence of Alzheimer's disease (AD), a multifactorial disorder, is on the rise, and the absence of effective therapies necessitates the discovery of novel treatment options. Previous attempts at target-based therapeutics for AD have faced challenges, but recent successes in amyloid beta-targeted immunotherapies have inspired new approaches. Motivated by recent advancements, in this study, we aimed to design and develop amyloid beta aggregation inhibitors with an α-ketoamide scaffold. Specifically, we synthesized a series of piperazine and piperidine-substituted ketoamide derivatives and further evaluated them for their potential in modulating amyloid beta aggregation.
Methods: The piperazine and piperidine-substituted ketoamide derivatives were synthesised in high purity and high yield using an appropriate chemical methodology and structurally characterized using NMR spectroscopy and mass spectrometry. Further, the synthesized compounds were subjected to in vitro evaluation for their potential to modulate the aggregation of amyloid beta 42 (Aβ42) using ThT-based aggregation kinetic assays.
Results: The percentage purity for all the compounds was >95. Among all the synthesized compounds, three compounds demonstrated a significant delay in amyloid beta aggregation, as evidenced by the aggregation kinetics assay.
Conclusion: Our findings highlight the potential of the α-ketoamide derivatives as promising hit compounds for further development into lead candidate for modulating the Aβ42 aggregation activity which is relevant to Alzheimer's disease treatment.
Disclosure: The authors declare no conflict of interest.

EPO-627 | Survival analysis in patients with early-onset frontotemporal lobar degeneration

M. Šarčević[1]; T. Stojković[2]; G. Mandić Stojemnović[2]; A. Živković[1]; P. Aleksić[1]; V. Kostić[2]; E. Stefanova[2]
[1]*Neurology Clinic University Clinical Center of Serbia;* [2]*Neurology Clinic University Clinical Center of Serbia, Medical Faculty University of Belgrade*

Background and Aims: The survival rate of patients with early onset FTLD is still undefined. The aim of this study is to determine the survival rates of FTLD behavioral variant (FTLDbv) and primary progressive aphasia (FTLDppa), and to identify clinical and demographic factors that influence it.
Methods: We included 82 patients, 61 with FTLDbv and 21 FTLDppa, observed from 2012 to 2019. Kaplan-Meier curve and Cox proportional hazard models were used for survival analysis with time from diagnosis to outcome (death or 2019y.) as independent variable.
Results: The mean age at diagnosis in the FTLDbv group was 55.36 ± 7.34 y, with 55.7% males, and 58.3 ± 5.8 y in FTLDppa group, with 47.6% men. In total 53 patients died (32 FTLDbv, 21 FTLDppa). The median survival in the FTLDbv group was 7 y. Age, age at onset, time from symptoms to diagnosis, MMSE and FAB scores were estimated, none of which influenced survival in these patients. Only the presence of motor symptoms (oculomotor disorders, dysphagia) shortened the lifespan of these patients ($p = 0.002$, median survival 3.75 y in group with, and 8 y without motor symptoms). Median survival in the FTLDppa group is 4.5 y, and older age ($p = 0.03$, median survival 5.5 y for younger, and 4 y for older patients) as well as older age at onset ($p = 0.03$, median survival 5.5 y in group below 60, and 3.75 y in group beyond 60) influenced survival in these patients.
Conclusion: Presence of motor symptoms is a clear indicator of faster progression of FTLDbv patients, while older age at onset shortens lifespan of FTLDppa early onset patients.
Disclosure: Nothing to disclose.

EPO-628 | MRI-guided brain stimulation with TPS ameliorates cognitive deficits and depressive symptoms in Alzheimer's disease (AD)

U. Sprick[1]; A. Günes[1]; M. Köhne[2]
[1]*Department of Neurostimulation Alexius/Josef Clinic, Neuss, Germany;* [2]*Alexius/Josef Clinic, Neuss, Germany*

Background and Aims: No effective long-term treatment has been found for the treatment of AD so far. MRI-guided TPS (Transcranial Pulse Stimulation) offers new perspectives to ameliorate AD-deficits. Pilot studies show beneficial effects on learning and memory of TPS.
Methods: 21 out-patients with AD (with light to moderate symptoms) received MRI-guided 6.000 pulses of TPS (0.2 mJ/mm^2 per single pulse, with a frequency of 4 Hz) per session bilaterally into the frontal, parietal and temporal cortex with Neurolith by Storz Medical. TPS-pulses were administered. Pulses were applicated over a period of 2 weeks (3 sessions per week). Cognitive capabilities (especially executive functions) of the patients were tested using the Stroop-Test (colour-word-interference-test) and the CERAD. Patients were tested using a pre – post design (t0 pre stimulation: t1 after 6 sessions, two weeks later).
Results: TPS-stimulation over a period of two weeks (6 sessions) showed ameliorating effects on performance in the Stroop-Test (pre vs. post; $p < 0.05$ – paired *T*-test). Single patients showed extraordinary improvements by shortening completer times in the Stroop-Test by half. Depressive symptoms of the patients were also

ameliorated. The BDI measured before and after the treatment diminished form 18.1 to 12.4 in the mean. No significant side-effects occurred during all the sessions in none of the patients.

Conclusion: The results of this pilot-trial show that cognitive impairments of executive functions and depressive symptoms in Alzheimer's disease may be ameliorated using TPS as a noninvasive brain stimulation method. No severe side-effects were observed.

Disclosure: The authors have no conflicts of interests to disclose.

EPO-629 | Disentangling empathy impairment along Alzheimer's disease continuum

[1]SOD Neurologia I, Dipartimento Neuromuscolo-Scheletrico e degli Organi di Senso, AOU Careggi, Florence, Italy; [2]Department of Neuroscience, Psychology, Drug Research and Child Health, University of Florence, Florence, Italy; [3]Regional Referral Centre for Relational Criticalities – Tuscany Region, Italy; [4]IRCCS Fondazione Don Carlo Gnocchi, Florence, Italy; [5]Nuclear Medicine Unit, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

Background and Aims: Little is known about empathy changes from the early stages of Alzheimer's Disease (AD). The aim of this study is to investigate empathy from Subjective Cognitive Decline (SCD) to Mild Cognitive Impairment (MCI) and AD dementia (AD-d).

Methods: Forty-five SCD, 83 MCI and 80 AD-d patients were included. Empathy was assessed by Interpersonal Reactivity Index (IRI) rated by caregivers before (T0) and after (T1) cognitive symptoms' onset. IRI was also self-administered to SCD patients. Facial emotion recognition was assessed by Ekman-60 Faces Test. Patients underwent CSF biomarkers analysis and cerebral FDG-PET SPM analysis.

Results: PD scores significantly increased from T0 to T1 in SCD, MCI and AD-d ($p<0.001$), while PT scores decreased in MCI and in AD-d ($p<0.001$). SCD AP+ showed a greater increase in PD scores over time (ΔPD T0-T1) than SCD AP- ($p<0.001$). SCD self-reported PT scores were lower than those of general Italian population (14.94±3.94, 95% C.I. [13.68–16.20] vs 17.70±4.36, 95% C.I. [17.30–18.10]). In AD continuum (SCD AP+, MCI AP+, AD-d), a positive correlation was detected between PT-T1 and brain metabolism in left posterior cingulate gyrus, precuneus and right frontal gyri; a negative correlation was found between ΔPT and brain metabolism in bilateral posterior cingulate gyri.

Table about descriptives and graphs.

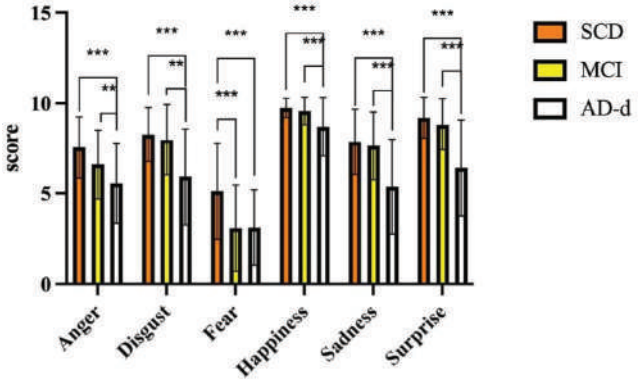

Table about descriptives and graphs.

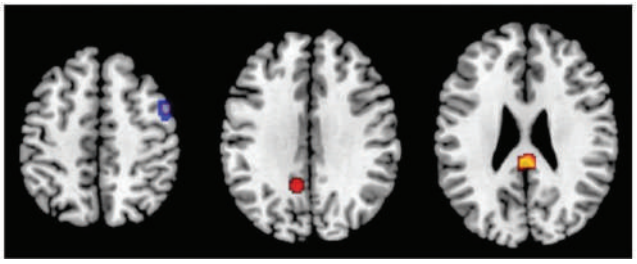


SPM analysis.

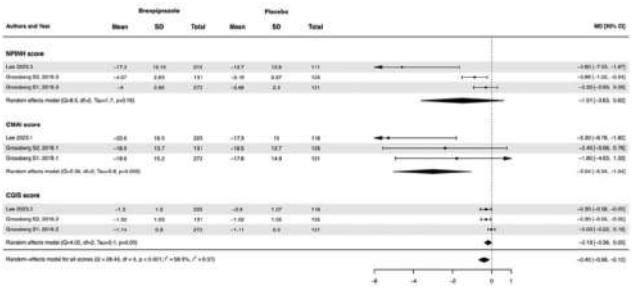
Conclusion: PT may be subtly involved since the preclinical phase of AD. Changes over time of PD are influenced by the underlying

Alzheimer's pathology and could potentially serve as an early AD neuropsychological marker.
Disclosure: Nothing to disclose.

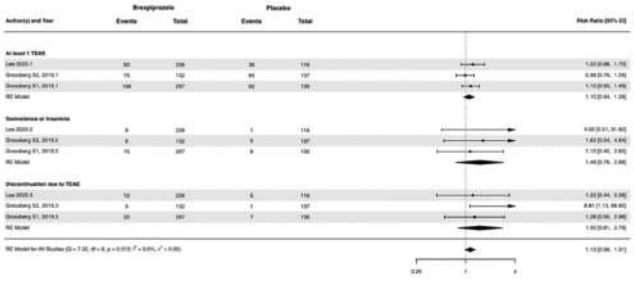
EPO-630 | Brexpiprazole for agitation in Alzheimer's disease: A systematic review and meta-analysis of randomized controlled trials

Z. Bakir[1]; R. Sudo[2]; M. Gobbo[3]
[1]*Department of Medicine, Sapienza University of Rome, Italy;* [2]*Department of Medicine, Federal University of Grande Dourados, Brazil;* [3]*Department of Medicine, Pontifical Catholic University of Rio Grande do Sul, Brazil*

Background and Aims: Agitation in Alzheimer's disease (AD) requires effective and well-tolerated interventions. Recently, Brexpiprazole has emerged as a promising therapeutic avenue.
Methods: We systematically searched ClinicalTrials.gov, PubMed, Embase, and Cochrane Library for randomized controlled trials (RCT) comparing Brexpiprazole to placebo in patients with AD presenting with agitation. A random-effects model was employed to compute mean differences and risk ratios using R software 4.3.1. The results were reported following the PRISMA guideline.
Results: A total of 3 double-blind RCTs were included, comprising 1,028 patients with an average age of 74 years. Throughout a 12-week mean follow-up period, Brexpiprazole was associated with no changes in Clinical Global Impression-Severity of illness (MD −0.19; 95% CI −0.38 to 0.00; $p=0.05$) and Neuropsychiatric Inventory-Nursing Home scores (MD −1.51; 95% CI −3.63 to 0.62; $p=0.16$). However, there was a notable improvement in Cohen-Mansfield Agitation Inventory score (MD −3.04; 95% CI −5.04 to −1.04; $p<0.01$). Additionally, no difference was observed for the incidence of at least 1 treatment-emergent adverse events (TEAE) (RR 1.10; 95% CI 0.94 to 1.28; $p=0.52$), discontinuation due to TEAE (RR 1.50; 95% CI 0.81 to 2.78; $p=0.20$), dizziness (RR 1.04; 95% CI 0.52 to 2.11; $p=0.86$), extrapyramidal disorders (RR 2.60; 95% CI 0.44 to 15.40; $p=0.99$), and all-cause death (RR 1.51; 95% CI 0.25 to 8.94; $p=0.48$)



Change in the Agitation Scores.



Adverse Events.

Conclusion: In this systematic review and meta-analysis of 3 RCTs and 1,028 patients, Brexpiprazole was associated with a modestly favorable modulation in agitation score, concurrent with a positive safety profile.
Disclosure: Nothing to disclose.

Child neurology/developmental neurology

EPO-631 | Neuroplasticity in children post-war trauma: A critical review of prefrontal, amygdaloid, and hippocampal alterations

R. Grace[1]; M. Polestino[2]; B. Carr[3]
[1]*College of Medicine, University of Florida, Gainesville, FL, USA;* [2]*College of Liberal Arts and Science, University of Florida, Gainesville, FL, USA;* [3]*Department of Psychiatry, University of Florida College of Medicine, Gainesville, FL, USA*

Background and Aims: This literature review endeavors to amalgamate current understanding of the impact of war trauma on neuroplasticity in children, with a specific focus on the prefrontal cortex, amygdala, and hippocampus. It examines the intricate interplay between these brain regions and their role in the cognitive, emotional, and behavioral development of traumatized children, elucidating how trauma-induced alterations in these areas contribute to various psychological disorders.
Methods: A comprehensive analysis of peer-reviewed journals was conducted, emphasizing neuroimaging studies (MRI and fMRI) that reveal changes in brain volume, activity levels, and functional connectivity in the prefrontal cortex, amygdala, and hippocampus. Attention was given to studies showcasing the effects of trauma on the developmental trajectory of these brain regions, including both adaptive and maladaptive neuroplasticity.
Results: The review delineates significant neuroplastic changes in the prefrontal cortex, amygdala, and hippocampus of children exposed to war trauma. It highlights a reduction in prefrontal cortex volume, associated with impaired decision-making and emotion regulation; amygdala hyperactivation, linked to increased anxiety and stress responses; and hippocampal volume reduction, correlated with memory impairments and altered stress regulation. Additionally, it discusses variations in neuroplastic responses based on the age at which trauma was experienced.
Conclusion: This review integrates diverse findings to provide a nuanced understanding of the neuroplastic changes in children

following war trauma, underscoring the critical need for specialized therapeutic interventions. These insights are pivotal for developing strategies to mitigate the long-term psychological and neurobiological impacts of such trauma, with a view towards fostering resilience and recovery in affected children.

Disclosure: Nothing to disclose.

EPO-632 | Clinical, humanistic, and economic burden of Rett syndrome: A systematic review

D. May[1]; M. Gill[2]; M. Arregui[3]; S. Cadarette[2]

[1]*Acadia Pharmaceuticals, San Diego, CA, USA;* [2]*Xcenda L.L.C, part of Cencora, Conshohocken, PA, USA;* [3]*Xcenda GmbH, part of Cencora, Hannover, Germany*

Background and Aims: Rett syndrome is a rare neurodevelopmental disorder characterized by severe functional impairment. A systematic literature review was conducted to examine the clinical, humanistic, and economic burden associated with Rett syndrome and its treatment.

Methods: Literature from relevant databases (through June 2023), recent congress proceedings, and clinical trial registries was reviewed. References were independently screened by two authors. Predefined outcomes from highly relevant publications were extracted and validated.

Results: Data were extracted from publications reporting on clinical ($n = 40$), humanistic ($n = 32$), and cost/healthcare resource use ($n = 11$) outcomes (Figure 1). Only 7 trials designed to assess treatment effect on clinical severity or other key components of Rett syndrome specified a primary endpoint (Table 1). Trofinetide led to significant improvement of the co-primary endpoints. Dextromethorphan polistirex led to a significant improvement in some clinical outcomes though the primary endpoint was not met. Mixed findings, including life-threatening safety concerns, were reported with glatiramer acetate. Mecasermin was associated with symptom worsening. Across humanistic outcomes, physical functioning and physical component quality of life scores were generally low while caregiver burden was high. Direct costs and healthcare resource utilization were high in the few studies reporting these outcomes.

Conclusion: Rett syndrome is associated with significant challenges including limited functional abilities for those affected, substantial cost, and caregiver burden. Several potential treatments have been studied but only trofinetide has been evaluated in a phase 3 trial and been approved in the US. Future research should consider the impact of this approval on the burden associated with Rett syndrome.

Disclosure: DM is employed by Acadia Pharmaceuticals Inc. MG, MA, and SC are employed by Cencora which received funds from Acadia Pharmaceuticals to support this research.

Table 1. Key results from studies designed to assess treatment effect on clinical severity or other key components of Rett syndrome with a specified a primary endpoint

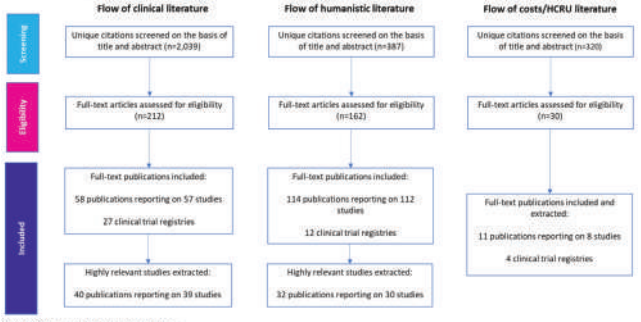
Intervention vs comparator	Trial phase	N	Primary outcome	Primary results reported by authors	Key clinical findings[a]
Trofinetide vs placebo	Phase II	82	Safety and PK	No significance testing reported; "All dose levels were well tolerated and generally safe"	Significantly improved Rett-specific global function and general global function
Trofinetide vs placebo	Phase III	187	Co-primary endpoints: RSBQ total score (change from baseline to week 12) and CGI-I score at week 12	Significant improvement for both co-primary endpoints	Significantly improved Rett-specific global function, general global function, and cognition/communication/psychosocial outcomes
Mecasermin vs placebo	Phase II	30	ADAMS Social Avoidance subscale, RSBQ Fear/Anxiety subscale, PTSVAS top three concerns, CGI-EI, PGI-EI, and the Kerr (overall) severity scale	The Kerr severity scale, ADAMS Depressed Mood subscale, Visual Analog Scale Hyperventilation, and delta average power change scores significantly increased, implying worsening of symptoms	Significantly worse Rett-specific global function and cognition/communication/psychosocial outcomes
Glatiramer acetate vs baseline	Phase II	10	Gait velocity	Gait velocity improved significantly from baseline.	Significantly improved ADLs and cognition/communication/psychosocial outcomes
Glatiramer acetate (no comparator)	Phase II	14	Safety and tolerability of the treatment as well as decrease in epileptiform activity as recorded in a 24-hour electroencephalograph	Terminated due to life-threatening safety concerns; prespecified outcomes not assessed	
Fingolimod vs baseline	Phase I/II	6	Efficacy: change in levels of BDNF in serum/CSF (cerebrospinal fluid) and change in deep gray matter volumes (thalamus, caudate, putamen, pallidum, hippocampus, amygdala and accumbens) measured by MRI. Safety: white blood cell/lymphocyte counts, liver enzymes, and occurrence of any (serious) adverse events	Primary outcome measures were not met	No significant changes
Dextromethorphan polistirex vs baseline	Phase II	38	Spike activity	There was no difference in the distribution of spike counts across doses for either visit 1 or 2 and no significant changes in spike count between the 2 visits for each dose	Significantly improved cognition/communication/psychosocial outcomes

Key: ADAMS – Anxiety, Depression, and Mood Scale; ADLs – activities of daily living; BDNF – brain-derived neurotrophic factor; CGI-EI – Clinical Global Impressions – Efficacy Index; CGI-I – Clinical Global Impressions – Improvement; CSF – cerebrospinal fluid; MRI – magnetic resonance imaging; N – sample size; PGI-EI – Parent Global Impression – Efficacy Index; PK – pharmacokinetics; PTSVAS – Parent Targeted Symptoms Visual Analog Scale; RSBQ – Rett Syndrome Behavior Questionnaire

[a] Key clinical findings summarizes primary outcomes as well as other clinical outcomes including Rett-specific function, general global function, activities of daily living, and cognition/communication/psychosocial outcomes

Blue – Significant benefit for intervention assessed compared to control/placebo or baseline; Grey – No significant differences for treatment compared to control/placebo or baseline; Red – Significantly worse results for the intervention assessed compared to control/placebo or baseline; No shading – Significance not assessed.

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow of literature diagrams for clinical, humanistic, and costs/HCRU outcomes.



Key: HCRU – healthcare resource use.

All publications meeting the population, interventions, comparators, outcomes, study design (PICOS) criteria were included. Data extraction was completed for highly relevant studies defined as clinical studies evaluating treatment effect as the primary objective and humanistic studies reporting utility values, lost work productivity due to caregiving, or validated QoL measures.

EPO-633 | Parsonage-Turner disease due to SEPTIN9 mutation: First report of an Italian family

F. Germano[1]; L. Bosisio[2]; M. Cataldi[3]; M. Grandis[4]; B. Tappino[5]; M. Traverso[6]; C. Solaro[1]; L. Nobili[2]; C. Fiorillo[2]

[1]*Neurology Unit, E.O. Ospedali Galliera, Genoa, Italy;* [2]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health Department of Neuroscience (DINOGMI), University of Genoa, Italy;* [3]*Child Neuropsychiatry Unit, IRCCS G. Gaslini Institute, Genoa, Italy;* [4]*Neurology Clinic, IRCCS, Ospedale Policlinico San Martino, Genova, Italy;* [5]*Central Laboratory of Analysis, IRCCS G. Gaslini Institute, Genoa, Italy;* [6]*UOC Medical Genetic, IRCCS G. Gaslini Institute, Genoa, Italy*

Background and Aims: Parsonage Turner disease is a neuralgic amyotrophy (NA) of the brachial plexus including idiopathic and rare hereditary forms (HNA). SEPTIN9-associated mutations have been involved. We report a HNA Italian family carrying a missense variant and reviewed related literature.

Methods: We provide clinical, electrophysiologic and genetic data of an 8-year-old girl with an HNA heterozygous pathogenic variant of SEPTIN9-gene and her affected father. A PubMed search was performed for cases of neurological diseases associated with SEPTIN9-mutations.

Results: A 6 years Italian girl with normal development came to our institute for pain in both shoulders with scapular girdle asymmetric hypotrophy, hyposthenia and hypotonia and dysmorphic features (hypotelorism, neck skin folds). No abnormalities were detected on NCS (nerve-conduction-study). After two years no more episodes of limbs pain were reported. NCS/EMG were repeated showing only chronic denervation signs. A closer look at the family history revealed that the child's father suffered from two episodes of transient upper-limbs pain/weakness in the past. Genetic test showed a heterozygous SEPTIN9-gene variant (c.262C>T;p.Arg88Trp) inherited from her father. We reviewed 107 subjects (49M, 58F)

Figure 1: A: dysmorphic features, hypotelorism, shortened palpebral fissures, epicanthal fold , long nasal bridge and neck skin folds; B,C: neuromuscular clinical finding, winged scapula, sloped shoulder and reduction of muscle strength in the right upper girdle.

Dysmorphic features.

General Data		
	Mean	Range
Age disease onset (years)	13	8 - 40
Age disease diagnosis (years)	35	03 - 2,5
Male	49	
Female	60	
HNA diagnosis	107/109	
CMT diagnosis	2/107	
Clinical Data		
Monophasic disease course	3/22	
Relapsing-remitting disease course	19/22	
Progressive disease course	1/22 (included CMT)	
Acute motor signs (upper limbs)	24/31	
Acute pain (upper limbs)	18/31	
Acute sensitive sings (upper limbs)	12/31	
vocal cords involvement	7/31	
Lower limbs involvement	1/31 (included CMT)	
Residual neurological sign	13/20	
NCS/EMG		
Axonal and demyelinating neuropathy	7/14	
Denervation	1/14	
Axonal neuropathy	1/14	
Brachial plexopathy (unclear whether diagnosed by NCS or EMG)	1/14	

Table 1: General, clinical and neurophysiological findings of the 109 SEPTIN9 patients included in our literature review.

with SEPTIN9-mutations (Three missense mutations and several SEPTIN9-gene duplications); symptoms onset 13 years, time onset-diagnosis 22 years. Typical NA features were founded.

Dysmorphic Features	
	N. of Subjects
Hypotelorism	32
Skin folds of the neck or arms	11
Short stature	10
Microstomia	7
Epicanthal folds	5
Small and shaped ears	3
Cleft palate	2
Nasal cysts	2
Blepharophimosis	2
Thin, downward sloping eyebrows	2
Ptosis	2
Low-positioned ears	2
Micrognathia	1
Finger furrows	1
Cleft uvula	1
Narrow face	1
Pectus excavatum	1
SEPTIN9 finding	
c.262C>T (p.Arg88Trp)	68/109
Gene Duplications	29/109
c.278 C>T (p.Ser93Phe)	1/109
c.-121G>C	2/109
c.140C>C (p.Val48Ala)	2/109 (CMT)

Table 2: Dysmorphic and genetic features of the SEPTIN9 cohort included in our review.

Conclusion: To the best of our knowledge, this is the first case of SEPTIN9-gene mutation associated with an HNA phenotype in an Italian family. The reported subjects' phenotypes don't appear related to the mutation type. Clinicians should consider HNA diagnosis in children with family history of upper-limbs neuralgia and dysmorphic features in order to improve long-term clinical outcome.

Disclosure: No disclosure.

EPO-634 | Sex-specific gut microbiome changes in a novel mouse model of autism

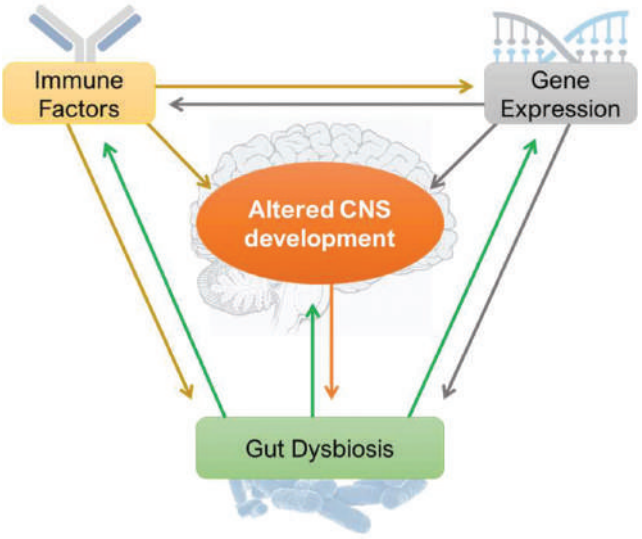
G. O'Byrne[1]; C. Fernando[2]; M. Quartey[1]; R. Heistad[1]; J. Hill[2]; D. Mousseau[1]

[1]Cell Signalling Laboratory, Department of Psychiatry, University of Saskatchewan, Saskatoon, Canada; [2]Western College of Veterinary Medicine, University of Saskatchewan, Saskatoon, Canada

Background and Aims: A bidirectional relationship has been demonstrated between the gut microbiome and the central nervous system. Though this field of study is still nascent, the so-called 'Gut-Brain Axis' (GBA) has been implicated as a major factor in neurological and psychiatric disease. TgsAPPα mice, which carry the transgene for human soluble amyloid precursor protein alpha, exhibit behavioral, neurochemical, and immunological phenotypes analogous to Autism Spectrum Disorder (ASD).

Methods: To further investigate the relationship between ASD and the GBA, we profiled the gut microbiomes of 3-month old heterozygous TgsAPPα mice and age- and sex-matched wildtype littermates, using cpn60 barcode sequencing.

Results: Pooled male and female data revealed differences in the proportional abundances of Bacteroides coprophilus, Pseudoflavonifractor capillosus, Bacteroides caecimuris, and Akkermansia muciniphila between TgsAPPα and wildtype groups. Stratifying the data for sex revealed a decrease in the proportional abundance of Prevotella dentalis, Lachnoanaerobaculum umeaense, and Clostridium amygdalinum in TgsAPPα males (cf. wildtype males) and an increase in the abundance of Flavonifractor sp. in TgsAPPα females (cf. wildtype females). The proportional decrease of Akkermansia muciniphila observed was maintained in TgsAPPα mice, regardless of sex.



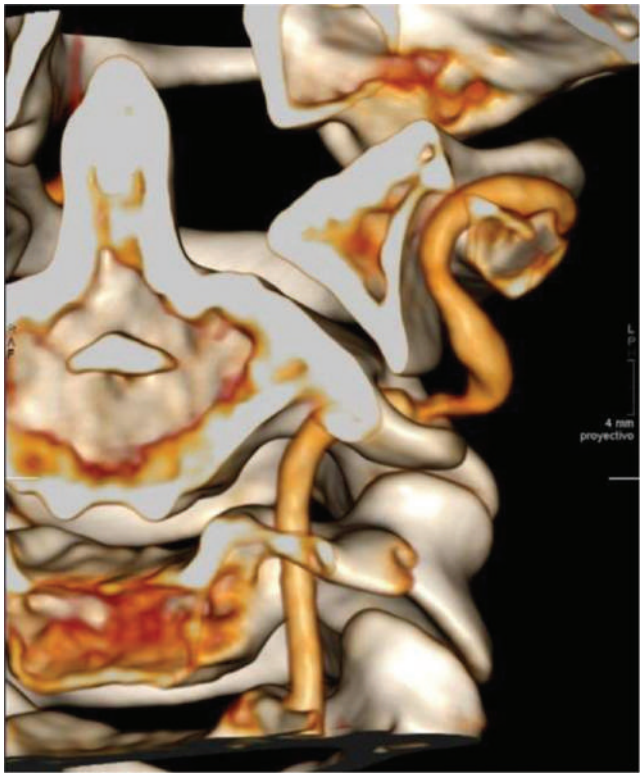
Role of the Gut-Brain-Axis in Autism Spectrum Disorder.

Conclusion: Our observations reinforce established links between Akkermansia muciniphila and ASD, and support the future use of TgsAPPα mice as a translational model for the development of microbiota-bases therapies for ASD.
Disclosure: Nothing to disclose.

EPO-635 | Rotational vertebral artery syndrome in a pediatric patient

I. Albajar Gomez[1]; J. Equiza[1]; P. Iruzubieta[1]; G. Nuñez[1]; J. Larrea[2]; M. Imaz[3]; B. Laña[3]; O. Martinez-mugica[3]; I. de Goñi[4]; I. Martí[3]
[1]*Neurology, Donostia University Hospital;* [2]*Radiology, Donostia University Hospital;* [3]*Pediatrics, Donostia University Hospital;* [4]*Neurosurgery, Donostia University Hospital*

Background and Aims: Rotational vertebral artery syndrome is an uncommon cause of vertebrobasilar stroke. Literature concerning pediatric patients is scarce.
Methods: We report a rare pediatric case of bow hunter's syndrome with illustrative neuroimaging findings.
Results: A 10-year-old patient, without relevant medical or family history, presented with cerebellar ataxia and nystagmus due to his third stroke since age 6. In previous episodes, etiologic studies were negative. Brain-MRI (image 1) showed multi-territory acute and chronic ischemic strokes. Brain-MRI showed an acute ischemic stroke in the cerebellum on Diffusion-WI (A), as well as contralateral lacunar chronic ischemic lesions on T2-WI (B). The previous episode presented as an acute right thalamic lesion with an intense restriction on Diffusion-WI (C) which initially misguided us towards metabolic and mitochondrial diseases. Cardiologic and hematologic tests were normal. His brain-CTA, brain-MRA, metabolic tests, vasculitis panel and exome for mitochondrial pathology were reported as normal. He underwent an angiography and CTA reconstruction (image 2). Angiography (A) revealed a basilar artery embolism, suggesting a proximal active embolic source, and a pseudo-aneurysmatic dilation of the vertebral artery. CTA reconstruction showed the left vertebral artery compressed by a protrusion of the inferior facet of the atlas (B), known as rotational vertebral artery syndrome or bow hunter's syndrome. Following excision, the patient has remained asymptomatic.



CTA reconstruction shows the left vertebral artery compressed by a protrusion of the inferior facet of the atlas.

Conclusion: Rotational vertebral artery syndrome must be ruled out in pediatric patients with vertebrobasilar strokes.
Disclosure: Nothing to disclose.

EPO-636 | Epidemiology of autism spectrum disorder in children in Kazakhstan: Data from UNEHS 2014–2021

K. Mussina; D. Syssoyev; A. Gaipov; D. Poddighe; D. Galiyeva
Department of Medicine, School of Medicine Nazarbayev University, Astana, Kazakhstan

Background and Aims: We aimed to describe incidence and prevalence of Autism Spectrum Disorder (ASD) and examine factors associated with all-cause hospitalizations in children registered in the Unified National Electronic Healthcare System (UNEHS) in 2014–2021 in Kazakhstan.
Methods: Cohort comprised of patients less than 18 years old with ASD defined according to the International Classification of

Diseases, 10th revision (ICD-10) as codes: F84.0-F84.1, registered in the UNEHS from 2014 to 2021. Socio-demographic factors were analyzed using descriptive, bivariate and multivariable statistical analyses. ASD incidence and prevalence were calculated per 100,000 population. Cox proportional hazard regression analysis was performed to examine factors associated with all-cause hospitalizations. **Results:** Cohort consisted of 8,660 children with ASD, 6,834 (78.9%) were males and 6,384 (73.7%) were urban residents. The mean age at diagnosis was 6.0±2.2 years. The majority of hospitalizations were due to psychiatric/neuropsychiatric cause (73%). Number of hospitalized children with ASD increased from 305 to 1053 patients from 2014 to 2021. Median follow-up was 2.8 (1.2–4.9) years. Pediatric ASD incidence rate increased from 9.0 to 25.8 per 100 000 from 2014 to 2021. Period prevalence rate significantly raised from 6.7 to 130.2 per 100 000 from 2014 to 2021. Age specific ASD incidence was highest for 6–10 years age group. Younger age, having GI disorders, anemia, epilepsy, hydrocephalus and cerebral palsy are significantly associated with all-cause hospitalizations.

EPO-637 | Early but not delayed cannabinoid treatment augments hypothermic neuroprotection after neonatal asphyxia

M. Chillida[1]; J. Alart[1]; G. Beldarrain[1]; A. Álvarez[1]; A. Bouzier-Sore[2]; D. Alonso-Alconada[1]

[1]*Department of Cell Biology and Histology, School of Medicine and Nursing, University of the Basque Country (UPV/EHU), Leioa, Spain;* [2]*Centre de Résonance Magnétique des Systèmes Biologiques, CNRS, University of Bordeaux, Bordeaux, France*

Background and Aims: Neonatal hypoxic-ischemic encephalopathy is one of the main causes of adverse neurological disabilities in newborns. Therapeutic hypothermia (TH) is the standard treatment used in clinics; unfortunately, it is not efficient in all cases. Promising new treatments are being investigated and cannabinoids have gained importance due to their neuroprotective properties. In a preclinical model of hypoxia-ischemia (HI), we aimed to establish the treatment window of the cannabinoid URB447 combined with TH.

Methods: On postnatal day 7, 101 Sprague Dawley rats were subjected to ischemia (left common carotid artery ligation) followed by hypoxia (120 min, 8%oxygen/92%nitrogen). The experiment included sham-operated controls ($n=10$). After HI, rats were cooled at 32.5–33°C for 3 h (TH-only; $n=32$). URB447 administration (i.p. 1 mg/kg) was before (URB447 + TH, $n=13$) or after (TH + URB447 $n=33$) the TH. The neuroprotective effect of the combined therapy was analyzed by histopathology.

Results: Animals that received URB447 before TH showed augmented hemispheric neuroprotection (95.08%) compared to TH-only (72.93%) and TH + URB447 (50.93%). This was further confirmed in the hippocampus, with percentage values of 98.54%, 45.49% and 40.29%, respectively. The tissue loss was also reduced when administering the compound before TH: URB447 + TH animals showed 9.51% of tissue loss, significantly lower ($p<0.05$) than those for TH-only (27.56%) and TH + URB447 (29.70%).

Conclusion: These results suggest that the administration of the cannabinoid URB447 before TH, but not after cooling, exerts adjuvant neuroprotective effects in a rat model of neonatal hypoxia-ischemia.

Disclosure: Acknowledgments: Grant MINECOR20/P66 funded by MCIN/AEI/10.13039/501100011033 and by "ERDF A way of making Europe", UPV/EHU predoctoral grant (PIFBUR22/03).

EPO-638 | URB447 reduces white matter demyelination and cerebral asymmetry and improves motor function after hypoxia-ischemia

M. Chillida[1]; J. Alart[1]; G. Beldarrain[1]; A. Álvarez[1]; A. Bouzier-Sore[2]; D. Alonso-Alconada[1]

[1]*Department of Cell Biology and Histology, School of Medicine and Nursing, University of the Basque Country (UPV/EHU), Bizkaia, Spain;* [2]*Centre de Résonance Magnétique des Systèmes Biologiques, CNRS, University of Bordeaux, Bordeaux, France*

Background and Aims: Perinatal hypoxia-ischemia may cause white matter injury, leading to newborn morbidities. Although therapeutic hypothermia (TH) is efficient, a substantial number of babies suffer from behavioral impairments. Here, we wanted to assess white matter demyelination and long-term outcomes after the administration of the CB1-antagonist/CB2-agonist drug URB447 combined with TH in a model of neonatal asphyxia.

Methods: 117 Sprague Dawley rats were subjected to hypoxia-ischemia (HI) by left common carotid artery electrocoagulation + 2 h at 8%oxygen/92%nitrogen on postnatal day 7 (P7). TH-treated rats were maintained at 32.5–33°C for 3 h. URB447 was administered immediately after HI. Resulting groups were: Sham ($n=18$), HI ($n=34$), HI+TH ($n=44$) and HI+URB447+TH ($n=21$). White matter was assessed at P14 by immunohistochemistry for myelin basic protein (MBP) and motor impairments evaluated at P40-P42 and P90.

Results: HI+URB447+TH obtained the best results on protecting white matter, with higher MBP ratios (1.01; $p<0.05$) than HI (0.34) and HI+TH-only (0.69), and similar to Sham (1.00). The cylinder test revealed no signs of hemiparesis or cerebral asymmetry in the combined therapy group (−5.57%; $p<0.05$), unlike HI (43.37%) or HI+TH-only (43.17%). Motor coordination was also better in the combined therapy group: Sham (190.5), HI (120.3), HI+TH-only (111.8) and URB447+TH (171.3).

Conclusion: CB1-antagonist/CB2-agonist drug URB447 enhanced hypothermia by ameliorating both white matter injury and long-term motor function in a preclinical model of neonatal encephalopathy.

Disclosure: Acknowledgments: Grant MINECOR20/P66 funded by MCIN/AEI/10.13039/501100011033 and by "ERDF A way of making Europe", UPV/EHU predoctoral grant (PIFBUR22/03).

EPO-639 | Motor ability and neural correlates in children with aromatic L-amino acid decarboxylase deficit

Y. Lee[1]; H. Lee[2]; W. Hwu[2]; L. Chou[1]

[1]*Department of Physical Therapy and Assistive Technology, National Yang Ming Chiao Tung University, Taipei, Taiwan;* [2]*Department of Medical Genetics, National Taiwan University Children's Hospital, Taipei, Taiwan*

Background and Aims: Aromatic L-amino acid decarboxylase deficit (AADCD) is a rare, autosomal recessive neurometabolic disorder resulting in impaired or delayed motor development. Traditional motor assessment tools were unsuitable for AADCD children due to variable motor ability among individuals. Cortical neural activity and connectivity are associated with the maturation of the motor system in typically developed children. This study aims to use EEG to explore the relationship between motor ability and cortical neural activity in children with AADCD.

Methods: Children with definitive diagnosis of AADC deficiency and were older than 24 months were recruited. Cortical activity (32-channel EEG system, ANT Neuro, Netherlands) was collected during the resting and the execution of arm reaches. The arm reach

performance was graded by the Grasping and Reaching Assessment of Brisbane (GRAB). The EEG data were divided into motor preparation and execution segments. Power spectral densities of the C3, Cz, and C4 channels were calculated in the alpha and beta frequency range. The Spearman correlation test measured the correlation between reaching abilities and power spectral density. The significant level is established at $p < 0.05$.

Results: Eight individuals who underwent gene therapy were enrolled; one participant demonstrated a GRAB score of 1, while the remaining participants all scored GRAB 3. Our preliminary results showed that AADC individuals with lower GRAB scores exhibited lower alpha power spectrum density in the resting phase.

Conclusion: Our findings provide a preliminary observation of the relationship between cortical neural activities and motor ability in AADCD children.

Disclosure: Nothing to disclose.

EPO-640 | Understanding lived experiences with KCNQ2-development and epileptic encephalopathy (KCNQ2-DEE) – Parent interviews

M. Potashman[1]; K. Rudell[2]; L. Abetz-Webb[3]; N. Suminski[2]; R. Doma[2]; A. Gold[2]; K. Jarodia[2]; C. Buckley[2]; M. Ridley[2]; J. Lerner[1]; J. Mather[1]; V. Coric[1]; J. Millichap[4]; A. Berg[5]

[1]Biohaven Pharmaceuticals, Inc; [2]Parexel International, US, UK and India; [3]Patient-Centered Outcomes Assessments, Ltd. Bollington, Macclesfield, UK; [4]Department of Neurology, Northwestern University Feinberg School of Medicine, Chicago, IL, USA and Precision Epilepsy, PLLC, Chicago, IL, USA; [5]Department of Neurology, Northwestern University Feinberg School of Medicine, Chicago, IL, USA and DEE-P Connections, Washington, DC, USA

Background and Aims: While quantitative descriptions of KCNQ2-DEE have been provided from in-depth survey data, limited qualitative interview-based data exists describing the patient-caregiver experiences with KCNQ2-DEE and the burden of disease. We performed this study to develop KCNQ2-DEE conceptual models to illustrate the disease- and quality of life (QoL)-related experiences and identify its most burdensome aspects.

Methods: One-on-one interviews were conducted with US-based parental caregivers of children (1–18 years-old, September through November 2023) with mild, severe, and profound KCNQ2-DEE phenotypes. Parents were recruited via a patient advocacy group (KCNQ2 Cures Alliance). Semi-structured interviews were audio recorded, transcribed, coded and analysed by ATLS.TI, following established qualitative research methods. Concept saturation was assessed, and 4 models were derived – one for each phenotype severity level and one overall model. The most burdensome disease aspects were discussed (rated on a 0–10 scale).

Results: Based on interviews with 53 parents, the most common concepts reported were communication difficulties, gross and fine motor problems, and chewing/eating difficulties; each worsening with increasing phenotype severity and with age. Communication challenges was the most burdensome symptom (mean = 8.6/10, $n = 47$, 87% participants). Epileptic seizures were a key concern in infancy, but once adequately controlled were rated as one of the least burdensome symptoms post-infancy (mean = 5.0/10, $n = 23$, 43% participants).

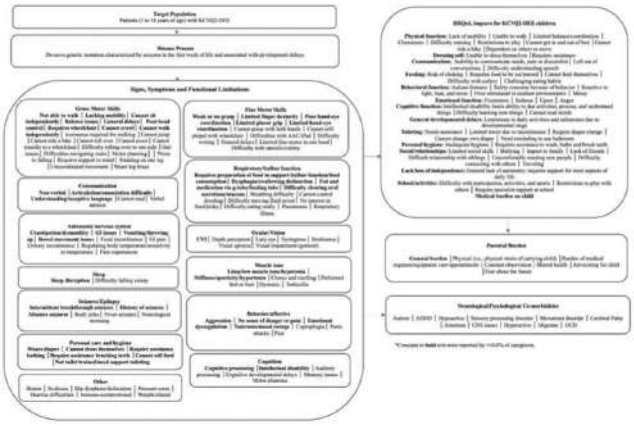

FIGURE 1 Parent-informed conceptual model (inclusive of all phenotypes and ages).

Conclusion: KCNQ2-DEE is a multifactorial condition that manifests through numerous symptoms, resulting in significant impacts on the child and parent. These findings identify the outcome domains important to families and patients that could inform measurement tools and endpoint selection in future therapeutic trials.

Background and Aims: Metachromatic leukodystrophy (MLD) is a lysosomal storage disorder caused by arylsulfatase A (ARSA) deficiency, leading to toxic sulfatide accumulation. Symptom onset varies, causing neurological deterioration. Pre-symptomatic interventions like autologous hematopoietic stem cell gene therapy (arsa-cel) for early-onset and hematopoietic stem cell transplantation (HSCT) for late-onset show success. This study details the first prospective newborn screening (NBS) for MLD, focusing on management and treatment experiences.

Methods: First-tier dried blood spot (DBS) samples from 109,259 newborns in the German NBS program were analyzed using electrospray ionization tandem mass spectrometry for sulfatide levels. Next-generation sequencing of the ARSA gene in samples with elevated sulfatides was conducted in the second tier. Confirmation involved assessing ARSA enzyme activity in blood, urinary sulfatides, and genetic sequencing. Identified neonates followed a standardized care pathway for management and treatment.

Results: Elevated sulfatide levels were found in 386 neonates, and genetic sequencing revealed ARSA gene variants in three samples. Conventional diagnostic testing confirmed MLD in all three cases. Two predicted with early-onset MLD underwent successful pre-symptomatic arsa-cel treatment at 9 months, while the third, predicted with late-onset MLD, was scheduled for allogeneic HSCT between 2 and 5 years.

Conclusion: This study highlights NBS for MLD's technical feasibility and high efficiency, emphasizing specificity and sensitivity. Disease onset prediction in three neonates allows timely treatment or monitoring following a standardized care pathway.

EPO-642 | Neuroimmunological indicators of children with autism spectrum disorders

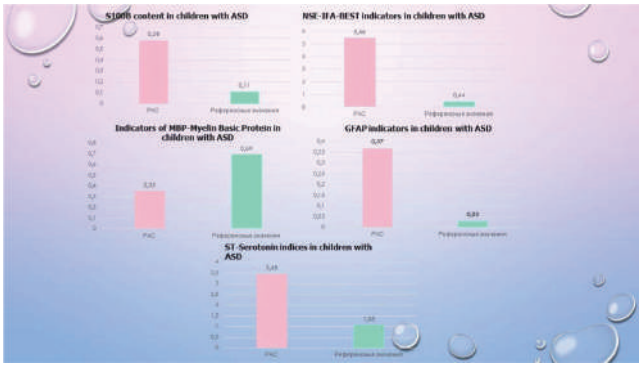
N. Khusenova; Y. Madjidova

Tashkent Pediatric Medical Institute

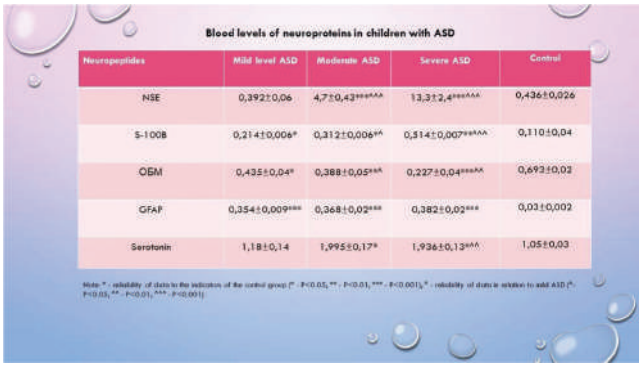
Background and Aims: Various neurochemical systems (glutamatergic, GABAergic, etc.) play an important role in the activity and maturation of the central nervous system. This makes it necessary to clarify and revise the existing hypotheses of the pathogenesis of neuropsychiatric diseases in children with ASD.

Methods: 45 children with ASD (main group; MG) were examined. Determination of neurotropic autoantibodies (NAAB) was performed using standard procedures of solid-phase immunoassay ELI-N-Test and test kits "Immunculus". The control group consisted of 20 practically healthy children of similar age (control group, CG).

Results: when assessing the average content of S100B protein in serum of the children of the MG children, a significant increase was observed in comparison with that of the CG children ($p = 0.005$). In 14 (31%) children with ASD, S100B values were slightly higher or at the upper limit of the norm in contrast to CG children. In children with ASD, there was a 12.4-fold increase in NSE relative to normal values (5.46 ± 0.84 vs. 0.44 ± 0.03; $p < 0.001$). The appearance of decreased indices of antibodies to OBP in serum testifies to the disruption of the blood-brain barrier, most significant in patients with ASD (0.69 ± 0.02 vs. 0.35 ± 0.03; $p < 0.05$). There was a 12.3-fold increase in GFAP values relative to normal values (0.37 ± 0.008 versus 0.03 ± 0.002; $p < 0.001$).



The content of neuroproteins in children with ASD was analyzed.



Blood levels of neuroproteins in children with ASD

Neuropeptides	Mild level ASD	Moderate ASD	Severe ASD	Control
NSE	0,392±0,06	4,7±0,43***^^^	13,3±2,4***^^^	0,436±0,026
S-100B	0,214±0,006*	0,312±0,006**^	0,514±0,007***^^^	0,110±0,04
OBM	0,435±0,04*	0,388±0,05*^^	0,227±0,04***^^^	0,693±0,03
GFAP	0,354±0,009***	0,368±0,02***	0,382±0,02***	0,03±0,002
Serotonin	1,18±0,14	1,995±0,17*	1,936±0,13*^^	1,05±0,03

Note: * - reliability of data in the indicators of the control group (* - P<0.05, ** - P<0.01, *** - P<0.001), ^ - reliability of data in relation to mild ASD (^ - P<0.05, ^^ - P<0.01, ^^^ - P<0.001)

Blood levels of neuroproteins in children with ASD.

Conclusion: Thus, in children with ASD, there is an imbalance in neuroimmunological status, so there is an increase in the level of S100B, NSE, GFAP, and a decrease in OBP.

Disclosure: To investigate the role of neuroproteins in the blood of children with autism spectrum disorders.

EPO-643 | Deriving reference limits for visual evoked potentials from historical data

P. Omland[1]; R. Li[2]; T. Szczepanski[3]; M. Engstrøm[1]; M. Uglem[1]; T. Sand[1]; K. Nilsen[3]

[1]Department of Neurology and Clinical Neurophysiology, St. Olavs Hospital, Trondheim, Norway; Department of Neuromedicine and Movement Science, Faculty of Medicine and Health Sciences, Norwegian University of Science and Technology, Trondheim, Norway; [2]Faculty of Medicine and Health Sciences, Norwegian University of Science and Technology, Trondheim, Norway; [3]Department of Neurology and Clinical Neurophysiology, Oslo University Hospital, Oslo, Norway

Background and Aims: Neurophysiological methods, including visual evoked potentials (VEP), rely on valid and accurate reference limits. VEP variables vary between laboratories, and may change over time because of changes in equipment and procedures. Therefore, there is a need for laboratory specific and updated reference limits. The traditional method for development of reference limits from healthy subjects has several ethical, practical, and economical challenges. We attempt to bypass these challenges by generating reference limits for VEP from historical data using the extrapolated norms (e-norms) method.

Methods: In the Norwegian DIGMINE project we have collected data from 1500 adult patients examined with pattern-reversal VEP at the section of Clinical Neurophysiology at St. Olavs University Hospital in Trondheim. VEP for 1138 and 362 patients were recorded on a Keypoint-Classic system (2006–2018) and a TruTrace-system (2018–2023) respectively. VEPs were recorded with a standardized procedure. Using e-norms we calculated reference limits for VEP variables, including P100 latency and N70-P100 amplitude.

Results: The resulting reference limits (+3SD) for P100 latency were 111 ms for both systems combined, 110 ms for the TruTrace-system and 112 ms for the Keypoint-system. The resulting reference limits (−3SD) for N70-P100 amplitude were 2.5, 2.7 and 2.3 μV respectively.

Conclusion: Historical data can efficiently be used to calculate reference limits for VEP. The resulting reference limits were similar but slightly stricter than those currently used in clinical practice at our laboratory. Our results indicate that historical data can be useful for developing and maintaining reference limits, and for monitoring data quality and effects of changes in equipment and procedures.

Disclosure: Nothing to disclose.

EPO-644 | Quality care for people with CDKL5 deficiency disorder: An expert panel opinion on the European patient journey

S. Amin[1]; R. Møller[2]; A. Aledo-Serrano[3]; A. Arzimanoglou[4]; P. Bager[5]; S. Jóźwiak[6]; G. Kluger[7]; S. López-Cabeza[8]; R. Nabbout[9]; C. Partridge[10]; S. Schubert-Bast[11]; N. Specchio[12]; R. Kälviäinen[13]

Background and Aims: Introduction: CDKL5 deficiency disorder (CDD) is a rare genetic disorder characterised by seizures and neurodevelopmental delays from infancy. To address the lack of evidence-based guidelines for standardised care of CDD in Europe, clinical experts and patient advocacy group (PAG) representatives from Europe convened to map the patient journey and provide

consensus on how to ensure quality care in routine clinical practice within the European setting.

Methods: Methods: Semi-structured one-to-one interviews were conducted by a third-party agency. Insights were collated into a visual representation of the Europe-specific clinical journey in CDD. Workshops followed to reach consensus, and validate the journey, and to identify challenges and provide expert opinion on potential solutions.

Results: Results: The CDD patient journey has three elements: clinical presentation/diagnosis, seizure management and multidisciplinary care. Clinical criteria for CDD diagnosis include seizure semiology and age at epilepsy onset. Genetic testing is crucial for diagnosis, allowing for appropriate seizure management, multidisciplinary care and outcomes. When planning pharmacotherapy, the refractory and variable seizure semiology, comorbidities, effects of polypharmacy and safety profiles of concomitant medications should be considered. Multidisciplinary collaboration and specialist access are essential for long-term care, support and improved quality of life, each adapting with the changing needs of the patients. The expert group highlighted disparity in management approaches and available resources; therefore, cross-country knowledge-sharing is key.

Conclusion: Conclusion: To achieve quality care of people with CDD, European practice recommendations are required that align on realistic treatment goals, diagnostic criteria and management approaches, and are adaptable.

Education & history of neurology

EPO-645 | Abstract withdrawn

EPO-646 | Abstract withdrawn

EPO-647 | Optimising continuing medical education: Exploring learning trends and preferences among European and US neurologists

P. Chen; J. White; C. Forde; C. Walsh
PeerVoice, Luxembourg, Luxembourg

Background and Aims: To optimise continuing medical education (CME) tailored for neurologists, this study investigates neurologists' CME participation patterns and preferences.

Methods: In 2023, a 20-minute electronic survey was administered to practicing neurologists in Europe and the United States. Recruitment employed the LiMA network of validated healthcare professionals. Question sequences were randomised to mitigate response bias. Each clinician was remunerated in their local currency for participating.

Results: Data were collected from 50 neurologists. Peer-reviewed journal articles (92%) and CME websites (70%) are the top two channels that neurologists used frequently to acquire medical information. Measured using a 5-point scale, content credibility (4.18) and clinical applicability (4.16) were rated as being notably more important than interactivity (2.96) and format novelty (2.84) in driving neurologists' CME participation. Most neurologists reported spending ≤20 minutes per online CME engagement (72%), and identified "having to complete assessment questions to access the education" as a barrier to their CME participation (80%). Linear regression analysis demonstrated a positive correlation ($b = 0.16$, $p < 0.05$) between neurologists' CME participation and increased frequencies of self-reported clinical practice change implementation. Primary changes implemented occurred in treatment plan management (59%), screening and/or diagnosis (51%), and patient monitoring (41%).

Conclusion: CME design needs to prioritize content over format. The identified barriers, notably the time constraints and compulsory assessment questions, highlight the importance of eliminating roadblocks to CME participation. The alignment between clinical practice change and CME participation amongst neurologists validates the effectiveness of CME in driving critical clinical behaviour to improve patient care.

Disclosure: Nothing to disclose.

EPO-648 | PhD and clinician-scientist pathway among neurology residents and junior neurologists in Europe – A survey from the RRFS

V. Carvalho[1]; T. Kobulashvili[2]; L. Cuffaro[3]; N. Vashchenko[4]; G. Sferruzza[5]; A. Gonzalez-Martinez[6]; A. Accoroni[7]
[1]*Department of Neurosciences and Mental Health (Neurology), Hospital Santa Maria-CHLN;* [2]*Department of Neurology, Neurocritical Care, and Neurorehabilitation, Christian-Doppler University Hospital, Paracelsus Medical University, Centre for Cognitive Neuroscience, Member of EpiCARE, Salzburg, Austria;* [3]*School of Medicine and Surgery, University of Milano-Bicocca, Milan, Italy;* [4]*Department of Neurology, Danish Headache Center, Copenhagen University Hospital – Rigshospitalet, Glostrup, Copenhagen, Denmark;* [5]*Vita-Salute San Raffaele University, Milan, Italy;* [6]*Department of Neurology and Immunology, Hospital Universitario de la Princesa & Instituto de Investigación Sanitaria Princesa (IIS-Princesa), Madrid, Spain;* [7]*Department of Clinical Neurosciences, Neurology Unit, Geneva University Hospital, Geneva, Switzerland*

Background and Aims: The decreasing number of clinician-scientists in neurology underscores the urgency of understanding the challenges encountered by early-career professionals to safeguard the future of academia in neurology. Our aim is to explore the characteristics of Ph.D. programs across Europe and the main challenges faced when embarking on an academic career.

Methods: From September to December 2023, an online survey was sent through email to EAN-RRFS members.

Results: We obtained 297 valid responders. 49% were residents, 43% had completed training, and 85% aspired to become a clinician-scientist. Of the 82% who were doing research, 39%

were enrolled in a Ph.D. programme and 15% already completed one. Ph.D. access and graduation criteria varied significantly and 74% of the respondents believed that better harmonization of PhD programs could be beneficial. Less than half of the Ph.D. were fully funded, with universities (31%) and governmental bodies (20%) being the most frequent funding sources. The most commonly perceived challenges included combining clinical activities with research (59%) and finding funding (52%). Among Ph.D. students, over 60% experienced stress, struggled with time management and maintaining a work/life balance, with around one-third expressing concerns about lack of supervision/communication from their supervisor.

Conclusion: We provide insight into the structure, content, perceived benefits, and challenges of doing a Ph.D. in Europe, as well as the difficulties perceived by early career neurologists entering research. Future measures could address these challenges to reduce the barriers for trainees to access a career in Academia.

Federación Española de Enfermedades Metabólicas Hereditarias. European Society for Phenylketonuria and Allied Disorders

Background and Aims: Digital Care Pathways for Rare Brain Diseases research project (2023–2024) is coordinated by the European Brain Council. The study is looking at unmet needs while using digital care pathways and aims to assess benefits of digital tools from patient's perspective after COVID-19 pandemic, presenting the phenylketonuria (PKU) case-study.

Methods: A survey was co-designed with PKU patients' representatives, translated into German and Spanish, and anonymously launched in EU Survey platform. The survey contained demographic questions, 13 questions about patient unmet needs on information, communication and education, 8 questions regarding patients' experience on access to care pathways during the COVID-19, and 13 questions on the role of digital tools in supporting PKU management.

Results: 75 respondents (59% patients, 41% parents) participated to the survey. Information about PKU and communication between patient and healthcare professionals are extremely important (44% and 60%), and education on digital platforms for the management of PKU is very important (47%). Digital tools are needed for sharing information and for communicating before the clinic visit (75%) and enhance understanding the information provided for treatment or monitoring (90%). On day-to-day PKU management, Apps, wearables, e-mail, telephone call could help in understanding information received from center and for communication (90%).

Conclusion: Treatment management and care delivered to PKU patients demonstrated benefits and interest for more use of digital tools in management and follow-up. Preliminary results provided valuable insight into understanding needs of PKU patients and defining best channels to engage and communicate with them. While looking at patient perspective, clinician perspective is equally important.

Disclosure: The study received financial support from Pfizer.

EPO-650 | Persistent postural perceptual dizziness (PPPD) in the neurology clinic

K. Radhakrishna; M. Gaughan; C. Russel

Neurology, St. Vincent's University Hospital, Dublin, Ireland

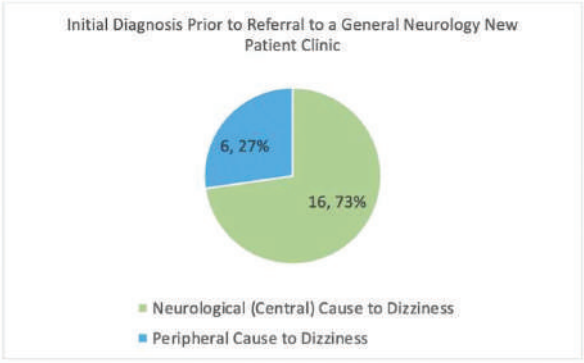
Background and Aims: Persistent postural perceptual dizziness (PPPD) is a recently introduced diagnosis which may be underrecognized. The Bárány Society has defined the condition as persistent dizziness/unsteadiness for ≥3 months causing significant functional impairment. Diagnosis is made clinically and vestibular diagnostic tests and neuroimaging are typically negative. The objectives of the study were to determine the proportion of referrals to a General Neurology New Patient Clinic which met the diagnostic criteria of PPPD and to determine response to treatment.

Methods: In this retrospective review, referral letters of 1315 patients to a General Neurology New Patient Clinic from 2021–2023 were screened for terms 'dizziness', 'vertigo', 'unsteadiness' and 'vestibular'. A chart review was performed to establish the group that met the diagnostic criteria for PPPD. Follow-up correspondences was reviewed to establish response to treatment.

Results: 202 (15.4%) patients were referred with 'Dizziness', 'Vertigo' or 'Unsteadiness'. 22 (1.7%) patients fulfilled the diagnostic criteria of PPPD. 10 (45.5%) were treated with Venlafaxine, conferred ≥50% subjective improvement of symptoms for 8 (80%) patients. Vestibular physiotherapy improved symptoms by ≥25% in 7 (100%) patients. CBT and effective communication of the diagnosis alone alleviated symptoms by 50% in 3 (14%) patients respectively.

Age, Mean (SD)	47.8 (9.96)
Males (%)	10 (45.5%)
Females (%)	12 (54.5%)
Co-morbidities:	
Peripheral Vestibular Conditions	7 (31.8%)
Neurological Conditions	7 (31.8%)
General Medical Conditions	3 (13.6%)
Head Trauma	1 (4.5%)
Psychiatric Conditions	4 (18.3%)
Mean Duration of Symptoms (Months), (SD)	33.5 (12.2)
Subjective Treatment Response to Venlafaxine:	
Number of patients tried Venlafaxine	10 (45%.5)
At least 50% Improvement with Venlafaxine	8 (80%)
25% Improvement with Venlafaxine	1 (10%)
No response To Venlafaxine	1 (10%)
Subjective Treatment Response to Vestibular Physiotherapy:	
Number of patients tried Vestibular Physiotherapy	7 (31%)
At least 25% Improvement with Vestibular Physiotherapy	7 (100%)
Subjective Treatment Response To CBT:	
Number of patients tried CBT	3 (14%)
At least 50% Improvement with CBT	3 (100%)

Subjective Treatment Response To Effective Communication of Diagnosis :	
Number of Patients who had the diagnosis of PPPD Explained to them	22 (100%)
At least 50% Improvement with Effective Communication of Diagnosis	3 (14%)



Conclusion: PPPD is a relatively common neurological condition, should be considered in patients with chronic vestibular symptoms which result in significant functional morbidity. In this cohort, treatment with Venlafaxine and vestibular physiotherapy resulted in significant improvement in symptoms.

Disclosure: Nothing to disclose.

EPO-651 | Online education improves specialists' knowledge and competence on management of depression in people with epilepsy

L. Thevathasan[1]; K. Carpenter[1]; C. Scot-Smith[1]; M. Mula[2]; L. Sander[3]

[1]Medscape LLC, London, UK; [2]St George's University of London, London, UK; [3]UCL Queen Square Institute of Neurology, London, UK

Background and Aims: To evaluate whether an online educational programme directed at European-based specialists, could improve knowledge on identification of depression in people with epilepsy and competence relating to management of depression in people with epilepsy.

Methods: The educational activity was a 15-minute online video with 2 European experts in Epilepsy. Educational effect was assessed using a 3-question repeated pairs, pre/post assessment survey. A paired-samples *t*-test was conducted to assess overall number correct and confidence change. p values < 0.05 (McNemar's test) are statistically significant. Cohen's d test was used for magnitude of effect of education on the overall outcomes (knowledge). The activity launched on 29 September 2023 and data analysed as of 11 December 2023.

Results: 461 neurologists and 196 psychiatrists participated in the programme, of which 54 neurologists and 39 psychiatrists completed pre- and post-assessment tests. Significant improvements were seen for both groups, with an average correct response rate of 33% and 27% pre-assessment, which increased to 69% and 64% post-assessment, for neurologists ($p < 0.001$; Cohen's $d = 1.12$) and psychiatrists ($p < 0.001$; Cohen's $d = 1.11$) respectively. Table 1 provides further results for each learning objective. Based on a self-reporting question, neurologists expressed a 61%, and psychiatrists expressed a 59%, increase in confidence following the education in managing depression in people with epilepsy.

Table 1

		Mean % of responses correct	Relative % change	P value	%*Improved on this learning objective	% #Reinforced on this learning objective
Increased knowledge regarding the identification of depression in people with epilepsy	Neurologists pre-	31	116	P <.001	57	30
	Neurologists post-	67				
	Psychiatrists pre-	31	116	P <.001	59	23
	Psychiatrists post-	67				
Greater competence related to managing depression in people with epilepsy	Neurologists pre-	35	111	P <.001	39	35
	Neurologists post-	74				
	Psychiatrists pre-	21	181	P <.001	38	21
	Psychiatrists post-	59				

*Improved: answers at least one more question correctly
#Reinforced: answers the same number of questions correctly pre/post

Table expressing knowledge and competence changes for neurologists and psychiatrists before and after education.

Conclusion: This study demonstrates the positive effect of online medical education on specialists' knowledge, competence and confidence in managing comorbid depression in people with epilepsy in Europe.

Disclosure: Lionel Thevathasan, Katherine Carpenter and Camille Scott-Smith are employed by Medscape LLC. An unrestricted educational grant for this programme was provided by Angelini Pharma. Marco Mula and Ley Sander have nothing to disclose.

EPO-652 | Online medical education improves specialists' knowledge on selecting antiseizure medications in people with epilepsy

L. Thevathasan[1]; K. Carpenter[1]; C. Scot-Smith[1]; R. Thomas[2]
[1]*Medscape LLC, London, UK;* [2]*Newcastle University Newcastle upon Tyne, UK*

Background and Aims: Post-pandemic education is variable, so we evaluated whether an online educational programme directed at European-based specialists, could improve knowledge on appropriate selection of antiseizure medications (ASMs) for people with focal epilepsy, particularly relating to mechanisms of action and latest clinical trial data.

Methods: The educational activity was a 29-minute online video with 1 European expert in Epilepsy. Educational effect was assessed using a 3-question repeated pairs, pre/post assessment survey. A paired-samples *t*-test was conducted to assess overall number correct and confidence change. p values < 0.05 (McNemar's test) are statistically significant. Cohen's d test was used for magnitude of effect of education on the overall outcomes (knowledge). The activity launched on 15 June 2023 and data analysed as of 20 October 2023.

Results: 2,214 neurologists and 769 psychiatrists participated in the programme, of which 218 neurologists and 38 psychiatrists completed pre- and post-assessment tests. Significant improvements were seen for both groups, with an average correct response rate of 49% and 31% pre-assessment, which increased to 72% and 47% post-assessment, for neurologists ($p < 0.001$; Cohen's $d = 0.80$) and psychiatrists ($p < 0.001$; Cohen's $d = 0.63$) respectively. Table 1 provides further results for each learning objective. Based on a self-reporting question, neurologists expressed a 43%, and psychiatrists expressed a 34%, increase in confidence following the education in knowledge on antiseizure medication selection.

Table 1

		Mean % of responses correct	Relative % change	P value	% Improved* on this learning objective	% Reinforced# on this learning objective
Increased knowledge regarding the latest clinical trial data for newer ASMs	Neurologists pre-	48	54	P <.001	44	45
	Neurologists post-	74				
	Psychiatrists pre-	33	52	P <.001	32	42
	Psychiatrists post-	50				
Increased knowledge regarding the mechanism of action of ASMs	Neurologists pre-	50	36	P <.001	19	49
	Neurologists post-	68				
	Psychiatrists pre-	26	62	P <.05	18	24
	Psychiatrists post-	42				

*Improved: answers at least one more question correctly
#Reinforced: answers the same number of questions correctly pre/post

Table of results expressing changes in knowledge on mode of action and clinical trial data before and after education.

Conclusion: This study demonstrates the positive effect of online medical education on specialists' knowledge and confidence in selection of antiseizure medications for people with focal epilepsy in Europe.

Disclosure: Lionel Thevathasan, Katherine Carpenter and Camille Scot-Smith are employed by Medscape LLC. Rhys Thomas has nothing to disclose. This educational programme was supported by an unrestricted educational grant by Angelini Pharma.

EPO-653 | Online medical education improves specialists' knowledge and confidence on sudden unexpected death in epilepsy

L. Thevathasan[1]; K. Carpenter[1]; C. Scot-Smith[1]; R. Shankar[2]; P. Ryvlin[3]; T. Tomson[4]
[1]*Medscape LLC, London, UK;* [2]*University of Plymouth Peninsula School of Medicine Plymouth, UK;* [3]*Department of Clinical Neurosciences Lausanne University Hospital (CHUV) Lausanne, Switzerland;* [4]*Department of Clinical Neuroscience Karolinska Institute, Stockholm, Sweden*

Background and Aims: To evaluate whether an online educational programme directed at European-based specialists, could improve knowledge and confidence relating to SUDEP, specifically the risks of SUDEP and desire among patients and caregivers to receive this information.

Methods: The educational activity was a 36-minute online video with 3 European experts in Epilepsy. Educational effect was assessed using a 3-question repeated pairs, pre/post assessment survey. A paired-samples *t*-test was conducted to assess overall number correct and confidence change. p values < 0.05 (McNemar's test) are statistically significant. Cohen's d test was used for magnitude of effect of education on the overall outcomes (knowledge). The activity launched on 3 August 2023 and data analysed as of 9 October 2023.

Results: 598 neurologists and 326 psychiatrists participated in the programme, of which 76 neurologists and 39 psychiatrists completed pre- and post-assessment tests. Significant improvements

were seen for both groups, with an average correct response rate of 32% and 22% pre-assessment, which increased to 76% and 58% post-assessment, for neurologists ($p < 0.001$; Cohen's d = 1.22) and psychiatrists ($p < 0.001$; Cohen's d = 1.04) respectively. Table 1 provides further results for each learning objective. Based on a self-reporting question, neurologists expressed a 54%, and psychiatrists expressed a 51%, increase in confidence following the education in discussing SUDEP with patients/caregivers.

Table 1

		Mean % of responses correct	Relative % change	P value	% *Improved on this learning objective	% #Reinforced on this learning objective
Increased knowledge regarding the need for clear communication around SUDEP with people with epilepsy	Neurologists pre-	12	450	P <.001	54	12
	Neurologists post-	66				
	Psychiatrists pre-	13	254	P <.001	36	10
	Psychiatrists post-	46				
Increased knowledge regarding the risk of SUDEP	Neurologists pre-	43	88	P <.001	58	32
	Neurologists post-	81				
	Psychiatrists pre-	27	137	P <.001	59	28
	Psychiatrists post-	64				

*Improved: answers at least one more question correctly
#Reinforced: answers the same number of questions correctly pre/post

Table of results expressing changes in knowledge relating to need for communication and risk associated with SUDEP before and after education.

Conclusion: This study demonstrates the positive effect of online medical education on specialists' knowledge and confidence in risks associated with and communication on SUDEP in Europe.

Disclosure: Lionel Thevathasan, Katherine Carpenter and Camille Scot-Smith are employed by Medscape LLC. Rohit Shankar, Philippe Ryvlin and Torbjörn Tomson have no disclosures. This educational programme was supported by an unrestricted educational grant by Angelini Pharma.

EPO-654 | Abstract withdrawn

EPO-655 | Antiseizure prophylaxis in routine neurosurgery practice: Urgent need for training

L. Manzo[1]; A. Pascarella[2]; S. Gasparini[2]; O. Marsico[2]; D. Tedeschi[2]; G. Idone[2]; R. Di Iorio[2]; D. Abelardo[2]; V. Cianci[1]; E. Ferlazzo[2]; U. Aguglia[2]

[1]Regional Epilepsy Centre, Great Metropolitan "Bianchi-Melacrino-Morelli Hospital", Reggio Calabria, Italy; [2]Department of Medical and Surgical Sciences, Magna Græcia University of Catanzaro, Italy

Background and Aims: Prophylactic antiseizure medications (ASMs) to prevent early and late seizures after craniotomy is not currently recommended, yet it is a common practice among neurosurgeons. This study investigates decision-making strategies regarding post-craniotomy ASM prescription in Italian Neurosurgery Units.

Methods: An online cross-sectional survey was conducted (November 2022-March 2023). The survey link was distributed via email to neurosurgeons of 110 Italian Pediatric and Adult Neurosurgery Units. The survey comprised 11 multiple-choice questions addressing ASM prescription for individuals without seizures or those experiencing early post-surgical seizures. Questions explored type and timing of prescribed ASMs, factors influencing decision, and drug withdrawal management.

Results: Eighty-two neurosurgeons from 64/110 Neurosurgery Units answered the survey. Forty-two out 82 (52.1%) neurosurgeons prescribed post-craniotomy ASMs for individuals without seizures: 9 routinely prescribed ASMs, 33 only under specific conditions (e.g., febrile seizures history, familiarity for epilepsy) or based on the surgical site. Levetiracetam was the most prescribed ASM (41/42; 97.6%). Thirty-one (73.8%) surgeons initiated ASMs before surgery. Thirty-two (39%) surgeons planned withdrawal within 6 months while 10 (10.2%) chose later suspension. Seventy-nine (96.3%) neurosurgeons prescribed ASM (mostly levetiracetam: 77/79; 97.5%) after an early post-surgical seizure. Only 4 (5.1%) surgeons routinely discontinued ASMs within 1 month, while 43 (54.4%) suspended them within 6 months and 32 (40.5%) continued beyond 6 months. Notably, 42 neurosurgeons managed ASM treatment independently, while 40 sought neurologist assistance.

Conclusion: This survey revealed widespread adoption of ASM prophylaxis after craniotomy in neurosurgery practice, despite lack of evidence about its usefulness, emphasizing the urgent need for training in this area.

Disclosure: Nothing to disclose.

EPO-656 | Gender disparities among neurology residents classifications in Portugal

F. Ladeira[1]; P. Faustino[2]; M. Soares[2]; V. Carvalho[3]

[1]Multiple Sclerosis Centre of Integrated Responsibility, Saint Joseph's Local Health Unit, Lisbon, Portugal; [2]Neurology Department, Saint Joseph's Local Health Unit, Lisbon, Portugal; [3]Neurology Department, Saint Mary's Local Health Unit, Lisbon, Portugal

Background and Aims: Gender disparities in medical professions have long been a subject of concern, with research consistently pointing to the role of implicit bias in shaping differential career outcomes for men and women. This study endeavors to investigate whether gender-based differentials exist in the evaluation of Neurology residents in Portugal.

Methods: We collected publicly available data encompassing gender (as a social construct), grades and rankings from two pivotal assessments administered at the beginning and ending of Neurology Residency: the National Board Exam (NBE) and Neurology Exam (NE), respectively. The NBE is a multiple-choice gender-blinded

evaluation, whereas the NE involves an oral gender-unblinded evaluation.

Results: Our analysis revealed that 36.5% of women and 21.6% of male residents achieved the superior quartile of the NBE ranking, which reflects a similar representation among top classifications when accessed through a gender-blinded exam. On the contrary, the proportion of male residents on the top classification of NE, a gender-unblinded evaluation, was more than twice higher than women (37.8% vs. 18.3%, $p < 0.05$), indicating a statistically significant disparity in performance between genders in the oral examination setting (Table 1).

Conclusion: The findings of the present study may imply that there are nuanced disparities in women's career as a neurologist resident in Portugal. Although the recruitment seems relatively balanced between genders, the gender-unblinded assessments unveil significant discrepancies favoring men.

Disclosure: Nothing to disclose.

EPO-657 | Burnout, depression and anxiety among neurology residents in Türkiye: A preliminary report

İ. Arslan[1]; B. Kılboz[2]; D. Arslan[3]; C. Ayvacıoğlu Çağan[4]; T. Saltoğlu[5]; M. Topçuoğlu[6]

[1]Gazi University Medical Faculty Neurology Departmant; [2]İstanbul Prof. Dr. Cemil Taşcıoğlu City Hospital; [3]Sincan State Hospital; [4]Bozkır State Hospital; [5]Ankara Bilkent City Hospital; [6]Hacettepe University Medical Faculty Neurology Departmant

Background and Aims: Neurology residency is a long and difficult journey in which the physical and mental well-being of trainees are essential for their clinical and academic success. This ongoing study aims to determine the mental status and factors that affect mental health of neurology residents in Türkiye and therefore improve the quality of neurology training.

Methods: Neurology residents throughout Türkiye were invited to take part in an online survey by the support of Turkish Neurological Association. Additionally to demographic and institutional data of all participants; Minnesota Job Satisfaction Questionnaire, Maslach Burnout Inventory, Beck Anxiety Inventory and Beck Depression Inventory were assessed.

Results: Anxiety was found in 62%, depression in 63.3% and burnout in 44% of the participants (n: 79). In correlation analyses, an increase in the duration of neurology training was associated with lower levels of depression (r: −0.21, p: 0.05) and anxiety (r: −0.34, p: 0.002). Working long hours was associated with a decrease in job satisfaction (r: −0.22, p: 0.04) and an increase in depression (r: 0.24, p: 0.02). Job satisfaction scores increased with more time devoted to education (r: 0.28, p: 0.01) and research (r: 0.22, p: 0.04). The presence of depression was less in residents who were able to rest after night shift (p: 0.01).

Conclusion: Preliminary data from our ongoing study demonstrates a high prevalence of burnout, depression, and anxiety among neurology residents in Türkiye. To reduce these factors, it may be beneficial to decrease the daily working hours, increase the time allotted for education and research, and provide rest after night shifts.

Disclosure: The current results are preliminary and the study continues.

EPO-658 | Ethical and neurological dimensions of Dr. Robert G. Heath's deep brain stimulation experiments

B. De[1]; M. Polestino[2]; B. Carr[3]

[1]School of Medicine, University of California San Francisco, San Francisco, CA, USA; [2]College of Liberal Arts and Science, University of Florida, Gainesville, FL, USA; [3]Department of Psychiatry, University of Florida College of Medicine, Gainesville, FL, USA

Background and Aims: This historical analysis revisits the pioneering yet ethically contentious deep brain stimulation (DBS) experiments of Dr. Robert Galbraith Heath. Heath's work in the mid-20th century focused on targeting limbic system components, such as the open-brain targeting of septal area, amygdala, and thalamus, aiming to unravel neurological foundations of psychiatric disorders. This retrospective study scrutinizes the specific neural circuits and neurotransmitter systems engaged in Heath's DBS trials, alongside their profound ethical implications.

Methods: A detailed examination of Heath's seminal publications and experiment records, particularly those documenting the septal stimulation for modulating depressive symptoms, the B-11 implant for psychiatric disorders, and interventions in schizophrenia and homosexuality, was conducted. The analysis involves a comprehensive review of limbic system circuitry, specifically the role of septal nuclei, amygdaloid complex, and thalamic connections, in conjunction with the dopaminergic and serotonergic pathways implicated in Heath's studies.

Results: Heath's DBS experiments revealed notable alterations in limbic circuitry functioning, particularly highlighting the role of septal and amygdaloid stimulation in modulating emotional and behavioral responses. The B-11 implant trials underscored the intricate interplay between deep brain regions in psychiatric symptomatology. Additionally, Heath's work raised pivotal ethical concerns regarding patient consent and the invasive nature of DBS, catalyzing a reevaluation of research protocols in neuropsychiatry.

Conclusion: Heath's forays into DBS epitomize a seminal yet polarizing epoch in neurology, spotlighting the nascent interplay between limbic neuromodulation and psychiatric therapeutics. This retrospection not only venerates his pioneering ethos but also subtly adumbrates the era's nascent ethical paradigms, affirming Heath's indelible imprint on the neurological vanguard.

Disclosure: An artifact supplementing this study is a book on psychosurgery, containing Heath's personal annotations and signature, providing a unique historical perspective.

EPO-659 | The history of Danish neuroscience

O. Paulson[1]; A. Schousboe[2]; H. Hultborn[3]
[1]*Neurobiology Research Unit, Department of Neurology, Rigshospitalet and University of Copenhagen, Faculty of Health and Medical Science, Copenhagen, Denmark;* [2]*Department of Drug Design and Pharmacology, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark;* [3]*Department of Neuroscience, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*

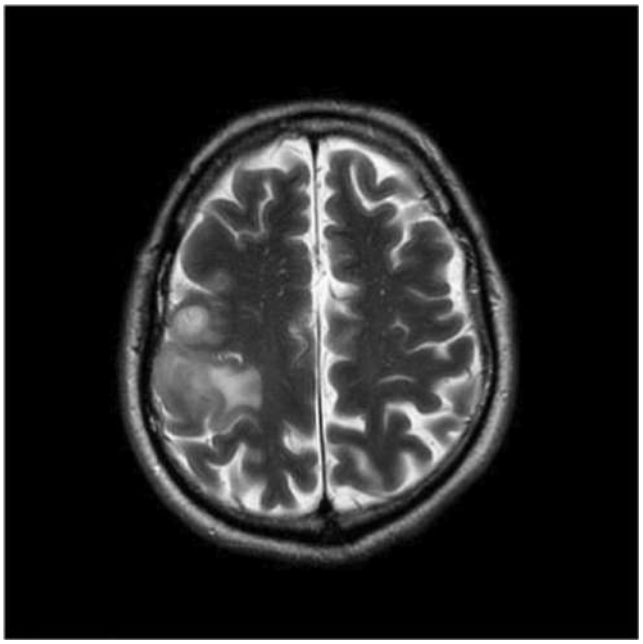
Background and Aims: The history of Danish neuroscience dates back at the 17th century, and was from the start linked to clinical disciplines. This continued in the 19th and 20th century with new initiatives linking basic neuroscience to clinical neurology and psychiatry. From the middle of the 20th century, basic neuroscience was developing rapidly within the preclinical university sectors. Clinical neuroscience continued and was even reinforced during this period with important translational research.
Methods: Literature review.
Results: Some highlights: Steno (1638–1686) was active in many scientific fields. Among his main contributions to neuroscience was the investigation of the anatomy of the pineal gland. René Descartes had proposed how the pineal gland was the seat of the soul, acting by rotation to distribute animal spirits. Steno demonstrated that the pineal gland was merely grey matter with black spots. In the 19th century Carl Lange (1834–1900) had main contributions in neurology and psychiatry. He rode a book in Danish, "On emotions – Psycho-Physiological Study" in 1885, translated to German, French and English. Fritz Buchthal (1907–2003) had a main role in the Danish and international development of clinical neurophysiology and especially electromyography. Niels A. Lassen (1926–1997) main research field was the cerebral circulation. He, his group and collaborators were the first to demonstrate that activation led to blood flow increase – functional activation. Finally, Jens Christian Skou (1918–2018) received the Nobel Prize in 1997 for the discovery of the sodium-potassium pump.
Conclusion: Danish Neuroscience has a strong history.
Disclosure: Nothing to disclose.

Neuro-oncology

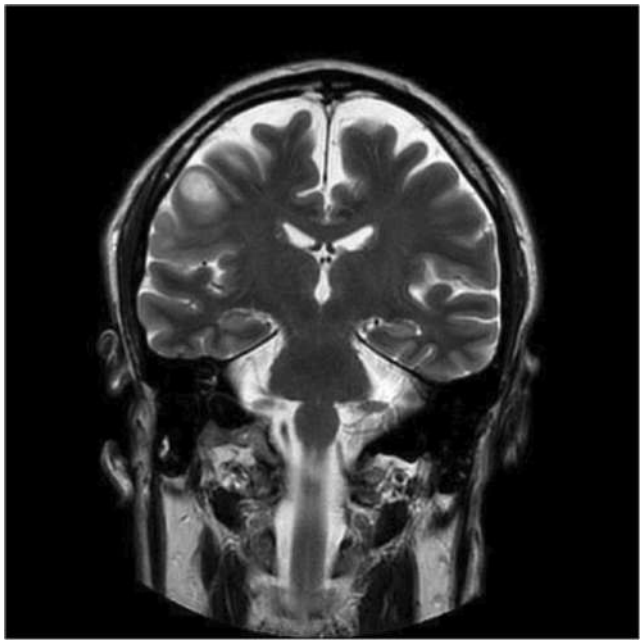
EPO-660 | Hemifacial spasm of central origin due to structural cause

A. Lorenzo Montilla; S. López Anguita; B. Gutiérrez Ruano; A. Muñoz González; C. Alarcón Morcillo; M. Olmedilla
Department of Neurology, Hospital Central de la Defensa Gómez Ulla

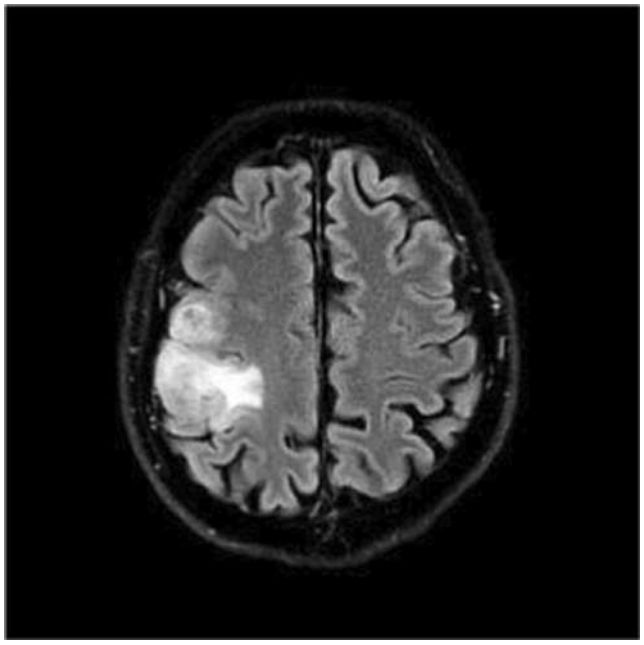
Background and Aims: Hemifacial spasm is a peripheral movement disorder consisting of irregular clonic/tonic involuntary movements of muscles innervated by the facial nerve. Its principal cause is an hyperexcitability of its nucleus or an abnormal transmission of the proximal nerve segment, usually of compressive origin due to a vascular structure; some atypical cases are caused by brain tumors, mainly infratentorial location. We present a case with central origin due to supratentorial lesion.
Methods: A 60-year-old male under neurology follow-up for epilepsy (motor focal aware seizures) of structural cause (right frontal SOL: non mutated IDH diffuse glioblastoma, TERT mutation, WHO CNS4), went to the emergency room because of arrhythmic spasmodic movements in bilateral frontal region (predominantly left), left orbicularis oculi and left hemiface. Thinking of continuous partial epilepsy, anti-seizure medication was increased, without any improvement. Asking again, these movements could be in relation to a distony: they improve during sleep and with sensory tricks and exacerbates with light, nervousness and speech, so infiltrations with botulinum toxin were performed, with marked improvement.
Results: Brain MRI: right fronto-parietal cortical thickening with obliteration of the sulci, hypertense on T2 / FLAIR and hypointense on T1, affecting opercular area and pre/post-central gyri; small subcortical pseudonodular area (12 × 5 mm) with subtle hypersignal in diffusion and a faint ring enhancement; stable compared to the previous one.



Brain MRI, axial T2.



Brain MRI, coronal T2.



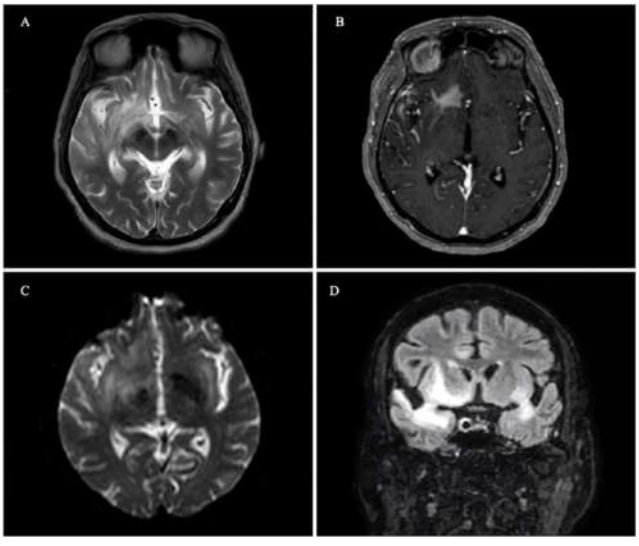
Brain MRI, axial FLAIR.

Conclusion: Hemifacial spasm due to supratentorial tumors may be explained by affectation of the contralateral motor cerebral cortex (irritation of the lower motor unit of the facial nerve) based on anatomical investigation in veterinary medicine.
Disclosure: Nothing to disclose.

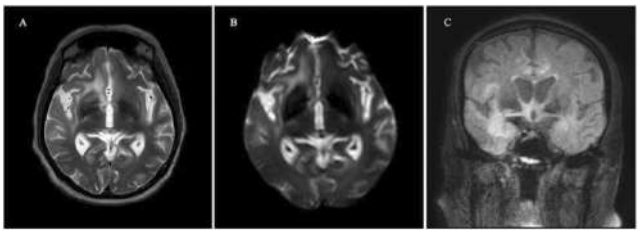
EPO-661 | A biopsy-verified case of CNS involvement of mycosis fungoides with positive RT-QuIC assay

A. Alexandratou[1]; E. Petrou[1]; A. Gamvroula[1]; A. Antoniou[1]; P. Vlahou[2]; G. Kolovos[1]; E. Alexiou[1]
[1]*Neurology Department, Evangelismos Hospital, Athens, Greece;*
[2]*Pathology Department, Evangelismos Hospital, Athens, Greece*

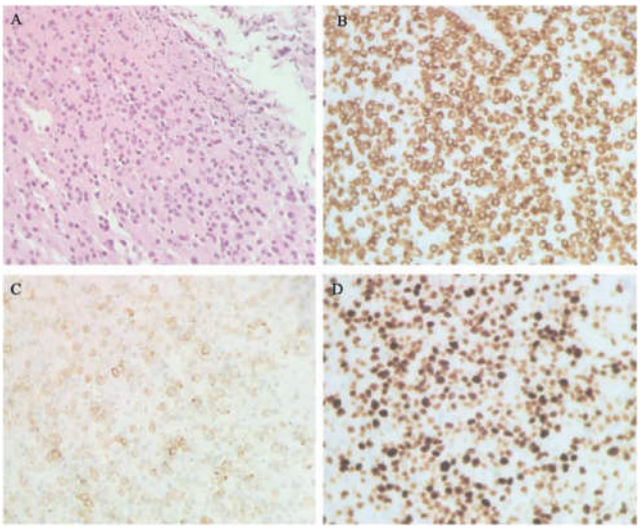
Background and Aims: We report a rare case of positive RT-QuIC assay in CNS involvement of mycosis fungoides.
Methods: A 73-year-old man presented with decreased consciousness and generalized convulsions. He had been formerly diagnosed with mycosis fungoides, which was in full remission. Clinical examination revealed profound cognitive deficits with fluctuating level of alertness during admission. A brain MRI showed multiple contrast-enhancing lesions in both hemispheres, while a first lumbar puncture indicated lymphocytic pleocytosis with elevated CSF protein.
Results: The rapidly progressive cognitive decline prompted investigations for Creutzfeldt-Jakob disease (CJD) with 14-3-3 and RT-QuIC assay, both of which came back positive. Meanwhile, flow cytometry analysis reported increased T-cell population, suggestive of CNS lymphoma. The RT-QuIC assay remained positive in the second, acellular, lumbar puncture. The CJD diagnosis was not further supported by imaging or EEG findings. A brain biopsy was performed, reporting brain infiltration by a highly malignant T-cell lymphoma, believed to represent large cell transformation of mycosis fungoides with CD30 expression. Treatment with pulsed steroids had some effect on the level of consciousness, although a degree of memory impairment remained.



Initial MRI scans of the brain. A. Axial T2 showing high signal in the right temporal lobe, B. Axial post-contrast scan, demonstrating an area of contrast enhancement in the right temporal lobe, C. Axial DWI, depicting a similar area of high signal in the right temporal lobe, D. Coronal FLAIR with high signal in both temporal lobes and extending to basal ganglia bilaterally.



Serial MRI scans of the brain after steroid treatment. A. Axial T2 and B. Axial DWI showing slight improvement of the high signal in the right frontotemporal area. C. Coronal FLAIR demonstrating bilateral temporal high signal to a lesser extent compared to the initial MRI; some areas of high signal are evident in the medial frontal lobes bilaterally. Image degraded my motion artefact.



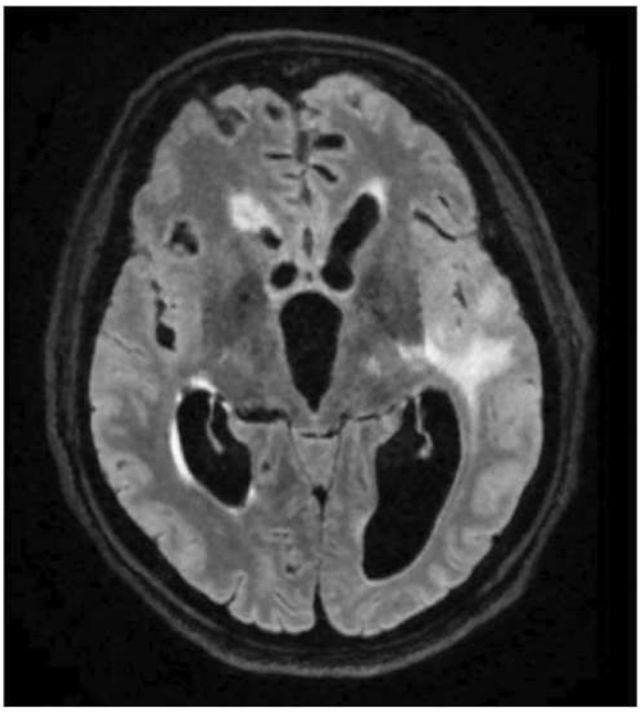
Histological images from the patient's brain biopsy. A. Infiltration of brain parenchyma by medium-sized lymphocytes with dark chromatin and irregular nuclear membrane (Haematoxylin and eosin ×400 magnification), B. CD3 expression in medium-sized lymphocytes.

Conclusion: RT-QuIC assay is able to accurately detect the pathogenic agent (PrPSc), identified to be responsible for CJD occurrence. Positive RT-QuIC assay has been strongly linked to CJD, with specificity reaching 99%, although it has been suggested that high CSF white cell count and protein can affect the results. The brain biopsy has confirmed CNS involvement of the cutaneous lymphoma; however, a possibility of subclinical coexistence of CJD remains.
Disclosure: Nothing to disclose.

EPO-662 | Primary leptomeningeal sarcomatosis: An exceptional cause of chronic, aseptic meningitis

S. Alejandro[1]; U. Patricia[1]; D. Renata[1]; V. Ana[2]; A. Carlos[1]; G. Guillermina[1]
[1]*Departamento de Neurología, Hospital Regional Universitario de Málaga;* [2]*Departamento de Anatomía Patológica, Hospital Regional Universitario de Málaga*

Background and Aims: Primary leptomeningeal sarcomatosis (PLS) represents less than 1% of primary intracranial tumors and is an even less frequent cause of non-infectious, chronic meningitis. Therefore, it should be taken into consideration when other causes of chronic meningitis have been dismissed.
Methods: We present the case of a 58-year-old man who presented a very suggestive granulomatous, subacute meningitis based on clinical findings. Nevertheless, every microbiological determination tested was negative and there were no specific findings in image tests.
Results: Our patient presented a wide range of symptoms: behavioral disorder, cognitive impairment, right hand drift, facial supranuclear partial palsy but no neck rigidity. Also, during hospitalization the patient developed seizures that required antiseizure medication. CT and MRI found digitiform edema in left parietotemporal lobes, meningeal thickening at that level and communicating hydrocephalus. Lumbar puncture resulted negative for every test underwent, as well as every other diagnostic procedure. Tuberculous meningitis was suspected at first, and antituberculous treatment was initiated. Due to poor evolution, brain biopsy was subsequently performed.



FLAIR-powered MRI showing digitiform left parietotemporal edema and meningeal thickening at that level.

Conclusion: PLS is an exceptional cause of chronic, aseptic meningitis which must be suspected when other more frequent etiologies are not present. Despite its fatal prognosis, holocranial radiotherapy showed little survival increasing, reaching up to 3 years in certain patients. Therefore, this diagnosis must be considered in certain scenarios.
Disclosure: Nothing to disclosure.

EPO-663 | The Last Bastion – 7 Cases of tectal gliomas with long follow up

D. Antão; J. Costa; J. Marques; I. Costa; D. Salgado
Neurology Department, Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal

Background and Aims: Brainstem gliomas are an heterogenous group of gliomas that appear predominately during childhood. Mesencephalic gliomas are usually invasive; however, tectal gliomas are a subtype with a slow growth rate. These are low grade gliomas with a relatively benign course, that turn symptomatic when patients develop obstructive hydrocephalus. Permanent neurological deficits are rare.

Methods: This work will explore demographic, clinical and radiological features of 7 patients with tectal gliomas with active follow up at an oncological hospital in Lisbon.

Results: The median age of these patients was 14 years and 57.1% were female. In 4 of 7 cases, the clinical manifestation was supratentorial hydrocephalus demanding neurosurgical treatment – 3 had ventriculoperitoneal shunt placement and 1 had ventriculostomy. The diagnostic was incidental in the remaining. 28.6% of the tumors had a cystic-like appearance on brain magnetic resonance. The majority (85.7%) had no enhancement after gadolinium injection. Only 1 patient was submitted to neurosurgical biopsy and the histology showed grade II astrocytoma. More than half of the subjects (57.1%) have no neurological deficits. The remaining had pupillary or oculomotor abnormalities. All patients are under surveillance, without treatment, with radiologic stability for many years.

Conclusion: Tectal gliomas are indolent brain tumors whose main symptoms relate to obstructive hydrocephalus. Similarly to the literature, this cohort shows slow growth tumors, with few associated symptoms and sustained imagiologic stability. This entity is a rare case in Neuro-Oncology as brain biopsy may be dispensed due to the risk of worsening symptoms while not changing patient management.

Disclosure: Nothing to disclose.

EPO-664 | Prognostic impact of surgical resection versus biopsy in patients with primary central nervous system lymphoma (PCNSL)

F. Bruno[1]; A. Pellerino[1]; E. Pronello[2]; R. Palmiero[1]; F. Cavallo[3]; L. Orsucci[4]; L. Bertero[5]; F. Rizzo[6]; F. Cofano[6]; D. Garbossa[6]; R. Rudà[1]
[1]*Division of Neuro-Oncology, Department of Neurosciences, University and City of Health and Science Hospital, Turin, Italy*; [2]*Neurology Unit, Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy*; [3]*Department of Molecular Biotechnologies and Health Sciences, Division of Haematology, University of Turin, Turin, Italy*; [4]*Division of Hematology, University and City of Health and Science Hospital, Turin, Italy*; [5]*Pathology Unit, Department of Medical Sciences, University of Turin and City of Health and Science University Hospital, Turin, Italy*; [6]*Division of Neurosurgery, Department of Neurosciences, University and City of Health and Science Hospital, Turin, Italy*

Background and Aims: Whether surgical resection, as compared to biopsy, may positively affect the outcome of Primary Central Nervous System Lymphoma (PCNSL) patients is controversial. In this study, we compared the clinical characteristics and outcome of PCNSL patients receiving either surgical resection or biopsy in our Institution.

Methods: We retrospectively collected clinical data of PCNSL patients, who underwent biopsy or surgical resection and were subsequently treated in our Institution from 2004 to 2023. Progression-free survival (PFS) and overall survival (OS) were defined as time from diagnosis and recurrence or death/censoring).

Results: We included 55 patients, with a median age of 66.0 years. 36 (65.5%) showed multifocal lesions at presentation. 32 (58.2%) underwent biopsy, whereas 23 (41.8%) surgical resection. 48 (87.3%) underwent adjuvant methotrexate-based chemotherapy. Unifocal vs multifocal lesions prevailed among patients undergoing surgical resection (20/23, 87.0%) vs biopsy (15/32, 46.9%), $p = 0.002$. Median PFS and OS of the whole cohort were 8.0 and 26.0 months. Surgical resection vs biopsy correlated with longer median PFS and OS both in a univariate (mPFS: 64.0 vs 7.0 months, $p = 0.031$; mOS: 68.0 vs 10.0 months, $p = 0.007$), and a multivariable analysis (HR 0.390, 0.168–0.907, $p = 0.029$). Conversely, unifocal vs multifocal presentation was the only variable with a favourable impact on the OS.

Conclusion: In our study, surgical resection, as compared to biopsy, was associated with longer PFS, but not OS, in PCNSL patients. Further studies on larger cohorts are needed to clarify whether surgical resection may be a feasible and safe option to improve survival in selected PCNSL patients.

Disclosure: Nothing to disclose.

EPO-665 | Progressive supra and infratentorial hypermetabolic white matter lesions non-typical of multiple sclerosis

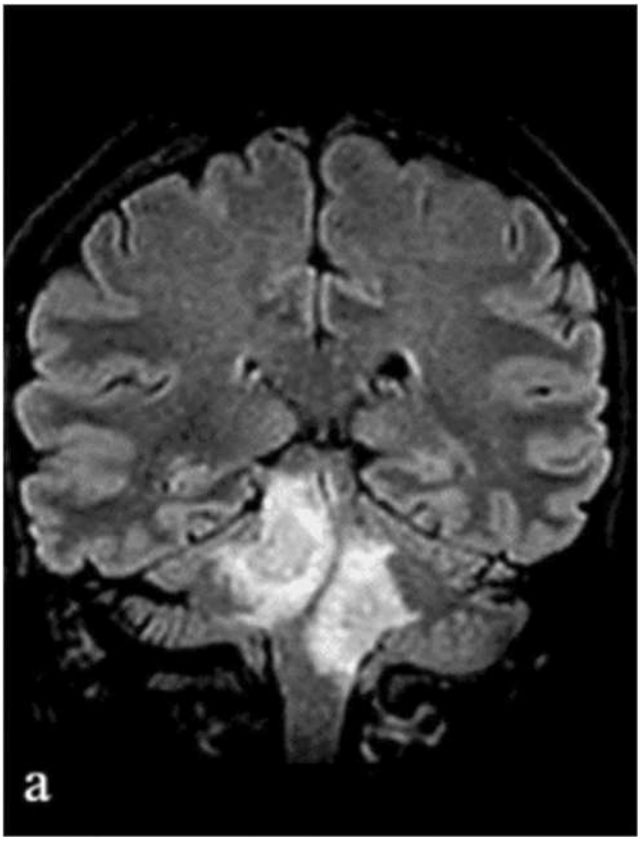
Department of Neurology, Consorcio Hospital General Universitario de Valencia, Valencia, Spain

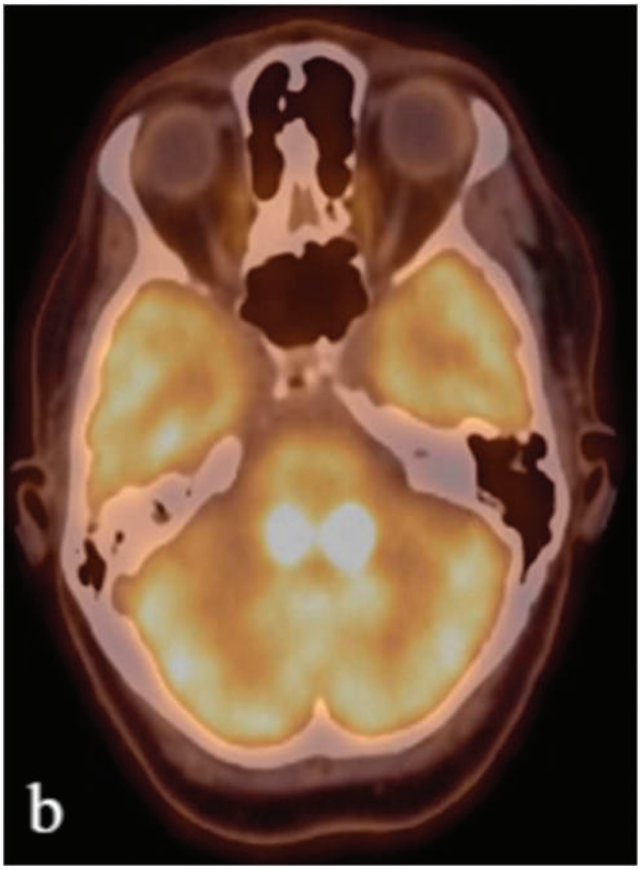
Background and Aims: A case report of a patient presenting progressive brainstem symptoms along with progressive supra and infratentorial white matter lesions (WML), hypermetabolic on Positron Emission Tomography-Computerized Tomography (PET-CT), mistakenly characterized as demyelinating.

Methods: Descriptive retrospective study of a case.

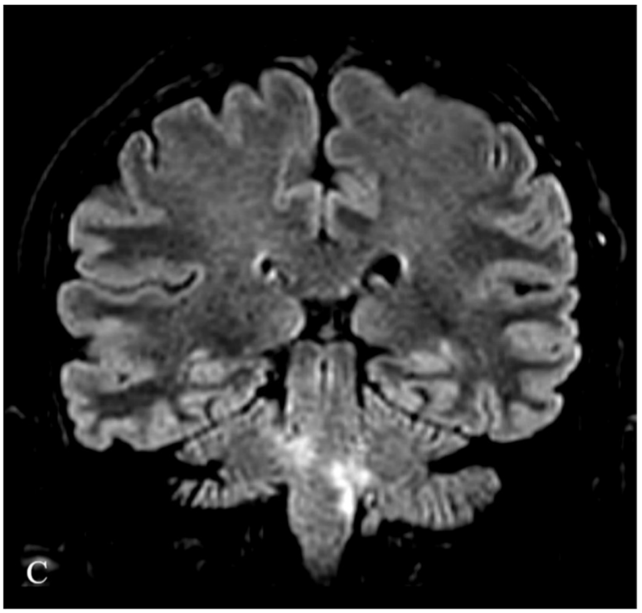
Results: a 43-year-old female presenting with progressive gait instability, paresthesia, left hemiparesis and left inferior facial palsy. Brain Magnetic Resonance Imaging (MRI) showed multiple supra and infratentorial WML, which were characterized radiologically as demyelinating. A total PET-CT showed hypermetabolic brainstem lesions, with no thoracoabdominal findings. Bloodwork, including tumor markers, autoimmunity serologies (antiMOG and AQ4 antibodies), as well as ophthalmologic slit-lamp examination and two cerebrospinal fluid (CSF) samples were all unremarkable. A course of intravenous corticosteroids resulted in slight clinical and radiological improvement. Further on, she presented signs of clinical worsening with multidirectional nystagmus, dysphagia, complete left facial and hypoglossal palsy with left hemianesthesia, and growth of the previous lesions in subsequent MRIs. A biopsy of the caudate lesion along with an intraventricular CSF sample were taken, showing findings suggestive of diffuse large B-cell lymphoma. MATRIX chemotherapy protocol was started, followed by autologous stem cell transplantation, with subsequent clinical and radiological improvement.



(a) T2-FLAIR weighted image showing hyperintense bilateral brainstem lesions.



(b) Brain PET-TC showing hypermetabolic activity in these lesions (calculated as SUV max 21, 8 [right] and 23.8 [left]).



(c) T2-FLAIR weighted image after 3rd chemotherapy cycle (MATRIX scheme) showing noticeable decrease in the size of the infratentorial lesions.

Conclusion: Primary central nervous system lymphoma is a rare cause of WML, with less than 10% showing infratentorial lesions. Previously associated with AIDS patients, neurologists should have a clinical suspicion in patients showing WML non-typical of known demyelinating diseases. A transient clinical and radiological improvement after corticosteroids is typical.

Disclosure: The author has no conflict of interest.

EPO-666 | MPNST as a very late complication of radiotherapy: Red flags, diagnostic considerations and role of nerve biopsy

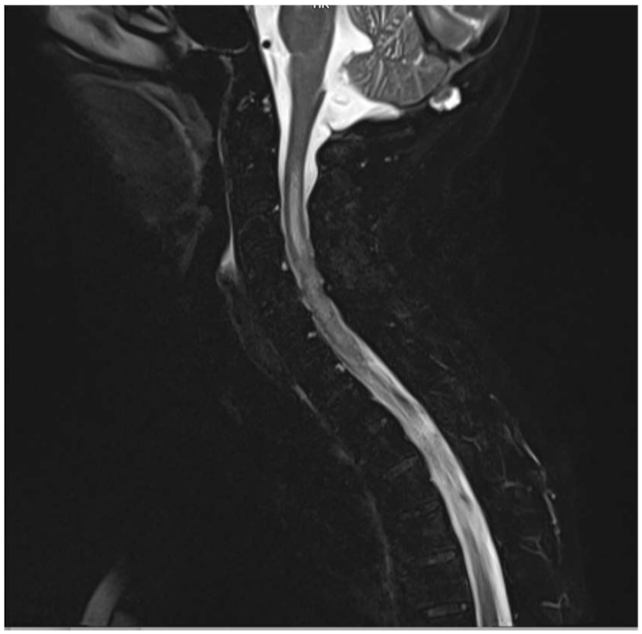
G. Salvucci[1]; R. Colombo[1]; M. Vizziello[1]; B. Pollo[2]; M. Grisoli[3]; G. Marucci[2]; E. Dalla Bella[1]; S. Usai[1]; G. Giaccone[2]; G. Lauria Pinter[1]; N. Riva[1]

[1]Unit of Neuroalgology, IRCCS Foundation "Carlo Besta" Neurological Institute, Milan, Italy; [2]Unit of Neuropathology and Neurology, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy; [3]Neuroradiology Unit, Foundation IRCCS Neurological Institute Carlo Besta, Milan, Italy

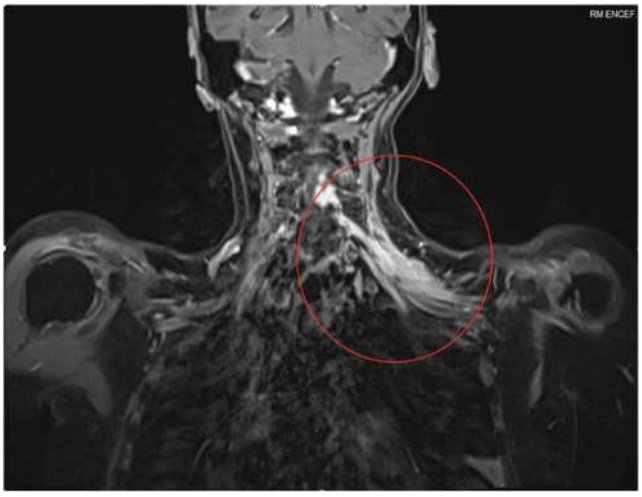
Background and Aims: MPNST is a rare, aggressive sarcoma that may arise up to many years following radiotherapy. We report a case of a fatal MPNST mimicking at onset an inflammatory brachial plexopathy and we propose diagnostic recommendations based on evidence from a systematic review.

Methods: case report of MPNST and systematic literature review.

Results: A 60-year-old female presented with progressive left upper limb proximal weakness. She was known for neck radiotherapy 36 years prior for Hodgkin lymphoma. Cervical MRI, CSF and FDG-PET were normal. Remarkably, brachial plexus MRI showed nerve roots modest thickening. IvIg and steroids treatment were not effective. Progression of symptoms occurred in the following year, when a new MRI revealed multiple cerebral and cervical T2-hyperintensities. An intradural biopsy allowed histological diagnosis of MPNST. The patients died 18 months after onset. Our literature review highlighted as major risk factors for post-radiation MPNST head and neck irradiation (77% of cases), occurred before the age of 35 years (62%). Mean time from radiation was 13.7 years. Importantly, 21/22 (95.5%) of cases presented with focal tumor-like enlargement, one case had brachial plexopathy without enlargement with hypermetabolism at PET-FDG. Mean survival from diagnosis in patients that underwent surgery is 14.3 months with 29.4% still alive at the moment of publication.



Cervical spine MPNST infiltration at MRI: diffuse C2-C7 intramedullary hyperintensity on T2-weighted sequences.



Brachial plexus MRI: T2 hyperintensity, thickening and enhancement of brachial plexus, especially first and second trunk.

Salvucci G, unpublished	neck	24	36	thickening and edema of brachial plexus	n	2 weeks

Clinical and radiological characteristics of all malignant peripheral nerve sheath tumors reported in the literature.

Conclusion: post-radiation MPNST can occur up to 40 years after radiotherapy and it can present as an isolate brachial plexopathy without focal hypermetabolism. Since surgery may be beneficial, close radiological monitoring and early diagnostic biopsy in high-risk patients with brachial plexopathy is strongly recommended.
Disclosure: Nothing to disclose.

EPO-667 | Extending the spectrum of paraneoplastic syndromes mediated by anti-Yo antibody

J. Bandeira Costa[1]; D. Antão[1]; A. Opinião[2]; J. Nunes[1]; J. Marques[1]
[1]*Neurology Department, Instituto Português de Oncologia de Lisboa, Lisbon, Portugal;* [2]*Medical Oncology Department, Instituto Português de Oncologia de Lisboa, Lisbon, Portugal*

Background and Aims: Stiff-person syndrome (SPS) is characterized by fluctuating hypertonia and painful muscular spasms increasing with external stimuli being frequently mediated by anti-GAD antibodies, or amphiphysin antibodies in paraneoplastic variants. We report a case of SPS, preceded by cerebellar ataxia, with positive titles of anti-Yo antibody.
Methods:
Results: A female patient, 69 years old – with previous history of peritoneal carcinomatosis secondary to Fallopian tube carcinoma, which underwent chemotherapy with carboplatin and paclitaxel and cytoreductive surgery – developed subacute dizziness, axial and appendicular ataxia and memory disturbances during the chemotherapy cycles. While brain-CT and MRI were normal, EMG documented an axonal sensory-motor polyneuropathy. Anti-Yo antibody was positive both in serum and LCR. Assuming a cerebellar degeneration associated with anti-Yo syndrome, intravenous immunoglobulin and high dose methylprednisolone were started. Due to absence of benefit regarding the ataxia and falls with osteoporotic fractures, treatment was suspended. During the following two months, she developed painful inferior limbs spasms, aggravated by external stimuli, with an ascending pattern of truncal and cervical involuntary muscular contractions, with hypertonia and gait impairment. While maintaining exclusively anti-Yo antibody positivity, a second EMG registered abundant continuous motor unit potentials detected on the inferior limb muscles, independent of voluntary muscular activity. Neuraxis-MRI, anti-GAD and amphiphysin were negative. Gradual recovery of autonomous gait occurred with 9 cycles of monthly IVIG.
Conclusion: We underline the diversity of clinical presentations of SPS while highlighting a possible association with Anti-Yo antibody, not yet described, and emphasizing the positive therapeutical response.
Disclosure: Nothing to disclose.

EPO-668 | Extranodal NK/T cell lymphoma with primary CNS manifestation – A case report

L. Müller-Miny; L. Lohmann; O. Grauer
Department of Neurology with Institute of Translational Neurology, University Hospital Münster, Münster, Germany

Background and Aims: Rare extranodal NK/T cell lymphoma (ENKTCL) occurs predominantly in Asian and Latin American countries and preferentially arises in the nasopharynx. Although EBV is normally restricted to B lymphocytes, it has been associated with tumor cells of NK/T cell origin in malignant NK and T cell tumors. EBV increases gene instability, incidence of ENKTCL and enhances escape mechanisms from T cell-mediated immune responses. We report here a rare case of EBV associated ENKTCL with a primary CNS manifestation and haemophagocytic lymphohistiocytosis (HLH).
Methods: This retrospective case report fulfills the CARE criteria.
Results: The patient initially presented herself for nuclear facial palsy. MRI of the brain showed brain stem lesions and elevated EBV copies were detected in the cerebrospinal fluid. An initial CT scan of the lungs and a sonography of the abdomen revealed no lesions. Over the course of two months, the patient developed progressive clinical symptoms and multilocular CNS lesions. Due to the high EBV copies, a rituximab infusion was performed to deplete the B cells, but did not improve clinical symptoms. The patient successively

developed a secondary HLH. A liver biopsy was performed due to the HLH-associated hepatomegaly, revealed an ENKTCL. An additional brain biopsy detected lymphocytic infiltration consistent with ENKTCL, mainly of NK cells and localized EBV type 1 in the tumor cells.

Conclusion: ENKTCL may initially manifest in the CNS. Unclear CNS lesions with massively increased intrathecal EBV copies may indicate a lymphoma in which malignant cells derived from NK/T cells can be infected with EBV.

Disclosure: Nothing to disclose.

EPO-669 | Successful identification and management of a SMART syndrome occurring 36 years after cranial radiotherapy

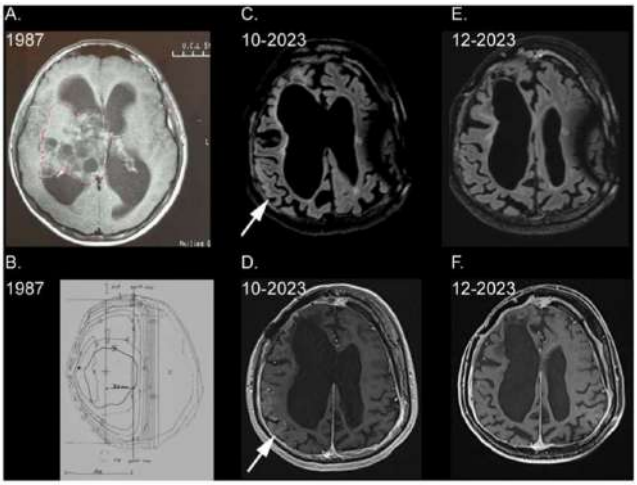
L. Lebrun[1]; D. Di Perri[2]; J. Raymackers[1]; C. Van Ruyssevelt[3]; V. Marneffe[4]

[1]Department of Neurology, Clinique Saint-Pierre Ottignies, Ottignies-Louvain-la-Neuve, Belgium; [2]Department of Radiation Oncology, Cliniques Universitaires Saint-Luc, Brussels, Belgium; [3]Department of Radiology, Clinique Saint-Pierre Ottignies, Ottignies-Louvain-la-Neuve, Belgium; [4]Department of Neurosurgery, Clinique Saint-Pierre Ottignies, Ottignies-Louvain-la-Neuve, Belgium

Background and Aims: Radiation therapy (RT) is a cornerstone in the management of brain tumors, either alone or combined with surgery and/or systemic therapy. SMART syndrome (stroke-like migraine attacks after RT) is a rare neurological disease believed to be a late-onset side effect of cranial RT and consists in stroke-like symptoms, epilepsy and migraine (Dossin et al., 2023; Shuper et al., 1995). This syndrome has been observed within a timeframe of 1 to 37 years after RT. Pathophysiology is believed to be multifactorial, involving white matter necrosis, vascular endothelial damage, demyelination and gliosis (Ota et al., 2023; Turnquist et al., 2020). We report a case of SMART syndrome presented with severe left hemiparesis and left facial palsy which was successfully managed with steroid pulse therapy (1000 mg/day, 5 days) (Jia et al., 2018; Ota et al., 2023).

Methods: We reviewed literature.

Results: On 4th day of treatment, he was able to walk again with a return to his basis state. Six weeks later, the patient condition was stable without any relapse. Strength on the left side was back to its initial level (i.e., slight paresis without any facial asymmetry).



A. T1 MRI sequence showing the tumour at the time of diagnosis (1987). B. Radiation dose distribution for the 24-Gy sequential boost (1987). C. T2 FLAIR MRI sequence showing hyperintensity of right parieto-occipital cortex (10-2023). D. T1 post-gadoliniu.

Conclusion: In conclusion, we report here a case of successful treatment of SMART syndrome occurring 36 years after RT, which is one of the latest occurrences of this syndrome ever described (Ota et al., 2023). We believe that recognizing SMART syndrome in patients with a history of cranial RT, even after a prolonged period, is crucial to avoid misdiagnosis and subsequent improper treatment.

Disclosure: Nothing to disclose.

EPO-670 | Autoimmune encephalitis in the era of immune-checkpoint inhibitors: Descriptive study in a tertiary hospital

M. Alanís Bernal[1]; A. Zabalza[1]; A. Vilaseca[1]; M. Sanz-Martínez[2]; L. Viñas Giménez[2]; X. Montalban[1]; H. Ariño[1]

[1]Department of Neurology and Centre d'Esclerosi Múltiple de Catalunya (Cemcat); Vall d'Hebron University Hospital, Barcelona, Spain; [2]Immunology Department, Vall d'Hebron University Hospital, Barcelona, Spain

Background and Aims: This study aims to characterize patients with autoimmune encephalitis (AE) in a tertiary hospital and explore its association with cancer and immune checkpoint-inhibitors (ICI) treatment, providing valuable insights for effective treatment strategies.

Methods: Retrospective single-centre study from 2017 to 2023 including patients with antineuronal antibody (ANA) (2 techniques) or with definite immune-related encephalitis secondary to ICI. We analyzed clinical differences between subgroups with or without cancer and with or without ICI exposure.

Results: Thirty-one patients were included [64.5% female, median age 59.7 (range 37.9–69.1)] with a median follow-up of 34.6 months (range 10.5–69.6). Patients had various ANA including GAD65 ($n=6$), Hu ($n=4$), NMDAR ($n=3$), Yo ($n=3$), other ANA ($n=13$) and two seronegative treated with ICIs. Median PNS-Care score was 7 (range

4–9.5). 19/31 (61.3%) were cancer-associated, 8 had neurological symptoms before cancer diagnosis, 7 after ICI and 4 after cancer diagnosis without ICI. Among patients with cancer, 14 were advanced (lymph nodes or distant metastasis) at neurological onset. 5/31 (16.1%) patients deceased, 4 due to tumor progression. Patients with concomitant cancer were older (median 62.0 years [range 49.8–71.0] vs 38.8 [range 21.2–61.6] $p < 0.05$) and had a shorter time to treatment from disease onset (median 1.2 months [range 0.5–5.0] vs 20.4 [range 3.4–33.3] $p < 0.05$), without differences in prognosis or ICI treatment in alive patients.

Conclusion: Our study suggests that patients diagnosed with AE in recent years are frequently associated with advanced cancer which is already under treatment. Future studies are needed to optimize the management of this prevalent subpopulation.

Disclosure: Nothing to disclose.

EPO-671 | Outcomes of patients with neoplastic meningitis undergoing ventriculoperitoneal shunting and intrathecal chemotherapy

M. Loghin

Department of Neuro-oncology, MD Anderson Cancer Center, Houston, TX, USA

Background and Aims: To present the outcomes of a retrospective cohort of patients with leptomeningeal disease (LMD) who received placement of ventriculoperitoneal shunt (VPS) and Ommaya reservoir for intrathecal chemotherapy.

Methods: We performed an in-depth chart review using electronic medical records of patients with LMD who had undergone placement of VPS and Ommaya in a single institution over a three-year period.

Results: Eighteen patients with LMD underwent VPS placement and Ommaya reservoir for intrathecal chemotherapy. Eleven patients had breast cancer, four had lung cancer, and the remaining three patients had thyroid, esophageal and uterine cancer respectively. Seventeen patients are deceased, and one patient was lost to follow up, and not included in our analysis. Sixteen (94%) patients had brain metastases. Eleven patients (61.1%) received radiotherapy prior to VPS placement. Karnofsky scores ranged from 60 to 90. Seven (41%) patients did not receive intrathecal chemotherapy due to rapid LMD progression. Ten (59%) patients received intrathecal Topotecan, and one received Cytarabine at the time of disease progression. The overall survival of these patients from time of VPS placement was 15.15 weeks (range 4.1–203.2), of which seven (41%) survived less than eight weeks. Six (60%) patients died from LMD progression, three (30%) from systemic disease progression, and one (10%) died of medical complications.

Conclusion: Our retrospective analysis suggests urgency for early diagnosis of LMD with increased intracranial pressure, along with spinal fluid diversion procedures for intrathecal chemotherapy administration. These interventions may allow for prolongation and improvement in quality of life.

Disclosure: Amulya Gottiparthy, Lauren Orda, Emily Morrow, and Monica LoghinDr. Gottiparthy has nothing to disclose. Mrs. Orda-Nguyen has nothing to disclose. Mrs. Morrow has nothing to disclose. Dr. Loghin has nothing to disclose.

EPO-672 | Prevalence of systemic neoplasms in a cohort of adult neurofibromatosis 1 patients: A single-center retrospective study

N. Setola[1]; G. Miele[1]; C. Santoro[2]; E. Vanore[1]; F. Napolitano[1]; M. Melone[1]

[1]Center for Neurofibromatosis & Rare Diseases and InterUniversity Center for Research in Neurosciences, Department of Advanced Medical and Surgical Sciences, 2nd Division of Neurology, University of Campania Luigi Vanvitelli, Napoli, Italy; [2]Department of Precision Medicine, University of Campania "Luigi Vanvitelli", Napoli, Italy

Background and Aims: Neurofibromatosis type 1 (NF1), the most frequent hereditary cancer predisposition syndrome, is characterised by occurrence of tumours in both central and peripheral nervous systems (CNS and SNP), with a 5–15% higher risk of developing a neoplasm outside CNS and SNP, compared to general population. Our study aims to assess systemic cancer prevalence in a patient's cohort.

Methods: Demographic and clinical data of NF1 patients, diagnosed according to established international criteria, were analysed.

Results: In a cohort of 127 individuals [54.2% women, median age 44.6 years (SD 17.5)], participating in NF1 surveillance programme for median duration of about 10 years, 13.38% (17/127) had systemic cancer. Patients' mean age at cancer diagnosis was 43.4 years (range 6.84–76.6). Breast cancer (23.8%) was the most frequently encountered malignancy, followed by prostate cancer (17.6%), gastrointestinal (11.8%), gynaecological (11.8%), bone (11.8%), pheochromocytoma (5.9%), melanoma (5.9%) and haematological cancers (5.9%). Except for sex-unrelated tumours, no difference was found between sexes. However, 2 out of 3 patients with a previous diagnosis of malignant peripheral nerve sheath tumour (MPSNT) developed bladder cancer and pheochromocytoma at a median follow-up of 3 years, with a significant correlation ($p = 0.041$).

Conclusion: NF1 patients develop systemic neoplasms more frequently than the general population. Co-presence of a MPSNT tumour seems to be correlated with an increased risk of developing systemic tumours later in life. Adequate cancer screening in NF1 patients therefore requires a lifelong care model to prevent aggressive cancer development and to improve patients' life expectancy and quality of life.

Disclosure: Nothing to disclose.

EPO-673 | Atypical debut of systemic lymphoma with CNS involvement

P. Garrido Jiménez; S. López Anguita; A. Lorenzo Montilla; J. Rodríguez Quinchanegua; A. Rodríguez Herrera; B. Gutiérrez Ruano; A. Muñoz González; F. Valenzuela Rojas; M. Olmedilla González
Hospital Central de la Defensa "Gómez Ulla"

Background and Aims: CNS involvement in patients with systemic lymphoma is an uncommon complication affecting ≤5% of patients, being even more atypical to debut with neurological manifestations. We present a case debuting with CNS symptoms with final diagnosis of lymphoma.

Methods: A 68-year-old male with 5 days of dysarthria, gait disturbance, bradypsychia and incoherent speech after tooth extraction 15 days before with uncertain infection, without fever or other systemic data.

Results: Brain CT was normal, laboratory tests showed hypercalcemia, EEG displayed moderate diffuse encephalopathy and LP showed 10 mononuclear leukocytes/mm^3 and hyperproteinorrachia 85 mg/dl without glucose consumption, suspecting possible encephalopathy due to hypercalcemia. The patient's level of consciousness worsened and he was admitted to the ICU requiring OIT. Suspicion of infectious encephalitis led to initiate antibiotic, which was suspended after negative microbiology. LP was repeated with 12 leukocytes/mm^3 and hyperproteinuria 53 mg/dl. Given the persistence of non-infectious inflammatory LP, a complete blood test performed showed pancytopenia, elevated beta2-microglobulin and LDH, a brain MRI without findings and another EEG with moderate-severe encephalopathy, so high-dose corticotherapy was started with excellent response and complete resolution of the symptoms. BM biopsy was normal. In the complementary etiological study, a PET-CT scan showed a hypermetabolic lesion in the left adrenal gland which was biopsied and demonstrated an intravascular lymphoma. Intrathecal+R-CHOP systemic chemotherapy was started with poor response.

Conclusion: Intravascular lymphoma is a rare subtype of diffuse large cell B-cell lymphoma that presents CNS involvement in 30–40% of cases and can be associated with adrenal gland involvement in up to 50–75%. This entity represents an important diagnostic challenge that requires a high clinical suspicion given the wide variability in its presentation and its low incidence.

Disclosure: Nothing to disclose.

EPO-674 | Peri-ictal Pseudoprogression: A rare entity to bear in mind in patients with brain tumors treated with radiotherapy

T. Mederer-Fernandez[1]; R. Sainz-Torres[1]; M. Borrell-Pichot[1]; M. Delgado-Romeu[1]; E. Granell-Moreno[2]; V. Ros-Castelló[1]; A. Sierra-Marcos[1]
[1]*Neurology Department, Hospital de la Santa Creu i Sant Pau;*
[2]*Neuroradiology Department, Hospital de la Santa Creu i Sant Pau*

Background and Aims: The differential diagnosis in patients with brain tumors treated with radiotherapy who present with epileptic seizures might be challenging. Apart from tumoral progression, one entity to consider is peri-ictal pseudoprogression (PIPG). Clinical features include recurrent epileptic seizures or status epilepticus and progressive focal deficits.

Methods: We present the case of a 63-year-old woman who presented in the emergency room due to progressive weakness in the left upper limb and recurrent focal motor seizures involving the left face with impaired awareness. She had a history of a grade II oligodendroglioma treated with surgery and adjuvant chemoradiotherapy seven years before. She was on remission accordingly to the brain MRI performed one month earlier.

Results: The electroencephalogram (EEG) showed electrographical seizures involving the right centrotemporal region (Figure A, B). Levetiracetam 1.5 g/12 h was initiated. Due to the persistence of clinical and electrographical seizures in the follow-up EEGs, lacosamide 150 mg/12 h was added with clinical improvement. However, the brachial paresis persisted. Brain MRI showed a cortical hyperintensity with meningeal enhancement in the right frontotemporal-parietal region, suggestive of PIPG. Patient was discharged. In the outpatient clinic, there was evidence of motor improvement and a gradual reduction of antiseizure drugs was performed without seizure recurrence.

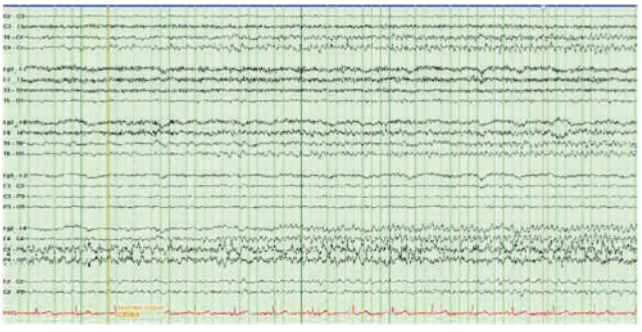


FIGURE A EEG part 1.

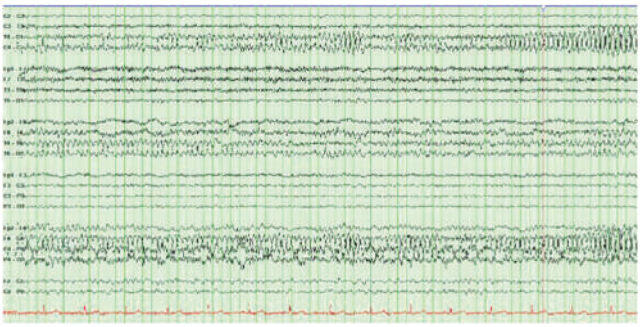

FIGURE B EEG part 2.

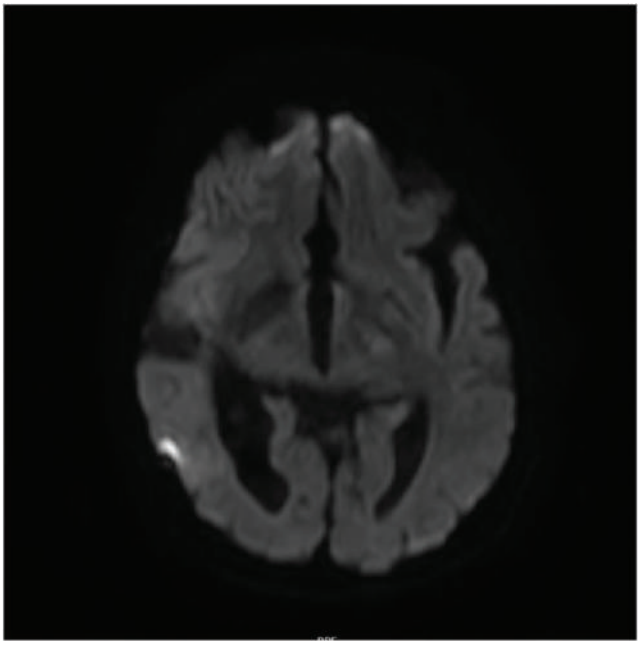

FIGURE C MRI.

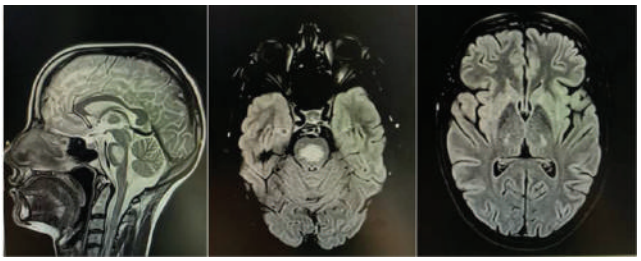
Conclusion: PIPG is a rare entity that should be considered in patients treated with radiotherapy who present with typical clinical and neuroimaging features. In the coming years, the incidence is likely to increase due to the recent indication of radiotherapy in low-grade gliomas, a treatment that was previously reserved for high-grade gliomas.
Disclosure: Nothing to disclose.

Neurological manifestation of systemic diseases

EPO-675 | Acute intermittent porphyria as a rare cause of pontine and extrapontine myelinolysis: A case report

A. Afanasieva[1]; M. Palchukovska[2]; M. Kholodova[1]; Y. Korets[1]; T. Slobodin[2]
[1]*Department of Neurology and Neurosurgery, LLC "Dobrobut-Clinic", Kyiv, Ukraine;* [2]*Department of Neurology, Shupyk National Healthcare University of Ukraine, Kyiv, Ukraine*

Background and Aims: Developing of severe hyponatremia attributed to inappropriate antidiuretic hormone secretion during a crisis of acute porphyria can be complicated by central pontine (CPM) and extrapontine myelinolysis (EPM). Usually acute intermittent porphyria (AIP) attacks manifest as a combination of abdominal pain, neuropsychiatric symptoms, and autonomic dysfunction.
Methods: A single case presentation.
Results: A 24-year-old female was admitted with a clinical and MRI signs of EPM and CPM. During 3 weeks before admission she was staying at the local clinic with intense abdominal pain, nausea with episodes of repeated vomiting, episodes of hyperthermia, hallucinations, confusion and electrolyte imbalance: Na – 117, K – 2.7, Cl – 78 mmol/L. Despite of electrolyte normalization, neurological examination revealed cognitive and behavioral changes, bulbar disorders, paresis of the right arm, head and hand tremors, cerebellar ataxia, and unable to walk independently. MRI showed symmetrical lesions of the basal nuclei, thalamus, central parts of the Varolii pons and cortex of both frontal lobes. After transferring to our clinic patient was successfully treated with intravenous immunoglobulin with resolving neurological symptoms of EPM and CPM. After accidental raspberry color of urine detection the assumption of possible intermittent porphyria was made. Urine analyses revealed increased concentration of porphyrin precursors porphobilinogen, delta-aminolevulinic acid, uroporphyrin, coproporphyrin.



Brain MRI shows hyperintensive pontine lesion (14 × 18 × 24 mm) and bilateral thalamic lesions (6 × 9 mm).

Conclusion: We report this case to emphasize the clinical manifestations of AIP, including combination of gastrointestinal syndrome and electrolyte imbalance, especially hyponatremia due to possible antidiuretic hormone deficiency that may threaten of CPM/EPM development.
Disclosure: Nothing to disclose.

EPO-676 | Cerebellopontine abscess due to Listeria monocytogenes

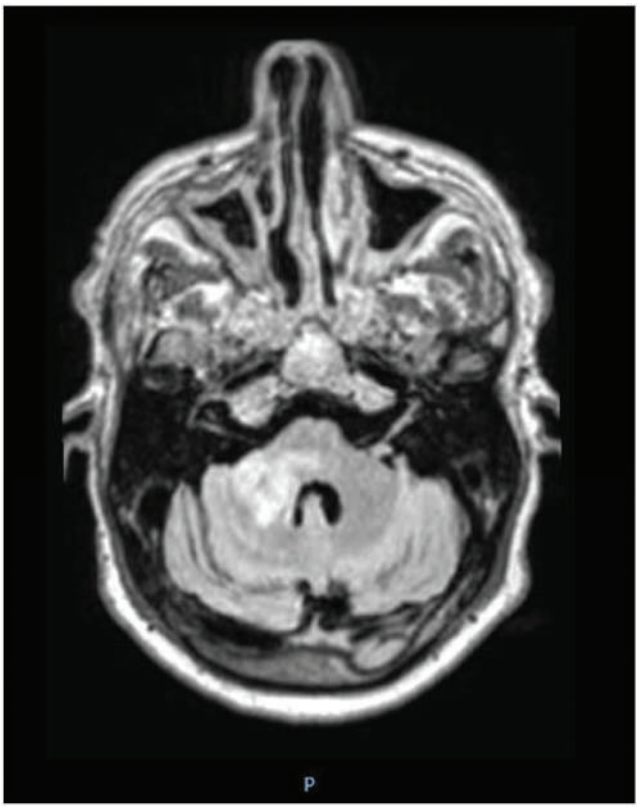
D. Landaeta Chinchilla
Integrated Neurology Department of Rey Juan Carlos University Hospital, Infanta Elena University Hospital and Villalba University Hospital/Mostoles-Madrid, Spain

Background and Aims: Listeria monocytogenes is a gram-positive anaerobic bacillus with special tropism for the central nervous

system. The main form of neurological involvement in adults is meningitis, with rhombencephalitis and brain abscess being rarer, but with a worse prognosis.

Methods: Clinical case.

Results: A 62-year-old man with type 2 diabetes came to the emergency department with fever, headache and hypoesthesia in the left hemibody of three days of evolution. Baseline CT, CT angiography and complete blood tests were performed in the emergency room without alterations. Brain MRI showed a heterogeneous lesion in the cerebellopontine angle and raised the possibility of infectious vs. tumor pathology. CSF study was performed with normal cell count and biochemical composition and negative multiparametric PCR. Given the persistence of fever and clinical progression with the appearance of dysphagia and dysmetria in the left extremities, neurosurgery was contacted to propose a stereotactic biopsy of the lesion. Multiplex PCR was performed on the extracted material and was positive for Lysteria Monocytogenes. In view of these findings, ampicillin was started at high doses.



Conclusion: We present the case of a patient with cerebellopontine abscess due to Listeria monocytogenes, an atypical presentation with high morbidity and mortality rates. In our patient, support with diagnostic tools such as stereotactic biopsy was key to lead to the etiologic diagnosis and guide targeted antibiotic treatment.

Disclosure: Nothing to disclose.

EPO-677 | Papilledema in hypocalcaemia: A condition not to overlook

A. Cordeiro; M. Grunho

Department of Neurology, Hospital Garcia de Orta, Almada, Portugal

Background and Aims: Papilledema associated with hypocalcaemia is rare, and its precise pathophysiology remains unclear. The proposed causal mechanisms include vasoconstriction and disturbances in cerebrospinal fluid (CSF) dynamics. The prognosis depends on the underlying cause of hypocalcaemia, as well as the promptness of the diagnosis and treatment.

Methods: Review of the patient's clinical records and of the relevant available literature on the topic.

Results: A 48-year-old female patient experienced a two-week progression of bilateral decreased visual acuity, more pronounced on the left eye. She also reported occasional generalized cramps and hand paresthesias over the prior year. Her past medical history included iatrogenic hypothyroidism (9 years before, due to multinodular goitre), gastric bypass surgery (3 years before), and obesity. Neurological examination revealed bilateral papilledema and reduced visual acuity (left: 0.3; right: 0.8). Optical coherence tomography confirmed asymmetric bilateral papilledema. Brain and orbital MRI were unremarkable. Blood work revealed severe hypocalcaemia (5.2 mg/dL [8.7–10.4 mg/dL]) and low parathormone. Extensive autoimmune and infectious serological testing was all negative. Calcium replacement was initiated. Lumbar puncture, performed already under treatment, showed normal opening pressure. The remaining CSF tests were normal/negative. Hypocalcaemia was attributed to the surgical hypoparathyroidism and the bariatric surgery. Three months later visual acuity had improved (0.8 bilaterally) and the papilledema had resolved.

Conclusion: Hypocalcaemia-associated papilledema is a rare, yet manageable condition. When faced with cases of papilledema, assessing calcium metabolism may prove essential, especially in people with a past history of thyroid/parathyroid surgery or other risk factors for hypocalcaemia. Awareness and prompt treatment, as in our case, is crucial for improving the prognosis in this clinical setting.

Disclosure: Nothing to disclose.

EPO-678 | CSF and blood signatures aid in distinguishing subtypes of limbic encephalitis

A. Dik[1]; A. Schulte-Mecklenbeck[1]; C. Strippel[1]; L. Bierhansl[1]; N. Meyer[1]; L. Korn[1]; M. Pawlowski[1]; S. Räuber[2]; S. Meuth[2]; N. Melzer[2]; J. Alferink[3]; C. Elger[4]; G. Meyer zu Hörste[1]; H. Prüß[5]; H. Wiendl[1]; C. Gross[1]; S. Kovac[1]

[1]*Department of Neurology with Institute of Translational Neurology, University of Münster, Münster, Germany;* [2]*Department of Neurology, Medical Faculty, Heinrich-Heine University of Düsseldorf, Düsseldorf, Germany;* [3]*Department of Psychiatry and Psychotherapy, University of Münster, Münster, Germany;* [4]*Department of Epileptology, University of Bonn, Bonn, Germany;* [5]*Department of Neurology and Experimental Neurology, Charité – Universitätsmedizin Berlin, Berlin, Germany*

Background and Aims: Limbic encephalitis (LE) represents a heterogeneous disease with antibodies targeting extracellular (LEextra) epitopes, intracellular (LEintra) epitopes, and anti-glutamic acid decarboxylase 65 LE (LE-GAD65). Moreover, LE can be diagnosed without evidence of antibodies (LEabneg). We aimed to determine immune profiles of these distinct forms of LE.
Methods: We apply computational biology to flow cytometry data of CSF/blood of LE patients comparing them to non-inflammatory controls (Ctrl) or patients suffering from relapsing remitting MS (RRMS).
Results: We identified discrete immune signatures in LE with antibody producing plasma cells and B cells as a specific feature of LEextra. In contrast, LE-GAD65 lacked inflammatory changes in CSF/blood immune profiles with LEintra falling in-between the two (LE-GAD65 and LEextra). Interestingly, similar to LE_GAD65 LEabneg showed no prominent inflammatory immune-signature.
Conclusion: Profiles identified may explain different treatment response to immunotherapy in subtypes of LE.
Disclosure: The authors have no relevant financial or non-financial interests to disclose.

EPO-679 | Risk factors, treatment and clinical outcomes of decompression sickness with neurological symptoms: A case-series study

B. Gómez Gozálvez; J. Sánchez Villalobos; J. Fajardo Sanchís; J. Bermejillo Barrera; M. Ruiz Perelló; F. Salazar Hernández; E. Carreón Guarnizo; D. Vidal Mena; E. Conesa García; M. Martínez Zarco; I. Díaz Jiménez; M. Ortega Ortega; M. López López; J. García Carmona
Neurology, University hospital Santa Lucía, Cartagena, Spain

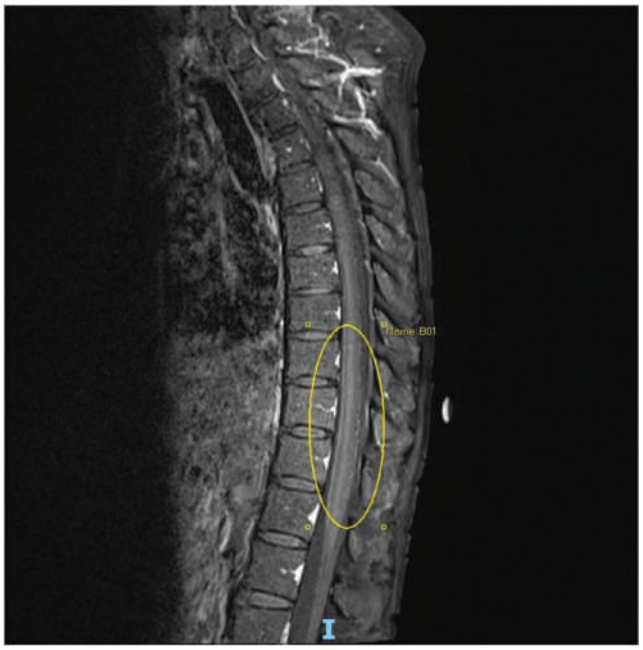
Background and Aims: The decompression sickness (DCS) is related to diving practice and could affect multiple organs, including the central nervous system. The incidence of DCS with neurological symptoms is estimated in 2.7/10,000 dives and may cause both brain and spinal cord symptoms. Given the little knowledge about the DCS, the potential severity of its neurological symptoms and the difficult acute diagnosis and treatment, here we report a case-series.
Methods: This is a retrospective single centre case-series study evaluating the risk factors and treatment of consecutive patients diagnosed with DCS at the Santa Lucía University Hospital, Cartagena; Spain, between 2003–2023. All patients received hyperbaric oxygen therapy.
Results: 15 patients were included in this study. All were Caucasian male, the median age was 47.3 (range: 22–66). The time of symptoms onset was 37.8 minutes after diving. 6 (40%) patients were diagnosed with brain hemispheric syndromes, 1 (6%) with posterior reversible encephalopathy syndrome (PRES), 3 (20%) with brainstem syndromes and 5 (33%) with spinal cord syndromes. MRI scans demonstrated multiple territory stroke lesions and spinal cord lesions in 12 (80%) and 5 (33%) patients, respectively. The main risk factor for DCS was an inadequate diving profile while patent foramen ovale was demonstrated in 4 patients (27%). The mean of the Modified Rankin Scale (mRS) after 3 months was 1.9.
Conclusion: An unsecure diving profile is the main risk factor. Both, a correct diagnosis and emergent treatment are the cornerstones in the management of the DCS by neurologists.
Disclosure: The authors declare no conflict of interest.

EPO-680 | Post-cytomegalovirus Guillain-Barre syndrome with anti-GM2 antibodies and acute transverse myelitis overlap syndrome

H. Ling
Department of Neurology, National Neuroscience Institute (SGH campus), Singapore

Background and Aims: A 55-year-old male presented with a three-week history of progressive lower limb weakness, distal limb paresthesia, resulting in gait instability and multiple falls. With a medical history of Angioimmunoblastic T Lymphoma and autologous stem cell transplant, he was immunosuppressed with tacrolimus. A recent hospitalization for CMV viremia infection, resolved with antiviral therapy, was noted. Clinical examination revealed flaccid lower limb weakness, impaired distal proprioception sense, and diminished deep tendon reflexes.
Methods: Nerve conduction studies demonstrated demyelinating sensorimotor polyradiculoneuropathy predominantly lower limbs. MRI of the lumbosacral spine exhibited mild enhancement along the cauda equina nerve roots. Cerebrospinal fluid (CSF) analysis revealed characteristic albuminocytologic dissociation. Anti-GM2 IgG was strongly positive. The patient was initiated on intravenous immunoglobulin (IVIG) infusion.
Results: He subsequently developed worsening of weakness with new sensory deficit up to T10 and urinary retention. MRI of the cervical and thoracic spine revealed longitudinally extensive transverse myelitis. Infective workup, autoimmune screen, paraneoplastic panel, anti-NMO Antibody, and anti-MOG Antibody, yielded unremarkable results. Treatment involved intravenous methylprednisolone with concurrent plasmapheresis, resulting in neurology recovery.

T2 sequence of the MRI cervical and thoracic spine.



T1 sequence with contrast of the MRI cervical and thoracic spine.

Conclusion: Previous cases of GBS and ATM overlap syndrome were associated with various infections, including campylobacter jejuni, Zika virus, Mycoplasma pneumonia, Legionella pneumophila, Bartonella henselae, influenza virus, paramyxovirus, mumps virus, and varicella infection. Our patient represents the first reported case of GBS and TM overlap syndrome associated with CMV infection. First-line therapy for GBS and ATM overlap are not well defined. Our case responded well to treatment with intravenous methylprednisolone and plasmapheresis, resulting in a favorable neurological recovery.

Disclosure: Nothing to disclose.

EPO-681 | Clinical manifestation and treatment efficacy of visual pathway involved neurosarcoidosis: A multicentre cohort

X. Zhang[1]; B. Balasubramaniam[2]; A. Patil[2]; S. Sharma[1]; T. Arun[3]
[1]*Oxford University Hospitals NHS Trust;* [2]*University Hospitals Birmingham NHS Trust;* [3]*University Hospitals Coventry and Warwickshire*

Background and Aims: Sarcoidosis affecting the anterior visual pathway (AVP) presents distinctly compared to other optic neuropathies, with delayed diagnosis leading to impaired visual outcomes. The objective of this study is to evaluate visual outcomes in neurosarcoidosis patients with AVP involvement, focusing on the impact of different manifestations and treatment initiation times.

Methods: Retrospective multi-centre cohort study.

Results: Forty-six neurosarcoidosis patients with AVP involvement from four UK tertiary centers were analyzed over a median follow-up of 1.90 years. Patients were categorized into optic neuritis (ON, $n=25$) and non-optic neuritis (NON, $n=21$) groups, and further into early treatment (ET, $n=13$) and delayed treatment (DT, $n=10$) groups. The ON group exhibited a more significant visual decline compared to the NON group ($p=0.015$), with similar baseline vision ($p=0.828$) and a slightly worse nadir vision (median 0.96LogMAR vs 0.3LogMar, $p=0.078$). Additional findings in the ON group included sudden visual loss ($p=0.072$), disc swelling ($p=0.086$), RAPD ($p=0.017$), T2 hyperintensity in AVP ($p=0.033$), and uninvolved chiasma ($p=0.064$). Visual acuity improvement, stability, and deterioration rates did not significantly differ between ON and NON groups ($p=0.765$). 22.2% of patients had final visual acuity worse than LogMAR 1.0 (29.1% in ON, 14.3% in NON). No significant difference was observed in overall visual improvement between ET and DT groups (61.5% vs 50%, $p=0.685$), with 30.8% in ET and 20% in DT having final visual acuity worse than LogMAR 1.0.

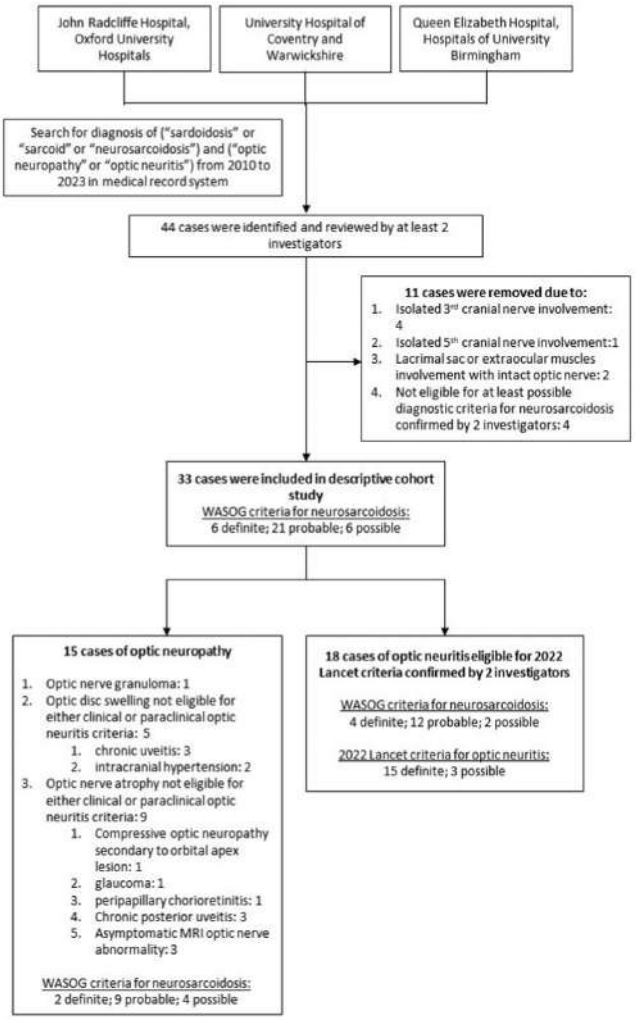


FIGURE 1 Retrospective Screening Flowchart.

Conclusion: AVP involvement in neurosarcoidosis shows varied clinical presentations. Delayed treatment yields a 50% non-responsiveness rate, not significantly differing from early treatment outcomes.

Disclosure: Nothing to disclose.

EPO-682 | Sensory involvement in patients with Sjogren's disease electrophysiological investigation

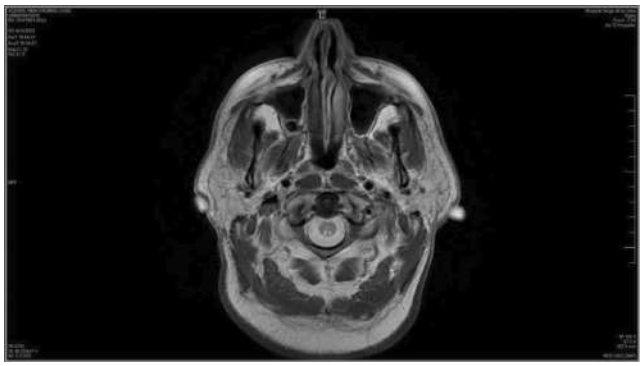
F. Erbaş; H. Erdem Tilki
Department of Neurology, Ondokuz Mayıs University, Samsun, Turkey

Background and Aims: Sjogren's syndrome (SS) is a chronic, progressive, systemic inflammatory disease characterized by lymphocytic infiltration of exocrine glands. The main objectives of the study were to determine phenotypical patterns of peripheral nervous system involvement and the frequency of peripheral and central sensory involvement. We have also aimed to show the topography and extent of peripheral and central involvement by electrophysiological methods, and to examine the correlation of clinical and electrophysiological findings in patients with primary Sjogren's syndrome.
Methods: Thirty patients with Sjogren's disease were examined clinically with sensory symptoms, neurologic examination, modified Toronto Clinical Neuropathy Score and electrophysiologically with nerve conduction studies and somatosensory evoked potentials (SEP). The control group consisted of 30 healthy volunteers matched with the study group in terms of age and gender.
Results: A statistically significant difference was found in the mean median motor latency, mean tibial motor latency and mean tibial minimum F latency in the nerve conduction study parameters compared between the patient and control groups. Polyneuropathy was detected in three patients and all of them had pure sensory neuropathy. There was a significant correlation between the modified Toronto Clinical Neuropathy Score and the presence of polyneuropathy. In SEP examination no difference was detected in P37 latency, P37-N45 amplitude and P37-TP latency between the two groups.
Conclusion: In conclusion, this finding may indicate; 1. Sensory involvement was found to be present in Sjogren's syndrome. The sensory involvement was localized to peripheral nerves. 2. The sensory fibers in the dorsal column of the spinal cord were preserved.
Disclosure: there is nothing to explain.

EPO-683 | Combined subacute degeneration of spinal cord due to b12 deficiency: Pernicious anemia with hemolysis

G. Rodrigo Stevens; S. Escalante Arroyo
Neurology Department, Hospital Verge de la Cinta, Tortosa, Spain

Background and Aims: Combined subacute degeneration is a neurological complication of B12 deficiency. Most common cause in adults is anemia perniciosa, due to autoimmune destruction of gastric parietal cells. It is associated to megaloblastic anemia with macrocytosis. Hemolysis is very rare and seen in only 10% of cases. It produces intramedullary ineffective erythropoiesis. B12 deficiency related hemolysis, presents as a pseudo-thrombotic microangiopathy (pseudo-TMA). Key features are low reticulocyte count and normal or mildly decreased platelets.
Methods: A 62 year-old male, with distal paresthesia, gait disturbance, fatigue and macrocytic anemia. His lab results showed low Hb 10 g/dl, elevated VCM 123 fL, elevated LDH 440 U/L, low haptoglobin 7.75 mg/dl, and schistocytes, with low absolute reticulocyte count (44.2 × 9, 1.72%). B12 levels were normal, but near to the normal low range 255 pg/ml. Hematology evaluation, ruled out autoimmune causes and TTP.
Results: He was admitted with suspicion of myelopathy. Initially, since B12 levels were normal and he had hemolytic anemia, cobalamin deficiency was not suspected. However, homocysteine levels were elevated 115 μmol/L. B12 deficiency was then suspected and intramuscular cobalamin was initiated. MRI showed typical signs of combined subacute degeneration. Pernicious anemia with elevated titers of anti-intrinsic factor antibodies (253.3 U/ml) was confirmed.



MRI. T2 axial. Inverted V sign: hyperintensity of dorsal horns, associated with combined subacute degeneration.

Conclusion: B12 deficiency can induce pseudo-microangiopathic hemolytic anemia in 10% of cases. Often, once hemolysis is seen, cobalamin deficiency is not investigated, leading to unnecessary tests. A normal lab result, must not rule out B12 deficiency when there is high clinical suspicion.
Disclosure: Nothing to disclose.

EPO-684 | A unique presentation of IgG4 disease with ocular, neurologic, and mastoid involvement

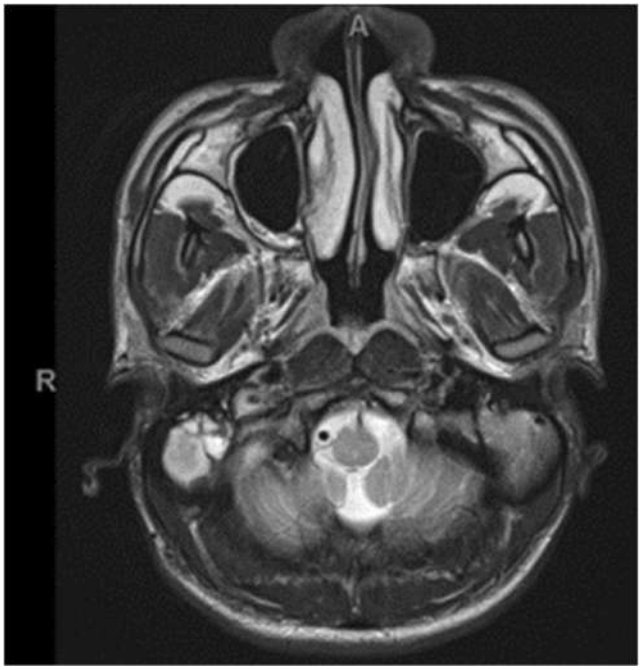
H. Narotam Jeena[1]; A. Afrogheh[2]; J. West[3]; F. van der Colff[4]; N. Brey[1]
[1]Division of Neurology, Tygerberg Hospital and Stellenbosch University, Cape Town, South Africa; [2]NHLS, Tygerberg Hospital and Stellenbosch University, Cape Town, South Africa; [3]Division of Otorhinolaryngology, Tygerberg Hospital and Stellenbosch University, Cape Town, South Africa; [4]Division of Ophthalmology, Tygerberg Hospital and Stellenbosch University, Cape Town, South Africa

Background and Aims: Immunoglobulin G4 (IgG4) disease typically presents as pancreatitis, retroperitoneal fibrosis, sclerosing cholangitis or interstitial lung disease. Central nervous system (CNS) manifestations are rare. This is the first description of IgG4 disease presenting as panuveitis with associated mastoiditis and raised intracranial pressure. Case presentation: 27 year old male with sudden onset unilateral headache. After a few days, acute bilateral loss

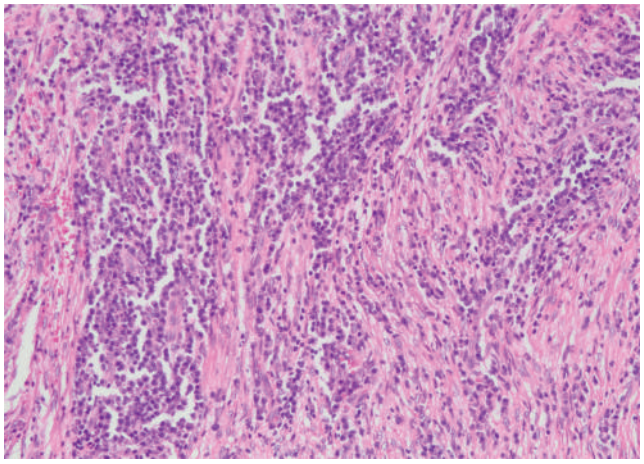
of vision, associated with tinnitus. He was found to have a non-granulomatous panuveitis and papilloedema.

Methods: CT brain demonstrated thickened optic nerves bilaterally and hyperostosis of the right mastoid. Right mastoid effusion in keeping with chronic mastoiditis was found on MRI. Lumbar puncture (LP) showed initial opening pressure exceeding 50 cm water, with normal chemistry and cell count. Serum ACE was raised, but CT chest and skin biopsy did not reveal any features of sarcoidosis. Mycobacterium tuberculosis, syphilis, mycoplasma pneumonia, HIV, and lymphoma test results were all negative. Sjogren, rheumatoid arthritis, and ANCA-vasculitis tests were also negative. There was no evidence of localised CNS infiltration and sinus thrombosis on imaging. Whole body FDG-PET confirmed mastoiditis.

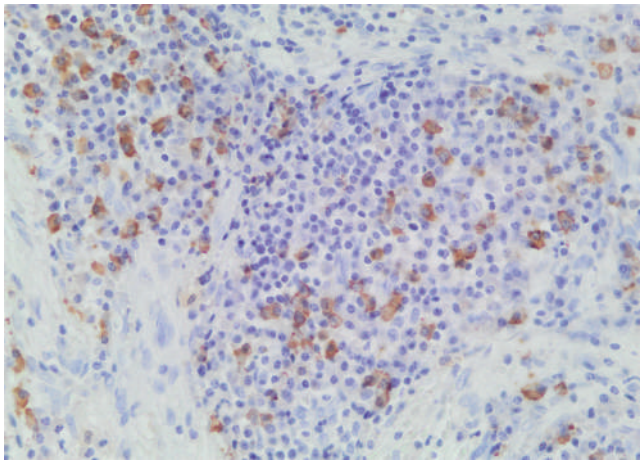
Results: Mastoid biopsy demonstrated a dense lymphoplasmacytic infiltrate with increased plasma cells and a storiform pattern of fibrosis.



T2 sequence MRI brain showing the hyperintense signal in the right mastoid.



200× microscopic examination revealing storiform fibrosis with an abundance of plasma cells.



400× immunohistochemistry showing more than 10 IgG4 positive cells per high power field.

Conclusion: The constellation of panuveitis, papilloedema (in the absence of inflammatory pseudotumour or secondary obstructive hydrocephalus following pachymeningitis), has not been previously described. There are only a limited number of reports of IgG4 chronic mastoiditis. The combination of FDG-PET/CT, along with biopsy may be prudent in atypical presentations. The patient was treated with high dose steroids, followed by long-term immunosuppressive therapy.

Disclosure: Nothing to disclose.

EPO-685 | The multisystem involvement of MERRF syndrome

J. Barbosa; A. Aldomiro; C. Semedo; C. Rosado Coelho
Neurology Department, Setúbal Hospital Center, Lisbon, Portugal

Background and Aims: Myoclonic epilepsy with ragged-red fibers syndrome (MERRF) is a mitochondrial multisystem disorder whose canonical clinical features are myoclonus, generalized seizures, ataxia, and ragged-red fiber myopathy. Approximately 80% of MERRF cases have the m.8344A>G mutation in the MTTK gene. Other clinical features include peripheral neuropathy, hearing loss, dementia, and multiple lipomas. The diagnosis is made in the presence of suggestive clinical findings and a genetic pathogenic variant.

Methods: A 63 year old man reports progressive proximal tetraparesia, exercise intolerance and involuntary movements of the right hand and foot. Additionally he has hearing loss and cervical lipomas. His mother also had cervical lipomas and died during his childhood. He has no siblings or children. Neurological examination showed proximal tetraparesis with muscular atrophy, right hand and foot dystonia with occasional focal myoclonia, ataxia, binasal hemianopsia, and hipoacusia.

Results: Cranial and cervical MRI were normal. EMG described axonal sensorimotor polyneuropathy. Blood analysis was unremarkable except for elevated CK. Ophthalmology evaluation revealed bitemporal optic atrophy. Cardiac evaluation revealed frequent supra ventricular extrasystole. The patient refused muscular biopsy.

A mitochondrial disease genetic panel revealed m.8344A>G mutation in the MTTK gene.

Conclusion: This case shows a defying diagnosis of a rare disease. Despite not all MERRF canonical features are present and the late age of onset, the patient has multiple suggestive clinical findings. The typical pathological genetic mutation found supports a MERRF diagnosis. The clinical and genetic heterogeneity of this disease renders this diagnosis a challenge, highlighting the need for future investigation.

Disclosure: Nothing to disclose.

EPO-686 | CAR T-cell-associated neurotoxicity: Single-center experience in a tertiary center

P. Martinez Agredano; I. Lorite Fuentes; A. Rodriguez Martin; M. Alvarez Soria; F. Acebron Sanchez-Herrera

Department of Neurology, University Hospital Reina Sofia, Cordoba, Spain

Background and Aims: Chimeric antigen receptor T cells therapy (CAR-T) have revolutionized the treatment of patients with relapsed and refractory B- cell malignancies. CART therapy is associated with significant toxicities including cytokine release syndrome (CRS) and immune cell associated neurological syndrome (ICANS). The objective of this study is to describe the outcomes and treatments of CRS and ICANS in our hospital.

Methods: Retrospective descriptive study following five patients diagnosed of refractory diffuse large B cell lymphoma (DLBCL) treated with CAR-T therapy by the Department of Hematology. We registered age, sex, type of CAR-T used, MRI, EEG, acute phase reactant, CRS grade, ICANS, and treatment either with Tocilizumab or steroid.

Results: All five patients treated in our center developed CRS. About 60% developed CRS grade 1 and 40% CRS grade 3. Acute phase reactant (Interleukin-6, C-reactive protein and ferritin) increased in all CRS presenting patients. ICANS incidence was 80% from whom 75% were treated with steroids. Neurological related symptoms improved in all patients after steroid therapy.

Conclusion: Early recognition and treatment of ICANS associated with CAR-T is determinant for successful outcomes in patient receiving this therapy. A multidisciplinary approach is crucial to improve patient outcomes.

Disclosure: The authors have nothing to disclose.

EPO-687 | Myositis, axonal polyneuropathy and stroke in acute toxoplasmosis infection

R. Ferrer Tarrés[1]; M. Garcia Huguet[1]; C. Vera Cáceres[1]; C. Martínez Follana[1]; I. Saurina Navarro[1]; C. Marco Cazcarra[2]; D. López Domínguez[1]

[1]*Department of Neurology, Hospital Doctor Josep Trueta, Girona, Spain;* [2]*Neuromuscular Unit, University Hospital of Bellvitge, Barcelona, Spain*

Background and Aims: Toxoplasma gondii is the most common cause of protozoan infection in humans. Toxoplasmosis has been associated with myositis and, in rare instances, with other neurological illnesses like polyneuropathies.

Methods: Description of a clinical case of a patient with systemic toxoplasmosis presenting several neurological affections such as myositis and sensory-motor axonal polyneuropathy.

Results: We present the case of a 56-year-old man from Gambia with heterozygous sickle cell disease. Following a recent trip to his native country, he was admitted to the hospital with a 20-day history of persistent fever, muscle pain, proximal debility, with an increase in CK levels. Serological tests showed positive IgM for T. gondii with a positive polymerase chain reaction. Antiprotozoal treatment and corticosteroids improved weakness and CK levels. Two weeks after admission, the patient experienced a progressive worsening of gait, autonomic dysfunction, and neuropathic pain. Examination revealed tetraparesis, bilateral facial paralysis, sensory ataxia, and generalized areflexia. Lumbar puncture indicated albumin-cytological dissociation, with no evidence of Toxoplasma in the cerebrospinal fluid. Electromyogram showed decreased sensory-motor amplitudes, with myopathic muscle recruitment. Plasma exchange was initiated suspecting Guillain-Barré syndrome, resulting in slight improvement. Brain MRI showed subacute thalamic ischemic lesion. Other autoimmune and infectious studies were rule out. Muscle biopsy indicated lymphocyte-predominant inflammation, MHC I overexpression and toxoplasma cysts, and peripheral nerve biopsy revealed mild axonal neuropathy.

Conclusion: In conclusion, we present a case of a patient with multiple systemic complications following toxoplasmosis infection. While neuromuscular complications have been documented, simultaneous involvement with polyneuropathy and myopathy has not been previously reported.

Disclosure: No disclosure.

EPO-688 | Acute neurological complications in liver transplanted patients: A retrospective single centre study

V. Lo Re[1]; F. Avorio[1]; G. Russelli[2]; G. Panarello[3]; R. Alduino[2]; A. Arcadipane[3]; S. Gruttadauria[4]

[1]*Neurology Service, IRCCS – ISMETT (Mediterranean Institute for Transplantation and Advanced Specialized Therapies), Palermo, Italy;* [2]*Research Department, IRCCS – ISMETT (Mediterranean Institute for Transplantation and Advanced Specialized Therapies), Palermo, Italy;* [3]*Department of Anaesthesia and Critical Care, IRCCS – ISMETT (Mediterranean Institute for Transplantation and Advanced Specialized Therapies), Palermo, Italy;* [4]*Department for the Treatment and Study of Abdominal Diseases and Abdominal Transplantation, IRCCS ISMETT (Mediterranean Institute for Transplantation and Advanced Specialized Therapies), Palermo, Italy*

Background and Aims: Neurological complications (NCs) occur in about 30 % of patients after orthotopic liver transplant (OLT). This study aimed to investigate early post-operative (PO) NCs after OLT

in our cohort of adult cirrhotic patients and to identify risk factors associated with the neurological outcomes.

Methods: We performed a retrospective single centre study; all patients who underwent deceased- and living-donor liver transplant between June 2014 and October 2021 were included. A PO acute NC was confirmed when symptoms and/or signs of central or peripheral central nervous system (NS) impairment occurred from the transplant but within the hospital stay.

Results: 275 men (73.14%) and 101 women (26.86%) were included; median age was 58 (range 22–70) years. NC occurred in 25% of patients. Encephalopathy was the most common NC (15.2%), followed by neurotoxicity (5.9%), seizures (3.7%) and central pontine myelinolysis (CPM) (3.2%). Patients with NCs had history of pre-transplant hepatic encephalopathy ($p<0.0001$), pre-surgical critical condition ($p=0.015$), higher Mayo End stage Liver Disease score ($p=0.0002$), history of pre-transplant renal insufficiency ($p=0.0124$) and a higher PO sodium shift ($p=0.01$).

Conclusion: Pre-operative neurological comorbidities, psychoactive drugs and age were not risk factors for PO NCs. NCs were correlated with PO adverse outcomes as infections, graft rejection, Intensive Care Unit (ICU) re-admission, in-hospital death, need of rehabilitation, in-hospital and ICU length of stay, post-surgical acute renal insufficiency. Our data confirm that the occurrence of NCs mostly depends on the severity of the pre-operative hepatic disease and/or systemic factors and do not depend on pre-operative neurological diseases other than HE.

Disclosure: The authors have nothing to disclose.

Sleep-wake disorders 2

EPO-689 | Clinical practice and actigraphic findings of daridorexant in chronic insomnia

D. Hoxhaj[1]; A. Colitta[1]; L. Troilo[1]; A. Pascazio[1]; F. Buracchi Torresi[1]; M. Fabbrini[1]; M. Maestri Tassoni[1]; F. Turco[1]; U. Faraguna[2]; G. Siciliano[1]; E. Bonanni[1]

[1]Department of Clinical and Experimental Medicine, Neurological Clinic, University of Pisa; [2]Department of Translational Research and of New Surgical and Medical Technologies, University of Pisa, Pisa, Italy

Background and Aims: Chronic insomnia, a prevalent sleep disorder, adversely affects daytime function and quality of life. This real-world study assesses the efficacy of daridorexant, a novel dual orexin receptor antagonist, in treating chronic insomnia using actigraphy over 1 and ongoing 3-month follow-ups.

Methods: Twenty-three adults (M 43.5%, F 56.5%, mean age: 56.5 ± 11.0 years) with chronic insomnia, according to the ICSD-3 criteria, were included in the study. Baseline and subsequent assessments at one month (23 patients) and three months (6 patients) involved the collection of subjective sleep parameters, including total sleep time (TST), wake after sleep onset (WASO), and latency to persistent sleep (LPS). Additionally, participants completed the Insomnia Severity Index (ISI) and the Insomnia Daytime Symptoms and Impacts Questionnaire (IDSIQ). Ten patients underwent actigraphy at both baseline and one month.

Results: After one month of treatment, there was a statistically significant reduction in subjective LPS by 28 minutes (p 0.050) and WASO by 57 minutes (p 0.007), accompanied by a 32-minutes increase in TST (p 0.046). Questionnaire scores indicated a clinically meaningful reduction: ISI by 6 points ($p<0.001$), IDSIQ-total score by 22 (cut-off >17, p 0.012), and IDSIQ-cognitive domain by 10 (cut-off >4, p 0.004). Actigraphic data revealed a noteworthy 52-minutes increase in TST (p 0.042).

Conclusion: Our data confirmed Daridorexant efficacy after 1 month of treatment. Not only all sleep subjective parameters improved, but actigraphy showed an objective TST increase of almost one hour. It positively impacted quality of life, enhancing daytime cognitive functions, and significantly reducing insomnia severity.

Disclosure: Nothing to disclose.

EPO-690 | Compulsive gambling associated with modafinil: A case report

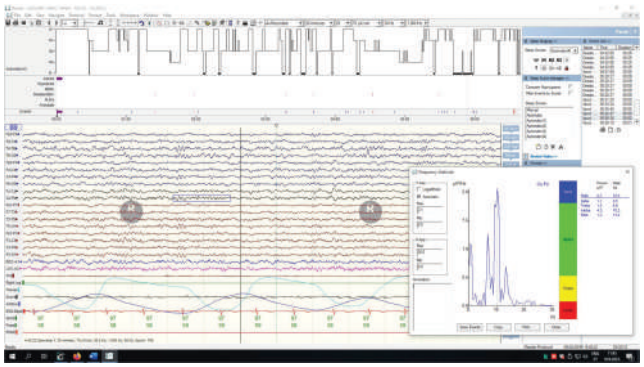
D. Račić

Department of neurology, University Clinical Center Republic of Srpska, Banja Luka, Bosnia and Herzegovina

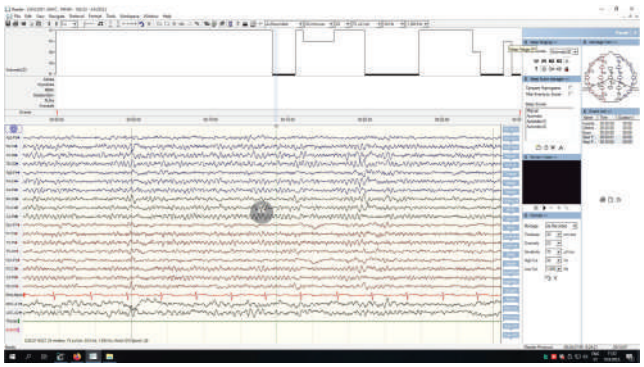
Background and Aims: We describe a case of new-onset compulsive gambling associated with the use of modafinil in a patient with type 1 narcolepsy (NT1).

Methods: Case report:

Results: A 21-year-old white woman presented to our clinic in 2023. She had history of excessive daytime sleepiness (EDS), cataplexy and sleep paralysis dating back for one year. She underwent diagnostic polysomnography (PSG) showed 7 REM sleep-onset periods, multiple sleep latency test (MSLT) with five naps showed an average sleep latency of 8 minutes and 2 sleep-onset REM periods, brain magnetic resonance (MR) imaging was normal. She was diagnosed with NT1 and commenced modafinil therapy started at a dose of 100 mg daily together with clomipramine 25 mg daily. She had no longer episodes of cataplexy but EDS symptoms only moderate controlled. One month later modafinil was increased at a dose of 200 mg daily. The patient's symptoms remained stable for the 8 months when she began gambling activities together with excessive alcohol abuse. On a follow-up visit she was refereed to psychotherapy together with lowering modafinil dose to 100 mg daily. Three months later, she reported improvement in the compulsive gambling and stopped drinking alcohol.



Polysomnography.



Multiple sleep latency test.

Conclusion: We described new-onset impairment of impulse control after taking modafinil which has been more commonly described in patients receiving dopamine agonist therapy.
Disclosure: Nothing to disclose.

EPO-691 | Pain in isolated REM sleep behavior disorder (iRBD): Study of association

G. Malomo[1]; E. Capriglia[1]; M. Solbiati[1]; L. Spelta[2]; A. Rubino[2]; C. Totaro[2]; D. Arnaldi[3]; P. Mattioli[3]; M. Pardini[4]; B. Orso[5]; F. Casoni[6]; L. Ferini Strambi[7]; A. Castelnuovo[7]; S. Natoli[8]; A. Pisani[9]; M. Terzaghi[1]

[1]Department of Brain and Behavioral Sciences, University of Pavia, Unit of Sleep Medicine and Epilepsy, IRCCS Mondino Foundation, Pavia, Italy; [2]IRCCS Mondino Foundation Pavia, Unit of Sleep Medicine and Epilepsy; [3]Neurophysiopathology, IRCCS Ospedale Policlinico San Martino, DINOGMI, University of Genoa; [4]DINOGMI, University of Genoa, Clinical Neurology, IRCCS Ospedale Policlinico San Martino; [5]DINOGMI, University of Genoa; [6]Department of Clinical Neurosciences, Neurology – Sleep Disorders Center, IRCCS San Raffaele Scientific Institute, Milan, Italy; [7]Department of Clinical Neurosciences, Neurology – Sleep Disorders Center, IRCCS San Raffaele Scientific Institute, Milan, Italy; "Vita-Salute" San Raffaele University, Milan, Italy; [8]Department of Clinical-Surgical, Diagnostic, and Pediatric Sciences, University of Pavia, Pavia, Italy; [9]Department of Brain and Behavioral Sciences, University of Pavia, IRCCS Mondino Foundation Pavia

Background and Aims: Non-motor symptoms in Parkinson's disease (PD) include chronic pain, which may occur in 20–80% of PD patients during the course of the disease. iRBD represents a prodromal phase for alpha-synucleinopathies including PD. Therefore, we aimed to identify the occurrence of pain and its characterization in an iRBD cohort.
Methods: 88 iRBD patients and 75 age- and sex-matched healthy controls were included; iRBD diagnosis was made according to ICSD-3rd criteria. Clinical evaluation included pain typology (PainDetect questionnaire) and pain perception (Brief Pain Inventory) together with motor evaluation (MDS-UPDRS), sleepiness (Epworth Sleepiness Scale), insomnia symptoms (Sleep Condition Indicator) and quality of sleep (Pittsburgh Sleep Quality Index), anxiety and depression (HADS-A, HADS-D) global cognition (MOCA), RBD scale (RBD questionnaire HK) and dopaminergic transmission (DAT-scan), measurements derived from PSG.
Results: Analysis of pain occurrence, typology and perception showed no statistically significant differences between patients and controls. In the iRBD group, statistically significant associations were detected between pain typology and perception and insomnia symptoms ($p=0.01$ and $p=0.15$ respectively) and sleep quality ($p<0.001$ and $p=0.03$ respectively). No association was found with other variables.
Conclusion: Chronic pain was not significantly increased in patients with iRBD. Mechanisms behind pain perception in iRBD may differ from those of PD-related neurodegeneration. We found a bidirectional correlation between pain and poor sleep quality in iRBD. Longitudinal data should be considered to evaluate a possible role as a marker of neurodegeneration.
Disclosure: Nothing to disclose.

EPO-692 | The levels of anxiety and depression in epilepsy based on insomnia phenotypes

H. Karkourian[1]; L. Atabekyan[1]; E. Balian[1]; A. Bichakhchyan[2]; H. Hovakimyan[2]; S. Khachatryan[1]

[1]Department of Neurology and Neurosurgery, National Institute of Health, Yerevan, Armenia; [2]Center for Sleep and Movement Disorders, Somnus Neurology Clinic, Yerevan, Armenia

Background and Aims: Insomnia is the commonest sleep disorder and is one of the most frequent of all mental health challenges. Insomnia phenotypes, namely sleep-onset (SOI), sleep-maintenance (SMI) and mixed insomnia (MI) are frequently encountered in adults with epilepsy (AWE). Our aim was to discover links between particular insomnia phenotypes with levels of depression and anxiety in AWE.
Methods: AWE were diagnosed according to international diagnostic criteria and enrolled from a specialized sleep and epilepsy clinic. According to insomnia clinical presentation we distinguished patients with no insomnia, SOI, SMI, and MI phenotypes based on interviews. Anxiety and depression were assessed using Hamilton Anxiety and Depression Rating Scales (HAMA and HAMD respectively). The ANOVA test was utilized for statistical analysis.
Results: A total of 170 AWE were interviewed for this study, with mean age 34.9 ± 13.4 (18–71), females – 46.5%. Seventy-eight

patients had insomnia (54.1%), divided into 29 (17.06%) with SOI, 11 (6.47%) with SMI, and 52 (30.59%) had MI. The mean values for HAMA and HAMD scales were 9.17 and 7.96 for no insomnia, 12.86 and 11.07 for SOI, 21.91 and 16.18 for SMI, 22.12 and 19.38 for MI, respectively ($p < 0.01$ for both scales). Box plots are presented in Figure 1 for HAMA and Figure 2 for HAMD.

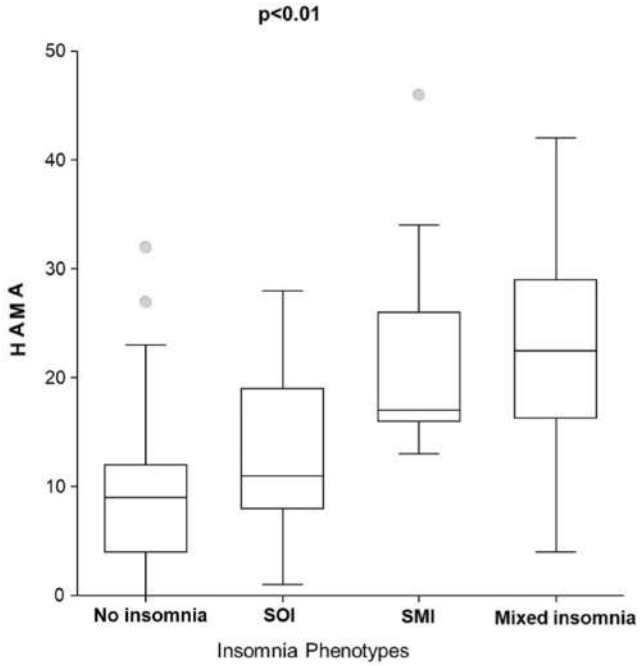


FIGURE 1 Box plot for Hamilton Anxiety Rating Scale (HAMA) according to insomnia phenotypes (SOI – sleep-onset insomnia, SMI – sleep-maintenance insomnia).

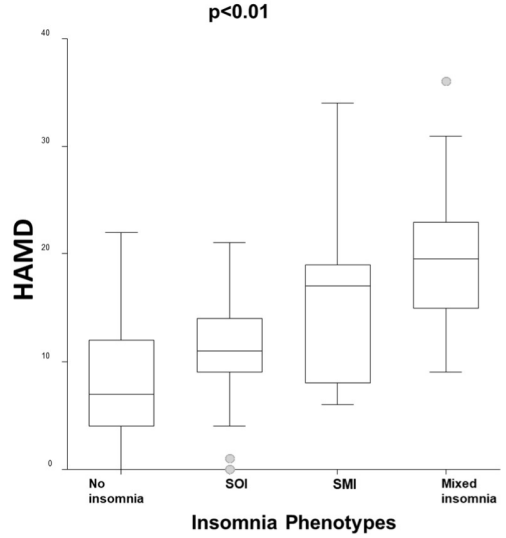

FIGURE 2 Box plot for Hamilton Depression Rating Scale (HAMD) according to insomnia phenotypes (SOI – sleep-onset insomnia, SMI – sleep-maintenance insomnia).

Conclusion: Our study highlighted a statistically significant difference in prevalence of anxiety and depression among AWE with different insomnia phenotypes. Specifically, AWE with no insomnia had the best profile, with gradually increasing severity in SOI, SMI, and MI respectively. Further research is needed to corroborate our findings.
Disclosure: Nothing to disclose.

EPO-693 | Case series of Prader-Willi syndrome and narcolepsy

I. Čelpačenko[1]; D. Burkojus[2]; G. Liakaitė-Obolevičienė[3]; E. Pajėdienė[1]
[1]Neurology Department, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Department of Pediatric Neurology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Department of Pediatric Pulmonology, Lithuanian University of Health Sciences, Kaunas, Lithuania

Background and Aims: Prader-Willi syndrome (PWS) is a rare genetic neuroendocrine disorder, which frequently presents with excessive daytime sleepiness (EDS) that may contribute to many clinical features of PWS. Sleep apnoea is a widely recognized cause of EDS in PWS, whereas other sleep disorders (SD), such as narcolepsy and cataplexy are only gaining recognition. PWS patients routinely undergo a polysomnography (PSG), however, more detailed differential diagnostics should be considered in patients exhibiting disproportionate EDS, as an effective treatment for narcolepsy is readily available and could substantially enhance patients' health, cognition, and behavioral problems.
Methods: Summarized patient's information included case history, Ullanlinna narcolepsy and Epworth Sleepiness scale scores, hypocretin-1 levels in cerebrospinal fluid (CSF), polysomnography (PSG) and Multiple Sleep Latency test (MSLT) results.
Results: Case series presents 1 male and 3 female patients with PWS, whose age ranged from 1 to 16 y/o. Based on clinical presentation, sleep studies and hypocretin-1 levels, all patients have been diagnosed with concomitant narcolepsy 1 type and sleep apnoea (Table 1)

Patient	No.1	No.2	No.3	No.4
Age	16 y/o	11 y/o	7 y/o	1 y/o
Sex	M	F	F	F
Ullanlinna scale (before treatment)	6 pts	22 pts	14 pts	-
Ullanlinna scale (after treatment)	24 pts	-	3 pts	-

FIGURE 1 Multiple Sleep Latency test (patient No. 2).

Conclusion: This case series demonstrates that excessive daytime sleepiness in PWS may be attributable not only to sleep apnoea, but also to coexisting narcolepsy. Similarities in clinical presentation pose a challenge for the clinicians, therefore narcolepsy tends to be underdiagnosed. Multidisciplinary care is crucial for timely narcolepsy diagnosis and treatment.

Disclosure: Evelina Pajėdienė is a Co-chair of the EAN Scientific Panel for Sleep-wake disorders.

EPO-694 | iSPHYNCS: A multi-omics approach towards novel biomarkers for narcolepsy and its borderland

J. D. Warncke[1]; K. Zub[1]; E. Wenz[1]; L. G. Fregolente[1]; J. van der Meer[1]; O. Gnarra[1]; R. Morrand[1]; A. Helmy[1]; Z. Zhang[2]; R. Khatami[2]; S. von Manitius[3]; S. Miano[4]; J. Acker[5]; M. Tafti[6]; A. Datta[7]; R. Rezaei[8]; U. Kallweit[8]; D. Bijlenga[9]; J. de Boer[9]; G. Lammers[9]; B. Yilmaz[10]; S. Mougiakakou[11]; A. Tzovara[12]; M. H. Schmidt[1]; C. L. A. Bassetti[1]

Background and Aims: The international Swiss Primary Hypersomnolence and Narcolepsy Cohort Study (iSPHYNCS) aims at providing new data to improve the management of primary central disorders of hypersomnolence (CDH). The main aims of iSPHYNCS are: (1) discovery of new biomarkers, and assessment of (2) treatment adherence, and (3) outcomes related to patients. This abstract presents initial data related to the first objective.

Methods: The study is ongoing at 11 study sites in Switzerland, Germany and The Netherlands and plans to prospectively include 500 CDH patients and 60 healthy controls by the end of 2026. Initial evaluations comprise questionnaires, video-polysomnography, the Multiple Sleep Latency Test (MSLT), the Sustained Attention Response Task (SART), and actigraphy. Further analyses include a wearable Fitbit device, the microbiome, peptidomics/proteomics, and genetics. This comprehensive approach includes the collection of bio-samples: plasma, serum, DNA, stool samples, and cerebrospinal fluid. AI-driven analyses, including unsupervised clustering, will be used for data-driven patient phenotyping, followed by a multimodal approach that combines various data types after domain-specific analyses.

Results: 194 participants have been recruited, including 7 children. This group comprises 37 individuals with narcolepsy with cataplexy (NT1), 134 with other primary CDH, such as narcolepsy borderland (NBL), and 23 HC. Initial analyses reveal notable differences among

NT1, NBL, and HC groups across various domains, including questionnaire responses, neuropsychiatric profiles, microbiome, and Fitbit data.

Conclusion: Following an initial three-year phase in Switzerland, the internationalization of iSPHYNCS in 2023 was successful. Preliminary results suggest novel and promising clinical, biological and digital markers of CDH.

Disclosure: The authors declare no conflict of interest and the study is supported by the Swiss National Science Foundation (320030_185362 and 32003B_215721).

EPO-695 | Comparative characteristics of patients with obstructive sleep apnea and COMISA syndrome and their adherence to therapy

K. Magomedova; Z. Umachanova; L. Geybatova
Department of Neurology, Dagestan State Medical University

Background and Aims: Insomnia and obstructive sleep apnea (OSA) are the two most common sleep disorders that are often comorbid to each other (comorbid insomnia and sleep apnea, COMISA).

Methods: Pittsburgh Questionnaire to determine sleep quality, the Epworth Sleepiness Scale. The study included 33 patients divided into 2 groups: 22 people with moderate and severe OSA and 11 people with moderate and severe COMISA syndrome. The diagnosis of OSA was verified according to respiratory sleep monitoring data. Average age of patients in group 1 was 53.5 years, the second group was 54.5 years. CPAP therapy was initiated for everyone, an automatic mode for 21 days. Follow-up visits were conducted after 1 and 2 weeks to monitor the effectiveness, technical characteristics and compliance of the treatment.

Results: Interpretation of the therapy data showed that in 11 patients of the first group, IAG averaged 6.9/h during the period of use, 5 patients were unable to use the device and refused therapy, in 7 patients of the 2nd group IAG was 14.9 /h, 6 patients were unable to use therapy and refused the study.

Conclusion: The data obtained indicate better adherence and better results of constant positive pressure therapy in patients with OSA without concomitant insomnia. It is advisable to offer treatment for both sleep disorders to patients with COMISA.

Disclosure: Nothing to disclose.

EPO-696 | Sex differences in isolated REM sleep behavior disorder: Insights from the FARPRESTO cohort

Angelo, Pescara, Italy*; [15]*Sleep Center, Dept. of Neurology, IRCCS Sacro Cuore Don Calabria, Verona, Italy*; [16]*Clinica Neurologica, DMED, Università di Udine, Italy*

Background and Aims: Inconsistent literature data hinders a comprehensive understanding of sex predominance and other sex-related distinctions in RBD. This investigation within the FARPRESTO multicentric, Italian, longitudinal cohort, aims to investigate variances between sexes in terms of the age of onset, diagnosis, and phenoconversion and to explore differences in cognitive and non-motor variables.

Methods: 558 iRBD patients were enrolled in the FARPRESTO study from 13 Italian centers, Age at RBD diagnosis, diagnostic delay, motor and non-motor symptoms, cognitive deficits, conversion rate to neurodegenerative disorders, and RBD-related injuries were analyzed according to sex. Statistical analysis utilized Mann-Whitney *U* and Pearson's chi-squared tests with significance set at $p < 0.05$.

Results: Mean age at the diagnosis was higher in females (males 62.0, females 65.0), whereas no significant sex differences in cognitive test scores were detected. Orthostatic hypotension and depression

were more prevalent in females (38.1 % vs 20.4 and 27.4 % vs 43.3 %, respectively). No difference in conversion rate has been reported. In addition, in women, injuries affecting patients at the first visit were significantly more frequent (71.0% vs 53.5%) than injuries affecting the partner or both.

Conclusion: Studies investigating sex differences in this field are still limited. However, as diagnostic and therapeutic possibilities advance, a nuanced understanding of sex-specific characteristics becomes increasingly essential for tailored clinical approach.

Disclosure: Nothing to disclose.

EPO-697 | The burden of insomnia and excessive daytime sleepiness: Switzerland's pilot study preliminary results

Background and Aims: At present, the specific needs of individuals affected by excessive daytime sleepiness (EDS) and/or insomnia (IN) complaints, in conjunction with its overall socio-economic burden remains unexplored. To address this gap, a pilot trial for a multi-stage, European-wide, multi-center research study is being conducted in Switzerland since mid-2023.

Methods: prospective, national, cohort observational study for the systematic evaluation of the burden of EDS and IN and its evolution 12 months after the first assessment. Patient recruitment is facilitated through nine primary care providers, concluding in June 2024. Primary outcomes include the feasibility of the study, while secondary outcomes focus on the prevalence of EDS/IN in primary care settings and the association between EDS/IN and health-related quality of life (QOL), assessed using validated instruments. Patients are screened for EDS/IN, and those with positive indications are invited to participate in the online portion of the study comprised standardized and socio-economic/health status questionnaires.

Results: To date, 632 subjects have been screened, with 238 (44%) presenting EDS and/or IN. Of these, 111 expressed interest in participation, with 43 enrolled in an online segment. Among those with symptoms, 58% of individuals expressed concern for their symptomatology. A significant positive correlation was found between the presence of concern and medication usage ($p < 0.01$).

Conclusion: This research will provide long-due information and report on important aspects of the QOL most associated with EDS/IN. First data indicate a high frequency of these disorders as well as significant links between patients 'concerns and pharmacotherapy use.

Disclosure: Nothing to disclose.

EPO-698 | "Wet, wobbly, wacky and woke?"

M. McDowell-Hook

Taranaki Base Hospital, New Zealand

Background and Aims: Normal pressure hydrocephalus (NPH) is defined by a clinical triad of urinary incontinence, gait apraxia and cognitive impairment. Recent research has identified a high prevalence of sleep disordered breathing (SDB) in these patients. This audit investigates the diagnosis and management of patients with NPH and the prevalence of SDB in clinical practice.

Methods: Retrospective audit of clinical records from January 2014 to January 2024 ($n = 26$). Audit standards for diagnosis, investigation and management were defined from regional NPH guidelines. Prevalence of SDB in clinical practice was defined by Epworth Sleepiness Scale of 10–15 or diagnostic polysomnography.

Results: 26 (100%) patients had supportive neuroimaging and 23 (88.5%) patients had the full symptom triad. 22 patients (84.6%) had documented high volume CSF lumbar punctures and underwent gait assessment pre- and post-procedure. 13 patients (50%) progressed to ventriculoperitoneal shunt insertion, with all demonstrating symptomatic improvement. Only 2 patients (7.7%) were diagnosed with SDB, managed with non-invasive ventilation.

Conclusion: Documentation of diagnostic symptom triad, investigation, and management was completed to a high standard. However, the documented prevalence of SDB was significantly lower than in previous studies. These results suggest that SDB in NPH patients may be underdiagnosed, prompting inclusion of SDB to local

protocols. Future studies could investigate whether diagnosis and treatment of SDB improves outcomes for these patients.
Disclosure: Nothing to disclose.

EPO-699 | Importance of sleep quality and the effects of deprivation on doctors amidst conflict in Sudan

M. Jaber Amin[1]; L. Mohamed Ali Elomeir[2]
[1]*Faculty of Medicine Alzaiem Alazhari University, Khartoum, Sudan;* [2]*Faculty of Medicine, University of Khartoum, Khartoum, Sudan*

Background and Aims: Healthcare professionals working in demanding environments and leading busy lives are more prone to burnout, disruptions in their sleep schedules, and sleep deprivation. These factors can affect their productivity and performance, potentially compromising patient care and medical outcomes. The main objective of this study was to evaluate the effects of sleep quality and deprivation on healthcare professionals in Sudan.
Methods: To achieve this objective, we conducted a cross-sectional study using a structured questionnaire after thoroughly reviewing the existing literature on Sudanese healthcare professionals. The study aimed to assess sleep quality, stress, anxiety, and depression and evaluate their impact on performance. Additionally, we explored the associations between personal backgrounds, susceptibility to burnout, and sleep disturbance.
Results: Our results revealed that the majority of participants experienced poor sleep quality and daytime sleepiness. We also found a significant prevalence of stress, anxiety, and depression among Sudanese healthcare professionals. Furthermore, we identified associations between demographic factors such as sex, marital status, profession, and sleep quality.
Conclusion: This study underscores a critical issue for physicians' health programs in Sudan, highlighting the importance for hospitals to implement measures that enable healthcare professionals to take more days off, obtain adequate sleep, and reduce on-call service days. It is imperative for healthcare professionals themselves to acknowledge the significance of these factors in preserving their own health and delivering sustainable healthcare services.
Disclosure: Nothing to disclose.

EPO-700 | Insomnia and excessive daytime sleepiness in patients with breast cancer

S. Slemenšek Avšič[1]; M. Ravnik[2]; M. Rakuša[3]
[1]*Faculty of Medicine, University of Maribor, Slovenia;* [2]*Department of Oncology, University Medical Centre Maribor, Maribor, Slovenia;* [3]*Division of Neurology, University Medical Centre Maribor, Maribor, Slovenia*

Background and Aims: Sleep disturbances in women with breast cancer are poorly detected and managed in routine clinical practice. Our study aim was to evaluate sleep patterns and excessive daytime sleepiness (EDS) in patients during breast cancer treatment.
Methods: Fifty-nine women were recruited. Demographic data, sleep, neuropathic pain, anxiety, and depression were evaluated with the Epworth scale (ES), Insomnia Severity Index (ISI), PainDetect, DN4, Beck Anxiety Inventory (BAI), and Hamilton Depression Rating Scale (HDRS). We calculated descriptive statistics. Mean values for demographic data and scale scores were calculated using an unpaired *T*-test or Chi-square test between patients with EDS (ES >10) and clinically moderate to severe insomnia (ISI >15). At the end, we calculated Spearman´s correlations.
Results: Mean age was 60.6 ± 14.4 years, mean disease duration was 15.4 ± 20.9 months, mean ES was 7.6 ± 5.6 and mean ISI was 10.4 ± 7.7. Twenty-two percent of patients had EDS, and 27% had clinically moderate to severe insomnia. There were no statistically significant differences between groups in age, disease duration, BMI, metastases, hormone receptor status, therapy, presence of neuropathic pain, polyneuropathy symptoms, and severity of depression and anxiety. We found a positive correlation between ES and ISI (rho = 0.397; $p < 0.01$). Clinically moderate to severe insomnia and EDS correlated with depression (rho = 0.572; $p < 0.01$ and rho = 0.355; $p < 0.01$, respectively), anxiety (rho = 0.613; $p < 0.01$ and rho = 0.290; $p < 0.05$, respectively), and neuropathic pain (rho = 0.272, $p < 0.05$, both conditions). Additionally, EDS correlated with BMI (rho = 0.271; $p < 0.05$).
Conclusion: Our results indicate that insomnia is more prevalent than EDS in patients with breast cancer. We should be vigilant for patients with neuropathic pain and neuropsychiatric symptoms.
Disclosure: I disclose no conflict of interest.

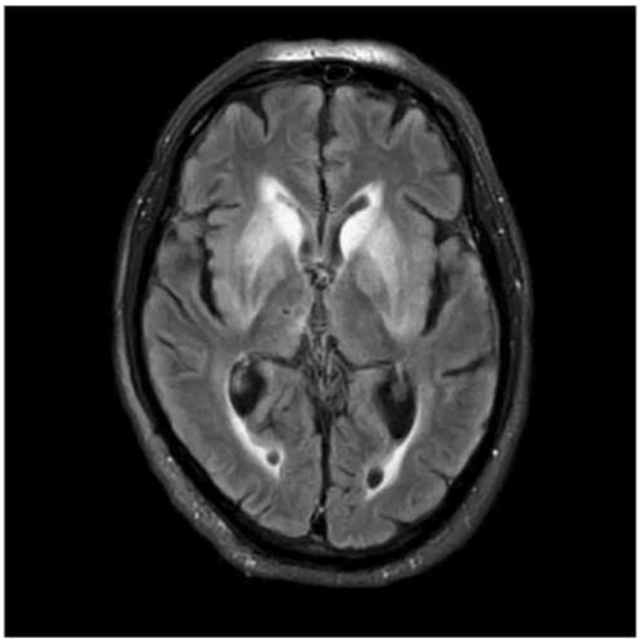
EPO-701 | Sleep-wake cycle disturbance as the first symptom in an anti-CV2/CRMP-5 encephalitis

B. Alberti Vall[1]; A. Martinez Viguera[1]; T. Mederer Fernandez[1]; S. Berton Ocampos[2]; S. Gimenez Badia[2]; L. Martin Aguilar[1]
[1]*Neurology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain;* [2]*Multidisciplinary Sleep Unit, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*

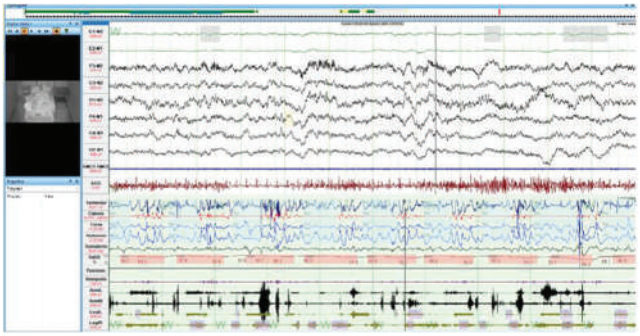
Background and Aims: We present the case of a patient with an anti-CV2/CRMP5 autoimmune encephalitis, whose initial and predominant symptoms were sleep disturbances. To our knowledge, no reported cases have highlighted sleep disturbances as the predominant clinical symptom, which tend to be overshadowed.
Methods: A 67-year-old male with a history of smoking, hypertension, and diabetes presented with a four-month course of symptoms that abruptly began with a severe alteration of the circadian sleep-wake pattern with night-time insomnia and excessive daytime sleepiness, and involuntary movements during sleep. Three months later he developed generalized weakness, gait disturbances, a toxic syndrome, dysarthria, and dysphagia. Neurological examination

showed bradypsychia, dysarthria, dysphagia, apraxia, bradykinesia, appendicular rigidity, and truncal ataxia.

Results: Video-polysomnography recorded undifferentiated periods of sleep and wakefulness, non-specific NREM sleep, with increased limb movements, and vocalizations during sleep. Positive anti-CRMP5/CV2 antibodies were detected in serum. Brain MRI revealed hyperintensities in the brainstem, both medial temporal lobes, and basal ganglia, consistent with striatal and limbic encephalitis. PET-CT scanning detected a thoracic hypermetabolic later confirmed as metastatic small cell lung carcinoma. Corticosteroid treatment as well as chemotherapy were started, with neurological improvement observed in a few days, and resolution of the sleep-wake cycle disturbance.



Brain MRI. Symmetrical hyperintensities in bilateral striatal regions as well as bilateral mesial temporal regions, compatible with a striatal and limbic encephalitis.



V-Polisomnography. Undifferentiated sleep and wakefulness periods, with undifferentiated N-REM (no graphoelements) and no registered periods of REM. OSA with significant desaturation.

Conclusion: This case underscores the importance of considering autoimmune encephalitis in the differential diagnosis of patients presenting with sleep disturbances and nonspecific neurological symptoms. These symptoms tend to be elusive and nonspecific and can lead to diagnostic delays. A multidisciplinary approach engaging both neurologists and sleep specialists can facilitate in an accurate and earlier diagnosis.

Disclosure: Nothing to disclose.

EPO-702 | Sleep architecture of patients with idiopathic hypersomnia and identification of neurophysiological markers for subtypes

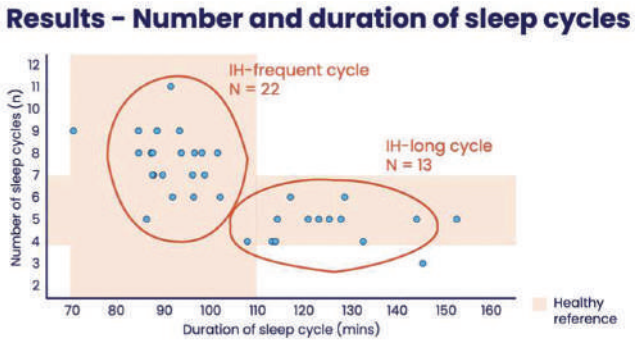
B. Harmes[1]; F. Tepel[1]; K. Šonka[2]; U. Kallweit[1]

[1]Center for Narcolepsy and Hypersomnias, Professorship for Narcolepsy and Hypersomnolence Research, Department of Medicine, University Witten/Herdecke, Germany; [2]Department of Neurology and Clinical Neuroscience Centre, Centre for Sleep and Waking Disorders, 1. Faculty of Medicine, Charles University, Prague, Czechia

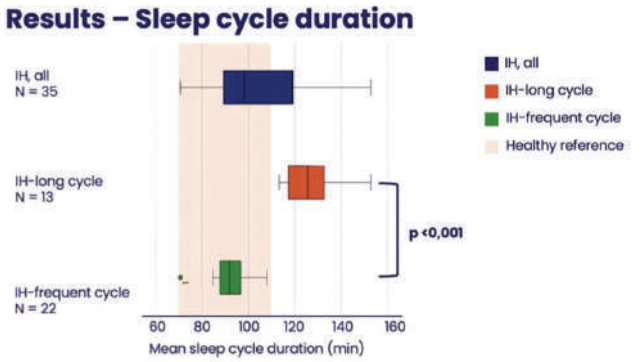
Background and Aims: Idiopathic hypersomnia (IH) is a rare neurologic disease characterised by excessive need of sleep including prolonged nocturnal sleep and excessive daytime sleepiness. Clinical observations have indicated at least two subtypes of IH, one associated with long sleep cycles. The aim of the study is to systematically examine differences in sleep architecture of patients with IH in order to identify particular neurophysiological parameters for subtypes.

Methods: In this retrospective pilot study polysomnography of 35 consecutive IH patients between 2017 and 2023 from two major sleep centres are analysed. Only patients without any psychopharmacological medication and without moderate or severe depression were included.

Results: 35 patients were included (27 female, 8 male). Mean age was 24.4 years. Mean total sleep duration was 605 ± 122 mins. Mean number of sleep cycles (MNSC) was 6.5 ± 1.9. Mean sleep efficiency was 93.8 %. Mean sleep cycle duration (MSCD) was 105 ± 20 mins. The MSCD of 22 patients was 92 ± 8 mins, their MNSC was 7.5 ± 1.5. The MSCD of the other 13 patients was 128 ± 13 mins, with a MNSC of 4.8 ± 0.8. With $p < 0.001$ for these two groups the difference in sleep cycle length is statistically highly significant.



Number (*n*) and duration of sleep cycles (mins).



Mean sleep cycle duration (mins).

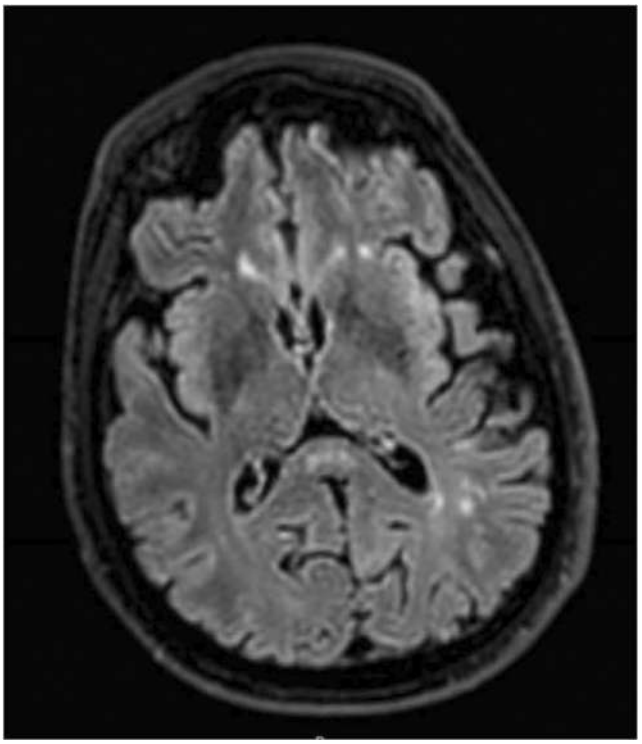
Conclusion: Data indicates two subtypes of IH: IH-long cycle is associated with long sleep cycles and a normal number of sleep cycles. IH-frequent cycle shows an increased number of sleep cycles and normal length of sleep cycles. Subtyping will contribute to the understanding of the etiopathogenesis and possibly to individualized therapy.
Disclosure: Nothing to disclose.

Neuroimaging 2

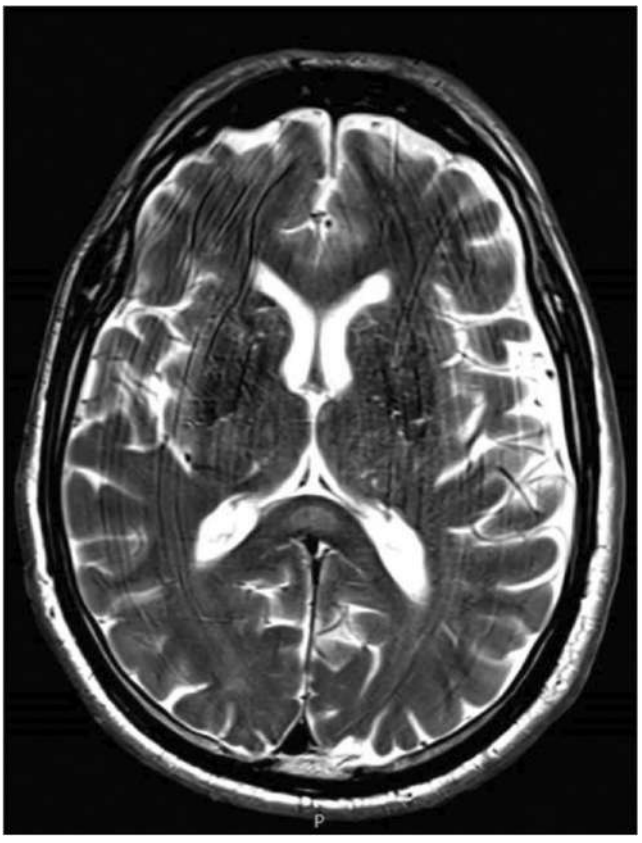
EPO-703 | MERS (Mild encephalitis with a reversible splenial lesion); a case report

A. Morillas; P. Gil; L. Carazo; V. González
Department of Neurology, Complejo Hospitalario of Jaén, Jaén, Spain

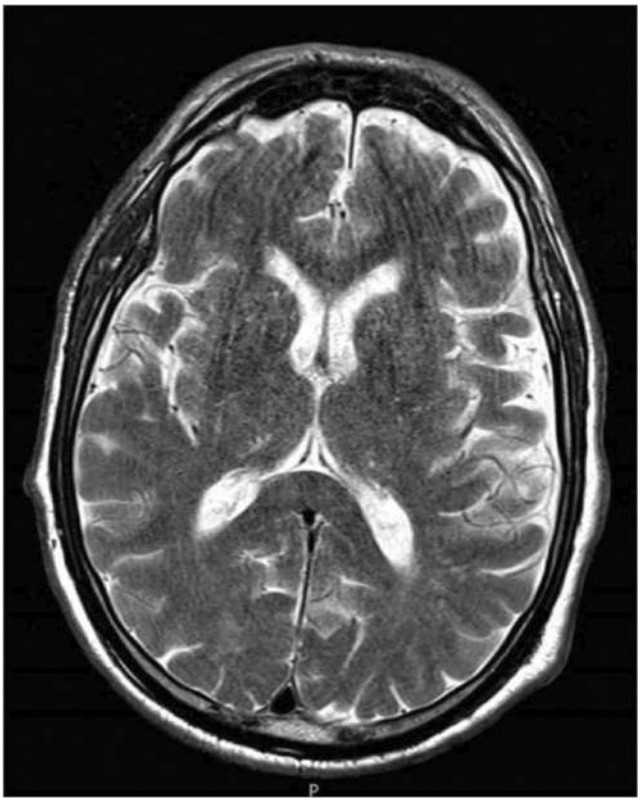
Background and Aims: Case of MERS (Mild encephalitis with a reversible splenial lesion) due to psychotropic drugs VS metabolic disorder.
Methods: In our hospital, we report the case of a 69-year-old man with a previous Bipolar Disorder, who develops abruptly a behavioral alteration and disorientation. Due to this, he is transferred to Neurology where he is diagnosed of MERS in possible relation to psychiatric medication and acute diarrhea.
Results: After the adjustment of the psychotropic drugs and the resolution of the diarrhea, the patient improved from the symptomatology and the hyperintense lesions disappeared in the Magnetic Resonance.



Initial cranial MRI of the patient shows an hyperintense lesion in the middle of SCC in FLAIR.



Initial cranial MRI of the patient shows an hyperintense lesion in the middle of SCC in T2.



Last cranial MRI shows a resolution of the lesion.

Conclusion: MERS is a reversible encephalopathy that affects the corpus callosum and can produce both neurological and psychiatric symptoms in relation to different etiologies, finding a hyperintense lesion in T2 and FLAIR sequences that are located in the splenium of the corpus callosum.

Disclosure: Nothing to disclose.

EPO-704 | Large scale white matter disruption and longitudinal degeneration in stroke

M. Aarabi[1]; L. Pini[2]; M. Corbetta[2]

[1]*Padova Neuroscience Center (PNC), University of Padova, Padova, Italy*; [2]*Department of Neuroscience, University of Padova, Padova, Italy*

Background and Aims: Stroke result in both local and distal brain connectivity alterations. While functional connectivity changes have been widely established, alterations in the structural connectivity patterns are still unclear. Here we assessed longitudinal changes of white matter organization in stroke and the relationship with behavior.

Methods: We prospectively enrolled first-time stroke patients, assessed at two-week and three-month intervals. Patients underwent behavioral and diffusion weighted-imaging (DWI) assessments. A latent factorial analysis was applied to behavioral data. Structural gradients were assessed for both intra- and inter-hemispheric tractography and averaged across networks. Statistical analyses included analysis of variance and longitudinal assessments through linear mixed model. Finally, we explored the relationships between structural gradients and behavior.

Results: Fifty patients (age 59 ± 11) and 29 controls (age 57 ± 11) were enrolled. Factorial analysis identified five cognitive factors, explaining 50% of variances. We reported three gradients for both intra- and inter-hemispheric connections (50% of variance). Network-wise analysis unveiled widespread acute stage alterations, impacting multiple networks for both intra- and inter-connectivity. Longitudinal assessment suggested significant degradation of this gradient structural organization. There was also an association between structural connectivity patterns and visuospatial-memory performance more strongly at the acute stage.

Conclusion: Stroke-induced structural connectivity damage extends beyond the lesion and worsens over time. The weak relationship between longitudinal changes in the structural organization and behavioral performance might implying that white matter modifications are independent with the recovery or disability status of stroke patients.

Disclosure: Nothing to disclose.

EPO-705 | High resolution intracranial vessel wall imaging in small vessel vasculitis of the central nervous system

A. Lotti[1]; A. Mariottini[2]; A. Barilaro[3]; G. Costantini[1]; E. Fainardi[4]; L. Massacesi[2]

[1]*Department of Neurosciences, Drug and Child Health, University of Florence, Florence, Italy*; [2]*Department of Neurology 2, Careggi University Hospital; Department of Neurosciences, Drug and Child Health, University of Florence, Florence, Italy*; [3]*Department of Neurology 2, Careggi University Hospital, Florence, Italy*; [4]*Neuroradiology Unit, Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy*

Background and Aims: Diagnosis of small vessels primary angiitis of CNS (SV-PACNS) is based on meninge/brain biopsy, but criteria for exposing to this invasive procedure high-risk cases only are lacking. In this study, accuracy of high resolution vessel wall MR imaging HR-VWI, a non-invasive method for visualizing SVs inflammation, for detecting patients at high risk of SV-PACNS was explored.

Methods: Patients with relapsing or chronic neurological symptoms/syndromes suggesting SV-PACNS ($n = 11$) or with secondary SV vasculitis of the CNS (SV-SACNS; $n = 4$) and patients with non-vasculitic brain hyperintensities (NVBH; $n = 34$; – multiple sclerosis, $n = 18$; – small vessel disease, $n = 12$; – migraine, $n = 4$) were enrolled. The patients received one MRI scan including HR-VWI sequences (3D PD weighted black blood with gadolinium) on a 3T scanner. SVs inflammation was considered present if linear HR-VWI enhancements corresponding to SVs and/or >3 punctiform enhancements noticeable in HR-VWI but not in other sequences were observed. HR-VWI enhancements corresponding to leptomeningeal enhancement, restricted diffusion areas or to microbleeds were excluded.

Results: HR-VWI positive SVs were observed in 7/15 SV-PACNS/SACNS (47%) and in 0/34 NVBH (0%), corresponding to 47%

sensitivity and 100% specificity. Stratifying the SV- PACNS/SACNS according to disease duration, 7/8 of the <1 year duration cases (87%) showed SV inflammation, thus in this setting increasing HR-VWI sensitivity to 87%.

Conclusion: In patients with short disease duration HR-VWI could represent an accurate tool for selecting patients at high risk of SV-PANCS eligible for cerebral/meninge biopsy. This probably because over time therapies mask the disease-related pathogenic inflammation.

Disclosure: Nothing to disclose.

EPO-706 | DAI changes of head injury patients in CT imaging: The HEAD Helsinki study

O. Raassina[1]; R. Autio[2]; J. Kinnunen[3]; M. Patronen[4]; I. Marinkovic[3]; H. Isokuortti[5]; J. Satopää[6]; J. Putaala[3]; M. Niemelä[6]

[1]Department of Radiology, University of Helsinki, Helsinki University Hospital, Helsinki, Finland; [2]Department of Radiology, Vaasa Central Hospital, Vaasa, Finland; [3]Department of Neurology, University of Helsinki, Helsinki University Hospital, Helsinki, Finland; [4]Statistics Finland, Helsinki, Finland; [5]Department of Intensive Care, University of Helsinki, Helsinki University Hospital, Helsinki, Finland; [6]Department of Neurosurgery, University of Helsinki, Helsinki University Hospital, Helsinki, Finland

Background and Aims: Diagnostic value of computed tomography (CT) imaging for diffuse axonal injury (DAI) changes is considered limited. We determined how many patients with magnetic resonance imaging (MRI) positive DAI changes had them visible in head CT after diagnosed traumatic brain injury (TBI).

Methods: Our retrospective register-based study cohort of patients with head injury treated at emergency hospitals in Helsinki between 01 January and 31 December in years 2010 and 2018. Confirmed DAI patients' initial and follow up head CTs were analyzed. Based on MRI findings, definitive corresponding CT findings were accepted according to Gentry's classification: Hemorrhagic and/or edematous strands at grey-white matter junctions in grade 1 and edematous and/or petechial contusions in grade 2 and 3. Small single petechial contusions located in the subcortical or white matter regions were excluded in grade 1.

Results: Of the 1963 screened patients, 64 had MRI positive DAI changes. A total of 24/64 (37.5%) MRI-DAI patients had visible DAI changes in CT, of which 9/24 (37.5%) were grade I, 6/24 (25.0%) grade II and 9/24 (37.5%) grade III. However, 7/24 (29.0%) did not show any visible changes during the primary CT obtained within 24 hours after the accident, and they only became evident in follow-up CTs taken 1–4 days after the initial scan.

Conclusion: Detection of DAI-changes in CT compared with MRI was low despite of increased sensitivity in follow-up CT scans. MRI-imaging combined with clinical history remain the primary source of tool for assessing DAI-changes in TBI-patients.

Disclosure: Nothing to disclose.

EPO-707 | Stroke echo scan from a neurologist perspective

P. Lochner; J. Stögbauer; F. Merzou; S. Krakau; S. Kottackal

Neurology, Saarland University Center

Background and Aims: More than 20% of ischaemic strokes occur due to a cardioembolic cause The point of care echocardiography (PoCUS) protocol comprises eleven aspects with binary responses focussing on specific target structures: functions of left ventricle, left atrium, right ventricle, valvular abnormalities, large intracardiac thrombi, aortic plaque thrombi, aortic plaque, pericardium and signs of hypovolaemia.

Methods: We applied this screening to identify stroke patients associated with an increased cardioembolic risk in order to find treatable cardioembolic causes and to find an interrater reliability between neurologist and cardiologist, whose diagnosis was chosen as the gold standard.

Results: According to the defined protocol, 50 patients (female, $n=24$; mean age = 62 a, SD 17 a) underwent the PoCUS echocardiography test. It displayed a global sensitivity of 77.8% and global specificity of 94.1% ($k=0.73$). This high sensitivity and specificity were achieved particularly with regard to the assessment of pumping function and enlargement of the cardiac cavities, but less for other items such as heart valve abnormalities (SEN 30%; SPE 97.4%), large intracardiac thrombi (SEN not available, SPE 100%).

Conclusion: A good interobsever reliability was found between neurologist and cardiologist. Future prospective studies are warranted to improve the interrater reliability.

Disclosure: Nothing to disclosure.

EPO-708 | Supra and infratentorial atrophy in cerebellar ataxias: Unveiling distinctions across different etiologies

S. Pisano[1]; S. Basaia[2]; O. Stojiljković[3]; S. Mesaros[3]; N. Dragasevic[3]; V. Kostic[3]; F. Agosta[4]; M. Filippi[5]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Neurology Department, Istituto Clinico S. Anna Hospital, Brescia, Italy; [2]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; [3]Clinic of Neurology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [4]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy; [5]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: This study investigates structural changes in patients with cerebellar ataxias (CA) due to different causes.

Methods: 28 Autosomal dominant (AD) CA patients, 17 autosomal recessive (AR) CA patients, 29 sporadic cases of CA, 8 multiple system atrophy patients (MSAc) and 20 controls were included. MRI

was performed; whole-brain Voxel-Based Morphometry (VBM) and cerebellar-optimized VBM (SUIT toolbox) were used to assess gray matter (GM) atrophy. Brainstem and superior cerebellar peduncles (SCP) volumes were estimated and compared.

Results: Compared to controls, all CA groups showed widespread GM cerebellar atrophy; additionally, AD and AR groups showed distinct clusters of supratentorial atrophy, mainly involving temporal and parietal regions. No supratentorial GM differences were found among CA groups. SUIT-VBM revealed more severe atrophy in the medial Crus-I and II in MSAc compared to AD, and in AR compared to AD. AD, AR, and MSAc groups exhibited reduced whole-brainstem, midbrain, and pons volumes compared to controls; AD and MSAc groups also exhibited reduced whole-brainstem and pons volumes compared to sporadic cases. AD and AR showed reduced medulla volumes compared to controls and sporadic cases. SCP volume reduction was evident in all CA groups compared to controls, with AD showing also decreased SCP volume compared to sporadic cases.

Conclusion: AD and AR groups showed supratentorial patterns of atrophy. Conversely, the sporadic group showed less involvement of brainstem structures. The evidence of distinct patterns of structural alterations in different CA etiologies might contribute to an improved differential diagnosis.

EPO-709 | Chronic active lesions contribute to depression in multiple sclerosis

M. Rubin[1]; P. Preziosa[1]; A. Meani[2]; M. Margoni[3]; N. Tedone[2]; M. Filippi[4]; M. Rocca[1]

[1]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy; [2]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; [3]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, and Neurorehabilitation Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; [4]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: Chronic neuroinflammatory processes may contribute to depression in multiple sclerosis (MS). Paramagnetic rim lesions (PRLs) and choroid plexus (CP) enlargement represent novel magnetic resonance imaging (MRI) markers of chronic inflammation in MS that are associated with more severe clinical disability. Currently, their interplay with the presence of depression remains unexplored. Here, we examined whether the number and volume of PRLs and CP enlargement may contribute to depression in MS patients.

Methods: Brain 3T MRI and clinical evaluation with the assessment of depression using Montgomery–Asberg Depression Rating Scale (MADRS) were obtained from 126 MS patients and 72 age- and sex-matched healthy controls (HC). Patients with MADRS score >9 were classified as depressed. PRLs were identified on phase images of susceptibility-weighted imaging, whereas CP volume was quantified using a fully-automatic method on 3D T1-weighted and FLAIR MRI sequences. Predictors of depression were identified using LASSO logistic regression.

Results: Forty-six out of 126 (36.5%) MS patients were depressed. Fifty-nine (46.8%) MS patients had ≥1 PRLs (median = 0, interquartile range = 0; 2). Compared to HC, MS patients showed significantly higher T2-hyperintense white matter lesion (WM) and normalized CP volume volumes, as well as lower normalized brain, thalamic, hippocampal and WM volumes (p from <0.001 to 0.023). PRL number (standardized-β = 0.078) and volume (standardized-β = 0.029) were independent predictors of depression (area under the curve = 0.60).

Conclusion: Higher number and volume of PRLs may contribute to the pathophysiology of depression in MS patients, emphasizing the role of chronic neuroinflammatory processes in determining depression independently from disease severity.

Disclosure: M Rubin, A Meani, N Tedone have nothing to disclose. P Preziosa received speaker honoraria from Roche, Biogen, Novartis, Merck, Bristol Myers Squibb, Genzyme, Horizon and Sanofi. Background and Aims: Idiopathic Parkinson's disease (iPD) features loss of presynaptic serotonergic function. Serotonergic loss has also been detected in autosomal dominant forms of monogenic Parkinsonism. In this study we present preliminary in vivo data of serotonergic terminal integrity in the striatum of symptomatic PRKN mutation carriers (PRKN-PD), an autosomal recessive form of monogenic Parkinsonism.

Methods: Eight individuals with PRKN-PD (mean age 49.32 ± 8.74, disease duration 9.51 ± 5.59 years, Hoehn & Yahr 1.81 ± 0.53), eight iPD patients (mean age 65.38 ± 7.58, disease duration 4.82 ± 4.17 years, Hoehn & Yahr 1.88 ± 0.99) and eight healthy controls (HC, mean age 46.25 ± 6.02) underwent clinical assessments, Magnetic Resonance Imaging (MRI) scans, and single [11C]DASB PET scan. Regions of Interest (ROIs) were delineated on each subject's T1 space MRI, using Multi-Atlas Propagation with Enhanced Registration (MAPER), with grey matter masking. The Logan reference model, with the posterior cerebellar grey matter excluding the vermis as the reference region, was utilised to generate parametric [11C]DASB distribution volume ratio (DVR) images with DVR-1 equal to non displaceable binding potential (BPND).

Results: PRKN-PD patients exhibited significant reduction in [11C]DASB BPND compared to HC in Putamen (−33.8%, $p < 0.001$), and Caudate (−37.2%, $p = 0.005$). iPD patients showed significant decrease of [11C]DASB BPND in putamen (−36.1%; $p < 0.001$) and caudate (−43.9%; $p < 0.001$) compared to HC. No significant difference in [11C]DASB BPND was observed between iPD and PRKN-PD patients in these regions.

Conclusion: These findings offer preliminary evidence of a noteworthy striatal loss in presynaptic serotonergic integrity among symptomatic PRKN mutation carriers. Ongoing data collection for additional PRKN carriers will further illuminate these findings.

Disclosure: Nothing to disclose.

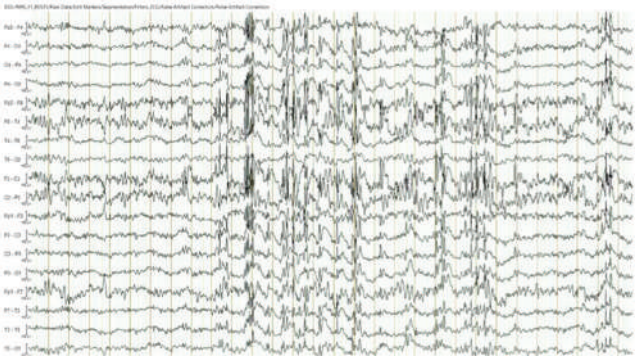
EPO-711 | BOLD fMRI functional connectivity informed by IEDs in high-risk and low-risk SUDEP epilepsy patients

S. Scolastico; F. Talami; A. Ballerini; S. Meletti; A. Vaudano
Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena

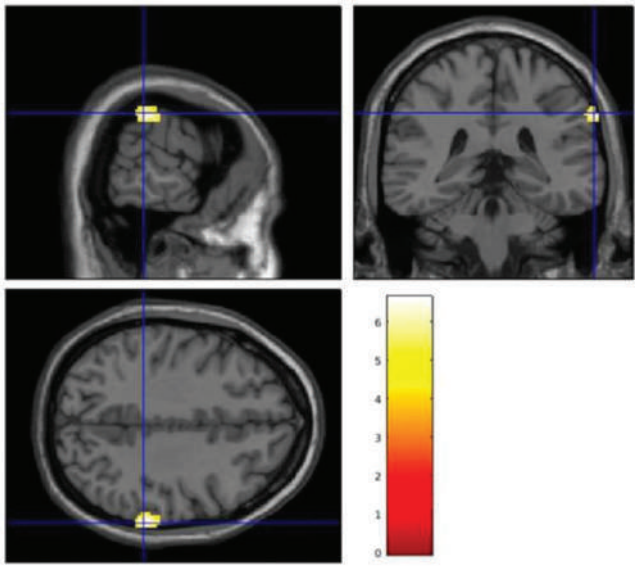
Background and Aims: According to recent literature, interictal epileptiform discharges (IEDs) might provide a facilitating environment for Sudden Unexpected Death in Epilepsy (SUDEP) to happen. Here, we explore the effects of IEDs on the functional connectivity between regions of interest (ROIs) known to be involved in the SUDEP pathogenesis and the rest of the brain in a population of high-risk (HR) and low-risk (LR) SUDEP epilepsy patients.

Methods: A cohort of 39 adult epilepsy patients was investigated with EEG-coregistered to fMRI and then stratified in HR and LR according to SUDEP-3 and SUDEP-7 inventories. Additional stratification was performed based on the occurrence of tonic-clonic seizures (GTC criteria). Seven ROIs were considered: Anterior Cingulate Cortex, Insula, Brainstem, Thalamus, Amygdala, Putamen. The IED-related functional connectivity between the ROIs and the rest of the brain was investigated through a Psychophysiological Interaction (PPI) analysis.

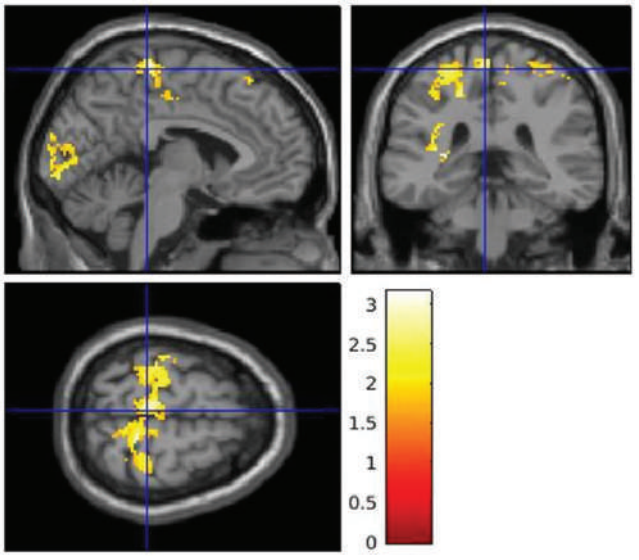
Results: In the SUDEP-7 and GTC stratified groups, PPI analyses show in HR versus LR an increased IEA-informed functional connectivity between amygdala, thalamus and putamen seeds and supramarginal gyrus and a decreased functional connectivity between the same ROIs and motor and premotor cortex. These patterns are consistent with the PPI results obtained with the same approach in a single "Probable SUDEP" case.



"Probable SUDEP" case interictal EEG trace acquired during fMRI.



Increased spike-related FC in the GTC HR group compared with LR patients between bilateral putamen and left supramaginal Gyrus.



Reduced spike-related FC in the SUDEP-7 HR groups compared with LR patients between bilateral thalamus and premotor cortex.

Conclusion: Our findings suggest that in SUDEP and HR patients compared to LR, IEA modulate the functional connectivity between specific subcortical ROIs and brain networks involved in response to stimuli and surroundings (SMG) and in the regulation of the cardiovascular system (premotor cortex) thus providing new insights in the pathogenesis of SUDEP.

Disclosure: Nothing to disclose.

EPO-712 | Availability and integration of neuroimaging research database in Nigeria

U. Ibrahim[1]; A. Moradeyo[2]; A. Idris[1]; I. Junaid[1]; Y. Olamilekan[3]

[1]Medicine and Surgery Department, Aminu Kano Teaching Hospital, Kano, Nigeria; [2]Medicine and Surgery Department, Lautech Teaching Hospital, Ogbomosho, Ibadan, Nigeria; [3]Physiology Department, University of Ilorin/University of Ilorin Teaching Hospital (U.I.T.H), Illorin, Nigeria

Background and Aims: Brain injuries and brain diseases in Nigeria are particularly prevalent, with an annual incidence of 2170 per 100,000 individuals. Approximately 78% of Nigeria's neuroimaging institutes use low-field-strength systems that are inefficient for generating conventional neuroimaging database.

Methods: DATA COLLECTION. The central repository data would be established in accordance with the highest ethical standards approved by the ethical committee of the diagnostic centers or its equivalent. Data would be collected from consented individuals presenting to the diagnostic centers for neuroimaging services. DATA PROCESSING. This neuroimaging data would be de-identified, with personal information removed for research accessibility by the help of African Brain Data Network.

Results: The prospective result of integrating neuroimaging research data would increase the availability of neuroimaging data, which would allow for more robust research. It would contribute to the advancement of neuroimaging and healthcare research in Nigeria.

Conclusion: Our research underscores the pressing need for an integrated neuroimaging data platform in Nigeria, a nation grappling with limitations in neuroimaging capabilities.

Disclosure: Nothing to disclose.

EPO-713 | Clinical use of tau PET in Aβ PET positive individuals: A case series – The HEAD study

V. Machado[1]; G. Povala[1]; G. Negrini[1]; P. Ferreira[1]; L. Amaral[1]; B. Bellaver[1]; L. Firoza[1]; D. Tudorascu[1]; W. Klunk[1]; W. Jagust[2]; V. Lowe[3]; D. Soleimani-Meigooni[4]; H. Oh[5]; B. Pascual[6]; B. Gordon[7]; P. Rosa-Neto[8]; S. Baker[2]; V. Machado[9]; T. Pascoal[1]

[1]*University of Pittsburgh, Department of Psychiatry, PA, USA;* [2]*Lawrence Berkeley National Laboratory, Berkeley, CA, USA;* [3]*Mayo Clinic, Department of Radiology, Rochester, MN, USA;* [4]*University of California San Francisco, Memory and Aging Center, San Francisco, CA, USA;* [5]*Brown University, Department of Psychiatry and Human Behavior, Providence, RI, USA;* [6]*Houston Methodist Research Institute, Department of Neurology, Houston, TX, USA;* [7]*Washington University in St. Louis, Department of Radiology, St. Louis, MO, USA;* [8]*Translational Neuroimaging Laboratory, McGill University Research Centre for Studies in Aging, Douglas Research Institute, Montréal, QC, Canada;* [9]*UNIVATES, School of Medicine, Lajeado, Brazil*

Background and Aims: Clinical phenotypes combined with structure imaging biomarkers, as levels of tau PET pathology, allow a sensitive and specific diagnosis of Alzheimer's disease (AD). We present here the cases of four patients who visited the memory clinic at the University of Pittsburgh Medical Center between June and December 2023 and underwent both Aβ and tau-PET scans.

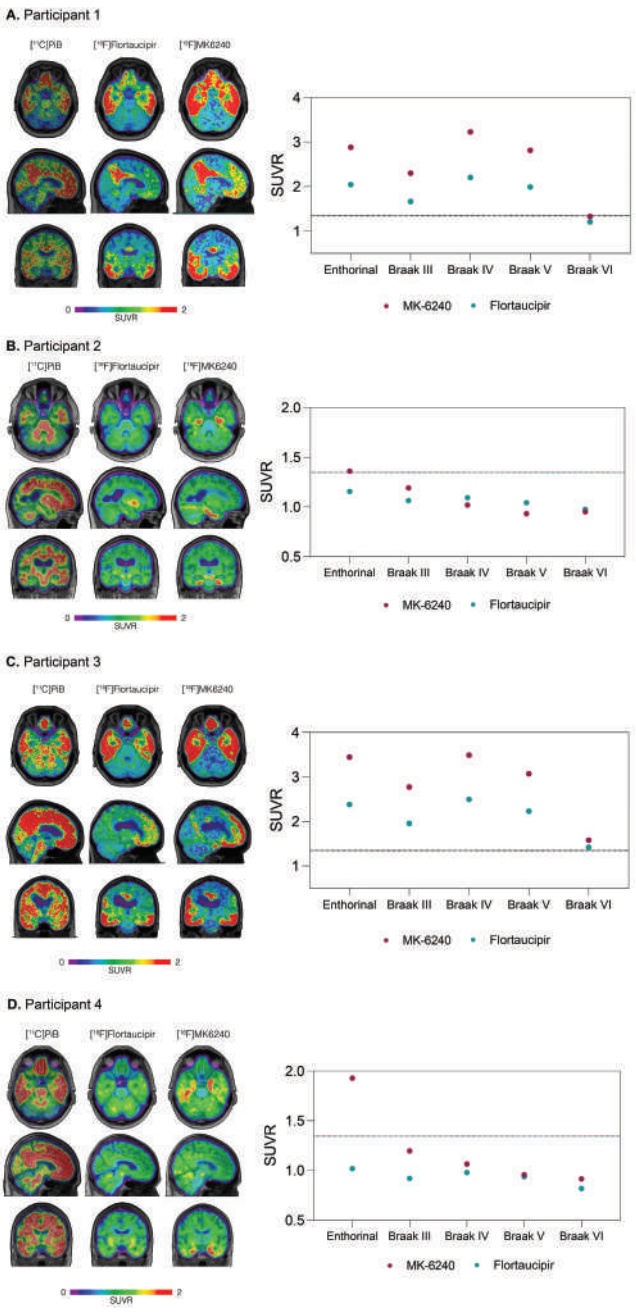
Methods: These individuals had standard clinical and cognitive outcomes, typical blood tests ordered in patients with memory impairment, MRI, PET PIB Aβ and two tau PET tracers (MK6240 and Flortaucipir).

Results: All patients had their blood tests normal. Patients 2–4 exhibited mild ischemic changes (Table 1). All patients tested positive for amyloid PET, with varied tau PET results. Patients 1 (MOCA = 6) and 3 (MOCA = 19), who were demented with impaired Instrumental Activities of Daily Living (IADL), had Braak stages V-VI using both tau PET tracers. Conversely, the mild cognitive impairment (MCI) Patients 2 (MOCA = 19) and 4 (MOCA = 9, neuropsych evaluation indicating MCI) tested positive for MK6240 but negative for FTP.

TAB 1 – Demographic and results

Patient	Age, y	Sex	MOCA	MRI	IADL	Aβ	AV1451 BRAAK	MK6240 BRAAK
1	71	M	6	Normal	YES	+	5	5
2	73	M	19	Ischemic changes	NO	+	0	1
3	74	F	14	Ischemic changes	YES	+	5	6
4	81	M	29	small PCA infarction	NO	+	0	2

Figure 1 - Amyloid and tau-PET in the participants



Tau PET-scans and the difference between the tracers.

Conclusion: The symptoms of typical amnestic AD presentation were confirmed with similar pattern of Aβ PET. Tau PET demonstrated greater variability, with lower levels observed in less cognitively impaired patients (Figure 1). This small series did not exclude that a low MOCA score combined with Aβ PET could be useful in identifying individuals in the earliest stages candidates to Aβ- lowering therapies. Larger samples are necessary in regarding these discrepancies between tau PET uptake and cognitive tests, reinforcing the need for tau PET markers as complementary tests.

Disclosure: Nothing to disclose.

EPO-714 | Exploring atypical forms of Alzheimer's disease through connectomics in early and late-phase amyloid PET and FDG PET

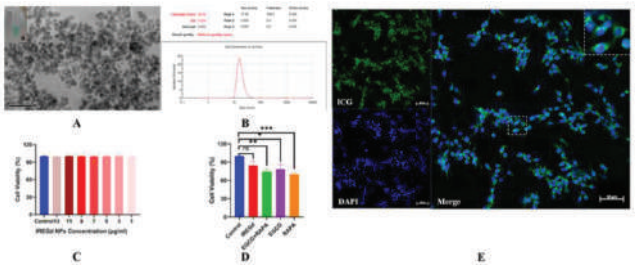
W. Kreshpa[1]; A. Cirone[2]; S. Garbarino[2]; F. Massa[1]; S. Raffa[2]; A. Chincarini[3]; L. Roccatagliata[2]; A. Uccelli[2]; S. Morbelli[4]; M. Pardini[1]
[1]Università degli studi di Genova, Genoa, Italy; [2]IRCCS Ospedale Policlinico San Martino, Genoa, Italy; [3]Genoa Division, National Institute for Nuclear Physics, Genoa, Italy; [4]Università degli studi di Torino, Turin, Italy

Background and Aims: Alzheimer's disease (AD) is the most common form of dementia, characterized by prominent amnestic impairment of insidious onset. However, atypical presentations such as logopenic variant of primary progressive aphasia, posterior cortical atrophy, corticobasal syndrome and frontal AD, pose diagnostic challenges. This study presents retrospective analysis investigating brain functional differences between typical and atypical AD. Specifically, a structural connectome, a comprehensive map of anatomical white matter connections, was employed alongside late-phase amyloid-PET, which resembles regional amyloid uptake. Additionally, this research aims to examine whether early-phase amyloid-PET can serve as a surrogate for synaptic dysfunction, similar to [18F]FDG-PET.
Methods: Thirty patients were selected: 13 with atypical AD and 17 with typical amnestic phenotype. Neuropsychological tests, MRI, [18F]FDG-PET, and [18F]FBB-PET were performed for each subject. Structural and functional images underwent spatial registration, segmentation, and intensity normalization, using a custom Python pipeline based on FreeSurfer and ANTs tools. Structural connectomes derived from probabilistic tractography on DWI images of 30 healthy subjects were employed.
Results: Results revealed a significant preservation of the hippocampus in atypical AD ($p < 0.05$). The connectome analysis demonstrated variations in interconnections among late-phase amyloid-PET uptake regions between atypical and typical AD. Furthermore, our findings support the hypothesis that early-phase amyloid-PET serves as a reliable marker for synaptic dysfunction.
Conclusion: These findings suggest that structural connectomes in PET imaging can reveil unique neurodegenerative pathways in atypical AD. Moreover, this study supports that early amyloid-PET phases provides similar information to [18F]FDG-PET on neurodegeneration among atypical AD patients.
Disclosure: Nothing to disclose.

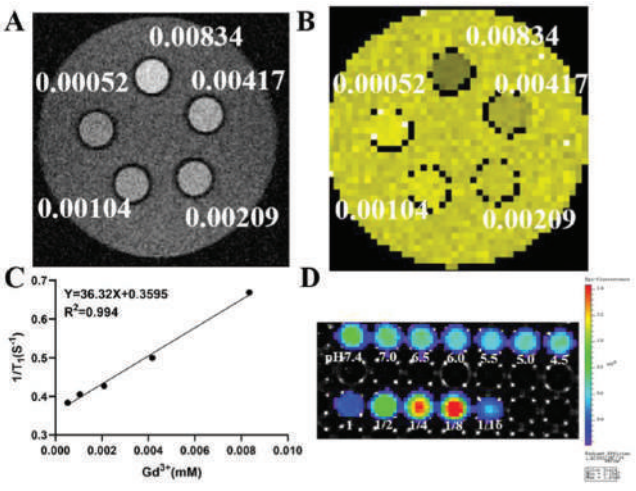
EPO-715 | Integrated diagnosis and treatment of acute ischemic stroke by nanoparticles based on MRI/NIR dual-modality imaging

L. Yang
Department of Radiology, The Second Affiliated Hospital, Medical College of Shantou University, Shantou, China

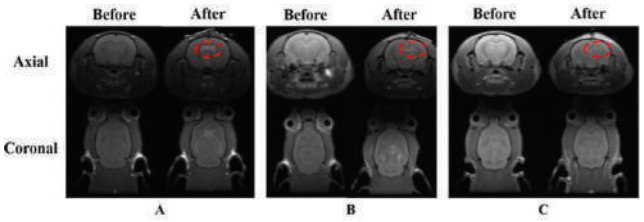
Background and Aims: Rapamycin (RAPA) is an effective autophagy modulator that can promote neuronal survival under ischemic conditions through rational autophagy regulation and is receiving increasing attention. However, its low solubility and poor stability seriously hinder its further application.
Methods: In this study, RAPA, indocyanine green (ICG), epigallocatechin gallate (EGCG), and Gd3+ serving as neuroprotective drugs, near-infrared fluorescence (NIRF) imaging agents, biomimetic coatings, and magnetic resonance imaging agents, respectively, were co-assembled into carrier-free, highly biocompatible ICG-RAPA-EGCG-Gd nanoparticles (IREGd NPs) for synergistic diagnosis and treatment of acute ischemic stroke.
Results: The results showed that the IREGd NPs had good stability and could load RAPA efficiently. IREGd NPs were efficiently uptaken by PC-12 cells and had a superior neuroprotective effect on oxygen-glucose deprivation and reoxygenation (OGD/R)-treated PC-12 cells than RAPA or EGCG. In addition, IREGd NPs showed good signal characteristics for MRI and NIRF imaging. Finally, in vivo, experiments confirmed that IREGd NPs preferentially aggregated in the ischemic hemisphere and were neuroprotective in transient middle cerebral artery occlusion (tMCAO) rats.



TEM (A) and DLS (B) display the characteristics of IREGd NPs. (C) Cell viability of PC12 cells after incubation with different concentrations of IREGd NPs for 24 h and (D) after incubation with EGCG+RAPA, EGCG, and RAPA for 24 h. (E) CLSM images of cell.



MR and NIF imaging properties of IREGd NPs. (A, B) T1-WI and T1-mapping images of different Gd3+ concentrations (mM) at pH = 7.4; (C) functions made with the Gd3+ concentration as the horizontal coordinate and 1/T1 (T1 represents the longitudinal relaxation.



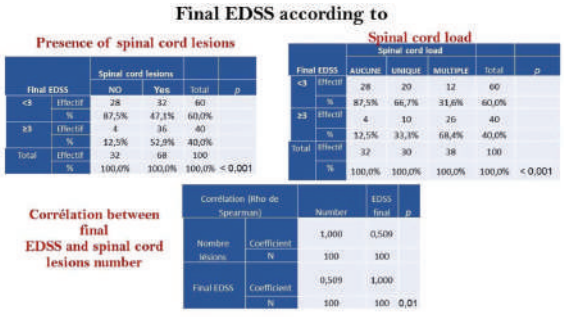
T1-WI images of in vivo lateral ventricles (A) and brain parenchyma (B) injected with IREGd NPs or PBS (C). Signal altered (A, B)/ unaltered (C) areas are within the red ovals.

Conclusion: Overall, carrier-free IREGd NPs provided a simple alternative approach to achieve bimodal imaging and therapeutic integration in acute ischemic stroke.
Disclosure: Nothing to disclose.

EPO-716 | Contribution of spinal cord magnetic résonance imaging (MRI) as a prognostic biomarker in multiple sclerosis

Y. Koubci; N. Lakri; H. Bouzenada
Central Hospital of Army, Algiers, Algeria

Background and Aims: Multiple sclerosis (MS) is the leading cause of acquired motor disability in young adults. The aim of this study was to determine the prognostic value of spinal cord lesions on the occurrence of relapses and the progression of short-term disability in MS patients.
Methods: A descriptive, monocentric, prognostic study of a cohort of 100 remittent MS patients, followed for 3 years, all with baseline MRI and follow-up MRI at 12 months and 30 months. Clinical evaluation was based on the Expanded Disability status scale (EDSS).
Results: Mean age at onset was 28.06 years, mean duration of the disease was 41 months. 68% of patients had spinal cord lesions at the initial stage; initial spinal cord involvement was predictive of relapse onset and worsening of disability over the course of the disease ($p < 0.001$), and an impact on ambulation in 19% of cases. Multiple spinal cord lesions were significantly associated with a high initial and final EDSS score (≥3) ($p = 0.001$; $p < 0.001$). Cervical and cervicodorsal sites were predictive of disability aggravation in more than half the cases. In axial terms, >60% of lateral lesions were associated with disability. Posterior lesions were associated with a final EDSS score <3 ($p < 0.001$). The absence of spinal cord lesions (32%) was associated with an initial and final EDSS score <3 ($p = 0.04$; $p < 0.001$)



Final EDSS according to spinal cord load lesions.

Peripheral nerve disorders

EPO-717 | Guillain Barre syndrome; clinical features and outcome in three referral hospitals in Cameroon

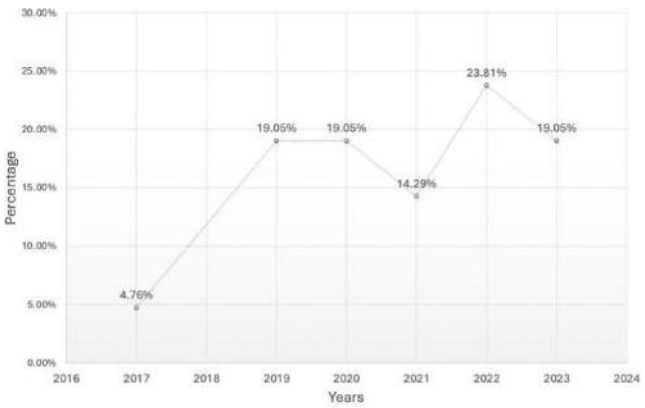
D. Gams Massi[1]; A. Shehou[2]; V. Sini[3]; M. Magnerou[4]; N. Mapoure[2]
[1]*Douala General Hospital/Faculty of Health Sciences, University of Buea*; [2]*Douala General Hospital/Faculty of Medicine and Pharmaceutical Sciences, the University of Douala*; [3]*Yaoundé General Hospital/Institut Supérieur de Technologie Médicale Yaoundé*; [4]*Douala Laquintinie hospital/Faculty of Medicine and Pharmaceutical Sciences, the University of Douala*

Background and Aims: Guillain Barré Syndrome (GBS) is an inflammatory pathology of the peripheral nervous which is characterized by bilateral and progressive sensory-motor impairment of the

peripheral limbs, sometimes extending to the respiratory muscles and cranial nerves. We aimed to determine the clinical features and outcome of Guillain Barré Syndrome cases in Cameroon.

Methods: We reviewed all cases of GBS admitted from January 2017 to March 2023, in General and Laquintinie hospitals of Douala and in Yaoundé General hospital. We excluded patient aged under 16 and incomplete files based on the Brighton diagnostic criteria. Data on sociodemographic characteristic, clinical features, workup, treatments and outcome data were collected and analyzed using SPSS 23.0.

Results: A total of 21 cases of GBS were included, and patients aged < 40 years represented 52.4% of cases. Men represented 61.9% of patients. The average admission rate was 3.5 cases/year. Mean age was 40.8 ± 17.6 years. Most frequent triggering factors were respiratory tract infection (38.1%), and immunization (14.3%). The most common signs were tetraparésis (85.7%), deep tendon areflexia (71.42%) and hyperesthesia (52.38%). Albumino-cytology dissociation was observed in 6 cases out of 11 CSF sampled. ENMG was performed in 11 patients and classified axonal type ($n = 7$) and the demyelinating type ($n = 4$). IV immunoglobulins were administered in 28.6% of patients. Pressure sores (57.9%) and autonomic disorders (14.3%) were the most frequent intra-hospital complications. We recorded 2 cases of in-hospital death.



Trend of admission of patients with GBS in Douala General and Laquintinie hospitals and Yaoundé General hospital.

Conclusion: Guillain Barré syndrome is an uncommon condition with sometimes dramatic complication which need more attention.

Disclosure: Nothing to disclose.

EPO-718 | Charcot-Marie-tooth type 2CC misdiagnosed as chronic inflammatory demyelinating polyneuropathy

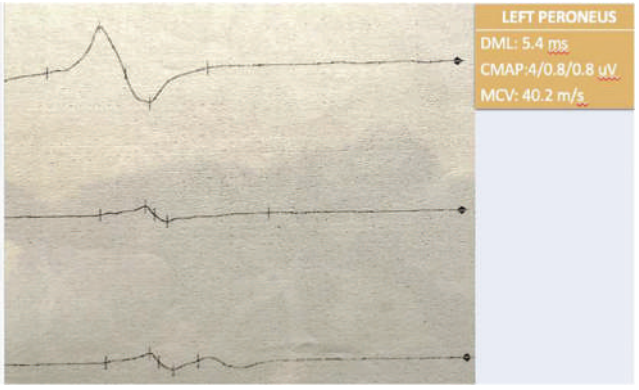
I. Di Sarno[1]; S. Tozza[1]; F. Santorelli[2]; R. Iodice[1]; R. Dubbioso[1]; L. Ruggiero[1]; M. Nolano[1]

[1]*Department of Neurosciences, Reproductive and Odonstomatological Sciences, University of Naples "Federico II", Naples, Italy*; [2]*Molecular Medicine, IRCCS Fondazione Stella Maris, Pisa, Italy*

Background and Aims: Charcot-Marie-Tooth (CMT) is a group of genetic neuropathies typically characterized by distal muscle wasting and sensory loss, pes cavus and areflexia. Herein we describe a case of Charcot-Marie-Tooth with equivocal features misdiagnosed as chronic inflammatory demyelinating polyneuropathy.

Methods: A 30-year-old woman was referred to our neuromuscular unit at 28 years old with proximal muscle weakness. Neurological examination showed weakness in lower limb (LL) muscles, marked proximally and mild distally, and absence of ankle deep tendon reflexes. Familial history was negative for neuromuscular diseases. Electromyography showed chronic neurogenic changes in proximal and distal muscles of LL. Nerve conduction study (NCS) showed both normal NCV and slowing with conduction blocks, so a diagnosis of CIDP was advanced and she was treated with intravenous immunoglobulins that were ineffective. At electrophysiological revaluation (after two months) CB in peroneal nerve was not more detectable as also distal CMAP had decreased.

Results: The hypothesis of genetic neuropathy was considered, and her 8-year-old son was evaluated. Neurological examination revealed mild weakness of distal and proximal muscles at lower limbs and mild pes cavus. Neurophysiological investigation showed an intermediate-axonal pattern. A targeted-NGS showed heterozygous frameshift mutation (c.3057dupG; p.K1020fs*43) in the NEFH gene, coding for the neurofilament heavy chain and causing CMT2CC, a rare form of axonal CMT with proximal weakness.



Conduction block in the proband peroneal nerve.

	Left	Right
MEDIAN		
SAP	7.7 uV	3.6 uV

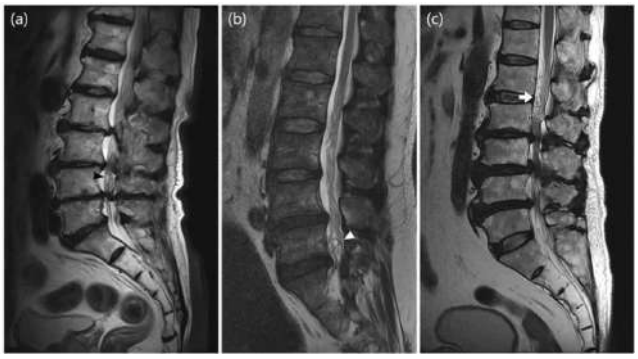
EPO-719 | **Abstract withdrawn**

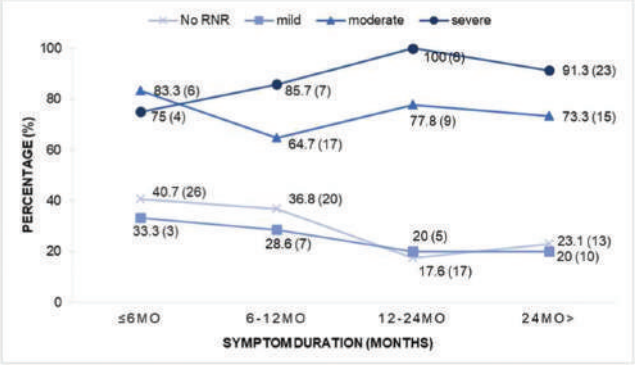
EPO-720 | **Redundant nerve roots on MRI can predict ongoing denervations in lumbar spinal stenosis patients**

K. Kim[1]; S. Park[1]; S. Hong[2]
[1]*Department of Rehabilitation Medicine, Seoul National University College of Medicine, Seoul National University Hospital, Seoul, Korea;*
[2]*Department of Radiology, Seoul National University College of Medicine, Seoul National University Hospital, Seoul, Korea*

Background and Aims: Redundant nerve roots (RNRs), which are abnormally elongated and tortuous nerve roots, can be developed secondary to degenerative spinal stenosis. It has been reported that RNRs are associated with worse clinical outcome after decompressive surgery. However, there are limited studies about clinical significance of RNR. This study aims to investigate association of RNRs and denervation potentials observed in electromyographic study (EMG).
Methods: Among 2003 patients who underwent electrodiagnostic study of lower extremities from January 2020 to March 2023, 193 patients were included demonstrating lumbar spinal stenosis on their spinal MRI. Their clinical information and image findings including presence and of RNRs were investigated. In the EMG study, presence of abnormal spontaneous activity (ASA) was collected. Statistical analysis was performed to compare the difference between patients with and without RNRs. Multivariate logistic regression analysis was conducted to find out factors associated with development of ASA.
Results: RNRs were associated with advanced age ($p<0.001$), longer symptom duration ($p=0.009$), narrower CSA ($p<0.001$) and higher frequency of ASA ($p<0.001$). Higher probability of ASA was correlated to the increasing redundancy of nerve ($p<0.001$). Multiple logistic regression analysis showed that occurrence of ASA was associated with narrower CSA, multiple stenotic sites, severe RNR.



Grading of RNR. (a) mild: the angulation at the most tortuous portion of the roots (black arrowhead) is less than 120 degrees but equal to or greater than 90 degrees, (b) moderate: the angulation at the most tortuous portion of the roots (white arrowhead).



Percentage of patients with ASA at extremities as symptom durations.

Independent Variables	B	S.E.	OR [95% CI]	P-value	VIF
Intercept	0.113	1.52	1.12 [0.06-22.04]	0.941	
Age	-0.003	0.02	0.99 [0.96-1.03]	0.878	1.08
Sex					1.02
Female	Reference				
Male	0.442	0.38	1.56 [0.74-3.28]	0.246	
CSA (mm^2)	-0.024	0.01	0.98 [0.96-0.99]	**0.013**	1.11
Multiple stenosis	1.388	0.39	4.01 [1.86-8.62]	**<0.001**	1.08
Severity of RNR					1.05
No RNR	Reference				
Mild	-0.677	0.57	0.51 [0.17-1.57]	0.508	
Moderate	0.771	0.48	2.16 [0.85-5.50]	0.106	
Severe	1.774	0.64	5.90 [1.67-20.8]	**0.006**	

Multivariate logistic regression model for factors potentially associated with presence of abnormal spontaneous activity at extremity muscles.

Conclusion: Presence of RNR, especially severe RNR, is a significant risk factor for development of denervation potentials in electromyographic study. It may help physicians to predict the prognosis of spinal stenosis patients.
Disclosure: None to disclose.

EPO-721 | Neurofilament light chain correlate with small nerve fibre damage parameters in hereditary transthyretin amyloidosis

L. Leonardi
AOU Sant'Andrea, Neurology Department

Background and Aims: Both serum neurofilament light chain (sNfL) levels and small fibre related variables, as skin biopsy and quantitative sensory testing (QST), are valuable disease biomarkers of hereditary transthyretin amyloidosis with polyneuropathy (ATTRv-PN). Our study aimed to explore the relations between sNfL and small fibre related skin biopsy and QST data in a cohort of ATTRv-PN patients and asymptomatic carriers.
Methods: We conducted a retrospective analysis of data from 34 individuals (13 ATTRv symptomatic patients and 21 pre-symptomatic carriers) who underwent sNfL dosage, skin biopsy, and QST, and analyzed correlations between sNFL, IENFD, and thermal cold (CDT) and warm detection thresholds (WDT).
Results: We found that both sNfL and small fibre related skin biopsy and QST parameters significantly differed between carriers and patients (sNfL: $p<0.0001$; IENFD: $p=0.0008$; CDT, WDT: <0.0001). sNFL levels were normal in all carriers and altered in 85% of patients; IENFD was abnormal in 41% of carriers and 77% of patients, CDT and/or WDT were impaired in 19% of carriers and 54% of patients. sNfL negatively correlated with distal IENFD ($r=-0.47$, $p=0.005$) and significantly correlated with small fibre related QST parameters impairment (CDT: $r=-0.68$, $p<0.0001$; WDT: $r=0.57$).
Conclusion: Our study showed that sNfL reliably discriminates symptomatic ATTRv-PN patients from pre-symptomatic carriers, and found significant relations between sNfL, skin biopsy, and QST small fibre related parameters, suggesting that sNfL might be a supportive criterion for symptomatic disease transition.
Disclosure: Nothing to disclose.

EPO-722 | Short-term treatment of CIDP with Efgartigimod: A single center experience in China

J. Lin; C. Sun; C. Zhao
Department of Neurology, Huashan Hospital, Fudan University, Shanghai, China

Background and Aims: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is a type of autoimmune neuropathy that presents treatment challenges due to the limitations of standard-of-care therapies. Efgartigimod, a neonatal Fc receptor antagonist, has shown potential in treating antibody-mediated disorders, but its effectiveness for CIDP treatment has not been established.
Methods: This single-center study in China evaluated the short-term efficacy and safety of Efgartigimod in five CIDP patients. Clinical effectiveness was assessed using the Inflammatory Neuropathy Cause and Treatment (INCAT) disability scale, Inflammatory Rasch-built Overall Disability Scale (IRODS), Medical Research Council (MRC) sum score, grip strength, Neuropathy Impairment Score (NIS), and Time Up and Go Test (TUG). Safety was evaluated by monitoring adverse events and measuring white blood cell count, serum albumin concentration, and plasma IgG concentration.
Results: All five (100%) patients responded to Efgartigimod treatment, with four (80%) meeting predefined effectiveness criteria within 8 weeks. Significant improvements were observed across clinical scales, with varied responses among patients. The average reduction rate in total IgG was 43%. Adverse events were minimal, with one patient experiencing transient diarrhea, and no aggravation of pre-existing conditions was noted.
Conclusion: Efgartigimod demonstrates promising efficacy and safety for short-term treatment of CIDP, offering a potential alternative therapy. This study provides valuable evidence from real-world application of Efgartigimod in CIDP, and the results indicate further research is warranted.
Disclosure: Nothing to disclose.

EPO-723 | Effectiveness and safety of ofatumumab in autoimmune nodopathy: A single-center cohort study

J. Lin; J. Hu; C. Zhao
Department of Neurology, Huashan Hospital, Fudan University, Shanghai, China

Background and Aims: Autoimmune nodopathy is a peripheral neuropathy characterized by acquired motor and sensory deficit with autoantibodies against the node of Ranvier or paranodal region in the peripheral nervous system. Ofatumumab is the first fully human anti-CD20 monoclonal antibody, and may bring benefits to patients with autoimmune nodopathy.
Methods: This prospective observational study included 7 patients with autoimmune nodopathy, receiving subcutaneous ofatumumab 20 mg every 4 weeks (q4w) (from Week 4, after initial doses on Days

1, 7, and 14). The INCAT disability score, I-RODS, grip strength, and TUG were collected at entry and every 4 weeks. Antibodies against NF155 and CNTN1 were tested every 4 weeks, using a cell-based assay at a titer of 1:100.

Results: Six patients with anti-NF155 antibodies and one patient with anti-CNTN1 antibodies were included in the studies. At the last visit, six of the seven patients showed clinical improvement on either the INCAT, centile I-RODS or grip strength. Three of the six patients did not respond well to rituximab. The median time of reaching minimal clinically important difference was 16 weeks. Six of the seven patients improved in the 3m-TUG, and the median time of the first improvement was 4 weeks. The paranodal antibodies in these patients remain positive during the follow up visit.

Conclusion: Ofatumumab 20 mg q4w subcutaneously was effective and safe in a part of patients with autoimmune nodopathy. The association between clinical improvement and anti-paranodal antibodies needs further investigation.

Disclosure: Nothing to disclose.

EPO-724 | Fatigue in chronic inflammatory demyelinating polyradiculoneuropathy

N. Başcı; A. Gündüz; M. Tütüncü; N. Uzun Adatepe
Department of Neurology, Cerrahpasa Medical Faculty, IUC, Istanbul, Turkey

Background and Aims: Fatigue is a common symptom in chronic inflammatory demyelinating polyradiculoneuropathy (CIDP), significantly affecting the patients' quality of life. In this study, we aimed to evaluate the severity of fatigue in CIDP patients and its correlation to other clinical and electrophysiological parameters.

Methods: This is a prospective study. We invited all patients with CIDP diagnosis according to latest criteria and performed Fatigue Severity Scale (FSS), INCAT (Inflammatory Neuropathy Cause and Treatment Disability Scale), I-RODS (Inflammatory Rasch-built Overall Disability Scale), Hamilton Depression Rating Scale (HAM-D), Pittsburgh Sleep Quality Index (PSQI) and Visual Analogue Scale (VAS) for pain, nerve conduction studies. The final score on FSS represents the average of nine items; a score above 4.0 indicates the presence of fatigue. We compared the clinical and electrophysiological findings between patients with and without fatigue.

Results: There were 27 patients with CIDP in study period (mean age: 54 ± 12.6 years; age range 19 and 73 years; %29.6 women). Among patients included, 26% had fatigue. All patients with fatigue had axonal involvement in the follow-up examination. The number of nerves with conduction block or reduced conduction velocity did not differ between groups. INCAT and I-RODS scales did not differ significantly between groups while PSQI, HAM-D and VAS scores were slightly higher in the fatigue group.

Conclusion: Fatigue can be related to various factors independent of disease progression; such as sleep, depression and pain.

Disclosure: Funding: TUSEB 2023-B-01 Group B Project.

EPO-725 | CASPR2 antibodies in CSF in Isaac's syndrome: Altering the central neuropathic pain perception?

R. Theologou[1]; Achilleos[1]; Liampas[1]; P. Neophytou[1]; R. Louka[1]; A. Artemiadis[2]; Tzartos[3]; G. Hadjigeorgiou[2]; P. Zis[2]
[1]Neurology Clinic, Nicosia General Hospital, Nicosia, Cyprus; [2]Medical School, University of Cyprus, Nicosia, Cyprus; [3]Neurology Clinic, Attikon Hospital, National and Kapodistrian University of Athens, Athens, Greece

Background and Aims: Isaacs syndrome (IS) or acquired neuromyotonia is a rare immune-mediated neuromuscular disorder, resulting in increased excitability of the peripheral nerves. Clinically it is characterized by fasciculations, cramps, excessive sweating and often presence of CASPR2 autoantibodies. IS can occur as a paraneoplastic condition, or it can remain idiopathic.

Methods: Case report and review of the literature.

Results: A 65-year-old man with a past medical history of prostate cancer, treated with radiotherapy 4 years ago, was referred to our Department because of a 3-year history of neuropathic pain and painful cramps in the lower limbs. Neurophysiological examination revealed spontaneous duplet, triplet and multiplet potentials in all muscles examined. IS was suspected and confirmed with the presence of positive VGKC, CASPR2 and LGI1 auto-antibodies in the serum and the cerebrospinal fluid, despite the fact there was no CNS involvement clinically. Our literature review identified six more IS cases in which CASPR2 antibodies were checked in the CSF. Out of these, two showed positive CASPR2 antibodies. In one IS remained idiopathic while in the other was associated with recurrence of malignant thymoma. Including ours, all 3 cases reported neuropathic pain.

Conclusion: To our knowledge, this is the first reported case of IS in a patient with a past medical history of prostate cancer and one of a few where CASPR2 antibodies were present in the CSF despite the lack of clinical features of CNS involvement. Presence of CASPR2 antibodies in the CSF in IS patients may be associated with an increased perception of neuropathic pain.

Disclosure: Nothing to disclose.

EPO-726 | Peripheral neural correlates of isolated genital numbness with selective serotonin reuptake inhibitor exposure

S. Wright[1]; P. Malladi[1]; S. Simeoni[1]; J. Panicker[2]
[1]Uro-Neurology, National Hospital for Neurology and Neurosurgery, UCLH NHS Foundation Trust, London, UK; [2]UCL Queen Square Institute of Neurology, Faculty of Brain Sciences, University College London, London, UK

Background and Aims: Isolated genital numbness is an uncommon neurological presentation and very little guidance exists on its assessment and aetiology. Selective serotonin reuptake inhibitors are an effective treatment for depression and anxiety disorders however

in recent years, it has become apparent there are sexual side effects and genital sensory changes have been described. We aim to describe the clinico-neurophysiologic profile in non-neurological individuals with isolated genital numbness and exposure to selective serotonin reuptake inhibitor (SSRI).

Methods: Consecutive referrals with impairment of genital sensation to a tertiary referral centre from 2018 to 2023. Urogenital clinical symptoms, contributing factors and past medical history were recorded. Pelvic sensory examination (pinprick and von frey hair) was performed at the time of sacral sensory neurophysiology testing.

Results: 12 Individuals were identified with genital numbness and current or previous exposure to SSRI (female, 33.3%). The median age was 37 years. Nine individuals reported an abnormal clinical pelvic sensory examination and had normal pelvic neurophysiology. Two individuals with SSRI exposure had abnormal pelvic neurophysiology. SSRI exposure was not a significant predictor for genital numbness. Seven reported sexual dysfunction.

Conclusion: Recent diagnostic criteria for post-SSRI sexual dysfunction is defined as somatic or erogenous genital sensation after treatment stops. We found 83% of individuals with genital numbness and exposure to SSRI had a normal pelvic neurophysiology examination. The concept of erogenous sensation is relevant and we postulate that the aetiology of SSRI associated genital numbness with normal neurophysiology is due to central sensory and emotional processing dysfunction.

EPO-727 | Unmet need in patients with chronic inflammatory demyelinating polyneuropathy: Results from a Real-World Survey

S. Rinaldi[1]; A. Borsi[2]; C. Gary[2]; W. Noel[2]; W. Karmous[2]; J. DeCourcy[3]; J. Wright[3]; Y. Taylor[3]; H. Iqbal[3]; L. Querol[4]
[1]*Nuffield Department of Clinical Neurosciences, University of Oxford;* [2]*Johnson & Johnson Innovative Medicine EMEA;* [3]*Adelphi Real World, Bollington, UK;* [4]*Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*

Background and Aims: Chronic inflammatory demyelinating polyneuropathy (CIDP) is a disabling neurological condition characterised by progressive muscle weakness and impaired sensory function. The aim of this study was to identify unmet needs among patients with CIDP.

Methods: Data were drawn from the Adelphi CIDP Disease Specific Programme™, a cross-sectional survey of neurologists in France, Germany, Italy, Spain, UK (September 2022 – April 2023), treating at least two CIDP patients per typical month. Patients completed patient-reported outcome assessments, including the Inflammatory Rasch-Built Overall Disability Scale (I-RODS) and Work Productivity and Activity Impairment questionnaire (WPAI:SHP). This real-world data is limited by participating physicians' confirmation of the included patient's CIDP diagnosis.

Results: 83 physicians provided data for 542 patients with CIDP, of whom 463 were receiving maintenance treatment (1st line: 293; 2nd: 140; 3rd: 26; 4th/5th: 4 [excluded from analyses]). Physicians reported dissatisfaction, or partial satisfaction with treatment for 57.9% of patients (1st: 57.7%; 2nd: 52.1%; 3rd: 92.3%). Across all lines, the most frequent reason for lack of satisfaction was "efficacy declining over time". Patients reported a mean (SD) I-RODS centile score of 59.8 (18.5) (1st: 61.8 [19.4]; 2nd: 56.6 [16.4]; 3rd: 57.4 [21.4]), and a mean WPAI percentage activity impairment of 43.0 (25.2) (1st: 40.1 [24.4]; 2nd: 47.3 [25.5]; 3rd: 50.0 [32.2]).

Conclusion: Patients with CIDP reported substantial disability and impairment in daily activities, and in many cases their physicians were not fully satisfied with treatment. Identifying factors associated with poor initial treatment response and loss-of-efficacy, and new therapeutic developments, may lead to improved outcomes for these patients.

Disclosure: Data collection was undertaken by Adelphi Real World as part of an independent survey, entitled the Adelphi Real World CIDP Disease Specific Programme. Janssen were one of multiple subscribers to the dataset. The study described here was funded by Janssen.

EPO-728 | Nodal-/paranodal autoantibody-associated autoimmune nodopathies in Estonian population

T. Unt; K. Kannel; S. Ütt; U. Thomson; A. Reitsnik; M. Maiorova; K. Gross-Paju
West-Tallinn Central Hospital, Neurology and Psychiatry Clinic

Background and Aims: Autoantibodies to peripheral nerve molecules seem to play role in the pathogenesis and also provide diagnostic, prognostic, and therapeutic value for autoimmune peripheral neuropathies, such as CIDP. Corticosteroids, intravenous immunoglobulin (IVIg) and plasma exchange are mainstays of treatment, yet some patients respond poorly to standard treatments. Disease-specific antibodies targeting proteins at the node and paranode of Ranvier, such as neurofascin-155 (NF155), contactin-1 (CNTN1), contactin-associated protein 1 (Caspr1), neurofascin-140/186 (NF140/186), have been described in small subsets of CIDP patients with similar clinical features, treatment response, namely poor response to IVig and more favourable to rituximab, and hence differing from typical CIDP.

Methods: This study presents an overview of autoimmune nodopathies in Estonian population based on cohort of polyneuropathy patients in West-Tallinn Central Hospital's Neurology department tested over a period form October 2022 to October 2023.

Results: 11 out of 112 patients tested positive for nodal-/paranodal autoantibodies: 7 for contactin1, 3 for NF155 IgG, 1 for NF155 IgM, 3 for NF155 IgG and IgM, 1 for contactin1 and NF155 IgG antibodies. Most frequent clinical picture among nodopathy patients was severe flaccid tetra- or paraparesis with sensory disturbances. Other clinical pictures included cerebellar findings, gait problems, but also central symptoms not reported in scientific literature as part of nodopathy syndrome.
Conclusion: Testing for nodal/paranodal antibodies can help improve diagnostic accuracy and guide treatment for polyneuropathy patients, especially those suspected of having inflammatory demyelinating polyneuropathy. Considering the varied clinical picture in our cohort, there also remains the question whether all positive results are of clinical significance.
Disclosure: Nothing to disclose.

EPO-729 | Characteristics and outcome of CIDP patients according to their electrodiagnostic certainty (2021 EAN/PNS criteria)

V. Loser; A. Vicino; K. Staedler; T. Kuntzer; M. Theaudin
Nerve-Muscle Unit, Neurology Service, Department of Clinical Neurosciences, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland

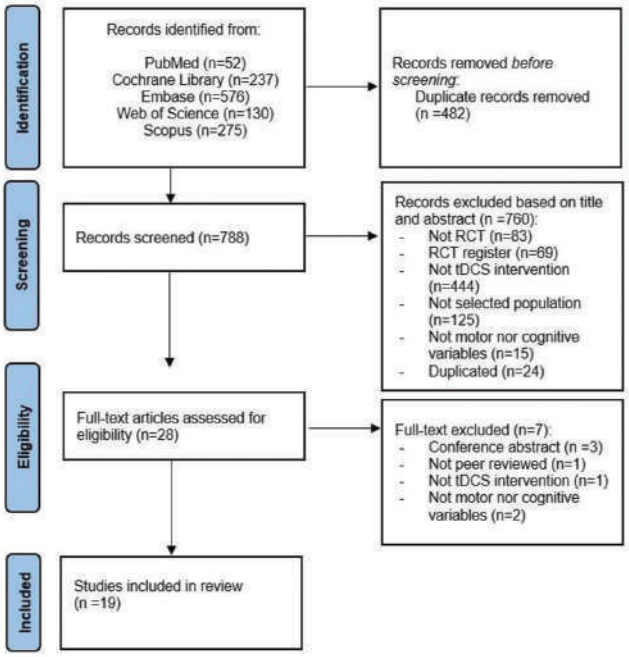
Background and Aims: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) has heterogeneous presentation and clinical course. The aims of this study are to describe the clinical and electrophysiological characteristics of patients with CIDP or possible CIDP, according to the latest 2021 EAN/PNS criteria, and to compare the long-term outcome in both groups.
Methods: We retrospectively included 29 adult "CIDP" and 21 "possible CIDP" patients. We reviewed their clinical data, which included the neuropathy impairment scale (NIS) and modified Rankin Scale (mRS), response to treatment, cerebrospinal fluid examination, and nerve conduction studies parameters. Data were collected at first evaluation of the patient (T0), and at one (T1), two (T2) and three years (T3).
Results: At baseline, CIDP patients had a higher NIS score (median NIS score of 38 versus 20.5, $p=0.03$), and more frequently a "typical CIDP" phenotype ($p=0.02$) than possible CIDP patients. Other variables did not differ significantly. CIDP patients tended to have a better objective response to immunotherapy (66% responders) than possible CIDP patients (43% responders, $p=0.15$). Between baseline and T3, there was a median (IQR) Δ NIS of −12.8 (−32, 0) and Δ mRS of −1 (−2, 0) for CIDP patients and 2.5 (−7.8, 8.5) and 0 (−0.8, 0) for possible CIDP patients ($p=0.01$ and <0.01 respectively).
Conclusion: "CIDP" patients had a more severe neuropathy, estimated with the NIS score, and "possible CIDP" patients had a more atypical phenotype at baseline. Our data suggest that patient outcome is better in CIDP than possible CIDP.
Disclosure: Nothing to disclose.

Neurorehabilitation

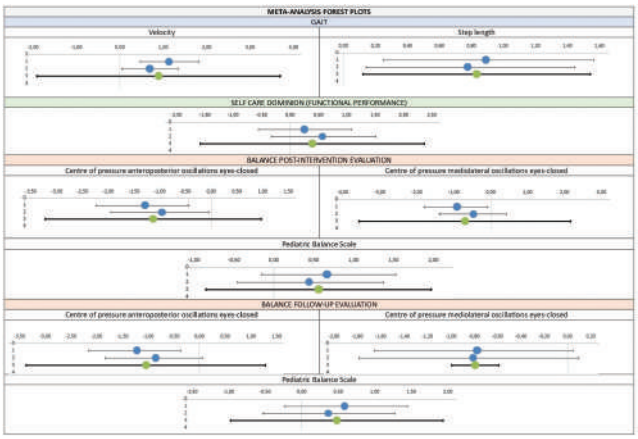
EPO-730 | TDCS effects on motor and cognitive function in paediatric brain injury: Systematic review and meta-analysis

A. Cerezo-Zarzuelo[1]; M. Rios-Lago[2]; F. Sanchez-Cuesta[3]; B. Gavilan-Agusti[4]; A. Hurtado-Martinez[3]; J. Romero-Muñoz[3]
[1]Psychology PhD Program, Universidad Nacional de Educación a Distancia (UNED), Madrid, Spain; [2]Department of Basic Psychology II, School of Psychology, Universidad Nacional de Educación a Distancia (UNED), Madrid, Spain; [3]Brain injury and Movement Disorders Neurorehabilitation Group (GINDAT), Institute of Life Sciences, Francisco de Vitoria University, Pozuelo de Alarcón, Spain; [4]Brain Damage Unit, Beata Maria Ana Hospital, Madrid, Spain

Background and Aims: Paediatric non-progressive brain injuries result in diverse impairments, including motor and cognitive issues. Transcranial direct current stimulation (tDCS), emerges as a technique to influence neuroplasticity processes as an adjunct therapy in rehabilitation. This review aims to assess tDCS effects on motor and cognitive variables in non-progressive paediatric brain injuries, correlation with intervention parameters and associations between functions.
Methods: A systematic review and meta-analysis were conducted, assessing randomized controlled trials in patients with paediatric brain damage and cognitive or motor variables with tDCS interventions. 5 databases were searched. PEDro scale, ROB-2 and GRADE assessed methodological and evidence quality.
Results: Data from 19 studies (447 participants) (fig.1) revealed positive effects on gait, balance, functional performance, and cognition. Upper limb function evidence remains inconsistent due to limited publications. Cognitive intervention influenced motor outcomes, and motor-centered interventions impacted functionality related to cognition. Meta-analysis showed statistically significant improvements in gait (SMDs: 0.83–0.90, $p<0.0001$), balance (Centre of pressure oscillations SMDs: −0.51 to −1.13, $p<0.02$; PBS SMDs: 0.48 to 0.56, $p<0.0001$) and self-care (SMD: 0.40, $p<0.01$) (Table 1). Mean PEDro scale score was 7.46. According to ROB-2, two studies presented low risk of bias, 12 studies had some concerns and 5 presented high risk. Quality of evidence is small for gait and self-care, and medium for balance.



PRISMA flow diagram.



Meta-analysis forest plots.

Conclusion: TDCS seems beneficial for cognitive and motor variables in paediatric brain damage. Both variables seem to be interconnected, so further research with homogeneous samples, standardized and combined protocols is needed.

Disclosure: Authors had no conflicts of interest. Funding by GMP foundation.

EPO-731 | Aerobic capacity moderates the association between cervical cord atrophy and disability in MS patients

M. Albergoni[1]; C. Dallari[1]; P. Preziosa[2]; A. Meani[1]; P. Valsasina[1]; M. Filippi[3]; M. Rocca[2]

[1]Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy; [2]Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy; [3]Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, and Vita-Salute San Raffaele University, Milan, Italy

Background and Aims: Cervical cord atrophy has been associated with disability in multiple sclerosis (MS). Higher aerobic capacity (AC) has shown positive effects on several symptoms related to MS, which may also influence disability level. This study aimed to understand whether AC moderates the association between cervical cord atrophy and disability in MS.

Methods: In this cross-sectional analysis, expanded disability status scale (EDSS), peak of maximal oxygen consumption (VO_2max) and mean upper cervical cord area (MUCCA) calculated from 3D T1-weighted brain MRI images were obtained for 60 MS patients and 36 healthy controls (HC). The HC group was used to define VO_2max *z*-scores and −1 standard deviation was considered as cut-off to identify patients with low or high AC. In MS patients, an age- and sex-corrected analysis was conducted to understand if AC can moderate the association between MUCCA and EDSS.

Results: Compared to HC, MS patients showed lower MUCCA and VO_2max values ($p<0.001$). The interaction between MUCCA and AC was significant ($\beta=-0.142$, $p=0.002$), indicating that the relationship between MUCCA and EDSS was moderated by AC. Lower MUCCA was associated with higher EDSS score only in patients with low AC ($\beta=-0.115$, $p<0.001$), no association was found in patients with high AC ($\beta=0.027$, $p=0.486$).

Conclusion: This study shows that AC is a moderator of the relationship between MUCCA and EDSS, suggesting that high level of AC may represent a functional reserve able to prevent or limit clinical disability in MS patients. Funding. Partially supported by Italian Ministry of Health (GR-2019-12369599).

Disclosure: M Albergoni, C Dallari, A Meani, and P Valsasina have nothing to disclose; P Preziosa received speaker honoraria from Roche, Biogen, Novartis, Merck Serono, Bristol Myers Squibb, Genzyme, Horizon and Sanofi, and research support from Italian Ministry of Health and Fondazione Italiana Sclerosi Multipla (FISM). EPO-732 | A combined neuromodulation protocol to enhance cognitive and lower limb rehabilitation in corticobasal degeneration

A. Hurtado-Martínez[1]; Y. González-Zamorano[2]; A. Martínez-Benito[1]; M. Moreno-Verdú[3]; D. De Noreña[4]; F. Sánchez-Cuesta[1]; J. Romero[1]

[1]*Brain Injury and Movement Disorders Neurorehabilitation Group (GINDAT), Francisco de Vitoria University, Pozuelo de Alarcón, Spain;* [2]*Cognitive Neuroscience, Pain, and Rehabilitation Research Group (NECODOR), Faculty of Health Sciences, Rey Juan Carlos University, Madrid, Spain;* [3]*Brain, Action and Skill Laboratory (BAS-Lab), Institute of Neuroscience (Cognition and Systems Division), UC Louvain, Woluwe-Sain-Laimbert, Belgium;* [4]*Brain Damage Unit, Beata María Ana Hospital, Madrid, Spain*

Background and Aims: Corticobasal Degeneration (CBD) is characterized by asymmetrical motor alterations and neuropsychological impairments. No effective therapy is known. Non-invasive neuromodulation can modulate cortical activity in other diseases, improving motor performance (1). Motor imagery and action observation are known to improve motor control and gait in several neurological disorders (2). We describe the outcome of a personalized neuromodulation protocol on a 71-year-old female, diagnosed with CBD. A PET-CT revealed right frontal hypoactivity. Although lower limb strength is normal, alien leg and apraxia rendered her wheelchair-bound. The objective was to assess the effectiveness of a non-invasive neuromodulation protocol—tDCS, Action Observation (AO), and Motor Imagery (MI)—for enhancing motor and cognitive performance.

Methods: 20 sessions of 20-minute 2 mA anodal tDCS stimulation over right M1, combined with 30-minute AO+MI (fig 1). Treatment was administered daily for 4 weeks. Training involved different movements each weekday (fig 2), with a gradual shift from AO to a more active approach as weeks progressed.

Results: Post-treatment improvements were observed in balance (16 to 23), functional strength (5TSTS 83 to 53), and partially sustained postural control enhancements (5TSTS 83 to 67 in follow-up). Persistent gains in set-shifting, inhibitory control (TMT-B), working memory (Inverse Digits), and attentional span (Direct Digits) were noted. Post-treatment improvements in emotional well-being and general health (SF-36) weren't sustained. FES-I scores remained stable post-treatment but rose during follow-up.

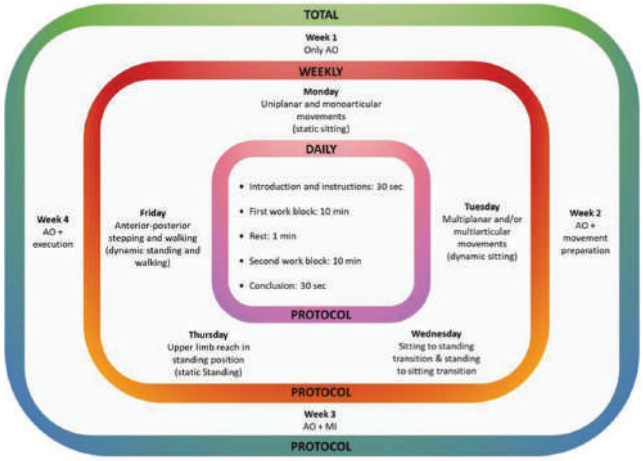

FIGURE 1 The four-week intervention protocol based on graded progression. AO: Action Observation; MI: Motor Imagery; tDCS: Transcranial Direct Current Stimulation.

Conclusion: The combined tDCS+AO+MI protocol maintained or improved balance, motor control, attentional, mnesic, and executive functions in a CBD patient, highlighting the potential of this technology in CBD rehabilitation and treatment.
Disclosure: Nothing to disclose.

EPO-733 | Motivation and recovery: An analysis of reward sensitivity and motor learning after ischemic stroke

A. Oppermann[1]; J. Maas[1]; J. Rogenz[1]; L. Opitz[1]; H. Am Ende[2]; H. Köhler[3]; A. Schmidt[3]; S. Brodoehl[4]; C. Klingner[4]; F. Wagner[4]
[1]*IZKF Graduate Program Experimental Medicine, Jena University Hospital, Germany;* [2]*Else Kröner Graduate School for Medical Students "JSAM", Jena University Hospital, Jena;* [3]*Biomagnetic Center, Jena University Hospital, Jena;* [4]*Department of Neurology, Jena University Hospital, Jena*

Background and Aims: Stroke is a major global cause of disability, posing challenges in neurological rehabilitation. Cerebral network reorganization and learning limitations are critical in this process. Despite the recognized importance of behavioral rehabilitation, the specific role of the brain's reward system in post-stroke learning remains unclear. Hypothesis: Building on our prior findings (Wagner et al., 2023), we posit an intrinsic link between the reward system's functionality and motor learning abilities after a stroke. We propose parallel recovery processes for both, with a gap in understanding their timelines.
Methods: A cohort study of 20 stroke patients (mean age: 67, range: 55–80 years) evaluated at t 3–4 months post-stroke. Motor learning and reward system functionality were assessed using the Monetary Incentive Delay (MID) task during MEG for connectivity analysis. A (VR) learning environment was used for five days to control fluctuations and to study motor learning consolidation.
Results: Patients displayed reduced reward sensitivity, needing greater incentives for improvement, and experienced learning deficits. These deficits correlated with altered connectivity patterns during the MID task, revealing stroke's impact on the reward system and behavior. Learning impairment closely linked to reward sensitivity, irrespective of lesion localization (Coherence Analyses ongoing).
Conclusion: By demonstrating the connection between stroke, reward sensitivity, and learning ability, this research contributes valuable knowledge to the field, suggesting why some stroke survivors continue to experience long-term challenges despite rehabilitation. The findings underscore the necessity of assessing reward sensitivity in stroke patients to optimize rehabilitation protocols, thereby maximizing their recovery potential.
Disclosure: Nothing to disclose.

EPO-734 | The role of sleep in motor memory consolidation in subacute stroke patients: A pilot study

A. Antonioni[1]; N. Cellini[2]; A. Ugolini[1]; A. Baroni[1]; G. Fregna[1]; N. Lamberti[1]; F. Manfredini[1]; P. Malerba[3]; S. Straudi[1]
[1]*Department of Neuroscience and Rehabilitation, University of Ferrara, Ferrara, Italy;* [2]*Department of General Psychology, University of Padua, Padua, Italy.;* [3]*School of Medicine, The OhioState University, Columbus, Ohio*

Background and Aims: Since sleep improves motor learning and stroke patients are frequently characterised by sleep disorders, it is essential to evaluate its contribution in memory consolidation in this context. While evidence already exists in chronic stroke, data are still scarce on the subacute phase during neurorehabilitation treatment. In order to characterise the role of sleep in subacute stroke, we evaluated: i) whether sleep promotes the consolidation of declarative and non-declarative memory; ii) possible correlations between sleep and motor and cognitive performance.
Methods: Eight subacute stroke patients, on different days, underwent two experimental conditions each including two sessions of the Memory Similarity Task (MST) and two sessions of the Finger-tapping Task (FTT). The two conditions, in randomised order, involved: (I) Day trial: patients were tested first at 8 am and, thereafter, at 8 pm, avoiding sleep during the day; II) Night trial: test times were reversed with a night's sleep between them. Moreover, sleep and biometric data were collected by means of a ©Fitbit device.

Results: Accuracy and recognition memory at MST showed a significant effect of session ($p < 0.001$). Furthermore, patients' recognition memory improved in the sleep condition rather than in wakefulness ($p = 0.041$). Similarly, FTT accuracy had a significant effect of session ($p < 0.001$). Moreover, an improvement in sleep-related accuracy was observed ($p = 0.025$). The session-by-condition effect was not statistically significant in both tasks.

Conclusion: Sleep seems crucial in the consolidation of procedural memory also in the subacute stroke timeframe. Thus, sleep quality interventions are fundamental in promoting recovery from the earliest stroke stages.

Disclosure: The authors declare no conflicts of interest. This work was supported by the project MNESYS (PE0000006) – A Multiscale integrated approach to the study of the nervous system in health and disease (DN. 1553 11.10.2022).

EPO-735 | Gait rehabilitation of patients after stroke using the C-Mill treadmill

P. Konecny[1]; G. Krejstova[2]; K. Konečná[3]
[1]*Clinical Rehabilitation Department of the Faculty of Physical Therapy and the Neurological Clinic of the Faculty of Medicine, Olomouc, Czechia;* [2]*Centre for Medical Rehabilitation of the Hospital and Neurological Department of AGEL Prostějov, Czechia;* [3]*Ordinace FBLR, Czechia*

Background and Aims: Patients after stroke often have gait disturbances with asymmetry, slowing, discoordination of gait and increased risk of falling. Gait rehabilitation on the C-Mill walking/treadmill is one way to improve gait parameters. Aim of the study: to test whether using the C-Mill treadmill will improve walking parameters such as walking speed and gait quality.

Methods: 20 probands in subacute to chronic stage after stroke participated in the study. All patients had gait impairment but with the condition of walking without support. Patients were randomly divided into a control group (standard rehabilitation + 1 hour of C-Mill walking per week) and an experimental group (standard rehabilitation + 5 hours of C-Mill walking per week). Before starting therapy, medical history and clinical tests were taken and questionnaires were filled in for all patients. After a 3-week hospitalization with intensive rehabilitation and C-mill walking training, an exit examination was performed. Gait speed, subjective perception of gait quality, and self-sufficiency were assessed.

Results: At baseline examination, patients in the experimental group showed clinically and statistically significant ($p < 0.05$) improvement compared to the control group. This was evident in all measured domains, i.e.: gait speed, subjective perception of gait quality and self-sufficient.

Conclusion: the combination of complex rehabilitation (physiotherapy, mechanotherapy, physical therapy and gait training on the C-Mill treadmill positively affects gait in patients in the subacute and chronic stage after stroke.

Disclosure: We have no conflicts of interest.

EPO-736 | Outcome measures to assess the efficacy of physical therapy in postural orthostatic tachycardia: A systematic review

H. Halbedl[1]; N. Campese[1]; B. Calió[1]; G. Schönherr[1]; R. Granata[1]; J. Mitterhuber[1]; G. Göbel[2]; G. Wenning[1]; A. Fanciulli[1]
[1]*Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria;* [2]*Department of Medical Statistics, Informatics and Health Economics, Medical University of Innsbruck, Innsbruck, Austria*

Background and Aims: Physical therapy is recommended as first-line treatment for individuals with POTS by expert consensus. There is a need to identify the evidence base of this treatment approach. Here we evaluated how primary (p) and secondary (s) outcome has been measured to date.

Methods: We systematically screened the databases PubMED, Cochrane and Web of Science combining the keywords: "Postural orthostatic tachycardia", "physical therapy", "exercise".

Results: We selected 17 studies and two study protocols. Change after exercising was measured by active standing test (primary np = 3, secondary ns = 10) or head-up tilt test (np = 5, ns = 3), cardiopulmonary exercise tests (np = 3, ns = 8), pulse-oximetry (np = 0, ns = 1), walking test (np = 0, ns = 1) or questionnaires (np = 1, ns = 13). Mean or highest heart rate response to exercise measured at different timepoints was a common outcome (np = 6, ns = 12). Further primary outcome measures were: time spend upright and steps per day ($n = 1$), number of individuals who fulfilled the POTS-criteria ($n = 2$) or peak oxygen uptake (VO_2max, VO_2peak) ($n = 3$). Symptom severity improvement as secondary outcome was assessed with the Short Form Health Survey in three studies, Composite Autonomic Symptom Score −31 items ($n = 2$), Vanderbilt Orthostatic Symptom Score ($n = 3$), Malmö-POTS-questionnaire and Boston Autonomic Symptom Questionnaire (one study each). Health related quality of life was assessed with the EQ-5D-5L in two studies and with the SF-36 in one.

Conclusion: Recent studies and ongoing trials adopt detailed outcome assessments, taking into account POTS clinical heterogeneity and focusing on meaningful changes of functional ability.

Disclosure: Nothing to disclose.

EPO-737 | Abstract withdrawn

EPO-738 | Role of supination, extension and abduction posture in upper limb spasticity prevention in acute stroke

V. Singh; A. Pathak; A. Kumar
Department of Neurology, Institute of Medical Science, Banaras Hindu University, Varanasi, India

Background and Aims: Post-stroke spasticity is a common complication of stroke. The study evaluated the efficacy of a posture opposite to the typical spastic posture i.e. Supinated forearm, Extended

fingers and elbow and Abducted and externally rotated shoulder (SEA) with wrist in neutral position (Figure 1) in acute stroke patients with flaccid weakness in prevention of development of spasticity.

Methods: Hemodynamically stable acute stroke patients between 18–80 years of age with flaccid upper limb weakness presenting within 72 hours were included. It was a prospective, single-center, randomized, open-label trial with blinded endpoint assessment.

Results: Of 170 acute stroke patients, 76 met the inclusion criteria. 38 patients randomized in each splint (Group 1) and control arm (Group 2). Ten patients lost to follow up. Of remaining 66 patients (34 in splint and 32 in control), the median age of patients was 55 years. Forty-two (64%) patients were male. There was no significant difference in baseline demographic, clinical, radiological, and biochemical parameters between the two groups (Table 1). At 3 and 6 months, there was significant difference (p value < 0.05) in Modified Ashworth upper limb spasticity score at elbow, forearm (pronation and supination), wrist and fingers between the two groups. Barthel Index for Activities of Daily Living was also significantly better in group 1 at 3 and 6 months (Table 2). However, there was no difference in mRS score during follow up.

Figure depicting the application of a splint keeping the flaccid upper limb of a patient in a SEA posture i.e. Supinated forearm, Extended fingers and elbow and Abducted and externally rotated shoulder (SEA) with wrist in neutral position.

Comparison of outcome measures between the two groups at 3 and 6 months.

Conclusion: SEA posture if applied early in acute stroke patients is effective in reducing the grade of upper limb spasticity.

Disclosure: Nothing to disclose.

EPO-739 | Creating interactive virtual reality applications for social deficit remediation in children with neurological disorders

M. Saard[1]; A. Roštšinskaja[1]; C. Kööp[1]; L. Uutsalu[2]; A. Kolk[2]
[1]*Faculty of Medicine, University of Tartu, Tartu, Estonia;* [2]*Department of Pediatrics and Neurology, Tartu University Hospital Children's Clinic, Tartu, Estonia*

Background and Aims: The aim was to evaluate the suitability of SocialVR applications developed for pediatric neurorehabilitation with assessing anxiety levels during difficult social situations.
Methods: 33 children aged 6–15 yrs participated: 17 with neurological disorders (ND) and 16 healthy controls. Therapist observed scenarios on screen, selecting the avatar's according to child's skills. Headsets Oculus Rift or HTC Vive were used. 10 difficult social VR metaphors with 2 levels of complexity were created by authors (cafeteria, cinema, bullying, etc.). Social anxiety was assessed by heart rate (HR) changes in all children and with Spence Anxiety Questionnaire (SCAS) in 14 children.
Results: Applications of varying severity were suitable and indicated for developing social neurorehabilitation. Most challenging situations were "friend losing a phone" (average HR rise 9.1) and "ball in neighbor's garden" (HR rise 9). Therefore, metaphors requiring patients to console or apologize showed higher anxiety compared to the control group (HR 7.9 and 8.3, respectively). Examination of social attention showed lower abilities in finding details. By SCAS 8/9 ND patients reported elevated anxiety base levels in at least one domain; only 2 out of 5 controls reported some anxiety symptoms.

FIGURE 1 Child with ND participating in a cafeteria metaphor during a social rehabilitation session.

Conclusion: Artificial VR environments allow children to practice communication skills in socially and emotionally challenging but safe situations. SocialVR is a new promising pediatric neurorehabilitation tool to support prosocial learning and reduce social anxiety in children.

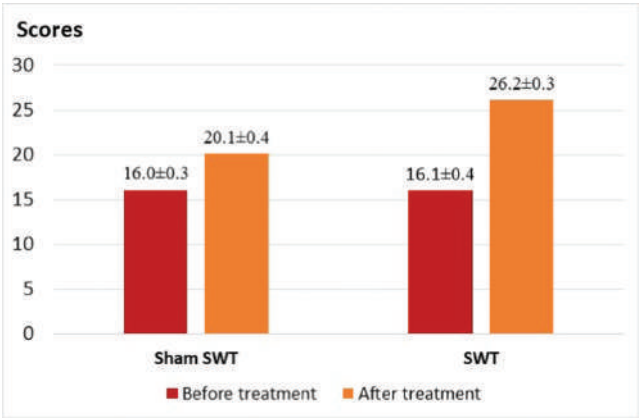
EPO-740 | Effectiveness of shock wave therapy in the treatment of patients with neurological post-COVID-19 erectile dysfunction

M. Al-Zamil[1]; D. Zalozhnev[2]
[1]*Department of Physiotherapy of Peoples' Friendship University of Russian Federation;* [2]*Department of Restorative Medicine and Neurorehabilitation, Medical Dental Institute, Moscow, Russian Federation*

Background and Aims: To study the effectiveness of shock wave therapy (SWT) in treatment of patients with neurological post COVID-19 erectile dysfunction compared to sham SWT.
Methods: We observed 40 patients with neurological erectile dysfunction after suffering from COVID-19. The patients were divided into 2 groups. In addition to standard drug therapy 20 patients underwent sham SWT (control group) and 20 patients received effective SWT (treatment group). Impairment of the pudendal nerve has been confirmed by clinical and neurophysiological examinations.
Results: The International Index of Erectile Function (IIEF) scores after SWT were 1.54 times higher than after sham SWT ($p < 0.01$). Sexual quality of life (QoL) became 1.52 times better after SWT compared to sham SWT ($p < 0.01$). In addition, SWT increased the effectiveness of PDE-5 inhibitor drugs in improving erectile function by 2.54 times ($p < 0.01$).



Dynamics of the international index of erectile function in the treatment of patients with erectile dysfunction after COVID-19 in the control and treatment groups.

Conclusion: SWT therapy has proven effective in improving erections in patients with neurological post COVID-19 erectile dysfunction. The high effectiveness of SWT is due to the activation of regenerative processes in tissues, improved blood circulation, increased excitability of nerve fibers, stimulation of neovascularization and normalization of NO levels in cavernous endothelial cells.
Disclosure: Nothing to disclose.

EPO-741 | Efficiency of low level laser therapy in improvement of fine movement skills after carpal tunnel decompression

M. Al-Zamil[1]; R. Kuliev[2]
[1]*Department of Physiotherapy of Peoples' Friendship University of Russia, Moscow, Russian Federation;* [2]*Department of Restorative Medicine and Neurorehabilitation, Medical Dental Institute, Moscow, Russian Federation*

Background and Aims: To compare the effectiveness of low level laser therapy of median nerve in improvement of fine movement skills after carpal tunnel decompression surgery.
Methods: We observed 50 patients with residual fine movement skills impairment after Carpal Tunnel Decompression Surgery. 25 patients underwent sham laser therapy (control group) and 25 patients received low level laser therapy (treatment group). Fine movement skills were assessed in all patients using the Jebsen-Taylor test before treatment, after treatment and after 3-months of follow-up period.
Results: After treatment: a significant improvement in Jebsen-Taylor's test scores was found in treatment group after low level laser therapy, but not in control group. The total test execution time in treatment group decreased by 12% ($t=2.14$, p-value$=0.036$). After 3 months of follow-up period additional positive therapeutic response was found in reduction of the test duration in all subtests by 10.6% ($t=4.91$, p-value$=0.01$).
Conclusion: Low-level laser therapy for the median nerve has been shown to be very effective in improving residual fine motor skills after carpal tunnel decompression surgery. This is due to decreased fiber axonopathy and effective reinnervation, which improve coordinated sensorimotor control of the fingers.
Disclosure: Nothing to disclose.

EPO-742 | Efficacy and safety of modafinil/armodafinil for post-traumatic hypersomnia: A systematic review and meta-analysis

R. João[1]; N. Pacheco[2]; M. Hidalgo[3]; Z. Bakir[4]; Y. Soares[5]; M. Oliveira[6]; J. Dantas[7]
[1]*Neurology Department – Doutor José de Carvalho Florence Hospital, São José dos Campos, Brazil;* [2]*Neurology Department – Harvard Medical School, Boston, USA;* [3]*Internal Medicine Department – Santa Marcelina Medical School, São Paulo, Brazil;* [4]*Internal Medicine Department – Sapienza University of Rome, Rome, Italy;* [5]*Internal Medicine Department – Federal University of Paraíba, João Pessoa, Brazil;* [6]*Internal Medicine Department – Federal University of Curitiba, Curitiba, Brazil;* [7]*Internal Medicine Department – Federal University of Rio Grande do Norte, Natal, Brazil*

Background and Aims: Traumatic Brain Injury (TBI) is a global health issue frequently related to chronic debilitating symptoms such as excessive daytime sleepiness (EDS). While the optimal management of EDS is still unclear, neurostimulants are often empirically employed. Thus, we aimed to perform a systematic review and meta-analysis to assess the efficacy and safety of modafinil/armodafinil versus placebo on post-TBI patients experiencing EDS.
Methods: We searched PubMed, Cochrane, Embase, Web of Science, and ClinicalTrials.Gov databases and identified studies comparing modafinil or armodafinil to placebo in post-TBI patients experiencing EDS. A random-effects model was used in all analyses.
Results: We included three randomized controlled trials involving 188 patients. The mean age was 34.11, and 61.9% were male. In patients treated with modafinil (dose range: 100–400 mg) or armodafinil (dose range: 150–250 mg), the mean Epworth Sleepiness Scale score was decreased in comparison to placebo (mean difference −1.70; 95% confidence interval [CI] −3.32 to −0.09; $p=0.04$; Fig. 1). The risk of insomnia was higher in the modafinil/armodafinil group compared to placebo (risk ratio 3.73; 95% CI 1.11 to 12.54; $p=0.03$). There was no difference between groups in the risk of other adverse events, such as nausea ($p=0.09$), headache ($p=0.56$), dizziness ($p=0.25$), and nasopharyngitis ($p=0.67$).

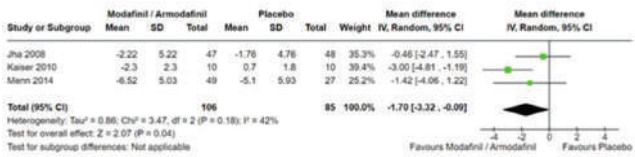


FIGURE 1 In patients with post-traumatic hypersomnia, somnolence, as measured by the Epworth Sleepiness Scale, was significantly reduced in the modafinil/armodafinil when compared to placebo.

Conclusion: Treatment with modafinil or armodafinil was associated with a significant reduction in somnolence in post-TBI patients when compared to placebo. However, this therapy also increased the risk of insomnia. Further research is warranted to optimize the risk-benefit profile of these agents in this population.
Disclosure: Nothing to disclose.

EPO-743 | EEG evaluation of the influence of rTMS in the rehabilitation of patients with ischemic stroke

S. Bozhinov[1]; P. Bozhinov[2]; P. Lambeva[3]
[1]*Heart and Brain Center of Clinical Excellence, Pleven, Bulgaria;* [2]*Medical University of Pleven;* [3]*Medical Center Galileo, Pleven, Bulgaria*

Background and Aims: Objective: To study the influence of rTMS on the state of the brain's bioelectric activity in patients with ischemic stroke in order to determine the prognostic parameters for better motor recovery and to develop an optimal therapeutic protocol.
Methods: For the period between January 2015 and September 2022, a total of 136 patients with ischemic stroke were included in the study. Patients were divided into three groups: In the first, 17 patients (12.5%) received 10 consecutive sessions of rTMS with LF stimulation in the unaffected hemisphere, in the second – 18 (13.2%) HF stimulation in the affected hemisphere, and in the third – 101 (74.3%) combined rTMS protocol in both hemispheres. EEG was performed in all patients before the start of the course and after the last session.
Results: The main trend of influence of rTMS on the brain activity is associated with a clear increase in the share of alpha rhythm, especially

pronounced in the combined stimulation group. A correlation was observed between the increase in alpha activity in the affected hemisphere, recorded on EEG, and the motor performance of the patient, demonstrated by the decrease in the motor threshold over the course of treatment.

Conclusion: rTMS appears to be a promising therapeutic method to improve functional recovery in patients with ischemic stroke. The routine use of EEG is an invaluable technique for monitoring and optimizing the individual effect of each patient during the course of treatment.

Disclosure: Nothing to disclose.

EPO-744 | Longitudinal goal attainment following treatment with abobotulinumtoxinA in adults with lower limb spasticity

V. Inestam[1]; J. Jacinto[2]; R. Zorowitz[3]; S. Ashford[4]; A. Grandoulier[5]; P. Maisonobe[5]; C. Hannes[6]; A. Esquenazi[7]

[1]Ipsen, Kista Sweden; [2]Centro de Medicina de Reabilitaçãode Alcoitão, Serviço de Reabilitação de adultos 3, Estoril, Portugal; [3]MedStar Health, Washington and Georgetown University School of Medicine, DC, USA; [4]London North West University Healthcare NHS Trust, Regional Hyper-acute Rehabilitation Unit, Northwick Park Hospital, London, UK; [5]Ipsen, Boulogne-Billancourt, France; [6]Ipsen, Munich, Germany; [7]MossRehab Jefferson Health, Elkins Park, PA, USA

Background and Aims: This prospective, observational study (NCT04050527) assessed the longitudinal attainment (over 16 months) of function-related goals after one or more abobotulinumtoxinA injections for lower limb spasticity in the clinical setting.

Methods: Ambulatory adult patients with unilateral lower limb spasticity (able to take at least 5 steps with/without assistance) were treated with abobotulinumtoxinA in accordance with local prescribing guidelines to achieve individualized function-related goals.

Results: At the population level, goal attainment was as expected over repeated cycles; mean cumulated GAS-leg *T* score at 16 months (primary endpoint) was 48.2 [47.4, 48.9] (mean change from baseline of 9.9 [9.1, 10.7]). Patients who were injected with injection guidance at baseline were significantly more likely to attain their goals than those in whom no guidance was used (odds ratio: 2.63 [1.72, 4.0], $p < 0.0001$). Patients treated concomitantly for upper limb spasticity were also more likely to attain their goals than those only injected in the lower limb (odds ratio: 2.3 [1.3, 4.3], $p = 0.005$). Adverse events (AEs) were reported by 56 (13.5%) patients; most were mild-moderate and considered unrelated to treatment. Six patients (1.4%) had an AE possibly/probably related to treatment.

Conclusion: This large, international study provides evidence for the benefit of repeated cycles of abobotulinumtoxinA in the lower limb in helping patients achieve meaningful goals, demonstrates the importance of appropriate injection guidance techniques and points to the benefit of treating the upper limb in combination with lower limb when clinically indicated. Treatment with abobotulinumtoxinA was generally well-tolerated and safe; no new safety issues were identified.

Movement disorders 7

EPO-745 | Movement disorders after basal ganglia ischemic lesions following mechanical thrombectomy: An emerging clinical entity

L. Rigon[1]; D. Genovese[2]; V. Brunetti[2]; V. Guglielmi[2]; I. Scala[1]; S. Citro[1]; A. Cimmino[1]; A. Bentivoglio[1]; P. Calabresi[1]; C. Piano[2]; G. Della Marca[1]

[1]Dipartimento di Neuroscienze, Università Cattolica del Sacro Cuore, Rome, Italy; [2]Dipartimento di neuroscienze, Organi di Senso e Torace, Fondazione Policlinico Universitario A. Gemelli IRCCS – UOC Neurologia, Rome, Italy

Background and Aims: Post-stroke movement disorders (PMDs) following ischemic lesions of the basal ganglia (BG) are a known entity, but data regarding incidence are missing. Ischemic strokes secondary to proximal middle cerebral artery (MCA) occlusion treated with thrombectomy represent a model of selective damage of the BG. Aim of this study was to assess prevalence and features of movement disorders after selective BG ischemia in patients with successfully-reperfused acute ischemic stroke.

Methods: We enrolled 64 consecutive subjects with acute ischemic stroke due to proximal MCA occlusion treated with thrombectomy. Patients were clinically evaluated by a movement disorders specialist for PMDs onset at baseline, after 6 and 12 months.

Results: None of the subjects showed an identifiable movement disorder in the subacute phase of the stroke. At 6- and 12-months respectively 7/25 (28%) and 7/13 (53.8%) of evaluated patients developed PMDs. The clinical spectrum of PMDs encompassed parkinsonism, dystonia and chorea, either isolated or combined. In most patients, symptoms were contralateral to the lesion, although a subset of patients presented with bilateral involvement and prominent axial signs.

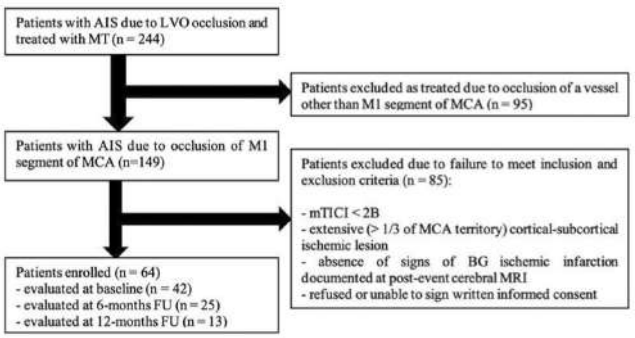

Figure 1: Flowchart of the study; Abbreviations: AIS: acute ischemic stroke; LVO: large vessel occlusion; MT: mechanical thrombectomy; MCA: middle cerebral artery; mTICI: modified treatment in cerebral ischemia score; BG: basal ganglia; MRI: magnetic resonance imaging; FU: follow-up

Flowchart of the study.

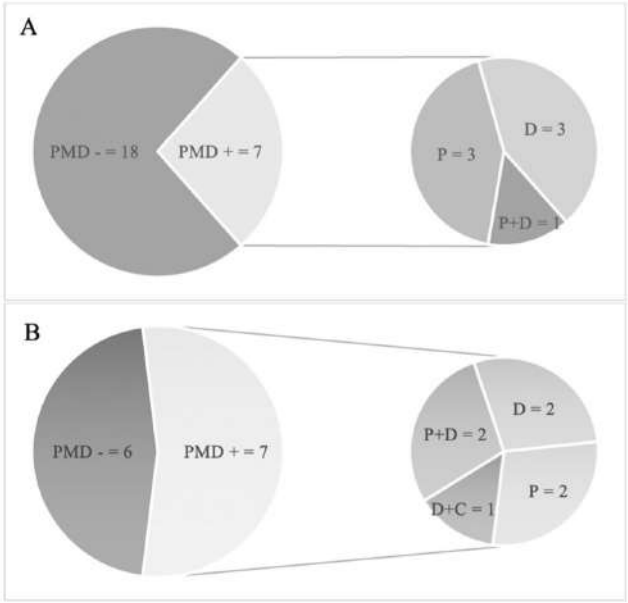

Figure 2: Prevalence and clinical subtype of post stroke movement disorders six (A) and twelve (B) months after the acute event. Abbreviations: PMD-: subjects who did not develop post-stroke movement disorders during the follow-up; PMD+: subjects who developed a post-stroke movement disorder throughout the follow-up; P: parkinsonism; D: dystonia; P+D: combined parkinsonism-dystonia; D+C: combined dystonia-chorea

Prevalence and clinical subtype of post stroke movement disorders six (A) and twelve (B) months after the acute event.

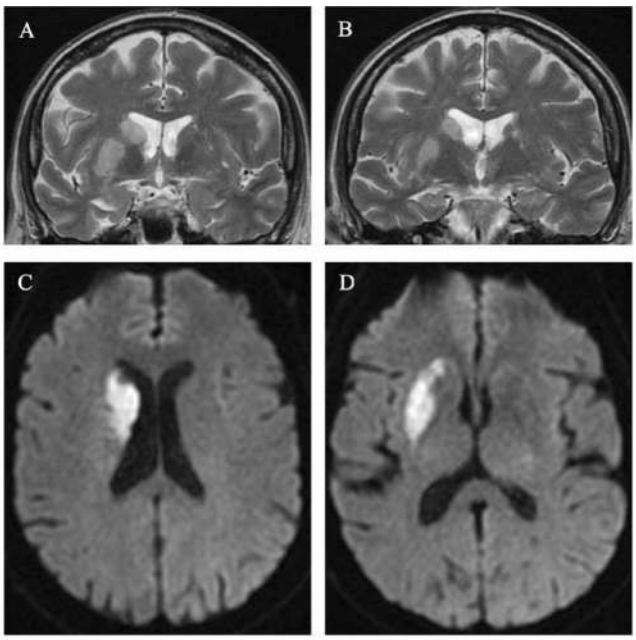

Figure 3: Selective ischemic lesion of the basal ganglia occurring after an acute proximal occlusion of the middle cerebral artery in a patient successfully treated with mechanical thrombectomy from our cohort. **A** and **B** panels: T2-weighted sequences coronal sections at the level of the basal ganglia; **C** and **D** panels: diffusion-weighted sequences axial sections at the level of the basal ganglia

Selective ischemic lesion of the basal ganglia occurring after an acute proximal occlusion of the middle cerebral artery in a patient successfully treated with mechanical thrombectomy from our cohort.

Conclusion: PMDs are not uncommon in a long-term follow-up of successfully reperfused acute ischemic strokes. A prosecution of follow-up in a multidisciplinary team is strongly advisable in patients with selective lesions of the BG after AIS, even if asymptomatic at discharge.

Disclosure: Nothing to disclose.

EPO-746 | Effect of a single session of transcranial pulse stimulation on tremor in Parkinson patients

P. Manganotti; M. LIccari; M. Catalan; P. Busan
Clinical Neurology, Department of Medical, Surgery and Health Services, University of Trieste, Italy

Background and Aims: Tremor is a common signs in movement disorders. Tremor itself is very sensitive to brain stimulation, from deep brain stimulation to Transcranial magnetic stimulation. Transcranial pulse stimulation (TPS) is a painless and non-invasive new technique which produces a magnetic field by low frequency ultrasound. Aim of the study is to investigate possible long term changes on cortical activity after Transcranial Pulse Stimulation in motor cortex in patients with Parkinson and tremor.

Methods: TPS was delivered in 14 patients affected by PD tremor dominant, which was measured at the baseline (T0) after the TPS (T1) and after 24 hours (T2). The resting tremor was present in all patients with an average of 9–10 Hz/sec. The treatment protocol was 4 Hz, 0.20 mJ/mm^2 by default. A single-session of 1500 pulses were delivered to the subjects' motor cortex (M1) of the contralateral to the most affected side of the tremor.

Results: We noted a reduction of tremore at T1 and T2 compared to baseline T0 in 13 patients, from 20% to 40% in amplitude, reaching a decrease of 57% in one case. In all the patients we noted a decrease in amplitude and duration of tremor at rest but not in frequency. No effect was note in placebo stimulation.

Conclusion: TPS as a new brain stimulation method induces a reduction of tremor for 24 hours without side effects documenting a significant physiological changes in these patients. TPS is a new techniques for brain stimulation effective on motor areas.

Disclosure: Nothing to disclose.

EPO-747 | Opicapone's real-world experience in Spanish patients with Parkinson's disease: The OPTIMO study

M. Luquin[1]; C. Martin[2]; I. Tegel[3]; C. Moreno[3]
[1]Clinica Universidad de Navarra; [2]Evidenze Group; [3]Bial Spain

Background and Aims: Opicapone (OPC), a third generation COMT inhibitor, has been shown to be generally well-tolerated and efficacious in reducing off time in two pivotal trials in patients with Parkinson's disease (PD) and motor fluctuations (MF) (BIPARK-I and -II). The OPTIMO study aims to confirm these data in the everyday

practice by evaluating the clinical performance of opicapone in Spanish movement Disorders Units.

Methods: OPTIMO was an observational, retrospective, post-authorization study in patients with PD conducted at outpatient consultations for movement disorders in 16 Spanish centers. The inclusion period lasted 12 months. Clinical data were collected before the start of treatment with OPC and between 3 and 7 months post-treatment. Adverse effects were documented, with particular focus on monitoring the development of dyskinesias.

Results: 245 patients were enrolled (mean age, 67.7 years; mean time of PD evolution, 8.3 years; mean levodopa daily dose, 620.7 mg). Treatment with OPC reduced the percentage of patients with wearing-off MF (98% vs. 61.6%), delayed-on ($p=0.010$), non-on ($p=0.027$) and non-motor fluctuations ($p=0.010$). The daily OFF-time was significantly reduced (143 vs. 67.9 minutes). 74.2% of patients described clinical improvement in MF, which did not worsen dyskinesias in 64.6%. No significant increase in ON-time with dyskinesias was observed. Only 8.6% of patients experienced OPC-related adverse events.

Conclusion: These results confirm the findings of previous clinical trials, demonstrating that, in routine clinical practice, OPC significantly reduces motor and non-motor fluctuations without a significant increase in severity of dyskinesias, along with a good tolerance profile.

Disclosure: Supported by BIAL Spain.

EPO-748 | Expanding phenotype of LRRK2 G2019S mutation: Case description of two sisters showing peculiar phenomenological traits

S. Cartella; S. Neri; G. Foti; G. Cartella
Movement Disorders Centre, Department of Neurology, Policlinico Madonna della Consolazione, Reggio Calabria, Italy

Background and Aims: LRRK2 is the most common risk gene for Parkinson's disease (PD). It presents with a milder course and a less common non-motor involvement than idiopathic PD.

Methods: The aim of this report is to describe LRRK2 phenomenology. We describe two sisters, one presenting with cervical dystonia (CD) and the other one presenting with typical parkinsonian features, although showing prominent non-motor fluctuations.

Results: A 80-year old lady was referred to our outpatient clinic due a 2-year history of head tremor. She showed cervical dystonia characterized by head tremor, inclination to the left side, left shoulder elevation, head rotation to the right, antecollis, retrocaput and limitation of range of motion. She had positive family history for Parkinson's disease (two of her mother's siblings, one of her father's and 5 of her own). Her sister was a 83-year old lady, who had been diagnosed with Parkinson's disease 8 years previously. Her major complaints were related to her non-motor fluctuations: her OFF phases were characterized by severe anxiety and pain. We run genetic testing for both patients and found the CD one to be a heterozygotic carrier of G2019S mutation and the PD sister to be a homozygotic carrier of the same mutation. We added safinamide and duloxetine to the treatment of the PD sister, with a major impact on non-motor fluctuations and QoL, and decided to treat the CD sister with levodopa/carbidopa, with considerable clinical improvement.

Conclusion: Our data may contribute to expanding LRRK2 phenotype and providing insights on its clinical course and treatment.

Disclosure: Dr Cartella SM received speaking honoraria from Zambon and Bial Dr Cartella G received speaking honoraria from Abbvie.

EPO-749 | Proinflammatory IgG glycans correlate with putaminal damage in patients with parkinsonism

S. Matosa[1]; A. Vuksan[2]; D. Snajder Mujkic[3]; J. Juric[4]; G. Lauc[5]; T. Gilman Kuric[1]; T. Mirosevic Zubonja[1]; Z. Popovic[1]; S. Juric[1]; J. Kragujevic[1]; A. Poturak[6]; S. Tomic[1]
[1]Department of Neurology, University Hospital Center Osijek, Osijek, Croatia; [2]Faculty of Medicine, University of J. J. Strossmayer in Osijek, Osijek, Croatia; [3]Clinical Institute for Nuclear Medicine and Radiation Protection, University Hospital Center Osijek, Osijek, Croatia; [4]GlycanAge d.o.o., Osijek, Croatia; [5]Genos Glycoscience Research Laboratory, Zagreb, Croatia; [6]Department of Gastroenterology, University Hospital Center Osijek, Osijek, Croatia

Background and Aims: Objectives: To examine the correlation between dopaminergic denervation evaluated with DaTSPECT and the different types of IgG glycans distributed into mature, youth, and shields glycan groups. The glycan mature group provides proinflammatory, while glycan youth and shield groups provide antiinflammatory potential to IgG antibodies.

Methods: Study design: Cross-sectional study with historical data Participants and methods: Data used in this study is part of another study that has been approved by the local ethical committee (R2-3775/2022). Patients diagnosed and treated with Parkinson's disease or atypical parkinsonism were included. Blood samples for evaluating IgG glycan composition were analysed by Genos Glycoscience laboratory in Zagreb. Data on DaTSPECT were analysed from the computer system of the patient registry.

Results: Results: Fifteen patients (10 male, 5 female) were evaluated, 12 with Parkinson's disease and 3 with atypical parkinsonism. The median age was 60 (IQR 55–66), and the disease duration was 3 (IQR 1–4) years. A negative correlation was observed between the IgG glycan mature group, right putamen (Rho = −0.626; $p=0.013$), and right putamen/caudate ratio (Rho = −0.703; $p=0.003$). A positive correlation was seen between the IgG glycan youth group with right putamen (Rho = 0.627; $p=0.012$) and right putamen/caudate ratio (Rho = 0.699; $p=0.004$), while the IgG glycan shield group positively correlated with right putamen/caudate ratio (Rho = 0.725; $p=0.002$). No significant correlation was observed between glycans, age, or disease duration.

Conclusion: Conclusion: Higher IgG glycan mature group values correlate with increased putaminal degeneration, while higher IgG

glycan shield and youth values correlate with reduced putaminal degeneration.

Disclosure: Gordan Lauc is named as an inventor on the GlycanAge patent and serves as the founder and CEO of Genos Ltd.

EPO-750 | Sleep evaluation in functional neurological disorder – Preliminary data of a pilot study

J. Bühler[1]; N. Schwab[1]; F. Messmer[1]; S. Weber[1]; J. van der Meer[2]; S. Duss[2]; S. Aybek[3]

[1]*Psychosomatic Medicine, Department of Neurology, University Hospital, Inselspital, Bern, Switzerland;* [2]*Sleep Wake Epilepsy Center, Department of Neurology, University Hospital, Inselspital, Bern, Switzerland;* [3]*Faculté des Sciences et de Médecine, Université de Fribourg, Fribourg, Switzerland*

Background and Aims: Functional neurological disorder (FND) is a common neuropsychiatric condition with high burden on patients and where self-reports often deviate from objective measures. Despite frequent observations of patients suffering from sleep disturbances as a comorbidity, studies evaluating sleep in FND are scarce. We thus aim to describe objective sleep parameters and patients' subjective perception of sleep in FND.

Methods: In a pilot study, FND patients and age- and sex-matched healthy controls (HC) completed the Pittsburgh Sleep Quality Index (PSQI; subjective), whereas patients additionally underwent a 2-week actigraphy measurement (objective). We describe subjective sleep quality in FND compared to HC. Furthermore, we report the FND cohort's objective sleep quality in terms of clinical relevance threshold and assess between-measure accuracy.

Results: 26 FND patients (73% female, mean age = 38.4 y) and 26 HC (73% female, mean age = 36.5 y) were included. Patients reported significantly worse scores of subjective sleep including a higher PSQI total score ($p < 0.001$). Similarly, subjectively reported sleep latency ($p = 0.014$), time-in-bed ($p = 0.032$) and sleep efficiency ($p = 0.009$) significantly differed between FND and HC. Analysis of actigraphy as objective sleep quality measure revealed reduced sleep efficiency (<85%) in 73% of patients. Moreover, in the FND cohort, an incongruency between objective and subjective reports was observed regarding sleep latency ($p = 0.005$).

Conclusion: This pilot study depicts sleep disturbances in FND patients compared to a healthy cohort and in terms of clinically relevant thresholds. Furthermore, we identified inaccurate perception of one's own sleep onset among FND patients. Studies on larger sample sizes are required to disentangle the role of sleep in FND.

Disclosure: Nothing to disclose.

EPO-751 | Prevalence, pre-existing conditions, and prior treatments among european adults diagnosed with Tardive dyskinesia

S. Reshef[1]; M. Edwards[2]; M. Forrest Gordon[3]; N. Chaijale[3]; A. Kurzeja[4]; M. Driessen[4]; C. Correll[5]

[1]*Teva Branded Pharmaceutical Products R&D, Inc., Parsippany, NJ, USA;* [2]*King's College London, London, UK;* [3]*Teva Branded Pharmaceutical Products R&D, Inc., West Chester, PA, USA;* [4]*Teva Pharmaceuticals Europe B.V., Amsterdam, The Netherlands;* [5]*The Zucker Hillside Hospital, Northwell Health, Glen Oaks, NY, USA*

Background and Aims: Tardive dyskinesia (TD) is a hyperkinetic movement disorder mostly associated with chronic antipsychotic (AP) exposure. TD prevalence and associated risk factors in Europe are understudied. This study aimed to evaluate TD prevalence, pre-existing conditions, and pre-TD treatments in European adult populations.

Methods: A retrospective study of adults (≥18 years) from 6 European healthcare databases representing Belgium, France, Germany, Italy, Spain, and United Kingdom (UK) was conducted. The index event was first TD diagnosis within the study period (1 Jan 2016–31 Dec 2021). To adhere to regional reporting practices, patient numbers <10 for France and <5 for all others were masked.

Results: Cumulative adult TD prevalence was 1, 3, and 3 per 100,000 in France (<88 of 11,171,508), Germany (660 of 23,235,594), and UK (78 of 2,486,459), respectively. Italy ($n = 1,829,406$), Spain ($n = 1,507,900$), and Belgium ($n = 712,035$) had <5 adults with TD reported, which did not enable prevalence calculations. In ages 18–40 years in France ($n = 4,148,423$), Germany ($n = 8,022,427$), and UK ($n = 1,221,030$), TD prevalence was <0.24, 0.96, and 1.06 per 100,000. For ages ≥41 years in France ($n = 7,023,085$), Germany ($n = 15,213,167$), and UK ($n = 1,265,429$), TD prevalence was 1.14, 3.83, and 5.14 per 100,000. In Germany and UK, 22%–46% of patients with TD had diagnosed schizophrenia, 34%–48% had schizophrenia spectrum disorder, and <5%–34% had anxiety disorders; 40%–56% previously received atypical APs and 15%–42% had received typical APs.

Conclusion: TD prevalence was low and variable across European countries, suggesting limited awareness, underdiagnosis, and coding differences in European health settings.

Disclosure: This study was supported by funding from Teva Branded Pharmaceutical Products R&D, Inc. Mark J. Edwards and Christoph U. Correll have received fees and/or honoraria from Teva Pharmaceuticals. Shoshana Reshef, Mark Forrest Gordon, Nayla Chaijale, Anna Kurzeja, and Maurice T. Driessen are employees and/or stockholders of Teva Pharmaceuticals.

EPO-752 | Post hoc analysis of foot abnormalities in patients with Friedreich ataxia in the MOXIe trial

S. Boesch[1]; P. Giunti[2]; S. Chimalapati[3]; W. Costello[3]; A. Goldsberry[3]; S. Rich[3]; C. Ruhl[3]; D. Lynch[4]

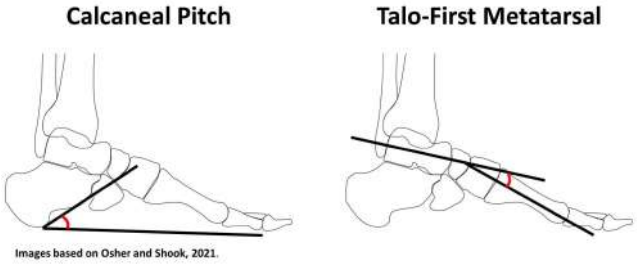
[1]*Department of Neurology, Medical University Innsbruck, Innsbruck, Austria;* [2]*Ataxia Centre, Department of Clinical and Movement Neurosciences, University College London, London, UK;* [3]*Department of Research and Development, Biogen, Cambridge, USA;* [4]*Departments of Pediatrics and Neurology, The Children's Hospital of Philadelphia, Philadelphia, USA*

Background and Aims: The MOXIe trial (NCT02255435/EudraCT2015-002762-23) evaluated omaveloxolone in patients with Friedreich ataxia (FA); 20% were considered to have severe pes cavus, determined by a flashlight test, and not included in the full analysis set (FAS). This exploratory analysis compared foot angle abnormalities in the MOXIe severe pes cavus and FAS populations.

Methods: Weight-bearing lateral foot radiographs were obtained and centrally read. Post hoc analyses assessed frequency and distribution of abnormalities in radiological angles indicative of pes cavus (calcaneal pitch >30°, talo-first metatarsal angles >5°) in the FAS and severe pes cavus populations (Figure 1).

Results: Patients with severe pes cavus ($n=20$) had similar baseline characteristics to FAS patients ($n=82$); ~90% of patients were ambulatory in each group. Overall, 11% and 45% of FAS and severe pes cavus patients, respectively, had an abnormal calcaneal pitch, and 42.7% and 50% had abnormal talo-first metatarsal angles (Table 1). Calcaneal pitch and talo-first metatarsal angles were distributed across a range of values in both populations, though the pes cavus population had more severe angle abnormalities (Figure 2). In patients with severe pes cavus, mFARS results at Week 48 directionally favored omaveloxolone versus placebo; in the all-randomized population, omaveloxolone demonstrated benefit over placebo. Safety profiles were similar between patients with versus without severe pes cavus.

Figure 1: Calcaneal Pitch and Talo-First Metatarsal X-Ray Angles Measured in MOXIe Part 2



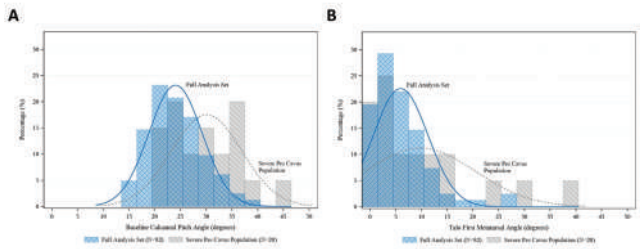
Images based on Osher and Shook, 2021.

Table 1: Baseline Foot X-Ray Results in the FAS and in Patients With Severe Pes Cavus

Parameter	Normal Range (Degrees)[a]	Direction for Deviation From Normal in Pes Cavus	N (%) Patients in FAS With Abnormal Angle N=82	N (%) Patients in Severe Pes Cavus Population With Abnormal Angle N=20
Calcaneal Pitch	20-30	Increased	9 (11.0)	9 (45.0)
Talo-First Metatarsal	0-5	Increased	35 (42.7)	10 (50.0)

Abbreviation: FAS=full analysis set.
[a] Osher L, Shook JE. *Clin Podiatr Med Surg.* 2021;38(3):303-321.

Figure 2: Distribution of Calcaneal Pitch (A) and Talo-First Metatarsal (B) Angles for Full Analysis Set and Severe Pes Cavus Population



Conclusion: Patients with severe pes cavus were not phenotypically or clinically distinct from the FAS. Pes cavus appears as a continuum in patients with FA. Omaveloxolone was safe and demonstrated benefit over placebo across a full spectrum of foot deformities.

EPO-753 | Path to prevention therapeutics platform trial in stage 2B neuronal alpha-synuclein disease: Study design and timeline

T. Simuni

Northwestern University, Chicago, USA

Background and Aims: To describe the study design and proposed timeline of the first interventional study in Neuronal α-Synuclein Disease (NSD).

Methods: P2P is a perpetual platform trial with a single Master Protocol dictating the conduct of the trial and regimen specific subprotocols outlining intervention specific aspects for each arm. Qualified participants will be recruited from the PPMI participants, based on NSD Stage 2B criteria (see Table 1). The study's Multiple Primary Endpoints include 1) DAT imaging as measured by the rate of progression in the mean striatum Specific Binding Ratio (SBR) and 2) rate of progression in the MDS-UPDRS part III score. Secondary endpoints include safety, tolerability and feasibility. The study will have an array of exploratory clinical (including digital) and biomarker measures. Participants will first be randomized in an equal manner among all of the regimen-specific sub-protocols for which they are eligible and then within the regimen to an active arm or placebo ($N=125$ per arm) in a K:1 ratio with K the number of active interventions. Intervention duration will be at least 24 months. The study is 90% powered to detect a slowing in either primary endpoint for each regimen, assuming a 30% slowing in DAT and a 40% slowing in MDS-UPDRS Part III.

Results: Interventions are being selected by a Therapeutic Evaluation Committee from >15 industry submitted applications. The study targets to start enrolment in the first 2 regimens in 2025.

Table 1. Data driven anchors for NSD-ISS

	Biologic anchors			Anchors of clinical signs or symptoms (stages 2A and 2B) and functional impairment (stages 3-4)[1,2]	
Stage	S	D[a]	G	Domain	Anchor(s)
Stage 0	-	-	*SNCA* [b]	—	—
Stage 1A	+	-	±	(1) Cognitive (2) Motor (3) Other non-motor	(1) MDS-UPDRS item 1.1 = 0; and (2a) Does not have subthreshold parkinsonism [c]; and (2b) is not on PD meds; and (3a) Does not have RBD; and (3b) is not hyposmic [d]
Stage 1B	+	+	±		
Stage 2A	+	-	±	(1) Cognitive (2) Motor (3) Other non-motor	(1) Item 1.1 = 1 AND MoCA ≥ 25; or (2a) Has subthreshold parkinsonism [c]; or (2b) is on PD meds; or (3a) Has RBD; or (3b) is hyposmic [d]
Stage 2B	+	+	±		
Stage 3	+	+	±	(1) Cognitive (2) Motor	(1a) Item 1.1 = 1 AND MoCA ≤ 24; or (1b) Item 1.1 = 2 AND MoCA ≥ 25; or (2) MDS-UPDRS-II = 3-13 AND either subthreshold parkinsonism [c] or PD meds
Stage 4	+	+	±	(1) Cognitive (2) Motor (3) Other non-motor	(1a) Item 1.1 = 2 and MoCA ≤ 24; or (1b) item 1.1 = 3 AND MoCA ≥ 25; or (2) MDS-UPDRS-II = 14-26; or (3) MDS-UPDRS-I (excluding item 1.1) = 13-24 [e]
Stage 5	+	+	±	(1) Cognitive (2) Motor (3) Other non-motor	(1a) Item 1.1 = 3 AND MoCA ≤ 24; or (1b) item 1.1 = 4 AND MoCA ≥ 25; or (2) MDS-UPDRS-II = 27-39; or (3) MDS-UPDRS-I (excluding item 1.1) = 25-36
Stage 6	+	+	±	(1) Cognitive (2) Motor (3) Other non-motor	(1) Item 1.1 = 4 AND MoCA ≤ 24; or (2) MDS-UPDRS-II ≥ 40; or (3) MDS-UPDRS-I (excluding item 1.1) ≥ 37

NSD is defined by presence of Alpha-Synuclein pathology, ultimately dopamine dysfunction, and stage dependent motor and non-motor clinical manifestations and related functional impairment. These participants were previously clinically defined as Parkinson's disease, Dementia with Lewy Bodies and Prodromal. The study is "nested" within the Parkinson's Progression Marker Initiative (PPMI) and sponsored by the MJFF.

Conclusion: We report the design of the first platform interventional study targeting NSD Stage 2B population.

EPO-754 | A closer look at eye movements in cervical dystonia

T. Gilman Kuric[1]; Z. Popovic[1]; A. Sadikov[2]; V. Groznik[2]; D. Georgiev[3]; A. Gerbasi[4]; S. Juric[1]; S. Matosa[1]; T. Mirosevic Zubonja[1]; S. Tomic[1]

[1]*Department of Neurology, Osijek University Hospital Centre, Osijek, Croatia;* [2]*University of Ljubljana, Faculty of Computer and Information Science, Ljubljana, Slovenia;* [3]*Department of Neurology, University Medical Centre Ljubljana, Ljubljana, Slovenia;* [4]*Department of Electrical, Computer and Biomedical Engineering, University of Pavia, Pavia, Italy*

Background and Aims: In the last few decades cervical dystonia (CD) has come under attention of experts in the field of movement disorders. The studies of its complex pathophysiology propose a disorganization within the motor cortex-basal ganglia-cerebellum axis i.e. network. For some time now, eye movements can serve as a good model for researching the motility of patients and thereby expand the knowledge about cervical dystonia.

Methods: 30 cervical dystonia patients and 30 matched healthy controls performed eye-movement examination including smooth-eye movements, prosaccade, antisaccade and memory saccade tasks on an eye tracker to assess automatic visual response.

Results: Cervical dystonia patients expressed poorer fixation ($p=0.02$) and target following ($p=0.04$) of smooth eye-movements on vertical axis, diminished maximum speed of prosaccades ($p=0.03$) which are of significant latency ($p=0.02$), more directional errors in the antisaccade task ($p=0.04$) and poorer execution of memory saccades testing ($p=0.002$). There were no changes in smooth eye-movements horizontally compared with healthy controls.

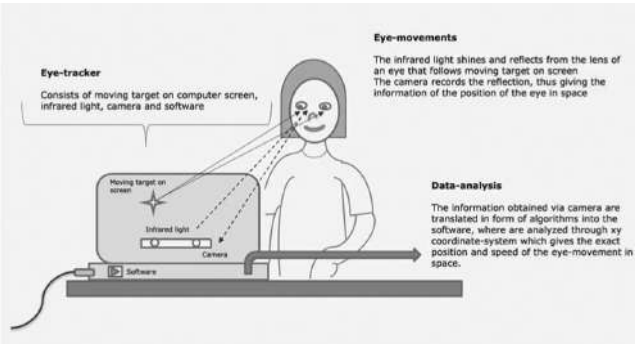

FIGURE 1 Representation of eye movements' analysis using an eye-tracker, original scheme.

Table 1. Comparison of eye-movements in cervical dystonia patients and healthy controls

Measured variables	Median (interquartile range) CD patients (n=30)	Healthy controls (n=30)	P*
Smooth eye-movements			
Horizontal eye-movement range 16 ms	0.584 (0.519 - 0.646)	0.544 (0.535 - 0.587)	0.16
Horizontal eye-movement fixation 16 ms	0.00810 (0.00653 - 0.0127)	0.00780 (0.00529 - 0.00967)	0.42

Conclusion: Based on the obtained results and known anatomic connections, we assume a more significant pathophysiology of the interstitial nucleus of Cajal in CD patients than was previously known, considering altered vertical but not horizontal smooth-pursuit. Also, we suggest changes of saccadic inhibitory control in patients with CD at multiple levels, including dorsolateral prefrontal cortex and frontal eye fields and their projections to the superior colliculus, suggesting alterations of corticobasal networking.
Disclosure: Nothing to disclose.

EPO-755 | Pisa syndrome and botulinum toxin injection in paraspinal muscle ipsilateral to the bending site

T. Lombardo; V. Cenacchi; G. Bellavita; V. Tommasini; M. Catalan; L. Antonutti; M. Liccari; P. Manganotti
Clinical Unit of Neurology, Department of Medical Sciences, University Hospital and Health Services of Trieste, University of Trieste, Trieste, Italy

Background and Aims: The aim of this study was to evaluate the clinical and electromyographical effects of Botulinum toxin injections in patients with Parkinson's disease (PD) suffering from Pisa syndrome (PS).
Methods: We recruited 16 PD patients with PS from the Movement Disorders Unit of Trieste (Italy). Each patient was evaluated at baseline, 1 and 3 months after BoNT injection, which was ipsilateral to the bending site regardless of EMG activation. We recorded demographic, PD- and PS-related clinical variables, including PDQ-8 and PGIC scales, and back pain evaluation (VAS scale). Muscular hypo- and hyperactivity patterns were assessed using superficial EMG recording. Lateral bending angle of the spine was calculated on the planar view photographs as the angle between the vertical axis and a line connecting the fulcrum of the bent spine with the C7 spinous process.
Results: Sixteen outpatients showed an initial reduction in bending degrees followed by a reversion (6.5 ± 3, 5 ± 1.5, 6.7 ± 6 degrees at baseline, 1 and 3 months respectively), a substantial stability in PDQ-8 scores, and a reduction in back pain. Accordingly to 91 and 100% of the patients, at 1 and 3 months respectively, their condition globally improved (PGIC scores ≥3). Qualitative EMG signal analysis showed an almost uniform improvement in paraspinal muscles activation.
Conclusion: Our study shows an efficacy in bending angle reduction after 1 month from the treatment with a reversion after 3 months, and a subjective clinical improvement. This may indicate a benefit deriving from ipsilateral injection regardless of EMG activity.
Disclosure: Nothing to disclose.

EPO-756 | Selection of candidates for treatment with deep brain stimulation among patients with focal and segmental dystonia

V. Markovic; A. Tomic; M. Jecmenica Lukic; N. Kresojevic; I. Petrovic; N. Dragasevic; M. Svetel
Movement Disorders Department, Neurology Clinic, Medical Faculty, Belgrade, Serbia

Background and Aims: Focal and segmental dystonia are commonly successfully treated with the application of botulinum toxin; however, a proportion of patients remains challenging. GPi deep brain stimulation (DBS) is successfully used in some of these patients, but their frequency and characteristics are still unknown.
Methods: We included 150 consecutive patients in cross-sectional study at the Neurology Clinic, Belgrade. A semi-structured survey was used to collect demographic and clinical data, relevant clinical scales to assess dystonia severity (BFMD) and psychiatric symptoms (HAMD; HAMA; Apathy scale). Current criteria were used to diagnose functional dystonia.
Results: Overall, patients were satisfied with the therapy: 74 (49.3%) felt better than 75%, and an additional 43 (28.7%) were 50% better compared to the period before starting botulinum toxin therapy. 33 (22%) respondents had an unsatisfactory therapeutic response (lower than 50%). These patients showed significantly worse scores regarding: BFMD, HAMD and HAMA. We further analyzed these patients found that 9 (6%) had purely functional dystonia, while further 9 (6%) were too old or had significant comorbities to be considered for DBS, thus leaving 15 (10%) potential candidates to be considered for DBS referral which showed no difference regarding duration and severity of the disease nor psychiatric symptoms severity, but they were significantly younger.
Conclusion: About 10% of the subjects with focal or segmental dystonia at the tertiary botulinum toxin center can be considered for DBS referral. Special precaution should be made to exclude patients with functional symptoms.
Disclosure: Nothing to disclose.

EPO-757 | Phenotypic heterogeneity of genetic forms of dystonia

V. Cukic[1]; A. Tomic[2]; A. Tuzinac[3]; M. Svetel[2]; I. Petrovic[2]; M. Jecmenica Lukic[2]; V. Markovic[2]; N. Dragasevic Miskovic[2]; N. Cerovac[4]; V. Kostic[5]
[1]*Neurology Department, General Hospital Pancevo, Pancevo, Serbia;* [2]*Neurology Clinic, University Clinical Center of Serbia, Belgrade, Serbia;* [3]*School of Medicine, University of Belgrade, Belgrade, Serbia;* [4]*Clinic of Neurology and Psychiatry for Children and Adolescents, Belgrade, Serbia;* [5]*Serbian Academy of Science and Arts, Belgrade, Serbia*

Background and Aims: Dystonia is a movement disorder characterized by continuous or intermittent muscle contraction that causes abnormal positions of body parts. It represents a clinically and

genetically very heterogeneous disease. More than 200 genes have been identified that are associated with different, mostly generalized forms of early-onset/infantile dystonia. The aim of this work is to describe the clinical characteristics and patterns of progression of different genetic forms of dystonia.

Methods: Carriers of DYT-TOR1A, DYT-THAP6 (isolated AD dystonia), DYT-GCH1 and DYT-SCGE (combined AD dystonia) mutations were included in the study. The data were obtained from the Registry of the Laboratory for Genetics, as well as from medical records. The assessment of the clinical picture was performed for each patient as typical or atypical based on the analysis of demographic data and phenotype analysis, which included data on initial presentation, progression and distribution of dystonia, presence of tremors, presence of other involuntary movements. Statistical processing included standard methods.

Results: Disease progression and dystonia spreading to unaffected regions occurred in all examined groups, according to specific patterns within the groups. There was no difference in the distribution of dystonia by region in DYT-TOR1A and DYT-THAP1 carriers. Additionally, atypical clinical presentation was described in all groups.

Conclusion: Our results indicate that two-thirds of patients with genetic forms of dystonia experience disease progression, while one-third of patients have signs of atypical manifestations. An adequate assessment of the clinical picture and recognition of the potential genetic basis of the disease significantly improves diagnostic and therapeutic strategies.

Disclosure: Nothing to disclose.

EPO-758 | Autosomal recessive spastic ataxia of Charlevoix-Saguenay (ARSACS) with novel mutation in SACS gene

Y. Seçil[1]; A. Subaşioğlu[2]; S. Gündoğan[1]; Ş. Arici[1]
[1]*İzmir Katip Celebi University Ataturk Education and Research Hospital Neurology Department*; [2]*İzmir Katip Celebi University Ataturk Education and Research Hospital Medical Genetics Department*

Background and Aims: Autosomal recessive spastic ataxia of Charlevoix-Saguenay (ARSACS) is a rare disease with cerebellar ataxia, peripheral neuropathy and pyramidal signs. It is caused by homozygous mutations in the SACS gene (1). It was first reported in the population of French descent in the Charlevoix Saguenay region of Quebec, Canada in 1978 (2). Over 200 pathogenic mutations have been described outside of Quebec (3, 4). ARSACS patients are not limited to a particular ethnic group (3, 4, 5). We present a patient with novel homozygous mutation in the SACS gene from Turkey.

Methods: Forty years old male, born of consanguineous marriage, presented with progressive ataxia and recurrent falls from 20 years of age. He has two cousins suffering from the similar symptoms. Neurological examination revealed ataxia, dysarthria, spasticity, walking difficulty, pes cavus deformity and polyneuropathy. Brain MRI scans show linear T2 and fluid attenuated inversion-recovery (FLAIR) hypointensities in the pons.

Results: Patient was diagnosed of Charlevoix Saguenay ataxia syndrome. Clinical exome sequencing revealed a homozygous frameshift mutation on exon 10 of SACS gene (NM_014363.6). The mutation, c.7720dup, p.Arg2574LysfsTer4 resulting in a stop codon and premature truncation of the protein.

Conclusion: This mutation is a novel variant that has not been published in the literature until now. According to the ACMG guidelines, as it causes the premature truncation, it can cause damaging effect. We present here a rare case of Charlevoix Saguenay ataxia that occurred secondary to a novel mutation in SACS gene from Türkiye.

Disclosure: There is no disclosure.

Neuropathies

EPO-759 | 3 Cases of canvas in a Spanish third level hospital

A. Zahonero Ferriz; R. Vilar Ventura; H. Benetó Andrés; A. Monclús Blecua; M. Fortanet García; C. Vilar Fabra
Servicio Neurología, Hospital General Universitario de Castellón

Background and Aims: CANVAS (cerebellar ataxia, neuropathy and vestibular areflexia syndrome) is a recently genetically diagnosed disease that is caused by abnormal expansion in RFC1 gene. It typically presents in middle age with a combination of neuropathy, ataxia, vestibular disease and dry cough. Typical findings are: pure sensory axonal neuropathy and bilateral vestibular areflexia.

Methods: 3 cases of CANVAS confirmed with genetic study treated in our center.

Results: We present 3 patients with a mean age at onset of symptoms of 50.6 years. None of them had a family history of neurological disease or consanguinity. The average delay time from the onset of symptoms to the first evaluation was 4.6 years, with the reason for consultation being sensory alteration in two of them and walking instability in one of them. 67% had a history of cough years before presentation. 67% developed cerebellar symptoms during follow-up. In complementary tests, 100% had pure sensory axonal polyneuropathy and only one showed bilateral vestibular areflexia. The delay time until the genetic study was 4 years from the first visit. All 3 had homozygous expansion for AAGGG in the RFC1 gene with a number of expansions between 400–2000.

Conclusion: CANVAS syndrome is a relatively recent entity and it is interesting to know the forms of presentation when it comes to properly identifying patients. Our case series presents concordant and discordant data with respect to other series described, which is explained by the variability of presentation and evolution of these patients, which makes the diagnosis of suspected onset difficult.

Disclosure: Nothing to disclose.

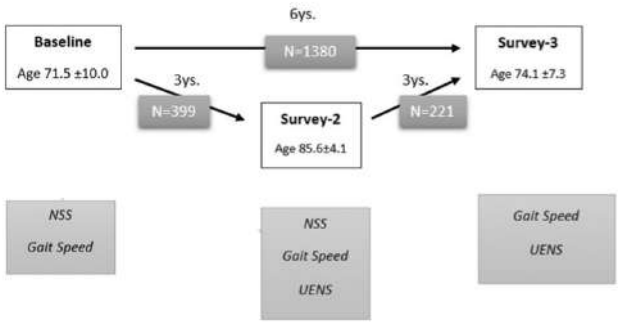
EPO-760 | Longitudinal follow-up of neuropathy symptoms, neuropathy signs and gait in older adults from good aging in Skåne study

A. Siennicki-Lantz; S. Elmståhl
Division of Geriatric Medicine; Department of Clinical Sciences, Malmö; Lund University, Sweden

Background and Aims: We aimed to study an extent of neuropathy symptoms and their association with clinical signs of neuropathy and gait speed during 3–6 years follow-up.

Methods: Older adults ($n = 2805$, females 55%, mean age 71.5 ± 10.0 ys.) answered on questionnaire Neuropathy Scale Score (NSS), modified for self-assessment (max score18). At survey-2, 399 who reached at least 80 ys, were re-examined after mean 3.4 ys (age 85.6 ± 4.1) with NSS, Gait Speed and Utah Early Neuropathy Scale (UENS). After further 3 ys, all were invited to survey-3: 211 from the survey-2 and the rest of the baseline cohort, totally 1598 at mean age 74.1 ± 7.3 ys (figure below).

Figure: Good Aging in Scania Study flow chart of 3 surveys and examinations specified.



Results: At baseline, median NSS was 0p (0–13; iQR = 1; 41.4% had ≥1p) and was associated with decreased Gait Speed (<1 m/s in 8.5%) (OR = 1.40; 95% CI 1.27–1.54; $p < 0.00001$). At survey-2, NSS (median 1.0; 0–11; iQR = 3; 68.2% had ≥1p) was associated with higher risk of neuropathy (UENS ≥7p) (OR = 1.36; 95% CI 1.21–1.53; $p < 0.00001$) and Gait Speed < 1 m/s (OR = 1.54; 95% CI 1.31–1.81; $p < 0.00001$). Difference in NSS between survey-2 and baseline (mean = 1 ± 1.86; range: −4–8) was associated with higher risk of neuropathy (OR = 1.38; 95% CI 1.21–1.57; $p < 0.00001$) and Gait Speed < 1 m/s (OR = 1.49; 95% CI 1.25–1.77; $p < 0.00001$). NSS at the baseline was also associated with higher risk of neuropathy in 1598 subjects at survey-3 (OR = 1.23; 95% CI 1.12–1.34; $p = 0.00001$) and gait speed < 1 m/s (OR = 1.50; 95% CI 1.30–1.72; $p < 0.00001$). In 218 oldest old, NSS time-difference between survey-2 and baseline (mean 0.7; p ± 1.66; range: −4–7) was associated with neuropathy in survey-3 (OR = 1.61; 95% CI 1.24–2.01; $p = 0.0002$).

Conclusion: in general population of older adults, self-assessed Neuropathy Scale Score and it's time change was sensitive for future clinical signs of neuropathy and decreasing gait speed.

Disclosure: The Good Aging in Skåne (GÅS-SNAC) project, was supported by the Swedish Ministry of Health and Social Affairs, the county Region Skåne, the Medical Faculty at Lund University, and the Swedish Research Council (grant number 2013-8604, 2017-01613, 2021-01437).

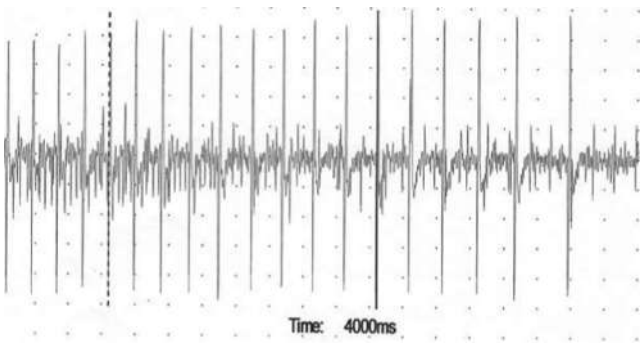
EPO-761 | A new method to objectify the degree of spontaneous activity seen during electromyography study of denervated muscles

A. Sreij; R. Sawaya
American University of Beirut Medical Center

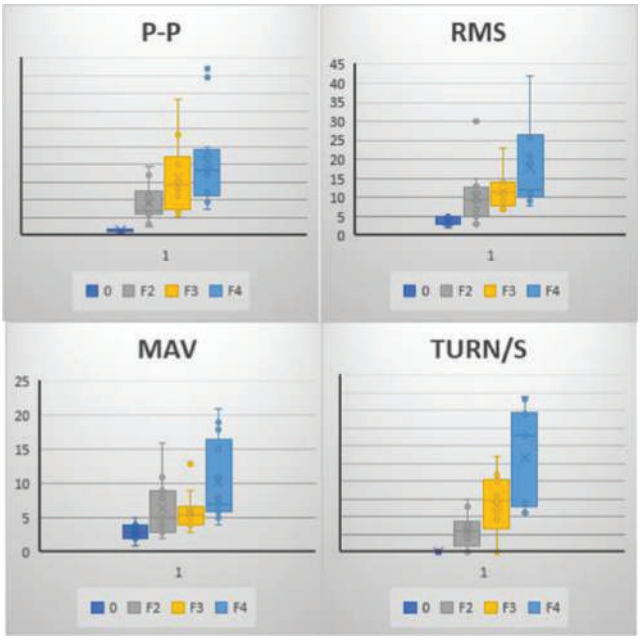
Background and Aims: The degree of spontaneous activity seen during electromyographic analysis of denervated muscles is conventionally defined by the electrophysiologist performing the procedure subjectively as mild, moderate, or severe. Discrepancy between physicians analyzing the quantity of spontaneous activity is not uncommon. The aim of this study is to create an EMG signal parameter capable of objectifying the degree of denervation activity of a given muscle through software analysis rather than subjective evaluation.

Methods: We analyzed the amount of spontaneous activity during the routine electromyographic study of patients referred for testing. We recorded the subjective evaluation of the quantity of spontaneous activity reported by the electrophysiologist. At the same time, we collected a 4 seconds epoch of that same activity. This epoch was incorporated in the electromyographic signal parameter analysis supplied by the manufacturers of the apparatus. The spontaneous activity was evaluated for the peak-to-peak value, root-mean-square, mean absolute value, and turns/second. We then correlated statistically the physician evaluation with the four parameters.

Results: The findings of the study confirm that the best objective electromyographic signal parameter reflecting the subjective evaluation of the experienced electrophysiologist was turns/second analysis of the epoch studied. The other three parameters did not correlate with the subjective evaluation.



Sample of EMG signal parameters recorded at time base: 200 ms and sensitivity: 50 uV/division.



The data collected for peak-to-peak value (P-P) uV, root-mean-square (RMS) uV, mean absolute value (MAV) uV, and turns/second through the software incorporated in the EMG machine from the manufacturer.

Conclusion: The turns/second electromyographic parameter seems to be the best electromyographic signal analysis reflecting the subjective opinion of the experienced electrophysiologist in defining the degree of denervation in a given muscle.

Disclosure: The authors have no conflict of interest and they did not receive any funding for this work.

EPO-762 | Small fiber dysfunction in chronic myeloid leukemia

A. Akkan Suzan[1]; T. Gurer[2]; A. Eskazan[2]; A. Gunduz[1]
[1]*Department of Neurology and Clinical Neurophysiology, Istanbul University-Cerrahpasa, Faculty of Medicine, Istanbul, Turkey*; [2]*Department of Internal Medicine, Division of Hematology, Istanbul University-Cerrahpasa, Faculty of Medicine, Istanbul, Turkey*

Background and Aims: In this study, we evaluated the frequency of small fiber dysfunction and the contribution of sympathetic skin response (SSR) in understanding small fiber function in patients with chronic myeloid leukemia (CML).

Methods: We evaluated all patients with CML who were receiving tyrosine kinase inhibitors (TKIs) and complained of neuropathic pain using a modified Toronto clinical neuropathy score (mTNS) and performed sensory and motor conduction studies. Based on clinical and nerve conduction studies, patients with large fiber neuropathy were excluded. In the remaining patients, we evaluated palmar and plantar SSRs and compared them with the findings of 13 healthy individuals.

Results: There were 18 patients with suspected small fiber dysfunction. The mean amplitude of the palmar and plantar SSR were lower in the patient group than those in the control group ($p=0.199$ and $p<0.001$, respectively). Comparing patients with CML and healthy individuals, ROC curve analysis showed the area under the curve was 0.64 for palmar and 0.94 for plantar SSR. If the plantar SSR amplitude cut-off value was 114 μV, sensitivity, and specificity were 67.1% and 50%, respectively. However, comparing patients with or without small fiber dysfunction, the area under the curve was low, and no cut-off value distinguished these groups.

Conclusion: Here, we report that dysfunction of small fibers can occur during CML and the use of TKIs. Plantar SSR is a nonspecific method that may be used in screening. The awareness of small fiber dysfunction and evaluation with nerve conduction studies, including SSRs in suspected patients are essential.

Disclosure: Nothing to disclose.

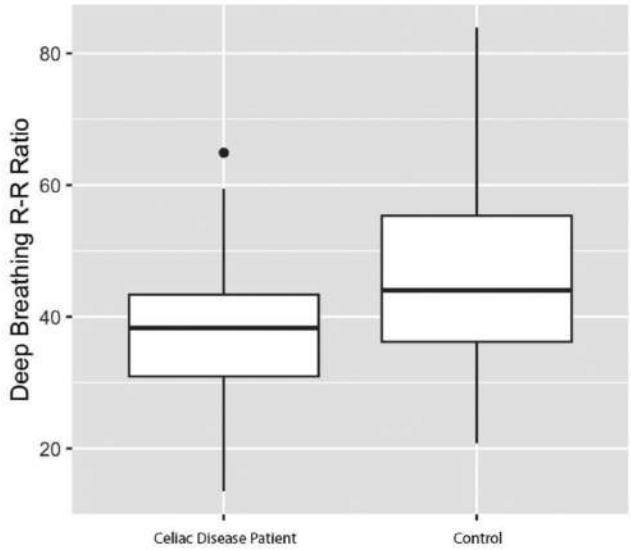
EPO-763 | Unveiling subclinical autonomic dysfunction in coeliac disease

O. Akan[1]; B. Kılboz[1]; B. Yaralıoğlu[1]; Y. Gökden[2]
[1]*Department of Neurology, University of Health Sciences, Prof. Dr. Cemil Tascioglu City Hospital, Istanbul, Turkey*; [2]*Department of Gastroenterology, University of Health Sciences, Prof. Dr. Cemil Tascioglu City Hospital, Istanbul, Turkey*

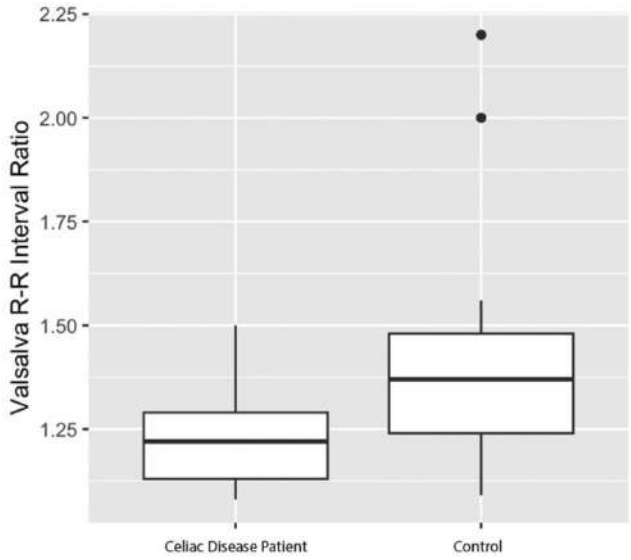
Background and Aims: Celiac disease (CD) patients can exhibit dysautonomia. Early detection can be crucial for timely intervention and managing complications such as syncope. This study aims to identify subclinical autonomic changes in CD patients using heart rate variability and sympathetic skin response tests, compared to healthy controls.

Methods: Serial CD patients from our gastroenterology outpatient clinic and matched controls underwent testing for sympathetic skin response and heart rate variability (including standing up and valsalva 30:15 ratio, and R-R interval ratios during normal and deep breathing) using the Natus Dantec Keypoint Focus device. Statistical analysis in R 4.3.2 included Welch's *t*-test and Mann-Whitney *U* test for means, Shapiro-Wilk test for normality, and descriptive statistics.

Results: The study included 38 CD patients (mean age 31.81 years, 33 females) and 30 controls (mean age 30 years, 20 females). CD patients had a mean disease duration of 5.26 years. IgA transglutaminase antibodies were positive in 15 patients, indicating lack of response to gluten-free diet. CD patients showed significantly lower deep breathing and valsalva R-R interval ratios compared to controls ($p=0.0065$-d$=0.706$ & $p=0.0011$-d$=0.40$). Median nerve proximal and distal CMAP amplitudes were significantly lower in IgA positive CD patients ($p=0.0092$-d$=0.83$ & $p=0.0065$-d$=0.706$).



Deep breathing R-R interval ratios.



Valsalva R-R interval ratios.

Conclusion: CD patients exhibit lower valsalva and deep breathing R-R interval ratios, suggesting subclinical autonomic dysfunction. Additionally, higher median nerve CMAP amplitudes correlate with diet unresponsiveness in CD patients. These findings underscore the need for further research and clinical monitoring.
Disclosure: Nothing to disclose.

EPO-764 | Motor unit number estimation (MUNE) test as assessment tool for motor impairment in Charcot Marie tooth disease

C. Bravi[1]; E. Merico[2]; V. Montano[1]; D. Viola[1]; E. Schirinzi[1]; G. Siciliano[1]
[1]*Department of Neuroscience, Neurological Clinic, Santa Chiara Hospital, University of Pisa, Italy*; [2]*Cardinal Giovanni Panico Hospital, Tricase, Lecce*

Background and Aims: Charcot-Marie-Tooth Disease (CMT) represents the most common form of hereditary neuropathy, often burdened by a significant motor impairment. Several clinical validated scales are used to evaluate the degree of disability and to estimate the progression of the disease. The aim of our study has been to evaluate the correlation between electromyography estimation of the residual motor units (MUNE), in targeted muscles, and data obtained by an extensive clinimetric assessment, in different CMT subtypes.
Methods: 29 CMT patients (11 males and 18 females, median age 52,45-SD = 13,90, median disease duration 28,93 years -SD = 17,11) were recruited, including CMT1, CMT2 and HNPP subtypes. For all patients MUNE calculation and clinimetric evaluation by means of CMTNSv2 and CMT-FOM scales were done.
Results: In CMT2 patients, statistically significant correlations were found between CMT-FOM sub-items scores (right/left dorsiflexion, left/right plantar flexion and "4 Stair Descend), CMTNSv2 total score and MUNE values (on Tibialis Anterior muscle). In CMT1 patients, statistically significant correlation between Tibial MUNE value and "4 Stair Climb" sub item score was observed; in HNPP patient no correlations were observed.
Conclusion: MUNE has proven useful for quantifying denervation, highlighting a direct correlation with clinimetric evaluation, in most severe forms of CMT. In less disabling forms, such as HNPP, MUNE appears to be less useful, due to the absent of clear correlations with the result obtained on the clinimetric scales. In future studies MUNE should be considered a surrogate laboratory marker to monitor disease course, also in a clinical trial setting.
Disclosure: Nothing to disclose.

EPO-765 | Neurophysiological outcomes of Rituximab responsive inflammatory neuropathies

D. Viola; V. Montano; C. Bravi; E. Schirinzi; G. Siciliano
Department of Clinical And Experimental Medicine, University of Pisa, Pisa, Italy

Background and Aims: Rituximab (RTX) significantly improves the clinical outcome of selected cases of inflammatory polyneuropathies (IPN) resistant to standard treatments. Here we present the preliminary data of a retrospective study we are conducting at the

Neurological Unit of Pisa University Hospital, aiming to characterize the neurophysiological effects of RTX on IPN.

Methods: The following data are collected: a) diagnosis of IPN; b) clinical, laboratory and demographical data; c) Inflammatory Neuropathy Cause and Treatment (INCAT) Disability Score before and after (6 months) RTX treatment; d) electrophysiological data before and after (6 months) RTX treatment. Electroneurography (ENG) parameters measured are: conduction velocity (CV), distal latency (DL) and amplitude (Am).

Results: Eight IPN patients (38% males; mean age 62.6 and SD 10.7 years) were included. Remarkable improvements were observed in in the whole group, with the mean CV and Am increased by 23% and 26% respectively, and DL reduced by 26%. Only two patients did not show a significant response to RTX, with no or limited changes observed after the treatment. Whole group INCAT was significantly lower post RTX treatment ($p = 0.042$).

Conclusion: The longer disease duration of the two non-responder patients (10 and 7 years) compared to the other subjects (3 years) might partially explain their poorer clinical and ENG outcome. This ENG-based study of RTX-treated IPN patients may aid in identifying individuals most likely to benefit from the therapy and refining optimal treatment timelines.

Disclosure: Nothing to disclose.

EPO-766 | Quantitative sudomotor axonal reflex test in patients with chemotherapy induced polyneuropathy

K. Shin; J. Eun

Department of Neurology, Haeundae-Paik Hospital, Inje University

Background and Aims: Chemotherapy induced polyneuropathy (CIPN) is one of the common neurological complications that can occur in patients undergoing cancer treatment. While research on risk factors for CIPN has been conducted, there is limited research specifically focused on small fiber neuropathy (SFN). In this study we conducted quantitative sudomotor axon reflex test to evaluate SFN in CIPN patients. Then, we aimed to identify predictors of SFN by analyzing independent variables.

Methods: This is a retrospective observational study conducted at a single institution. Clinical and electrophysiological variables between groups with SFN and without SFN (non-SFN) were analyzed using *t*-tests, Mann-Whitney tests, and chi-square tests. Logistic regression analysis was performed for variables that showed significant differences.

Results: A total of 102 patients with CIPN included in the study. Among them, 25 patients had SFN and 77 patients did not. When comparing the two groups, significant differences were observed in age ($p = 0.0422$), gender ($p = 0.0221$), history of diabetes ($p = 0.0791$), and history of radiation therapy ($p = 0.0035$). On the other hand, variables such as duration of cancer, duration of chemotherapy, type of chemotherapy agents, and number of chemotherapy agents did not show significant differences. Quality of Life Questionnaire – Chemotherapy Induced Peripheral Neuropathy (QLQ-CIPN20) and the results of the nerve conduction study also did not show significant differences. In logistic regression analysis, the only significant predictor was the history of radiation therapy.

Conclusion: Older age, male, history of diabetes mellitus, and having not been treated with radiation therapy is related with SFN in CIPN patients. Among them, radiation therapy was the most significant factor.

Disclosure: There is no conflict of interest.

EPO-767 | Exploring etiologies and diagnostic precision in hypoglossal neuropathy cases

H. El Mouhajir Mohamed[1]; C. Rodríguez Sánchez[1]; C. Moñino Riquelme[2]; G. Torres Sanchez[1]; L. Garcia-Blanco[3]; A. Juanatey[1]

[1]Neurology Service, Hospital Universitario Juan Ramón Jiménez, Huelva, Spain; [2]Rehabilitation Service, Hospital Universitario Juan Ramón Jiménez, Huelva, Spain; [3]Neurology Service, Complexo Hospitalario Universitario de Ourense, Spain

Background and Aims: Isolated neuropathy of the hypoglossal nerve is a rare cranial neuropathy, typically arising as a secondary condition linked to lesions in one of its five nerve segments (nuclei, cisternal segment, hypoglossal canal, extracranial portion, and tongue segment).

Methods: This study presents a multicentric series involving consecutive patients seeking medical attention for unilateral tongue paralysis. Comprehensive otorhinolaryngological examinations and craniocervical MRI scans were conducted. In cases where these assessments yielded negative results, electromyography was subsequently performed.

Results: The study comprised six patients (4 female, aged 57–84), with all cases detailed in Table 1. Notably, two patients exhibited hypoglossal nerve compression—Pt1 due to synovial cyst in the atlanto-occipital joint, and Pt5 with a clival bone lesion linked to multiple myeloma. Pt2, despite a negative MRI, displayed electromyogram indications of bulbar amyotrophic lateral sclerosis (ALS), and she progressed to bilateral tongue paralysis within a month and full bulbar involvement within 3 months. Pt3 presented with hypoglossal compression at the carotid artery, a unique manifestation of carotid extracranial dissection. Pt4, experiencing idiopathic XII neuropathy, fully recovered within a month. Finally, Pt6 showed a vascular vertebral artery loop at the cisternal nerve portion and was ultimately diagnosed with microvascular XII neuropathy due to multiple vascular risk factors. He demonstrated clinical stability after a thorough examination and several months of follow-up.

Table 1. Patients with unilateral isolated neuropathy of the hypoglossal nerve

	Relevant Comorbidities	Final Diagnosis	Clinical Follow-up
Pt1. Female, 77	None	**Synovial cyst in the atlanto-occipital joint**, occupying the hypoglossal canal	Stability
Pt2. Female, 84	None	**Amyotrophic lateral sclerosis**	Bilateral progression in one month. Bulbar ALS debut
Pt3. Male, 63	Intervened splanchnic aneurysm	**Extracranial carotid artery dissection** with external mural hematoma compressing the hypoglossal nerve	Stability
Pt4. Female, 57	None	**Idiopathic neuropathy**	Full recovery
Pt5. Female, 74	Multiple Myeloma	**Multiple Myeloma lytic lesion** in the lower half of the clivus with meningeal extension, affecting the hypoglossal canal.	Neurological stability. Multiple Myeloma progression
Pt6. Male, 76	Smoker. Hypertension.	**Microvascular** / compressive due to vascular vertebral artery loop at the cisternal nerve segment	Stability

TABLE 1 Patients with unilateral isolated neuropathy of the hypoglossal nerve.

Conclusion: While hypoglossal neuropathy is uncommon, clinicians should remain vigilant for potential secondary etiologies. In instances where routine MRI testing proves inconclusive, electromyography and diligent follow-up play pivotal roles in ensuring an accurate diagnosis.

EPO-768 | Neurofilament light chain as a universal biomarker in neuropathies

I. Glāzere[1]; K. Ivanova[1]; D. Pretkalniņa[1]; T. Čupāne[2]; M. Roddate[1]; V. Ķēniņa[1]

[1]Riga Stradinš University, Rīga, Latva; [2]Children's Clinical University Hospital, Rīga, Latvia

Background and Aims: Neurofilaments, specifically their light chains (NfL), are released following neuroaxonal injuries. Charcot–Marie–Tooth disease (CMT) is a hereditary neuropathy with no effective treatments or sensitive markers available for clinical use. Chronic autoimmune neuropathies arise from an immune response against peripheral nervous system antigens. NfL levels have potential as biomarkers for both conditions, and this study seeks to assess and compare NfL levels to aid in clinical differentiation and improve patient care.

Methods: In this study, a total of 44 Charcot–Marie–Tooth disease (CMT) patients, 34 individuals with chronic autoimmune neuropathy, and 44 control subjects were included. Plasma neurofilament light chain (NfL) concentrations were quantified using the Single molecule array (Simoa) NfL assay. CMT diagnoses relied on genetic testing, while diagnoses for CIDP and MMN followed the European Federation of Neurological Societies/Peripheral Nerve Society (EFNS/PNS) criteria.

Results: Sex and age distribution did not significantly differ among the groups. Both CMT and autoimmune neuropathy patients exhibited significantly higher NfL levels than controls ($p < 0.05$). Importantly, there was no significant difference in NfL levels between the two patient groups ($p = 0.22$).

Conclusion: Our study confirms elevated NfL levels in CMT, CAN, and SS neuropathy patients compared to controls. Remarkably, despite the distinct nature of these neuropathies, NfL levels did not significantly differ among the patient groups. These findings underscore the potential of NfL as a universal biomarker and warrant further exploration in neuropathology research.

Disclosure: This research has been developed with financing from the Latvian Science Council, Project Discovering biomarkers of disease progression and variability in Charcot-Marie-Tooth neuropathy, No lzp-2021/1-0327.

EPO-769 | Abstract withdrawn

EPO-770 | Temporal kinetics of sensorimotor and autonomic recovery in Guillain Barre syndrome

R. Mahajan; J. Kalita

Department of Neurology, Sanjay Gandhi Post graduate Institute of Medical Sciences, Lucknow, India

Background and Aims: Guillain-Barré syndrome (GBS) is characterized by rapidly progressive quadriparesis with or without sensory or autonomic dysfunction. There is paucity of information regarding recovery pattern in GBS. We evaluate the temporal kinetics of recovery and its pattern among demyelinating (AIDP) and axonal (AMAN) forms.

Methods: Patients with GBS diagnosed on clinical, laboratory and neurophysiological criteria, were included and disabilities were evaluated on Hughes score. Motor, sensory, cranial nerve and autonomic recovery days were recorded and compared among AIDP and AMAN at 3 months. Early recovery was defined as an improvement ≥2 Hughes grades within 4 weeks of symptom onset and late recovery as improvement beyond 4 weeks.

Results: 42 patients were analyzed. Median age was 31 years and 26.2% were females. Autonomic dysfunction recovered in all and at the earliest with median of 12 days (5–69); followed by bulbar weakness and facial weakness with median of 15 days (2–81) & 19 days (4–86) respectively. Sensory function improved over a median period of 20 days (5–66). Motor recovery occurred in 17 (40.5%) patients with median of 65 days (20–90). Dysautonomia occurred more frequently in AIDP (68% vs 10%; $p = 0.03$) than AMAN. Recovery patterns were comparable in AIDP and AMAN. 20 (47.6%) patients had early recovery and proportion of patients in demyelinating vs axonal were similar.

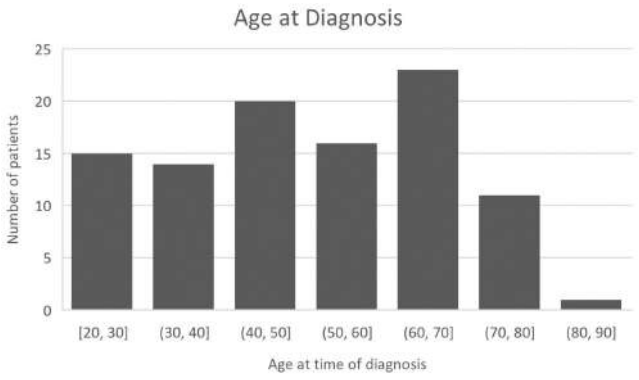
Conclusion: The neurological recovery in GBS occurred first in autonomic followed by bulbar, facial, sensory, and motor functions. The recovery is comparable between AMAN and AIDP.

Disclosure: Nothing to disclosure.

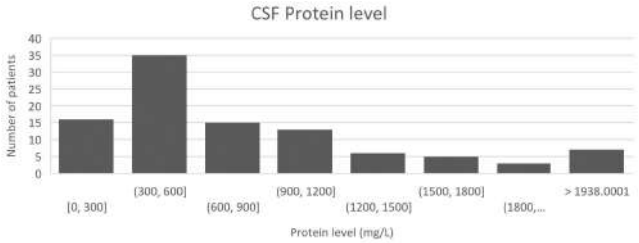
EPO-771 | A 15-year retrospective analysis of Guillain Barre syndrome in the adult population of the Maltese Islands

M. Bonello; A. Ferriggi; F. Gauci; H. Schembri; G. Vella
Neurosciences Department, Mater Dei Hospital, Malta

Background and Aims: Guillain Barre Syndrome (GBS) has a worldwide overall incidence rate of 1–2 cases per 100,000 people per year 1. It typically presents with ascending lower limb weakness, associated with hypo/areflexia. Most patient require hospitalization and active treatment with IVIg of Plasma Exchange. The aim of the study is to retrospectively analyze the adult cohort of patients who were admitted with GBS in the Maltese Islands.
Methods: Data were retrospectively collected from National Registries and discharge summaries. Demographic details, infectious screens, lumbar puncture results, nerve conduction study results, treatment regimens and outcomes were collected.
Results: A total of 100 patients were diagnosed with GBS; M = 68. The median age was 53 years. The average length of inpatient acute hospital care was 22.1 days (±32.4SD) (Chart 1). 60% had a previous infection documented. All patients underwent lumbar puncture, most of which happened within 48 hours of admission. 55% of patients had albuminocytological dissociation, with a protein level of >500 mg/L) (Chart 2). 72% were discharged home, 24% needed rehab, 2% passed away during their inpatient stay and 2% required admission to a long-term facility.



Age distribution of our local cohort.



CSF protein levels.

Conclusion: The Maltese population has a similar incidence rate of GBS with a relatively low mortality. Clinical correlation between CSF protein level, presence of positive serum anti-gangliosides and length of hospital stay, and long-term outcomes is being sought.
Disclosure: Nothing to disclose.

EPO-772 | Charcot-Marie-tooth type 2P in a Spanish family with the novel variant in the LRSAM1 gene: p.Gln698_Gln701del

N. Rabaneda-Lombarte[1]; J. Alonso-Pérez[2]; S. Díaz-González[2]; A. Menéndez-Albarracín[1]; B. Yugueros-Baena[1]; A. González-Manero[3]; A. Castellano-Vicente[4]; C. Gómez-López de San Román[5]; C. Casasnovas-Pons[6]; A. Martínez-Piñeiro[1]; S. Figueroa-Bonaparte[1]
[1]Departamento de Neurociencias, Hospital Universitari Germans Trias i Pujol, Badalona; [2]Unidad Enfermedades Neuromuscular, Servicio de Neurología, Hospital Universitario Nuestra Señora de Candelaria, Fundación Canaria Instituto de Investigación Sanitaria de Canarias (FIISC), Tenerife; [3]Servicio de Neurología, Hospital General La Mancha-Centro, Alcázar de San Juan; [4]Servicio de Neurología, Hospital de Valdepeñas, Ciudad Real; [5]Servicio de Neurología, Hospital General de Segovia, Segovia; [6]Servicio de Neurología, Hospital de Bellvitge, L'Hospitalet de Llobregat

Background and Aims: Charcot-Marie-Tooth disease (CMT) is the most common hereditary neuropathy. The CMT2 subtype is typically caused by mutations in MFN2 and GDAP1; other genes such as LRSAM1 are exceptional. LRSAM1 mutations specifically cause CMT2-P, characterized by progressive sensory-motor neuropathy. Twelve mutations in LRSAM1 causing CMT2-P have been documented, but each one has been reported only in a single individual or family. Here, we present a Spanish family with dominant CMT2-P associated with a novel mutation in LRSAM1 recently identified in a single study in French families.
Methods: Analysis of clinical, electrophysiological, and laboratory findings of patients diagnosed with CMT2-P and carriers of the c.2093_2104del mutation in LRSAM1 gene.
Results: Eight patients within a single family were identified, with onset spanning 23–52 years. Pes cavus were the onset symptom in 5 patients. Currently, they exhibit distal weakness in upper limbs (1 patient), lower limbs (3 patients), or both (3 patients). Bilateral atrophy of hand interossei muscles and short extensor muscle of toes was observed. Achilles areflexia was evident in all patients, with patellar areflexia in 5. Seven experienced lower limbs hypoesthesia, and 3 neuropathic pain. A sensory predominant axonal polyneuropathy was observed in all patients, with a motor component in 5. Exome sequencing revealed the heterozygous pathogenic variant c.2093_2104del (p.Gln698_Gln701del) in the LRSAM1 gene.
Conclusion: This study reports for the first time a Spanish family afflicted by the p.Gln698_Gln701del variant in the LRSAM1 gene causing CMT2-P. The presence of pes cavus and axonal sensory polyneuropathy are characteristic features of this disease.
Disclosure: None.

EPO-773 | Clinical outcomes, disease course, and QoL in patients with multifocal motor neuropathy: iMMersioN, study in progress

S. Peric[1]; L. Querol[2]; S. Altamimi[3]; I. Van de Walle[4]; E. Persson[4]; I. Van Hoomissen[4]; G. Szmyd[4]; M. Vujcic[4]; M. Hamwright[4]; O. Van de Steen[4]; C. Arvin-Bérod[4]; J. A. Allen[5]
[1]*University of Belgrade, Faculty of Medicine, Neurology Clinic, University Clinical Center of Serbia, Belgrade, Serbia;* [2]*Hospital de la Santa Creu i Sant Pau, Neuromuscular Disorders Unit, Barcelona, Spain;* [3]*The Neurology Group, Pomona, CA, USA;* [4]*argenx, Ghent, Belgium;* [5]*University of Minnesota, Department of Neurology, Minneapolis, MN, USA*

Background and Aims: Multifocal motor neuropathy (MMN) is a rare, peripheral, immune-mediated, chronic neuropathy resulting from motor nerve conduction block due to IgM auto-antibodies leading to axonal degeneration and progressive disabling asymmetric limb weakness with absence of sensory loss. Data on patient experience and clinical management of MMN are limited to small cohorts and retrospective analyses. There is a need to further understand MMN diagnosis, disease course and management and to characterise the healthcare resource use of patients with MMN.
Methods: iMMersioN (NCT05988073), a global, prospective, longitudinal study, will enrol approximately 150 participants. No investigational medicinal product will be administered. Participants will be observed as they receive standard of care treatments. Site visits will coincide with regular MMN treatment visits and will occur approximately every 3 months, and participants will be followed for up to 24 months. In certain countries, optional blood samples may be collected from participants.
Results: The objectives of the iMMersioN study are: to characterise MMN participant profiles, assess disease management and disease course, including outcomes measures such as MMN-RODS, MMRC-10, and adjusted INCAT, estimate the economic burden and impact of MMN on quality of life, and collect data on relevant disease biomarkers such as autoantibody titers against gangliosides, components of the complement cascade, and a marker of neurological degeneration. The first participant was enrolled on 29 November 2023.
Conclusion: iMMersioN is an ongoing global, prospective, longitudinal study to examine clinical outcomes, disease course, resource utilization and health-related quality of life in adult patients with MMN.
Disclosure: SP received lecture honoraria from argenx, Viatris, Pfizer, Teva Actavis, Berlin-Chemie Menarini, Mylan, Wörwag, ADOC, Remedica and Salveo; research grants from argenx, Kedrion Biopharma and Octapharma; consultant fees from argenx, Dianthus Therapeutics and Mylan; and travel grants from Octapharma, Kedrion Biopharma, Teva Actavis, Sanofi Genzyme, Pfizer, Roche, ADOC, Wörwag, Medis, and Berlin-Chemie Menarini; and reports no other conflicts of interest outside or related to this work. JA has received consulting honoraria from argenx, Alexion, Akcea, CSL Behring, Johnson & Johnson, Grifols, Takeda, and Sanofi.

MS and related disorders 7

EPO-774 | Abstract withdrawn

EPO-775 | Nocturnal melatonin ingestion alleviated dynamic postural imbalance and muscle weakness in multiple sclerosis

S. Jallouli[1]; S. Sakka[2]; M. Damak[2]; S. Ghroubi[1]; I. Ben Dhia[1]; A. Yahia[1]; C. Mhiri[2]; M. Elleuch[1]; O. Hammouda[3]
[1]*Research Laboratory of Evaluation and Management of Musculoskeletal System Pathologies, LR20ES09, University of Sfax, Sfax Tunisia;* [2]*Laboratory of Neurogenetics, Parkinson's Disease and Cerebrovascular Disease (LR12SP19), Habib Bourguiba University Hospital, University of Sfax, Sfax, Tunisia;* [3]*Interdisciplinary Laboratory in Neurosciences, Physiology and Psychology: Physical Activity, Health and Learning (LINP2), UFR STAPS, UPL, Paris Nanterre University, Nanterre, France*

Background and Aims: Endogenous melatonin (MEL) deficiency in patients with multiple sclerosis (PwMS) was linked to pain and fatigue that induce postural imbalance and muscle weakness. Exogenous MEL has been shown to present anti-fatigue and analgesic effects. Despite this association between physical and perceptual disorders, no study has examined the acute effect of MEL intake on dynamic postural stability and muscle strength in PwMS. This study aimed to investigate the effect of nocturnal MEL ingestion on dynamic postural control and leg muscle strength the following morning in PwMS.
Methods: Fourteen PwMS (28.36 ± 6.81 years) were assessed before and after nocturnal ingestion of 6-mg MEL or placebo (PLA). A force platform was used to evaluate dynamic postural balance in the frontal and sagittal planes. Leg muscles strength (5-sit to stand test (5-STST)), fatigue (Hooper index), nociceptive pain (visual analogue scale (VAS)), and neuropathic pain neuropathic pain 4 questions (DN4)) were also evaluated.
Results: MEL decreased posturographic parameters compared with PLA [frontal plane: center of pressure (CoP) path length (CoPL): 7.56% ($p = 0.02$), mean CoP velocity: 11.1%, ($p = 0.00003$); sagittal plane: only CoPL: 9.1% ($p = 0.005$)]. MEL reduced duration of 5-STST, and scores of VAS and DN4 compared with PLA (8.19% ($p = 0.008$), 84.44% ($p = 0.04$) and 37.69% ($p = 0.023$), respectively). Compared

with PLA, MEL alleviated fatigue (42.29% ($p=0.044$)) and enhanced sleep quality (30.2% ($p=0.012$)).

Conclusion: A single dose of MEL enhanced dynamic postural stability and lower-extremity muscle strength probably through alleviating pain, fatigue, and sleep disorders in PwMS.

Disclosure: Nothing to disclose.

EPO-776 | Incidence of relapses after meningococcal vaccination in clinical trials of eculizumab and ravulizumab in AQP4+ NMOSD

S. Fam[1]; K. Allen[2]; B. Parks[3]

[1]*Global Medical Affairs, Alexion, AstraZeneca Rare Disease, Boston, MA, USA;* [2]*Biostatistics, Alexion, AstraZeneca Rare Disease, Boston, MA, USA;* [3]*Clinical Development, Alexion, AstraZeneca Rare Disease, Boston, MA, USA*

Background and Aims: Ravulizumab and eculizumab are complement C5 inhibitors (C5ITs) approved for anti-aquaporin-4 antibody-positive (AQP4+) neuromyelitis optica spectrum disorder (NMOSD). Because C5ITs are associated with increased *Neisseria meningitidis* infection risk, patients are generally advised to be vaccinated ≥2 weeks before receiving C5ITs; however, vaccination may further activate the complement pathway. Patients with complement-mediated diseases, including NMOSD, may experience increased signs and symptoms of their underlying disease when vaccinated before C5IT initiation. We report on relapses occurring within 4 weeks of meningococcal vaccination administered before initiating C5IT in patients screened in CHAMPION-NMOSD (NCT04201262) and enrolled in PREVENT (NCT01892345).

Methods: Patients analyzed included those with vaccination data who were screened in CHAMPION-NMOSD, irrespective of screening outcome, and those randomised to placebo or eculizumab in PREVENT (vaccination data unavailable for screen failures). Outcomes were relapses occurring within 4 weeks of last meningococcal vaccination and before study drug initiation.

Results: In CHAMPION-NMOSD ($N=71$), 1 enrolled patient was excluded from this analysis because of vaccination before AQP4+ confirmation. Among remaining patients (57 enrolled; 13 screen failures), 2/70 (2.9%) patients experienced a relapse; both were screen failures. In PREVENT, 3.1% (3/96) of eculizumab and 10.6% (5/47) of placebo patients had a relapse.

Conclusion: This retrospective analysis indicates a low relapse incidence (2.9%–3.1%) within 4 weeks of meningococcal vaccinations before C5IT initiation and up to 10.6% for those randomised to placebo. Available information precludes determination as to whether relapses observed are attributable to meningococcal vaccination or inherent relapse risk among patients with AQP4+ NMOSD.

Disclosure: All authors are employees of Alexion, AstraZeneca Rare Disease and hold stock options in AstraZeneca. This study was funded by Alexion, AstraZeneca Rare Disease. Medical writing and editorial support were provided by James Banigan, PhD, CMPP, and Melissa Austin of Apollo Medical Communications (Guilford, CT), part of Helios Global Group, with funding from Alexion, AstraZeneca Rare Disease.

EPO-777 | MS-STAT2 (UCL cohort) baseline analysis: ABILHAND and nine-hole peg test in secondary progressive multiple sclerosis

S. Apap Mangion[1]; C. Wade[1]; T. Williams[1]; N. John[2]; A. Calvi[1]; A. Bianchi[1]; F. Dr Angelis[1]; A. Doshi[1]; S. Wright[1]; M. Shatila[1]; M. Braisher[1]; J. Blackstone[3]; R. Farrell[1]; J. Chataway[1]

[1]*Queen Square Multiple Sclerosis Centre, Department of Neuroinflammation, UCL Queen Square Institute of Neurology, Faculty of Brain Sciences, University College London, London, UK;* [2]*Monash University, Department of Medicine, School of Clinical Sciences, Clayton, Australia;* [3]*Comprehensive Clinical Trials Unit, Institute of Clinical Trials and Methodology, University College London, London, UK*

Background and Aims: Upper limb (UL) dysfunction affecting 80% of people with MS is associated with reduced independence and quality of life. The Nine-Hole Peg Test (9HPT) is an important progressive MS clinical trial measure, ABILHAND is a 23-item patient reported outcome measure (PROM) covering UL function, shown to correlate variably with the 9HPT depending on the trial mean/median EDSS. Given the ease with which PROMs can be collected, it is important to assess their potential to predict trial relevant clinically reported measures.

Methods: Blinded ABILHAND total scores were calculated, logits calculated using rehab-scales.org, and analysis with reciprocal 9HPT performed using Spearman's correlation and linear regression.

Results: ABILHAND data from 232 trial participants (female $n=177$, male $n=54$), median EDSS of 6.0 (4.0 to 6.5) was analysed. The mean dominant hand 9HPT was 34.1 s, and non-dominant was 34.4 s. Correlation between ABILHAND total score and reciprocal 9HPT was moderate (rho −0.53). There was not a significant change when subgrouping into low/high EDSS groups; or scoring only the easy/difficult ABILHAND items. ABILHAND total scores accounted for variance of: 18% of the 9HPT dominant hand, 27% of the non-dominant hand, and 27.8% of the combined result.

Conclusion: ABILHAND has moderate negative correlation with 9HPT. The discrepancy in hand variance accountability may reflect the implied practical bimanual functionality assessed in the ABILHAND items, and relatively reduced functional reserve of the non-dominant hand. However ultimately the variance was similar when 9HPT results were combined. Longitudinal information will be available late 2024/early 2025 to explore this relationship in more detail.

Disclosure: In the last 3 years, JC has received support from the Health Technology Assessment (HTA) Programme (National Institute for Health Research, NIHR), the UK MS Society, the US National MS Society and the Rosetrees Trust. He is supported in part by the NIHR University College London Hospitals (UCLH) Biomedical Research Centre, London, UK. He has been a local principal investigator for a trial in MS funded by MS Canada. A local principal investigator

for commercial trials funded by: Ionis and Roche; and has taken part in advisory boards/consultancy for Biogen, Janssen, Lucid, Merck, NervGen, Novartis and Roche. The other authors have no disclosures related to this work.

EPO-778 | Autologous hematopoietic stem cell transplantation (AHSCT) in relapsing multiple sclerosis (RMS): A real-world study

S. Malucchi[1]; F. Sperli[1]; R. Bottero[1]; M. Lo Re[1]; D. Quartana[1]; A. Oggero[1]; M. De Gobbi[2]; A. Bertolotto[3]; M. Malentacchi[1]; A. di Sapio[1]

[1]*Department of Neurology and CRESM, University Hospital San Luigi Gonzaga, Orbassano (Italy);* [2]*Department of Clinical and Biological Sciences, University Hospital San Luigi Gonzaga, Orbassano, Italy;* [3]*NICO-Neuroscience Institute Cavalieri Ottolenghi, Orbassano, Italy; Koelliker Hospital, C.so Galileo Ferraris, Turin, Italy*

Background and Aims: In recent years treating MS patients early and efficaciously has become prevalent. Literature data agree that a better treatment response occurs when therapy starts in the early phase. The use of AHSCT in MS evolved, passing from a "rescue therapy" in patients who failed all the available DMTs, to an earlier use. No guidelines exist about its correct placement in drugs sequencing; due to its safety profile, AHSCT is usually reserved to patients with hyperaggressive onset or poor responder to highly efficacious therapies. Aim of the study: to describe a series of 24 RMS patients who received AHSCT in our Center.

Methods: 24 RMS patients underwent AHSCT between 2001 and 2023; 23 had a relapsing remitting course, 1 had a relapsing progressive course. Two out of 24 had an aggressive onset. Clinical and demographic characteristics are presented in table 1. 15 patients received BEAM+AGT as conditioning regimen, 1 received BEAM without ATG; 1 patient received only BEAM and subsequently underwent a second AHSCT.

Results: Median EDSS changed from 2.0 at the time of AHSTC to 1.5 at the last follow up visit. 62.5% patients were in NEDA-3 status at the last visit. Limiting the analysis to patients who received BEAM+AGT as conditioning regimen, 82.3% was in NEDA-3 status at the end of follow up. No major adverse event occurred.

Table 1: Patients' characteristics

PATIENTs	
F/M	18/6
Disease phenotype (n°)	RR (23); RP (1)
Age at AHSCT	18 - 46 years (median 28 years)
Disease duration at AHSCT	0.5-16.7 years (median 6.8 years)
EDSS at AHSCT	1.0 - 9.0 (mean 3.2; median 2.0)
N° of previous DMTs	0-5 (median 2)
Follow up after AHSCT	0.5-20.6 years (median 8 years)

RR: relapsing remitting
RP: relapsing progressive

Conclusion: AHSCT represents a highly efficacious treatment in patients with aggressive disease course. Careful selection and both hematological and neurological evaluation should be performed in order to better define risks and benefits.

Disclosure: SM received speaker honoraria from Biogen, Merck, Sanofi, Novartis, Roche. FS received honaria for talking from Novartis. MM received compensation from Alexion and Novartis. ADS received honoraria from Biogen, Novartis, Roche, sanofi, Merck, Alexion and Sandoz and has been reimbursed by Merck, Biogen, Sanofi, Novartis and Roche for attending conferences.

EPO-779 | The remyelinating potential of non-invasive neuromodulation and its effects on cognition

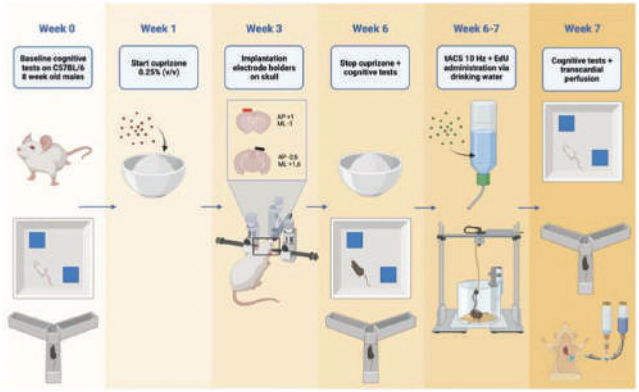
T. Scheinok[1]; J. Van Schependom[1]; D. De Bundel[2]

[1]*AIMS Lab, Center for Neurosciences, UZ Brussel, Vrije Universiteit Brussel, Brussel, Belgium;* [2]*Laboratory of Pharmaceutical Chemistry, Drug Analysis and Drug Information (FASC), Vrije Universiteit Brussel (VUB), Brussels, Belgium*

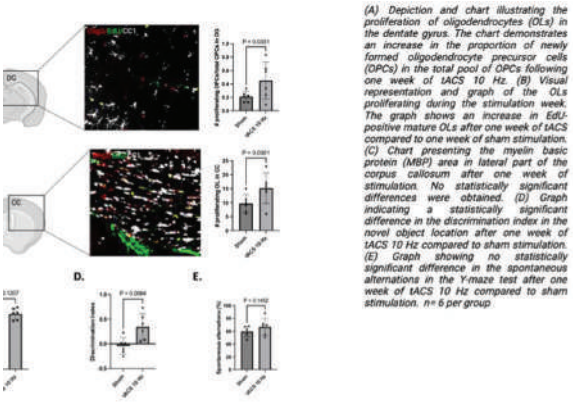
Background and Aims: Previous preclinical studies have revealed that neuronal activity can enhance remyelination and that different patterns of neuronal activity can be sensed by oligodendrocytes. These techniques, however, are not translatable to people with MS due to their invasive nature. In that regard, we intend to investigate the potential of tACS at different frequencies in the cuprizone model.

Methods: Eight-week-old mice receive a cuprizone diet for six weeks enabling demyelination whereafter the mice are reverted to a normal diet allowing partial remyelination. During the withdrawal phase, mice receive either tACS at one, five or 10 Hz or sham stimulation for a week. Readouts include cognitive tests such as the novel object location task and the y-maze as well as immunohistochemistry.

Results: Preliminary results indicate that one week of tACS at 10 Hz leads to improved cognition as demonstrated by improvements in the discrimination index during the novel object location task ($p = 0.0064$). The improvements were not associated with enhanced remyelination in the corpus callosum ($p = 0.1207$). However, the number of mature oligodendrocytes colocalizing EdU was increased in the corpus callosum after one week of tACS 10 Hz compared to sham stimulation ($p = 0.0301$).



Overview of the project.



(A) Depiction and chart illustrating the proliferation of oligodendrocytes (OLs) in the dentate gyrus. The chart demonstrates an increase in the proportion of newly formed oligodendrocyte precursor cells (OPCs) in the total pool of OPCs following one week of tACS 10 Hz. (B) Visual representation and graph of the OLs proliferating during the stimulation week. The graph shows an increase in EdU-positive mature OLs after one week of tACS compared to one week of sham stimulation. (C) Chart presenting the myelin basic protein (MBP) area in lateral part of the corpus callosum after one week of stimulation. No statistically significant differences were obtained. (D) Graph indicating a statistically significant difference in the discrimination index in the novel object location after one week of tACS 10 Hz compared to sham stimulation. (E) Graph showing no statistically significant difference in the spontaneous alternations in the Y-maze test after one week of tACS 10 Hz compared to sham stimulation. n= 6 per group

Summary of the results.

Conclusion: One week of tACS at 10Hz during the withdrawal phase of cuprizone leads to improved spatial working memory. While we do not show increased remyelination, we do report an acceleration of maturation of OLs within the OLs proliferating in the corpus callosum. Future experiments will confirm whether these findings can be confirmed and whether different stimulation frequencies might be more effective in remyelination.

Disclosure: Thomas Scheinok received a travel grant from Merck of 250 euros for the EAN congress in 2022. Other authors have nothing to disclose.

EPO-780 | Effectiveness of telemedicine neurologic examination in real-life settings

Background and Aims: The importance of telemedicine applications in neurology practice has been widely recognized during the COVID-19 period, although there is no clear scientific evidence about the feasibility of general neurological examinations performed with telemedicine. In this study, we aimed to determine the effectiveness of telemedicine neurologic examination (TNE) in real-life conditions and in various disease groups.

Methods: In this multicenter, prospective, and cross-sectional study, patients with various neurological diagnoses were first evaluated face-to-face. These patients were then evaluated by a randomly assigned physician via TNE in terms of 42 different components performed with video conferencing tools used by the public in daily life. These components were scored as categorical variables. Fleiss-Kappa analysis was used for interrater agreement.

Results: The study included 93 patients 64 of whom were female. Among all, 39 patients had demyelinating diseases, 15 headaches, 9 movement disorders, 6 dementia, 8 neuromuscular diseases, 6 epilepsy, 5 strokes, and 4 other neurological disorders. During the in-person examination, 17.2–50.5 percent of the patient population had abnormal neurological findings in four different domains.

The telemedicine exam had almost perfect interrater agreement in 4 domains (Kappa > 0.8), substantial agreement in 16 domains (Kappa = 0.6–0.8), moderate agreement in 10 domains (Kappa = 0.4–0.6), and slight agreement in 8 domains (Kappa = 0.2–0.4). Although a rather heterogeneous distribution was observed in all neurological examination domains, the best performance was observed in cranial nerve examinations, paresis testing, and cerebellar system examinations.

Conclusion: Our study provides scientific evidence that many components of the neurological examination can be effectively implemented with telemedicine.

Disclosure: Nothing to disclose.

EPO-781 | Conversational agent engagement patterns among individuals with MS: A retrospective analysis of the mHealth application

S. Demir[1]; S. Colakoglu[2]; Z. Polat[2]; M. Durmus[2]; E. Sezgin[3]; M. Tutuncu[4]

[1]*University of Health Science, Sancaktepe Sehit Prof.Dr.Ilhan Varank Training and Research Hospital, Department of Neurology, Istanbul, Turkey;* [2]*Albert Heath Ltd, Clinical Development & Research;* [3]*Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH, USA; The Ohio State University College of Medicine, Columbus, OH, USA;* [4]*Istanbul University – Cerrahpasa, Department of Neurology, Istanbul, Turkey*

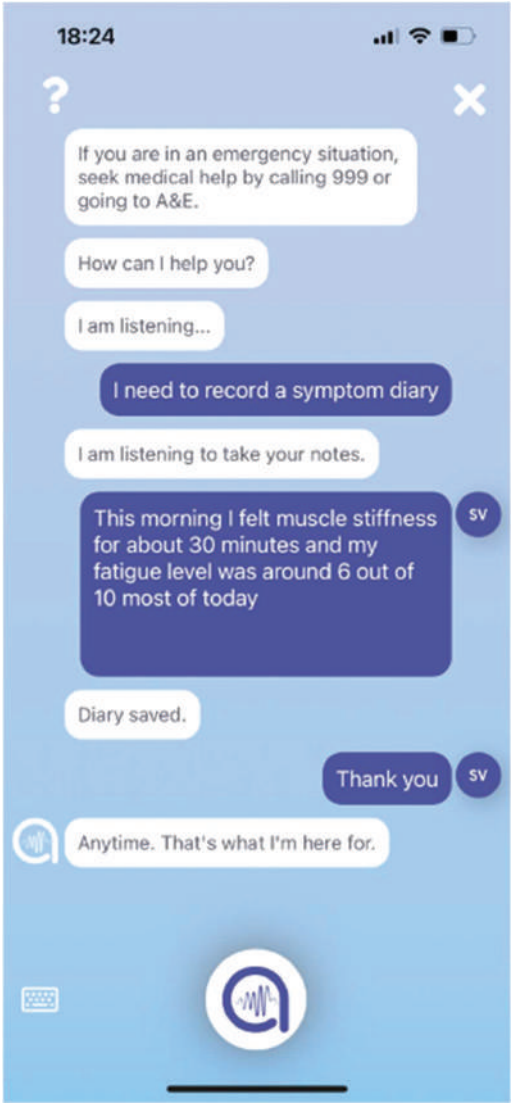
Background and Aims: This study analyzes the engagement patterns of MS-diagnosed individuals with "Albert MS+" a mHealth application tailored for MS self-management and remote monitoring, with conversational agent (CA) support.

Methods: We retrospectively analyzed the data based on the intent classification during conversations with CA such as accessing health information, recording clinical parameters, treatment-related queries, small talk, and fallbacks.

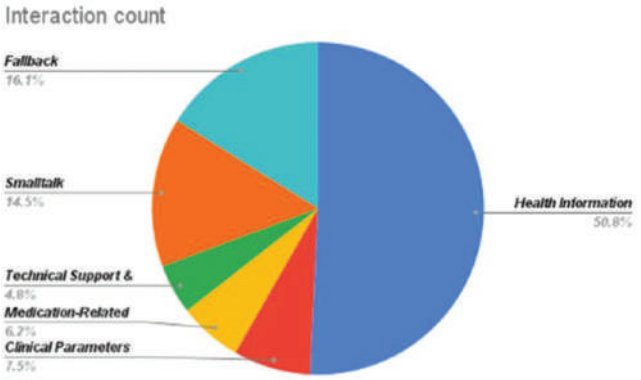
Results: A total of 263 individuals diagnosed with MS for up to 20 years were enrolled to use Albert. Out of these, 125 participants interacted with the CA 1196 times between 2022 and 2023. The demographic profile showed an average age of 36.3 years with a predominance of females (72.57%) and a high educational background, as 69.6% are university graduates. The average duration since diagnosis was 7.5 years. Health Information accounted for 50.8% of total interactions. Within this category, the specific queries around MS, telehealth, and pharmacy information represent significant areas of user engagement indicating a high demand for accessible health-related information. Clinical parameters and medication-related topics together made up 13.7% of interactions. Smalltalk constituted 14.5% of the interactions. Fallbacks comprised 16.1% of interactions, this highlights opportunities for improving the agent's understanding and response accuracy.

Intent Category	Definition	Conversation examples
Health Information	This category includes interactions about health advice or medical knowledge specifically related to Multiple Sclerosis (MS). Example: - Ask MS-related health questions, - Show pharmacy on duty, - Get a telehealth appointment	User: Is there a specific diet that's recommended for someone with MS? CA: There's no one-size-fits-all diet for MS. Some individuals with MS follow specific diets, like the Mediterranean diet or low-saturated fat diets, to manage their symptoms. You can consult with a nutritionist in the app or your healthcare provider on your next visit for personalized advice. Also, you can watch the video in the app that provides useful dietary tips for MS patients. User: Thank you.
Clinical Parameters	This category focuses on tracking and recording clinical data related to MS or other health metrics such as blood pressure, blood glucose level Example: - Record a symptom diary - Record blood pressure or glucose level, - Upload a clinical document (e.g. lab report)	User: I'd like to track my MS symptoms over time. CA: Keeping a symptom diary can be very helpful. You can log your symptoms, their severity, and any factors you think might be contributing to them. We also have a feature in the app that allows you and your physician to track your symptoms and view trends over time. Would you like to start by recording today's symptoms? User: Yes, that would be great. CA: I'm listening ...
Medication - Related	Actions related to the management and understanding of medications, supplements, or treatments, applicable to routine health maintenance or MS-specific management. Example: - Record medication, - Mark medication as taken, - Show daily medication schedule	User: I need to record my new medication. CA: Can you tell me the name of the medication? User: Fingolimod. CA: Your medication is saved as Fingolimod. You can edit it later from the My Health menu. How often should I remind you this? User: Once a day. CA: What time will you be taking it? User: 9 a.m. CA: I recorded your medication info and set a reminder
Non-clinical	Casual interactions and system guidance to ensure a comfortable and supportive user experience, these address general inquiries and navigate uncertainties. Example: -Fallback, -Smalltalk, -Technical Support & Guidance	User: [Attempts to speak, but the speech is unclear and not transcribed correctly] CA: I'm sorry, I didn't catch that. Could you please repeat what you just said? User: [Attempts to speak again, but the speech is still unclear and not transcribed correctly] CA: It seems we're having trouble understanding your message. I apologize for the inconvenience. If you're experiencing an urgent issue, it's important to contact a healthcare professional directly or dial emergency services. Remember, this platform is not a substitute for professional medical advice, diagnosis, or treatment. Please try to rephrase your concern or reach out to your healthcare provider for immediate assistance.

Categories of intents created by the patients using the app.



An example of a clinical parameter recorded by a patient via conversational agent.



The distribution of intent categories.

Conclusion: The analysis underscores the conversational agent's role in providing health information, and supporting self-management and indicates a potential to enhance user experience by improving its response capabilities.
Disclosure: Nothing to disclose.

EPO-782 | Prognostic biomarkers of silent progression in multiple sclerosis (MS): Report from an Italian cohort

V. Gasparini[1]; M. Jaafar[1]; T. Carandini[2]; L. Ghezzi[3]; F. Certo[1]; M. De Riz[2]; C. Fenoglio[3]; F. Triulzi[2]; D. Galimberti[3]; A. Pietroboni[2]
[1]University of Milan, Milan, Italy; [2]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]Department of Biomedical, Surgical and Dental Sciences, Dino Ferrari Center, University of Milan, Milan, Italy

Background and Aims: Silent progression is a central topic in MS, with a lack of prognostic indicators. This study aims to discern radiological and biochemical markers to identify silent progressors from relapsing-remitting MS (RR-MS).
Methods: A total of 42 untreated RR-MS subjects were enrolled. Twenty-two out of 42 were identified as silent progressors (SiPr) (Cree et al., 2019). Each patient underwent a 3-Tesla Magnetic Resonance Imaging (MRI) at diagnosis. Serum levels of neurofilaments light chains (Nfl) and Glial Fibrillary Acidic Protein (GFAP) were assessed on 29 subjects. Comparison between groups were analyzed using Student *t*-tests or the non-parametric Mann-Whitney test. Univariate and multivariate linear regression analysis were performed to assess association between different neuroradiological quantitative data and being SiPr.
We used Spinal Cord Toolbox (SCT) software to acquire cervical spinal cord volumes at C2-C3 from T1-weighted MRI images. SCT created a 3D mask, and convolutional neural networks (CNN) facilitated spinal cord segmentation.
Results: At the univariate analysis lesion load, count of cortical and spinal lesions, choroid plexus volume, and cervical spinal cord volume resulted predictors of silent progression. However, at the multivariate analysis, only the number of spinal cord lesions was a significant predictor of silent progression. No significant differences in Nfl and GFAP levels were noted across groups.

	OR	95%CI		p (<0.05)
Number of lesions	1.04	1.01	1.07	**0.022**
Lesion load	1.13	1.02	1.25	**0.019**
Cortical lesions	1.24	1.05	1.46	**0.010**
Spinal lesions	5.72	2.08	15.67	**0.001**
Paramagnetic Rim Lesions	14.24	0.92	219.75	Not significant (0.057)
NchP	3.70	1.13	12.20	**0.031**
Cervical volume	0.80	0.67	0.96	**0.016**

Univariate analysis of radiological characteristics among non-SiPr and SiPr. OR: odds ratio; CI: confidence intervals; NchP: normalized choroidal plexus volume.

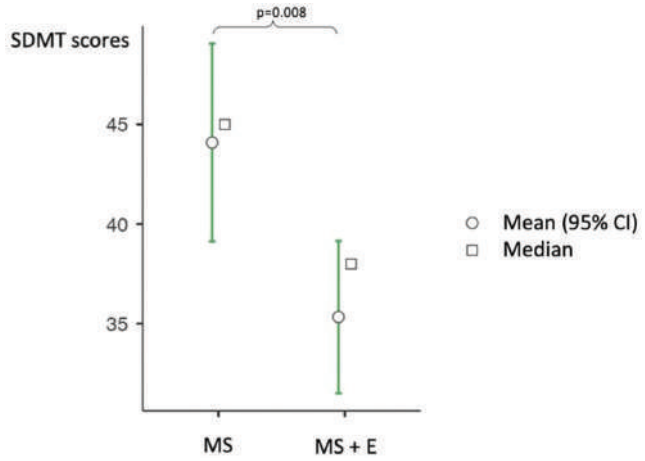
Conclusion: The study highlights spinal cord lesions as key predictors of silent progression in MS. SiPr presented a more enlarged choroidal plexus compared to non-SiPr patients, suggesting a chronic inflammatory state and an impairment of periventricular remyelination. Identifying RR-MS patients with worse prognosis and faster progression from onset could enable targeted therapeutic interventions for improved outcomes.
Disclosure: Nothing to disclose.

EPO-783 | Cognitive and neuropsychological features among patients with multiple sclerosis and epilepsy

V. Pozzilli[1]; C. Tortorella[2]; L. Prosperini[2]; S. Ruggieri[2]; S. Haggiag[2]; C. Gasperini[2]; A. Cruciani[1]; F. Capone[1]; V. Di Lazzaro[1]; L. Celani[1]; G. Evangelista[3]; G. De Luca[3]; S. Cipollone[3]; V. Tomassini[3]; F. Dono[3]
[1]Department of Neurology, Neurophysiology and Neurobiology, University Campus Bio-Medico, Rome, Italy; [2]Department of Neurosciences, San Camillo-Forlanini Hospital, Rome Italy; [3]Institute for Advanced Biomedical Technologies (ITAB) and Department of Neurosciences, Imaging and Clinical Sciences, University G. d'Annunzio of Chieti-Pescara, Chieti, Italy; MS Centre, SS. Annunziata University Hospital, Chieti, Italy

Background and Aims: Epilepsy is 2–3 fold more common in patients affected by multiple sclerosis (pwMS) compared to the general population. Currently it is not elucidated whether patients with MS and epilepsy (MS+E) exhibit distinct cognitive and neuropsychological features compared to MS patients.

Methods: Our study aimed to assess the cognitive and neuropsychological impact of epilepsy on MS. Data including clinical features of MS, epilepsy, and medications were collected. Neuropsychological tests including the brief cognitive assessment for MS (BICAMS), the general anxiety disorder-7, beck's depression inventory and symptom checklist-90 for psychiatric morbidity were administered.
Results: kkThirty-three MS+E patients and 33 MS controls matched for age, sex and MS duration were included. MS+E individuals showed lower processing speed ($p < 0.01$) and visuospatial memory scores ($p = 0.03$). Seizure onset timing influenced seizure freedom, as in those who manifested their first seizure within 1 year of MS onset had higher seizure freedom rates ($p = 0.03$). Slowing and/or epileptic activity in at least one EEG were associated with elevated psychological distress. In MS+E patients, higher levels of psychological distress were associated to lower verbal learning test abilities ($p = 0.04$). Compared to the general population, MS+E patients yielded higher scores in somatization, depression, anxiety, phobia, paranoid ideation, and psychoticism ($p < 0.001$), with phobia deviating the most from normative values.



Symbol digit modalities test (SDMT) scores in patients with MS + E (epilepsy) compared to MS.

Conclusion: Epilepsy in MS is associated to worse cognition and psychological morbidity, particularly phobia. This suggests a need for comprehensive patient care, possibly addressing the neuropsychological aspect. Larger studies are needed to confirm such findings.
Disclosure: Nothing to disclose.

EPO-784 | Assessing spatio-temporal pattern of thalamic damage in multiple sclerosis patients

V. Penati[1]; E. Portaccio[1]; A. Caporali[1]; M. Betti[1]; C. Ballerini[1]; C. Fabbiani[2]; R. Bonacchi[3]; E. Fainardi[2]; E. De Meo[1]; M. Amato[1]
[1]*Department of Neurofarba, University of Florence, Florence, Italy;* [2]*Neuroradiology Department, Careggi, Florence, Italy;* [3]*Neuroradiology Department, Vita-Salute San Raffaele University, San Raffaele Hospital, Milan, Italy*

Background and Aims: Thalamic atrophy is one of the earliest changes occurring during multiple sclerosis. Several pathogenetic mechanisms underlying thalamic damage have been hypothesized including Wallerian degeneration from white matter lesions (WM) and cerebrospinal fluid (CSF)-immunocytotoxic factors mediated damage. We aim to identify long-term trajectories of thalamic nuclei damage and the contribution of its progression in determining clinical disability and cognitive impairment.
Methods: A cohort of 108 MS patients underwent annual 3T MRI scans (3DT1- and T2-weighted images) and clinical/cognitive assessments for up to 8 years from disease onset. Thalamic nuclei segmentation was performed using Freesurfer 7.2.0. Growth models by alternating conditional expectation evaluated long-term thalamic volume changes. Linear regression models determined the relationship between thalamic damage progression and clinical disability and cognitive decline.
Results: Bilateral thalamic nuclei adjacent to CSF exhibited a slower, steady volume loss, while those near white matter demonstrated rapid progression. Using growth models, we identified a relative progression index (γ), reflecting shared variance in thalamic nuclei volumes. Significant correlations were found between γ and clinical disability, information processing speed, and executive functions.
Conclusion: The study confirms heterogenous pathogenetic mechanisms in thalamic damage: Wallerian degeneration due to macroscopic white matter damage and CSF-cytotoxic mediated damage. The identified index (γ) effectively links thalamic damage to cognitive impairment and clinical disability, suggesting its potential as a biomarker for disease monitoring and aiding in treatment strategy identification.
Disclosure: Nothing to disclose.

EPO-785 | Carotid intima media thickness, neutrophil to lymphocyte ratio, and platelet to lymphocyte ratio in multiple sclerosis

N. Eissazade[1]; S. Eghdami[2]; E. Alizadeh Najmi[3]; D. Hemmati[1]; Z. Mirzaasgari[3]
[1]*Student Research Committee, School of Medicine, Iran University of Medical Sciences, Tehran, Iran;* [2]*Cellular and Molecular Research Center, Iran University of Medical Sciences, Tehran, Iran;* [3]*Department of Neurology, Firoozgar Hospital, School of Medicine, Iran University of Medical Sciences, Tehran, Iran*

Background and Aims: Limited evidence suggests that carotid intima-media thickness (cIMT) and neutrophil-to-lymphocyte ratio (NLR) increase in patients with MS. Furthermore, platelet-to-lymphocyte ratio (PLR) can increase in neuroinflammatory and autoimmune diseases, and it is better interpreted when measured along with other biomarkers, such as NLR. We aimed to assess cIMT, NLR, and PLR levels and their possible correlation in patients with MS.

Methods: We included 110 patients and 110 healthy controls in this case-control study. All participants underwent complete history taking, and general and neurological examination. Expanded Disability Status Scale was used to assess disability. cIMT was measured with B-mode ultrasound images, 10 mm before the bifurcation of the common carotid artery.

Results: NLR, PLR, and cIMT were significantly increased in patients with MS, compared to healthy controls ($p < 0.001$). Among patients with MS, higher cIMT ($p < 0.001$) was significantly associated with older age ($p < 0.001$), higher BMI ($p < 0.001$), higher EDSS scores ($p = 0.005$), older age of disease onset ($p < 0.001$) and SPMS type ($p = 0.003$). Further linear regression analysis revealed that cIMT was marginally associated with higher NLR values ($p = 0.055$). After controlling for confounding factors, cIMT was significantly associated with NLR ($p = 0.047$), and not with PLR ($p = 0.2$). The cut-off value of mean cIMT (sensitivity: 84%; specificity: 49%) for discriminating mild-to-moderate and severe disability was calculated as 0.5.

Conclusion: Higher cIMT levels are significantly associated with higher NLR levels. cIMT could be used as a simple, rapid, and cost-effective inflammatory marker for MS disability. Further multicenter studies with larger sample sizes are needed to validate the findings of this study.

Disclosure: Nothing to disclose.

Neuro-ophthalmology/neuro-otology

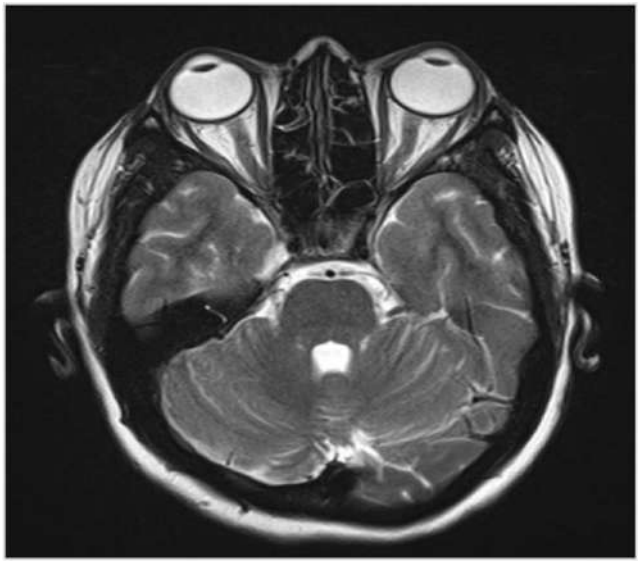
EPO-786 | A case series of five fulminant idiopathic intracranial hypertension (IIH) patients at a tertiary care hospital

S. Mandal; S. Biswas
Bangur Institute of Neurosciences, IPGME&R and SSKM Hospital, Kolkata, India

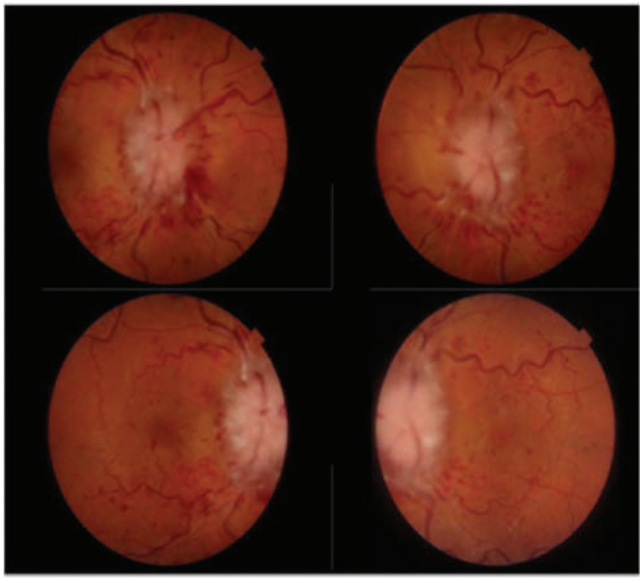
Background and Aims: Fulminant IIH, presents with abrupt symptom onset and signs of intracranial hypertension, progressing to rapid vision decline within four weeks.

Methods: This case series evaluates clinical, ophthalmological, and radiological features in five non-obese female patients aged 28–40 years.

Results: Comprehensive evaluation of these patients, revealed symptoms like acute migranous headache, nausea, diplopia and transient visual obscurations (TVO's). Progression to near-total blindness occurred swiftly within 14 days, with one patient experiencing this within 48 hours. Uniform grade 4 papilledema was observed, including two cases with associated peripapillary hemorrhages. The CSF opening pressure ranged from 35 to 45 cm of H_2O. Optical coherence tomography (OCT) illustrated increased retinal nerve fiber layer (RNFL) thickness. MRI findings aligned with IIH, coupled with evidence of transverse sinus stenosis. Optic nerve sheath diameter (ONSD) measured by MRI exceeded 6mm in all cases. Four patients underwent medical management with acetazolamide and temporary CSF drainage for ongoing rapid visual loss. One patient underwent delayed optic nerve sheath fenestration after conservative management. Notable improvements in headache, nausea, and TVO's with subjective visual function improvement. Visual fields remained severely altered.



MRI consistent with IIH.



Papilledema with peripapillary hemorrhage.

TABLE: CLINICAL, OPTHALMOLOGICAL AND RADIOLOGICAL PARAMETERS

	CASE 1	CASE 2	CASE 3	CASE 4	CASE 5
AGE	33	29	35	40	28
BMI	22 kg/m2	21.6 kg/m2	22 kg/m2	23.7 kg/m2	22.5 kg/m2
VISUAL ACUITY & EOM	Hand movement; B/L lateral rectus palsy	Hand movement; B/L lateral rectus palsy	Hand movement; B/L lateral rectus palsy	Hand movement; B/L lateral rectus palsy	Hand movement; B/L lateral rectus palsy
FUNDOSCOPY	grade 4 papilledema	grade 4 papilledema	grade 4 papilledema+ peripapillary hemorrhage	grade 4 papilledema+ peripapillary hemorrhage	grade 4 papilledema
OCT	RNFL thickening	RNFL thickening	RNFL thickening	RNFL thickening	RNFL thickening
CSF OPENING PRESSURE	38 cm H2O	35 cm H2O	40 cm H2O	45 cm H2O	42 cm H2O
MRI	consistent with IIH*	consistent with IIH*	consistent with IIH*	consistent with IIH*	consistent with IIH*
MR VENOGRAPHY	U/L transverse sinus stenosis	U/L transverse sinus stenosis	B/L transverse sinus stenosis	B/L transverse sinus stenosis	U/L transverse sinus stenosis
ONSD	6.1 mm	6.1 mm	6.3 mm	6.3 mm	6 mm

* MRI findings in IIH: optic nerve tortuosity, flattened posterior aspect of sclera, dilated perioptic sheath, partially empty sella

Conclusion: Fulminant IIH, characterized by distinctive traits, is not universally linked to obesity. Acute symptoms, near-total blindness, grade 4 papilledema, significantly elevated CSF opening pressure, and raised ONSD can help initiate swift identification and management thereby preventing potential permanent visual loss. Immediate medical therapy with temporary CSF drainage is vital in cases of anticipated intervention delay.

Disclosure: Nothing to disclose.

EPO-787 | Clinical and multimodal imaging findings in traumatic optic neuropathy

S. Kamoun[1]; M. Rekik[1]; K. Moalla[2]; A. Jallouli[1]; M. Damak[2]; C. Mhiri[1]; A. Trigui[1]

[1]*Ophthalmology Department, Habib Bourguiba Hospital, Sfax, Tunisia;* [2]*Neurology Department, Habib Bourguiba Hospital, Sfax, Tunisia*

Background and Aims: Traumatic optic neuropathy (TON) is a grave complication of cranio-orbital injury, causing visual involvement. The severity may range from simple contusion to complete avulsion of the optic nerve. We review clinical presentation and multimodal imaging findings in TON.

Methods: Retrospective review of patients with the diagnosis of TON. Clinical records of patients treated in ophthalmology department of Habib Bourguiba Hospital were collected.

Results: Our study included 8 patients with an average age of 22,2 years comprising 7 males and 1 female. All patients complained of sudden vision loss following blunt ocular trauma. Neurological examination was normal in all patients. The TON was unilateral in all cases. Visual acuity was limited to counting fingers in all cases with an afferent pupillary defect. Fundus examination showed signs of partial optic nerve avulsion in two patients, was normal in others. Optical coherence tomography showed a disruption of optic nerve axons in two patients diagnosed with optic nerve avulsion and was normal in 6 cases. Orbital scan revealed orbital fractures in two patients with a bony fragment adjacent to the optic nerve in one case. Six patients received high-dose corticosteroid. Improvement of visual acuity was achieved in one case.

Conclusion: The diagnosis of TON is clinical, based on visual acuity impairment with the afferent pupillary defect. Optical coherence tomography reveal the disruption of optic nerve axons at the scleral rim in optic nerve avulsion. There is no consensus in the management of TON and visual recovery is uncertain.

Disclosure: Nothing to disclose.

EPO-788 | The condition of vestibular and auditory function in patients with established endolymphatic hydropsis

A. Poddubnyy[1]; I. Maryenko[2]; N. Greben[1]; S. Likhachev[2]; A. Kleban[2]; A. Smolyak[1]; V. Lisotskaya[1]

[1]*The State Institution "Republican Scientific and Practical Centre of Otorhinolaryngology", Minsk, Belarus;* [2]*The State Institution "Republican Scientific and Practical Center of Neurology and Neurosurgery", Minsk, Belarus*

Background and Aims: One of the causes of recurrent cochleovestibular syndrome is endolymphatic hydrops (EH) in Meniere's disease (MD). The study was to assess vestibular and auditory function in patients with a fixed EH according to MRI data.

Methods: 32 patients with MD were examined (of the criteria of the Barany Society, 2015) 21 women and 11 men, average age 53.22 ± 12.6 years). 2 groups were identified: definite MD (DMD), $n = 17$ and probable MD (PMD), $n = 15$. Tonal threshold audiometry (TTA), vestibulometry with functional tests (de Klein's test, hyperventilation, Valsalva, Dix-Hallpike, McClure-Pagnini) with registration of spontaneous (SN) and provocative nystagmus (PN), brain MRI and inner ear (IE) with delayed intravenous or transtympanal by contrast.

Results: The TTA data the average value of the hearing threshold on the affected side in the DMD group – 47.08 ± 23.18 dB, in the PMD group – 36.31 ± 22.25 dB, ($p > 0.05$). SN was registered in 2 (12%) of 17 and PN in 9 (53%) patients with DMD. In the PMD group SN was not registered, in 5 (35%) PN was registered on the lesion side. Significant vestibular hyporeflexia on the hearing loss side was detected in 100% patients with DMD and PMD. In the PMD group brain MRI and IE did not reveal MR signs of EH. In the DMD group MRI revealed EH in 8 (47%) of 17 patients ($p < 0.05$) on the affected side it corresponded (100%) to the detected hearing loss and vestibular hyporeflexia.

Conclusion: The results obtained make it possible to objectify the EG during subcompensation, which is confirmed by MRI diagnostics.

Disclosure: Nothing to disclose.

EPO-789 | Clinical and evolutionary characteristics of optic neuritis inaugurating multiple sclerosis: About 38 Algerian patients

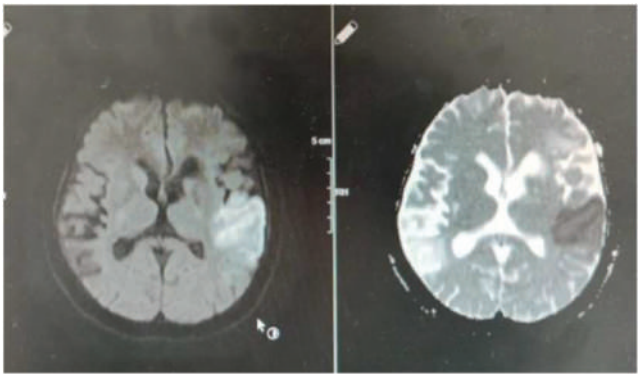
S. Bourokba[1]; F. Boulaneb Bediar[2]; N. Toubal[1]
[1]*Department of Neurology, CHU Annaba, Algeria;* [2]*Department of Ophthalmology, CHU Annaba, Algeria*

Background and Aims: Optic neuritis (ON) is a frequent clinical presentation in multiple sclerosis (MS), which may be inaugural or occur during the course of the disease, and is considered in the literature to be a factor with a good prognosis. We describe the clinical and evolutionary characteristics of optic neuritis in 38 Algerian patients.
Methods: Prospective longitudinal descriptive and analytical study over a 3-year period in the neurology department of the CHU annaba Algeria, involving patients over 15 years of age presenting with inaugural ON alone or associated with other neurological signs.
Results: Out of 79 patients, 38 were diagnosed with clinically defined MS according to the 2017 McDonald criteria; sex ratio F/M = 4.42, mean age 29.39 ± 10.61 years; ON was acute in 86. 8%, unilateral in 84.21%, painful in 81.57%, Uhthoff's phenomenon was present in only 6 patients, distance visual acuity was <1/10th in 31.81%, fundus appearance was normal in 68.18%, neurological examination revealed multifocal CNS involvement in 55.28%, orbital MRI was performed in only 11 patients, with ON found in 8; brain MRI met Barkhoff criteria in 68.42%, with active lesions in 6 patients; spinal cord MRI was pathological in over half of cases, dominated by cervical myelitis; symptomatic treatment based on high doses of corticosteroid was initiated in 76.3%, with a good response in the majority of cases.
Conclusion: This study enabled us to assess the characteristics of ON inaugurating MS in an Algerian population; Is ON in MS really a good prognostic factor?
Disclosure: Nothing to disclose.

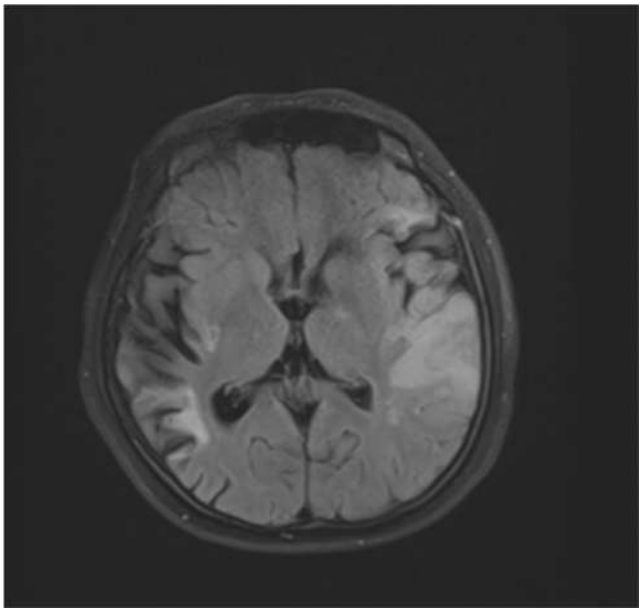
EPO-790 | An exceptionally uncommon stroke syndrome: A case of cortical deafness

C. Örken; O. Çelik; S. Dirkeç; C. Bolcu Emir
Neurology Department, Prof Dr Cemil Taşcıoğlu Education and Research Hospital, İstanbul, Turkey

Background and Aims: Cortical deafness is an extremely rare condition that arises from bilateral cortical lesions in the primary auditory cortex. Its main clinical manifestation is a sudden bilateral hearing loss. Diagnosis is challenging due to its rarity and similarity to other language and communication disorders, such as Wernicke's aphasia, auditory agnosia, or pure word deafness.
Methods: Case report.
Results: We present a 33-year-old female with an acute onset of complete bilateral hearing loss. The hearing loss was attributed to a subacute cortical infarction at the level of the superior and transverse temporal gyri on the left, and an older cortical infarction at a similar location on the right. The etiology of these recurrent cardioembolic infarcts was her mechanical heart valve.



Initial diffusion MR.



MRI, 3 months.

Conclusion: Both the peripheral and central auditory pathways must be intact for proper hearing. Auditory signals from each ear are evaluated bilaterally in the cerebral cortex. Therefore, for a complete hearing loss, there must be damage to both auditory cortices, the Heschl's gyri. As a result, stroke-induced deafness is an exceptionally uncommon situation that should be kept in mind in a patient presenting with acute bilateral hearing loss to treat appropriately and to prevent permanent disability.
Disclosure: Nothing to disclose.

EPO-791 | "Complete external ophthalmoplegia" as an adverse reaction to Adalimumab

C. Nieva Sánchez; A. García Díaz; A. Freixa Cruz; L. Perez Girona; E. Ruiz Fernández
Neurology Department, Arnau de Vilanova University Hospital, Lleida, Spain

Background and Aims: "Complete external ophthalmoplegia" refers to the inability of the eyes to move conjugately in all gaze positions. It is caused by damage to the brainstem conjugate gaze control nuclei.
Methods: A 51-year-old male, treated with Adalimumab for primary uveitis suffered sudden horizontal binocular diplopía two weeks after Adalimumab administration, which was firstly orientated as microangiopathic IIIpc palsy. He was found two weeks later with a sudden worsening with a complete external ophthalmoplegia. The patient was admitted to the neurology department for study.
Results: In 2017, a magnetic resonance imaging (MRI) conducted in context of the uveitis, revealed a subcortical small hyperintense lesion. A follow-up MRI one week after the initial clinical presentation identified a small hyperintense lesion located parasagittally in the dorsal tegmentum of the pons. Another MRI during admission (15 days later) demonstrates an increase in size of the lesion, showing diffusion restriction. The cerebrospinal fluid (CSF) exhibited mild pleocytosis. Rest of the ancillary tests were normal. The patient received high-dose methylprednisolone for five days, showing favorable evolution of symptoms. Due to suspicion of adverse drug reaction, Adalimumab was discontinued. Subsequent follow-up MRI shows an inflammatory activity regression.
Conclusion: We report a case of an adverse reaction to Adalimumab consisting of brainstem inflammation with complete external ophthalmoplegia. Anti-TNF-alpha therapy is not indicated in patients with central demyelinating diseases. Our patient had a previous suspicious lesion so that may not have been the best option.
Disclosure: No conflicts of interest.

EPO-792 | Abstract withdrawn

EPO-793 | Vestibular perceptual thresholds in patients with persistent postural perceptual dizziness

H. Rust[1]; J. Allum[2]; K. Roushan[3]; C. Stieger[2]; B. Seemungal[4]; F. Honegger[1]
[1]Department of Neurology, Vestibular Neurology Unit, University Hospital Basel, Switzerland; [2]ORL Department, Division of Neuro-Otology, University Hospital Basel, Switzerland; [3]ORL Private Pracitce, Liestal, Switzerland; [4]Centre for Vestibular Neurology, Imperial College London, UK

Background and Aims: Persistent postural perceptual dizziness (PPPD) is a common functional disorder. It is characterized by a chronic sensation of dizziness which is exacerbated by upright posture. PPPD usually evolves as a consequence of a vestibular or other illness. With standard vestibular testing being usually normal in those patients with PPPD we studied whether there are changes in vestibular perception.
Methods: 12 patients with PPPD were assessed, 10 males, 2 females (mean age 60 years). The diagnosis of PPPD was established according to the criteria of the Bárány Society from 2017. 23 healthy controls were assessed, 11 males, 12 females (mean age 42.3 years). Vestibular perceptual thresholds were determined for yaw-plane rotations with randomly presented half cosine stimuli. Patients were assessed for handedness, Dizziness Handicap Inventory (DHI), Ten-item personality inventory (TIPI) and Hospital Anxiety and Depression scale (HADS).
Results: Vestibular perceptual thresholds in PPPD patients did not significantly differ from those of normal controls. There was no correlation between age and elevated thresholds. The number of trials needed to determine the respective threshold was not related to lower threshold values. Handedness was not correlated with direction errors when indicating motion perception. There was no correlation between DHI values and high or low thresholds.
Conclusion: Patients with PPPD did not differ from normal controls regarding vestibular perceptual threshold values for yaw-plane rotations. There was no correlation between age and threshold value.
Disclosure: Nothing to disclose.

EPO-794 | Neurological aspect of peripapillary retinal nerve fiber layer changes analysis in idiopathic intracranial hypertension

M. Janani[1]; B. Shalbafan[2]; H. Lanjanian[3]; H. Sajjadi[4]
[1]Student Research Committee, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [3]Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [4]Ophthalmic Research Center, Research Institute for Ophthalmology and Vision Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran

Background and Aims: Papilledema is a biomarker of the elevated intracranial pressure (ICP), observable in fundoscopy. Optic Coherence Tomography (OCT) is a superior method that provides valuable real-time information about retinal nerve fiber layers (RNFL) and uneven RNFL distribution and thickness, with more density in the temporal circumpapillary bundle (Figure-1). This allows us to observe sequential changes even before the formation of overt papilledema and diagnose Idiopathic Intracranial Hypertension (IIH) in its early stages.
Methods: In this study, we have enrolled 4 patients whose OCTs were suggestive of elevated ICP based on Sajjadi et al 2017 patterns. Their investigation included: ICP measurement by lumbar puncture (LP), circumpapillary RNFL thickness assessment in temporal, superior, nasal and inferior (TSNI) quarters (Figure-1) and Brain Magnetic Resonance Imaging (MRI). As normal people and patients with overt papilledema can be diagnosed definitely, they have been excluded from our study.

Results: As demonstrated in table-1 Despite all cases having elevated ICP, case 2 and 3 had RNFL thicknesses were in the normal chart and case 1 had minimal elevation in RNFL thickness and surprisingly case 4 had generalized depression.

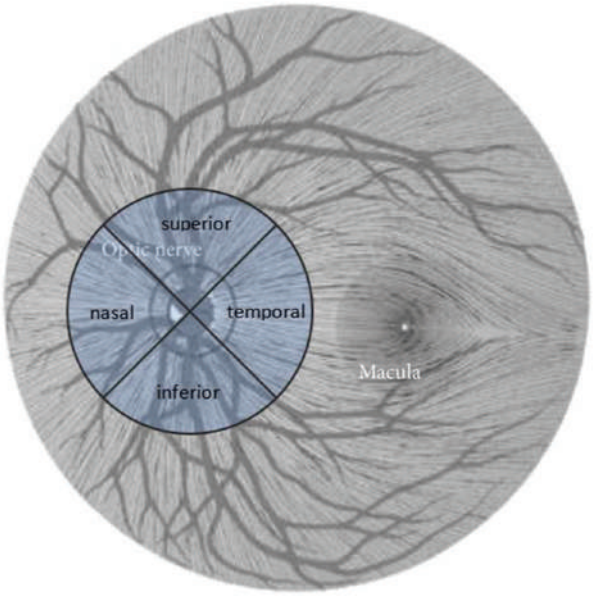


Figure 1: the radiation of RFNL and maculopapillary bundle – peripapillary section is divided into temporal, superior, nasal and inferior quadrants

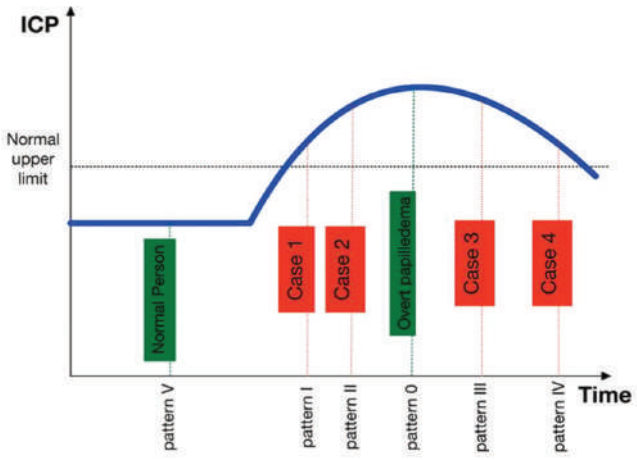

Figure 2: Allocated Sajjadi patterns and presented cases in Rising ICP progression diagram from normal case to increasing ICP and then Normal pressure hydrocephalus with decreased ICP due to pressure redistribution to solid tissues.

Patterns	RNFL thickness in TSNIT quadrants				CSF pressure incremental progress	Reversible RNFL damages	Reversible brain damages
	T	N	S	I			
0	↑↑	↑↑	↑↑	↑↑	Rapid progression	Variable	Variable
1-case 1	↑↑	↑	↑		Slow progression	Yes	Variable
2-case 2	↑	↑	↑	↑	Slow progression	Yes	Variable
3-case 3	↔	↑	↑	↔	Variable	Variable	Variable
4-case 4	↓	↓	↓	↓	Variable	No	Variable
5	↔	↔	↔	↔	-	-	-

***Table 1:** In detail RNLF thickness analysis per each Sajjadi patterns and RICP progression timeline, ophthalmic and brain damage reversibility (↑: elevation, ↓: depression, ↔: normal thickness)*

Conclusion: As demonstrated in table-1 Despite all cases having elevated ICP, case 2 and 3 had RNFL thicknesses were in the normal chart and case 1 had minimal elevation in RNFL thickness and surprisingly case 4 had generalized depression.

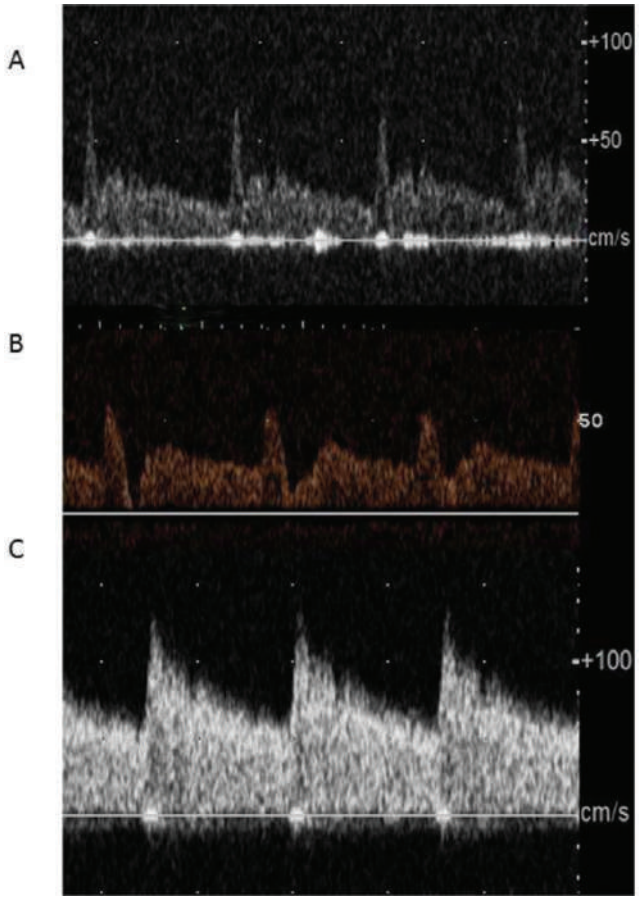
EPO-795 | The diagnostic potential of mesosystolic notch in transcranial Doppler for reversible cerebral vasoconstriction syndrome

V. Chavignier[1]; A. Lecluse[2]; S. Godard[2]; S. Henni[1]; J. Fortrat[3]
[1]*Service de Médecine Vasculaire, CHU Angers, Angers, France;* [2]*Service de Neurologie, CHU Angers, Angers, France;* [3]*Univ Angers, Inserm, CNRS, Équipe CARME, SFR ICAT, Angers, France*

Background and Aims: Reversible Cerebral Vasoconstriction Syndrome (RCVS) poses diagnostic challenges due to its manifestation through severe headaches and dynamic vascular abnormalities, with confirmation typically requiring invasive procedures like arteriography, computed tomography angiography (CTA), or magnetic resonance angiography (MRA). The centripetal evolution of vasospasm and the absence of specific clinical criteria hinder early detection.

Methods: In our center, we systematically employed transcranial Doppler (TCD) in suspected RCVS cases, obtaining crucial information on velocity, Lindegard index, and flow turbulences. To assess TCD's diagnostic potential, we conducted a one-year survey of all TCD examinations, with a specific focus on suspected RCVS cases. A total of 191 TCD examinations were performed, including 38 on 23 patients with suspected RCVS.

Results: Within the cohort, a distinctive TCD flow pattern was identified in four cases, characterized by a mesosystolic notch reaching the baseline or elevating the pulsatility index, notably within seven days of headache onset in three patients. Despite subnormal arteriography results in two cases, only two out of the four patients received a confirmed RCVS diagnosis. TCD, however, normalized during follow-up in all four cases.



Illustrations depicting deep mesosystolic notches in two patients diagnosed with reversible cerebral vasoconstriction syndrome (A and B), contrasted with a typical cerebral artery flow pattern observed in a normal case (C).

Conclusion: This study highlights the potential diagnostic significance of a mesosystolic notch on TCD in RCVS, offering a non-invasive and easily repeatable criterion for early detection and follow-up monitoring. Although not universally conclusive, the presence of a mesosystolic notch on TCD may serve as a pathological finding associated with RCVS, providing valuable insights for early diagnosis and supporting clinical decision-making to prevent exacerbation of conditions when observed.

Disclosure: Nothing to disclose.

EPO-796 | Analgesia-related dizziness

M. Villar-Martinez; P. Amarasena; R. Wilcha; P. Goadsby

Wolfson Sensory Pain and Regeneration Centre (SpaRC), Institute of Psychiatry, Psychology and Neuroscience, King's College London, UK

Background and Aims: Dizziness and vertigo are frequent symptoms reported in migraine during spontaneous and triggered attacks. Medication-Overuse Headache is a type of secondary headache that could be attributed to frequent use of analgesia in patients with an underlying headache. Our impression is patients with vestibular symptoms of unknown cause may have a migrainous biology and potentially frequent use of painkillers. Our aim was to study the relationship between analgesia and vertigo in a migraine cohort.

Methods: This study is part of the prospective cohort questionnaire-based IMPARTS at King's College Hospital. We did a cross-sectional analysis from February-September 2023. We used SPSS 28 and generalised linear models including linear and binomial (normal and logit functions, respectively), adjusted for normality as appropriate. Presence of vertigo or total score in the Situational Vertigo Questionnaire were dependent variables. Presence of triptans, NSAIDs, opioids, paracetamol and medication overuse were selected as predictors.

Results: The consumption of paracetamol was a predictor for a higher score of vertigo in patients that describe dizziness ($n=96$, $\beta=0.56$, $p=0.045$). The remaining painkillers and the presence of overuse, and none the predictors for the presence of dizziness, were significant. Medication overuse had a slightly higher percentage in the group that reported dizziness (24% vs 20%, NS).

Conclusion: The consumption of analgesia, specifically that of paracetamol, may be related with the presence of more vertiginous symptoms in those patients that report dizziness in spontaneous attacks. More power is needed to determine if those symptoms are due to "Medication-Overuse Dizziness".

Disclosure: Nothing to disclose.

EPO-797 | Extrapulmonary tuberculosis presenting as diplopia in an immunocompetent patient

M. Domine[1]; P. Boned Fustel[2]; N. Blanco Sanromán[1]; M. Coronel Coronel[1]; M. Bort Martí[2]; L. García Fernández[2]

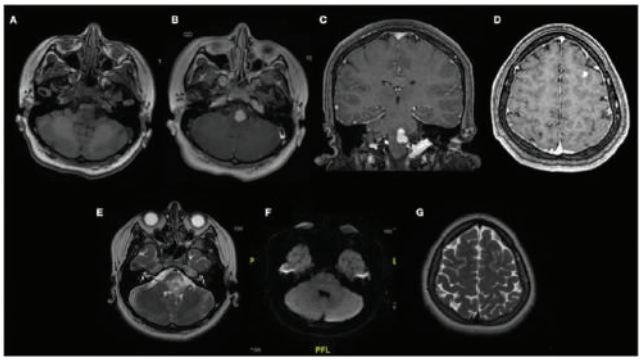
[1]*Neurology Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain;* [2]*Ophtalmology Department, Hospital Universitario i Politècnic La Fe, Valencia, Spain*

Background and Aims: Extrapulmonary tuberculosis, accounting for 10–15% of cases, can manifest in various forms, including central nervous system involvement. While meningitis is the more common presentation, it is essential to consider tuberculoma in the differential diagnosis of cerebral masses, particularly in immunocompetent individuals.

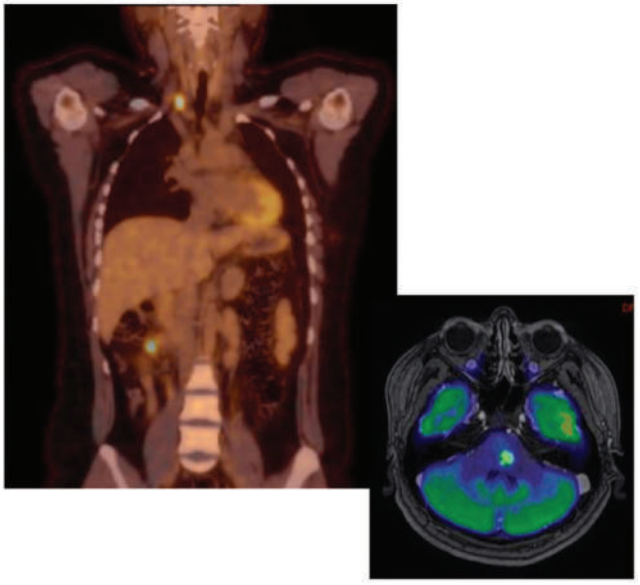
Methods: We report an 18-year-old woman with no significant medical history, presenting to the emergency department with a two-week history of binocular diplopia. Physical examination revealed left sixth cranial nerve paralysis.

Results: Blood analysis and cranial CT scan yielded no significant findings. Brain MRI identified a 1.8 cm oval lesion in the left bulbar region extending into the pons, accompanied by extensive vasogenic edema. Cerebrospinal fluid analysis showed no biochemical, cytological, or microbiological abnormalities. PET-CT revealed lesions with heightened glucose metabolism in the bulb and axillary regions. Ultrasound-guided fine-needle aspiration of lymphadenopathy demonstrated histiocytic groups on a necrotic background with cellular

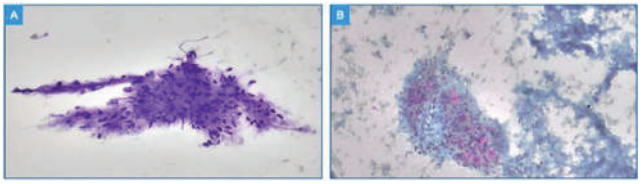
debris, indicative of necrotic granuloma. PCR on the sample tested positive for Mycobacterium Tuberculosis, and Quantiferon was also positive. Upon further inquiry, relatives reported a history of tuberculosis during pregnancy. One year of quadruple anti-tuberculous therapy led to symptom remission and lesion resolution.



Focal lesion with oval morphology, measuring 1.8 cm, located in the bulbar region with extension towards a hypointense protuberance in T1-weighted sequence (A). The lesion homogeneously enhances in T2-weighted sequences (B, C), with extensive perilesional.



Whole-body FDG-F18 PET-CT revealing a lesion in the brainstem with increased glycolytic metabolism and hypermetabolic supraclavicular right lymph nodes. Additionally, smaller nodes with metabolism are observed in the high right paratracheal region.



A. Cytological staining with Giemsa reveals a cluster of cells with broad cytoplasm and oval-shaped nuclei, suggestive of histiocytes. B. Papanicolaou-stained cytology displays a cluster of histiocytes on a necrotic background, indicative of a necrotic gr.

Conclusion: This case highlights the atypical presentation of extrapulmonary tuberculosis in an immunocompetent patient, emphasizing the importance of considering infectious etiologies in the differential diagnosis of neurological manifestations and brain masses. Early detection and treatment are critical in mitigating the associated high morbidity and mortality.

Disclosure: Nothing to disclose.

EPO-798 | The influence of virtual reality on the optokinetic nystagmus parameters in patients with stroke

A. Kramarenko; I. Maryenko; S. Likhachev
Republican Research and Clinical Center of Neurology and Neurosurgery, Minsk, Belarus

Background and Aims: Using virtual reality (VR) in patients with stroke rehabilitation is a promising way for motor and oculomotor function recovery. Pathophysiological similarity of motor disorders after stroke and oculomotor phenomena makes it possible to use the oculomotor function assessment as a non-invasive method for rehabilitation effectiveness evaluation. We aimed to assess the dynamics of optokinetic nystagmus (OKN) under the influence of VR training.

Methods: We examined oculomotor function in 23 patients, using electronystagmography, to explore vertical and horizontal OKN. We registered OKN twice in every patient: before the first training in VR, and after the last one. OKN fast and slow phase amplitude and velocity were measured and analyzed before and after training.

Results: There was a noticeable decrease in asymmetry coefficient (CA) for all horizontal OKN phases characteristics ($p=0.06$). CA of fast phase amplitude before starting VR training was 11%, at the end of the course – 5%. CA of OKN slow phase amplitude decreased from 32% to 5% ($p<0.05$). CA of OKN slow phase velocity decreased from 23% to 7%, $p<0.05$. Also, we discovered absent vertical optokinetic nystagmus (OKN) in 18/23 (78%) patients before training. In 6 patients out of 18 (33%) restoration of the vertical OKN was detected after VR training course.

Conclusion: OKN abnormalities in stroke are common. OKN registration may be used to assess the effectiveness of VR in rehabilitation. Vertical OKN restoration and eye movement asymmetry decrease after VR training demonstrates significant restorative potential of VR for oculomotor functions in patients with stroke.

Disclosure: Nothing to disclose.

EPO-799 | Effect of duration and severity of migraine on ocular structures

Y. Walha[1]; M. Rekik[1]; K. Moalla[2]; S. Kammoun[1]; A. Trigui[1]; M. Damak[2]; C. Mhiri[2]
[1]*Ophthalmology Department, Habib Bourguiba Hospital, Sfax, Tunisia;* [2]*Neurology Department, Habib Bourguiba Hospital, Sfax, Tunisia*

Background and Aims: Migraine is a complex neurovascular disorder. The pathophysiology of the disease suggests that duration and severity lead to more ocular changes. We investigate the effect of duration and severity of migraine on macular thickness using optical coherence tomography (OCT).
Methods: A cross-sectional case-control study conducted at the Habib Bourguiba University Hospital in Sfax. This study included migraine patients and control subjects. Mean macular thickness measurements (MMT) was performed by OCT. Years of evolution were recorded. Severity was assessed using the MIDAS (Migraine Disability Assessment Scale) and MIGSEV (migraine severity scale) scores.
Results: One hundred and twenty eyes from 60 patients (60 eyes in the migraine without aura (MWoA) group and 60 eyes in the migraine with aura (MWA group) were included. Control group included 30 age and gender matched healthy participants (60 eyes). The mean duration of migraine was 12.27 ± 5.88 years. According to the MIGSEV score, migraine was considered of intermediate severity in 43.3% and 50% of MWoA and MWA patients respectively. According to the MIDAS score, migraine caused moderate disability (Grade III) in 43.3% and 26.7% of MWoA and MWA patients respectively. OCT revealed a significant reduction in both groups compared to the control group. Prolonged disease duration was not associated with decreased MT. The severity was the determinant factor of MMT.
Conclusion: Migraine has strong effect on the macular structures. The duration of the disease does not affect the MMT, while the severity has a stronger effect on MMT.
Disclosure: Nothing to disclose.

EPO-800 | The impact of the frequency and the duration of migraine attacks on macular thickness

Y. Walha[1]; K. Moalla[2]; M. Rekik[1]; S. Kammoun[1]; A. Trigui[1]; M. Damak[2]; C. Mhiri[2]
[1]*Ophthalmology Department, Habib Bourguiba Hospital, Sfax, Tunisia;* [2]*Neurology Department, Habib Bourguiba Hospital, Sfax, Tunisia*

Background and Aims: Migraine episodically leads to the activation and sensitization of the trigeminovascular system leading to vasoconstriction not only of cerebral blood vessels but also of retinal blood vessels. We investigate the frequency and the duration of migraine attacks on macular thickness (MT) using optical coherence tomography (OCT).
Methods: This study aimed to compare MT, measured using OCT, among patients diagnosed with migraine with aura (MWA) and migraine without aura (MWoA), compared to healthy controls. The mean MT (MMT) and pericentral quadrants was measured conforming to the segmentation of the Early Treatment Diabetic Retinopathy Study.
Results: One hundred and twenty eyes from 60 patients (60 eyes in the MWoA group and 60 eyes in the MWA group) were included. The control group consisted of 30 age- and gender-matched healthy participants (60 eyes). The frequency of attacks was between one and four per month in 66.7% of MWoA and 56.7% of MWA. The frequency of attacks was between 4 and 12 hours in 50% and 76.7% of MWoA and MWA respectively. The frequency of attacks was correlated with the MMT, superior parafoveal thickness, and superior, nasal and inferior perifoveal thickness in both groups, while the attack duration does not affect the MMT.
Conclusion: Migraine patients with and without aura are prone to have damages in MT. In our study, the thinning of MT is significantly influenced by the duration of migraine attacks than their duration.
Disclosure: Nothing to disclose.

Muscle and neuromuscular junction disorder 4

EPO-801 | Assessment of sympathetic sudomotor function in myotonic dystrophy type 1 with electrochemical skin conductance

M. Schön; I. Castro; J. Castro; M. De Carvalho; M. Oliveira Santos
Serviço de Neurologia, Departamento de Neurociências e de Saúde Mental, Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal

Background and Aims: Myotonic dystrophy type 1 (MD1) is an autosomal dominant disease caused by an expansion of CTG repeats. One of the most controversial manifestations consist of its potential autonomic involvement. The electrochemical skin conductance (ESC) is a non-invasive neurophysiologic technique, which has been considered a reliable tool in the assessment of small-fibre neuropathy caused by diabetes mellitus, hereditary ATTR amyloidosis, Fabry disease, and amyotrophic lateral sclerosis.
Methods: ESC measurements were prospectively investigated in 18 consecutive MD1 patients (8 males, 44%) with a median age of 46 years (1st–3rd IQR, 37–55), that were compared with a group of 24 age and sex-matched healthy subjects as controls. Their nerve conduction studies were normal and none of the individuals had a previous history of diabetes or was taking any anticholinergic medication.
Results: ESC values from MD1 patients did not differ from controls: hands [74 μS (1st–3rd IQR, 67–78) vs 79 μS (1st–3rd IQR, 67–85, $p = 0.27$)] and feet [81 μS (1st–3rd IQR, 77–85) vs 81 μS (1st–3rd IQR, 78–85, $p = 0.87$]. No significant correlation was found between hands and feet ECS measurements and the disease duration or

number of CTG repeats, as well as between feet ESC and anterior tibialis weakness ($p > 0.05$).

Conclusion: This innovative technique does not confirm the potential involvement of cholinergic unmyelinated postganglionic sympathetic C fibres in patients with DM1. An altered function of the target organ due to smooth muscle compromise seems to be a possible explanation for those manifestations rather than the primary involvement of the autonomic nervous system.

Disclosure: Nothing to disclose.

EPO-802 | Identification of novel plasma biomarkers for myasthenia gravis prognostication

M. Li[1]; M. Petersson[1]; F. Piehl[2]; S. Brauner[2]

[1]Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden; [2]Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden & Department of Neurology, Karolinska University Hospital, Stockholm, Sweden

Background and Aims: Myasthenia Gravis (MG) is an antibody-mediated neurological disease characterized by potentially life-threatening muscular fatigability. Currently, there are no established prognostic biomarkers predicting outcomes, and the understanding of the underlying immunopathogenesis is limited.

Methods: Plasma from 60 newly diagnosed MG patients and 51 age- and sex-matched healthy controls (HCs) were assayed on the Olink EXPLORE 1536 panel, measuring 1460 pre-selected soluble proteins. Protein expression was calculated as relative NPX values, and corrected for age, sex, and sample handling. Groupwise expression differences were calculated using post-hoc ANOVA test. Prognostic power was determined using survival analyses investigating time to remission (defined as quantitative MG score, QMG, ≤2 and no rescue treatment within 3 months).

Results: Baseline characteristics of patients were: Average age 59.5 years (SD 18.6), 36.7% females, 88.3% AChR+, QMG 5.9 (SD 4.4) and 86.7% were untreated. Significant differences between MG patients and HC were observed in nine proteins, with the strongest association observed for oligodendrocyte myelin glycoprotein (OMG; adj. $p < 0.0001$), which aside the nervous system also is expressed in leukocytes. Four of the nine proteins were associated to the STAT1/3 pathway. Altered expression of proteins linked to T-cell activation and migration were significantly associated with earlier remission within one year from sampling, including increased CCL27 and ITGAV expression, and decreased CLEC4D expression (all adj. $p = 0.033$).

Conclusion: We observed plasma proteins differentially expressed between new-onset MG and matched HC. Additionally, we identified proteins linked to T-cell activation and migration as potential biomarkers of medium-term disease remission.

Disclosure: SB has received in non-restricted research grants from UCB Pharma and Janssen, not related to this study. FP has received research grants from Janssen, Merck KGaA and UCB, and fees for serving on DMC in clinical trials with Chugai, Lundbeck and Roche, and preparation of expert witness statement for Novartis.

EPO-803 | Sensitivity to change and meaningful change thresholds of the quick motor function test (QMFT) in Pompe disease

N. van der Beek[1]; A. Sjöström-Bujacz[2]; C. Daskalopoulou[3]; D. Papageorgiou[3]; K. An Haack[4]; V. Gallego[5]; P. DasMahapatra[5]; N. Thibault[5]; A. Zaher[6]; N. Armstrong[5]; M. Kruijshaar[1]; A. van der Ploeg[1]

[1]Erasmus MC University Medical Center, Center for Lysosomal and Metabolic Diseases, Rotterdam, The Netherlands; [2]IQVIA, Solna, Sweden; [3]IQVIA, Athens, Greece; [4]Sanofi, Chilly-Mazarin, France; [5]Sanofi, Cambridge, MA, USA; [6]Sanofi, ON, Canada

Background and Aims: QMFT is a 16-item validated scale for assessing motor function in Pompe disease. Objectives were to determine whether QMFT was sensitive to changes in patient's status and inform on meaningful change thresholds (MCTs) for within-patient change.

Methods: Using blinded, pooled data from COMET (NCT02782741) study of late-onset Pompe disease (LOPD), sensitivity to change was examined from baseline to Week 49. Mean QMFT total score was investigated among those who improved, worsened, and remained unchanged based on other collected and theoretically related clinical outcomes assessments (COAs) via Kruskal-Wallis analysis. Spearman correlations of changes between QMFT and COAs were also examined. CMT for within-patient change was estimated via anchor approaches, based on anchors with appropriate correlations (>0.371 corresponding to d = 0.8), and distribution approaches (0.5 standard deviation [SD] and standard error of measurement [SEM] to estimate a lower bound; minimal detectable change [MDC] for upper bound).

Results: Sensitivity to change was indicated, due to the expected pattern between changes in QMFT and most COAs (Table 1) and high correlations between QMFT and the COAs (Table 2). Summary statistics for change scores for improvement ranged from mean/median of 3.0–8.0 points (Table 3). Distribution results were 0.5 SD = 5.16 points; SEM = 3.94 points; and MDC = 10.92 points. Considering the above, the within-patient MCT for improvement ranged from 5.16 to 10.92 points.

EPO-804 | Efficacy, safety, and factors predicting response in Rituximab therapy for generalised myasthenia gravis

N. Thambirajah; G. Logou; S. Sumaria; R. Howard; D. Kullmann; J. Spillane

National Hospital for Neurology and Neurosurgery, Queen Square, London, UK

Background and Aims: Rituximab (RTX) is an anti CD20 monoclonal antibody approved for use in refractory generalised Myasthenia Gravis (gMG). We aimed to assess the efficacy, safety, and factors predicting response in RTX therapy for gMG.

Methods: A retrospective observational study was conducted at our centre. Case notes of patients with gMG treated with rituximab from 2019 to 2023 were analysed. Positive outcomes were recorded if, at six months a) a reduction of at least 2 points in MG Activities of Daily Living (ADL) or 3 points in MG composite scale occurred, or b) if at one year – treatment escalation was not required, or c) if either prednisolone or intravenous immunoglobulin were weaned.

Results: Of the 32 patients included in the study, 26 (81.2%) were female and 6 were male. Eighteen (56.2%) were acetylcholine receptor antibody positive (AchR) and thirteen were muscle-specific kinase (MuSK) antibody positive. Mean age at start of treatment was 46.8 years (range 25–76) and mean disease duration was 13.2 (±10) (range 1 to 47). Patients had previously received an average of 4 immunosuppressive agents (range 1–7). Twenty (62.5%) patients responded to RTX. 76.9% (10/13) of the MuSK positive group responded compared to 50% (9/18) of the AchR positive cohort. Age and thymectomy were unrelated to outcomes while time to treatment of less than 10 years was correlated to positive outcome. A multi-morbid patient died of COVID-19 two months after treatment.

Conclusion: Rituximab is effective in MuSK gMG but variably effective in AchR gMG.

Disclosure: 1. Nothing to disclose 2. Has received travel support from UCB and been on an advisory board for Alexion 3. Nothing to disclose 4. Nothing to disclose 5. Nothing to disclose 6. Has received speakers fees and travel support from Argenx and served on an advisory board for UCB.

EPO-806 | Patient characteristics and exacerbations in incident myasthenia gravis: Analysis of US commercial insurance claims data

P. Mina-Osorio[1]; J. Arackal[2]; J. Wang[3]; J. Schwinn[1]; B. Venker[3]; L. Miller-Wilson[1]

[1]Immunovant, Inc., New York, NY, USA; [2]University of Health Sciences & Pharmacy, St. Louis, MO, USA; [3]Roivant Sciences, Ltd., New York, NY, USA

Background and Aims: The incident myasthenia gravis (MG) population in the United States (US) is not well-characterized. Many patients experience exacerbations despite the use of conventional immunosuppressive treatments; however, this has not been studied in detail.

Methods: This retrospective analysis used Inovalon claims data to estimate the incidence of MG among adults aged ≥18 years in the US for 2019. Patient characteristics, treatment utilization patterns, and exacerbation frequency were assessed in the incident population.

Results: We identified 1,372 incident patients with MG, corresponding to a raw incidence rate of 4.9 per 100,000 persons, and an adjusted incidence of 5.2 per 100,000 after extrapolating to the US population. More than half (56.9%) of the patients were women, and the median age for women (58 years) was lower than for men (62 years). Hypertension was the most common comorbidity,

occurring in 50.4% of patients. Among 920 patients who received medication, 773 (84.0%) received acetylcholinesterase inhibitors. Among 1,204 incident patients with ≥1 year of continuous follow-up, 387 (32.1%) experienced exacerbations, with the majority experiencing ≥3 exacerbations. Median (interquartile range [IQR]) time to first exacerbation was 7 (60) days, and in patients with >1 exacerbation, the median (IQR) time from the first to subsequent exacerbation was 25 (42) days.

Patient characteristic	Incident cohort (N=1,372)
Women, n (%)	781 (56.9)
Median age (IQR), years	
Women	58 (25)
Men	62 (17)
Comorbidities, n (%)[a]	
Hypertension	692 (50.4)
Hyperlipidemia	410 (29.9)
Type 2 diabetes	307 (22.4)
Gastroesophageal reflux disease	284 (20.7)

TABLE 2 Treatment utilization in the incident population.

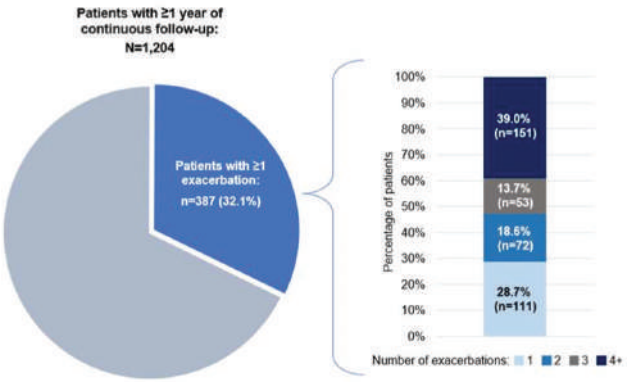

FIGURE 1 Number of MG exacerbations in incident patients with ≥1 year of follow-up.

Conclusion: The estimated incidence of MG among adults in the US was 5.2 per 100,000 persons. Approximately one-third of patients experienced exacerbations within a year, with >50% of those patients having ≥3 exacerbations. These findings highlight the unmet need for targeted therapies that provide sustained symptom control.

EPO-807 | Characterisation of patients with myasthenia gravis in France: A cluster analysis of patients from the SPOON study

S. Sacconi[1]; G. Solé[2]; A. Crochard[3]; J. Bertocchio[4]; A. Archer[5]; P. Boulanger[6]; P. Villy[3]; A. Richard[3]; J. Camdessanché[7]
[1]Système nerveux périphérique et muscle, CHU de Nice, Université Côte d'Azur, NICE, France; [2]Service de Neurologie et Maladies Neuromusculaires, CHU de Bordeaux, Centre de Référence des Maladies Neuromusculaires AOC, Hôpital Pellegrin, BORDEAUX, France; [3]UCB Pharma, Colombes, France; [4]SKEZI, Annecy, France; [5]AFM Telethon Groupe d'intérêt Myasthénies, EVRY, France; [6]AMIS (Association des Myasthéniques Isolés et Solidaires), La Chapelle En Serval, France; [7]Service de Neurologie, Centre de Référence des Maladies Neuromusculaires PACA-Réunion-Rhône Alpes, CHU de Saint-Étienne, Hôpital Nord, Saint-Étienne, France

Background and Aims: The SPOON study was an online patient survey about living with myasthenia gravis (MG). The present analysis aimed to identify potential patient subgroups with different disease characteristics and experiences, and to document their aspirations about living with MG.
Methods: Cluster analysis was performed using ascending hierarchical clustering. The characteristics of each cluster were described. Differences in characteristics between clusters were tested using the χ^2 or Student's *t*-test as appropriate.
Results: The cluster analysis included 255 participants. Three clusters were identified, which accounted for 52.5% of the inertia in the

sample (Figure 1). Characteristics of the clusters are described in Table 1. Cluster 1 ($n=83$; 32.5%), mostly comprising women (86%) diagnosed at an older age than cluster 3, appears to be the one most affected by MG, with 78% of the patients with current symptom exacerbation and a heavier burden of disease. Cluster 2 ($n=44$; 17.3%) mostly comprises men diagnosed later in life with a lower disease burden. Cluster 3 is the largest cluster ($n=128$; 50.2%) and is principally women (94%) diagnosed at a younger age than cluster 1, with stable disease (96.9% without current symptom exacerbation), a moderate disease burden and relatively low psychological burden. Aspirations about living with MG are similar across clusters: for all clusters, the main aspiration is to be more physically active (Figure 2).

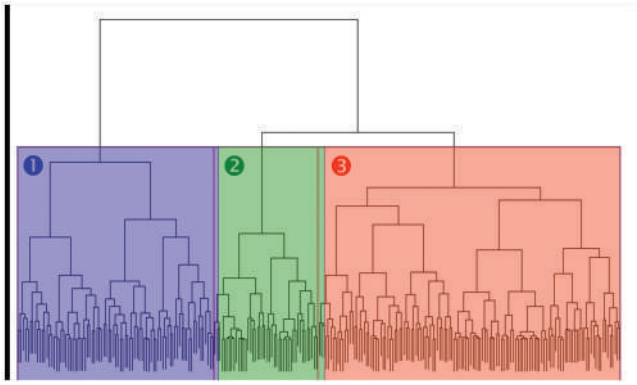

FIGURE 1 Cluster dendrogram obtained after hierarchical ascending classification.

	Cluster 1 n=83	Cluster 2 n=44	Cluster 3 n=128	P value
Gender : women/men (n, %)	68 (**86%**) / 11 (14%)	3 (7%) / 40 (**93%**)	116 (**94%**) / 8 (6%)	**<0.001**

Background and Aims: Efgartigimod, a human IgG1 antibody Fc-fragment, reduces IgG levels through neonatal Fc receptor blockade. In the ADAPT-SC study, subcutaneous (SC) efgartigimod PH20 (coformulated with recombinant human hyaluronidase PH20) was shown to be noninferior in total immunoglobulin G reduction compared with intravenous (IV) efgartigimod. Participants completing ADAPT-SC or enrolled in ADAPT+ were eligible for the ongoing ADAPT-SC+ open-label extension, which sought to evaluate long-term safety, tolerability, and efficacy of efgartigimod PH20 SC in participants with gMG.

Methods: Efgartigimod PH20 SC 1000 mg was administered in cycles of 4 once-weekly injections. Subsequent cycles were initiated ≥28 days from the last dose based on clinical evaluation. MG-ADL score assessed clinical efficacy.

Results: Through December 2022, 179 participants received ≥1 dose of efgartigimod PH20 SC, with a mean (SD) treatment and follow-up time of 395 (116) days, resulting in 193 participant-years of follow-up. Treatment-emergent adverse events (TEAEs) were predominantly mild/moderate. The most frequent TEAEs (Table 1) were injection site erythema (29.1%), COVID-19 (22.3%), and headache (20.1%). TEAEs, serious TEAEs, and infections did not increase with subsequent cycles through Cycle 9 (Figure 1). Improvement from cycle baseline (mean [SE] improvement at Week 4) was observed in Cycle 1 in MG-ADL total score (−4.0 [0.24]) with consistent and repeatable improvements seen through Cycle 9 (Figure 2), and the number of participants achieving minimal symptom expression (MSE) at any time in each cycle ranged from 35.5% to 43.5%.

	Efgartigimod PH20 SC (n=179; PYFU=193.4)	
	ER[a]	n (%)
Any TEAE, n (%)	9.0	152 (84.9)
Any TEAE grade ≥3, n (%)	0.4	36 (20.1)
Any serious TEAE, n (%)	0.3	33 (18.4)
Any injection site reaction, n (%)	3.2	82 (45.8)
Any infection, n (%)	1.0	91 (50.8)
Fatal event[b], n (%)	<0.1	4 (2.2)
Discontinued study treatment owing to TEAEs[c], n (%)	<0.1	4 (2.2)
Most commonly observed TEAEs[d], n (%)		
Injection site erythema	1.7	52 (29.1)
COVID-19	0.2	40 (22.3)
Headache	0.6	36 (20.1)
Nasopharyngitis	0.2	28 (15.6)
Diarrhea	0.2	24 (13.4)
Injection site pain	0.2	21 (11.7)
Injection site pruritus	0.2	19 (10.6)
Injection site bruising	0.2	18 (10.1)

ER, event rate; MG, myasthenia gravis; PYFU, participant-years of follow-up; TEAE, treatment-emergent adverse event.
[a]ER was calculated as number of events per total PYFU. [b]Fatal events (metastatic renal cell cancer, cardiac arrest, pulmonary mass, and COVID-19/respiratory failure) were not related to efgartigimod PH20 SC treatment, as determined by investigators. [c]Treatment discontinuation due to metastatic renal cell cancer (Cycle 1, death), cardiac arrest (Cycle 2, death), COVID-19/respiratory failure (Cycle 3, death), and MG crisis (Cycle 1). [d]Most frequent TEAEs occurring in >10% of participants receiving efgartigimod PH20 SC.

TABLE 1 Summary of TEAEs.

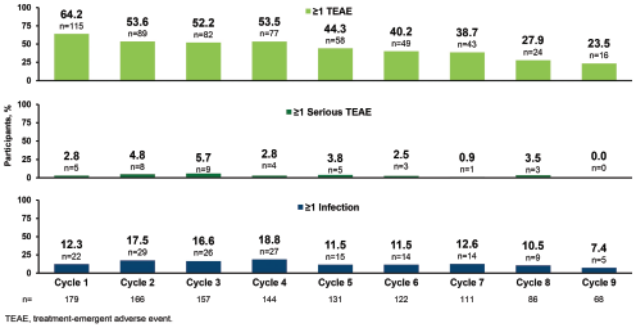

FIGURE 1 TEAEs by Cycle.

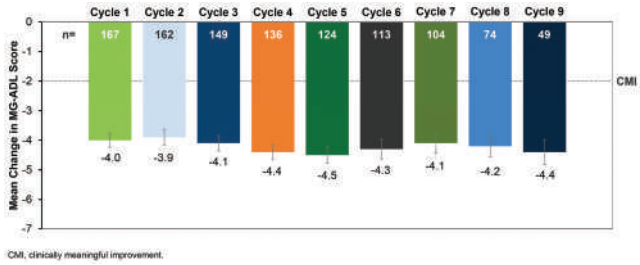

FIGURE 2 Mean Change in MG-ADL From Study Baseline at Week 4.

Conclusion: Treatment with multiple cycles of efgartigimod PH20 SC was well tolerated and efficacious, consistent with efgartigimod IV in ADAPT/ADAPT+.

EPO-809 | BCMA-targeted CAR T cell therapy in the management of refractory myasthenia gravis

M. Qu[1]; X. Rong[1]; Y. Zhao[1]; X. Sun[1]; M. Lv[1]; Y. zhou[2]; G. Tang[2]; M. Liu[1]

[1]*Department of Neurology, Affiliated Hospital of Qingdao University;* [2]*Danlo Med., Co., Ltd*

Background and Aims: Chimeric antigen receptor (CAR) T cell therapy shown promise in treating hematologic malignancies and autoimmune diseases. This study reports an ongoing Investigator-initiated trial (IIT) involving B-cell maturation antigen (BCMA)-targeted CAR T therapy for refractory myasthenia gravis (MG) patients with anti-acetylcholine receptor (AChR) antibodies positive.

Methods: The study enrolled seven patients (3 females and 4 males) with a median quantitative myasthenia gravis score (QMGS) of 15 (range: 11–27), a median age of 50 years (range: 24–64), and a median disease duration of 4 years (range: 1.25–11). After lymphodepletion, autologous BCMA-targeting CAR T cells were administered as a single infusion at doses ranging from 1.7×105/kg to 10×105/kg.

Results: The results showed all patients developed grade 1 or 2 Cytokine Release Syndrome (CRS), and no neurotoxicity syndrome was observed. The most common adverse events of grade 3 or higher were hematologic toxicity. One patient was infected with the COVID-19 virus but recovered rapidly after supportive therapies. The expansion of CAR T cells in vivo was associated with clinical symptom improvement and normalization of laboratory parameters, including serum anti-AChR IgG. MG syndromes remission was achieved in all seven patients after 3 months, and the median QMGS decreased to 5 (range: 0–11) from 15 at baseline (range: 11–27). During a median follow-up of 4 months (range: 3–10 months), drug-free remission was maintained after CAR T cell administration.

Conclusion: In conclusion, the study demonstrated that BCMA-targeted CAR T therapy is a safe and effective treatment for refractory MG.

Disclosure: Nothing to disclose.

EPO-810 | Late-onset Pompe disease: Patient journeys from symptom onset to diagnosis

R. Martínez Marín[1]; A. Doerr[2]; R. Gould[2]; J. Heuterman[3]; P. Rajasekhar[4]

[1]*Neurology Service, Hospital Universitario La Paz, Madrid, Spain;* [2]*Fulcrum Research Group, Waltham, MA, USA;* [3]*Global Medical Affairs, Sanofi, Amsterdam, The Netherlands;* [4]*Global Rare Diseases Strategy & Operations, Sanofi, Cambridge, MA, USA*

Background and Aims: Pompe disease is a rare neuromuscular disorder caused by deficiency of acid alpha-glucosidase, leading to lysosomal glycogen accumulation and consequential progressive muscle weakness, respiratory dysfunction, and functional disabilities. Pompe disease has a broad clinical spectrum in terms of affected body systems, symptom onset age, and progression rate. We aim to describe the path from symptoms onset to diagnosis in late-onset Pompe disease (LOPD) to gain a better understanding of the diagnostic journey.

Methods: Data about demographic, clinical pre-diagnosis symptoms, and diagnostic experience were collected by independent researchers during a 30-minute pre-interview survey and 60-minute telephone interview with patients or their caregivers.

Results: 56 patients with Pompe disease were interviewed; 51 had LOPD. Main demographic/clinical characteristics are given in Table 1. Frequencies of pre-diagnosis symptoms are summarised in Figure 1; the most frequent was lower limb weakness (86% [44/51] patients). Patients with earlier symptoms in life received a quicker diagnosis than older ones; 75% (9/12) aged 1–9 years were diagnosed within 2 years of symptoms versus 36% (14/39) aged ≥10 years. Most patients (66% [33/51]) were referred by healthcare professionals to neuromuscular specialists/neurologists with a final diagnosis made mainly by neuromuscular specialists (39% [20/51]) and neurologists (31% [16/51]) often as part of a team of physicians (Figure 2). Key tests leading to diagnosis: muscle biopsy ($n=18$), genetic testing ($n=12$), blood panel ($n=8$), dry blood spots ($n=5$), liver biopsy ($n=1$). Around one-third of patients were misdiagnosed before Pompe disease was confirmed.

EPO-811 | Near fiber segment jitter in the diagnosis of myasthenia gravis

R. Mandeville[1]; J. Luk[1]; O. Garnes-Camarena[2]; D. Stashuk[3]
[1]Beth Israel Deaconess Medical Center, Boston, MA, USA; [2]Jimenez Diaz Foundation University Hospital, Madrid, Spain; [3]Systems Desing Engineering, University of Waterloo, Ontario, Canada

Background and Aims: Near fiber EMG (NFEMG) focuses on the activity of muscle fibers close to the electrode, can be applied to routinely acquired needle EMG, and offers the ability to semi-automatically assess neuromuscular junction stability in a conceptually similar manner to single fiber EMG (SFEMG).

Methods: NFEMG was blindly applied to SFEMG recordings of 50 patients tested at BIDMC in the prior 18 months. In those without myopathy or neuropathy, we performed 10-fold cross validation using two E-Ref-based NFEMG jitter value thresholds to establish the performance of several different criteria for classifying patients as MG or non-MG, compared to clinical diagnosis, in each of the 10 testing sets as well as the full cohort.

Results: 12 of 50 patients were diagnosed clinically as MG after SFEMG testing (3 diagnosed as myopathy, 1 as neuropathy). Of those without myopathy or neuropathy, the sensitivity for detecting MG using NFEMG was 100% while the specificity ranged from 89% to 95% (mean of 90%). When testing on the whole cohort, sensitivity and specificity were 100% and 94%.

Conclusion: NFEMG performs well in diagnosing MG. Due to the ease of application to routine EMG and the minimal need for training, NFEMG may represent an effective screen prior to referring for SFEMG or as a viable alternative diagnostic test when SFEMG is not available, potentially addressing a significant global healthcare disparity.

Disclosure: Nothing to disclose.

EPO-812 | Natural history of distal and myofibrillar myopathies assessed by clinical and technological outcome measures (Dista-Myo)

S. Bortolani[1]; A. Vicino[2]; M. Gambella[3]; L. Villa[3]; M. Rabuffetti[4]; A. Marzegan[4]; V. Trombetta[1]; M. Cheli[2]; A. Parrotta[3]; E. Rolle[5]; E. Torchia[6]; B. Ravera[6]; M. Monforte[1]; J. Hogrel[7]; E. Ricci[6]; T. Mongini[5]; S. Sacconi[3]; L. Maggi[2]; G. Tasca[8]

[1]*UOC di Neurologia, Fondazione Policlinico Universitario "A. Gemelli" IRCCS, Roma, Italy;* [2]*Neuroimmunology and Neuromuscular Diseases Unit, Foundation IRCCS Neurological Institute Carlo Besta, Milano, Italy;* [3]*Department Centre de référence des maladies Neuromusculaires, Centre Hospitalier Universitaire (CHU) de Nice, France;* [4]*IRCCS Fondazione Don Carlo Gnocchi, Milan, Italy;* [5]*Department of Neurosciences "Rita Levi Montalcini", University of Torino, Torino, Italy;* [6]*Università Cattolica del Sacro Cuore, Rome, Italy;* [7]*Institut de Myologie, GH Pitié-Salpêtrière, Paris, France;* [8]*John Walton Muscular Dystrophy Research Centre, Newcastle University and Newcastle Hospitals NHS Foundation Trusts, Newcastle Upon Tyne, UK*

Background and Aims: Dista-Myo is an international multicentre longitudinal study that integrates validated motor function scales with novel technological tools for gait and strength assessment in patients with distal (DM) and myofibrillar myopathies (MFM). The study aims to gather natural history data and build a new toolbox for the evaluation of these disorders.

Methods: Patients were assessed by Motor Function Measure (MFM-32), timed tests and dexterity tests as functional outcome measures; technological outcome measures included Myotools for muscle strength evaluation, and wireless insoles for gait analysis.

Results: Forty-seven patients were assessed at baseline. Ninety-six% showed reduced MFM-32 scores, while 65% underperformed on 6MWT. Most patients presented impaired distal muscle strength (80% at ankle dorsiflexion, 92% at ankle plantar-flexion, 50% at grip and pinch level). Metrics extracted from gait analysis significantly differed between patients and controls and correlated with distal muscle strength and functional scores. Preliminary analysis of the changes at 12 months showed a mild but significant decrease in MFM-32 scores and MyoTools strength values compared to baseline, with a moderate responsiveness.

Conclusion: Baseline results showed heterogeneous impairment in the global motor function in our cohort of patients with DM and MFM. Distal muscle weakness and gait ability were efficiently captured by the combination of functional and digital outcome measures. MyoTools are promising digital tools able to define the extent of weakness even in severely affected patients and to capture changes in longitudinal studies.

EPO-813 | Assessing the suitability of the Neuro-QoL fatigue to evaluate fatigue in patients living with myasthenia gravis

S. Pease; K. Scippa

Janssen Global Services, LLC

Background and Aims: Generalized myasthenia gravis (gMG) is a rare, chronic, autoantibody-mediated neuromuscular disease characterized by fatigable muscle weakness. The objectives of this research were to identify an appropriate patient-reported outcome (PRO) measure to assess fatigue in patients living with gMG and to conduct patient interviews to evaluate the content validity of the measure.

Methods: A literature review identified the Neuro-QoL Fatigue as a suitable candidate PRO to assess fatigue in gMG. Twenty-three interviews were conducted with adults living with gMG. All participants were recruited from the United States via research partners following IRB approval. Each interview explored the symptoms and impacts of gMG on participants' daily lives. The last 8 interviews included debriefing of the Neuro-QoL Fatigue to determine its appropriateness for use in gMG. Interviews were recorded and transcribed verbatim, and data were thematically analyzed.

Results: All participants reported experiencing fatigue as part of their experience with gMG and that fatigue impacted their ability to carry out daily life activities and participation limitations. Among those asked to provide bothersome ratings, 80% ($n = 12$ of 15) reported that fatigue was their most bothersome symptom. The debriefing exercise demonstrated that nearly all participants interpreted the Neuro-QoL Fatigue instructions, items, and recall period as intended.

Table 1. Interview participant demographic characteristics (n=23)

Characteristic	Interview sample (n=23)

EPO-814 | Very late onset myasthenia gravis with an unexpected high titer of AChR Abs: A new serological subtype?

E. Strataki; S. Bellos; L. Lymperopoulos; V. Zouvelou
1st Neurology Department, National and Kapodistrian University of Athens, Greece, Eginitio Hospital, ERN EURO-MND

Background and Aims: Very late onset myasthenia gravis (VLOMG) (onset ≥65 years) is typically associated with low titers of acetylcholine receptor antibodies (AChR Abs), consistent with the age-related thymic atrophy. This study investigates the occurrence and characteristics of VLOMG patients with high levels of AChR Abs at diagnosis.

Methods: We performed a registry-based search for VLOMG patients with longitudinal follow-up between 2008–2023. Clinical data were collected through our MG-database.

Results: Of 69 VLOMG patients we identified 11 (15.9%) with a titer of AChR Abs ≥100 nM/L (radioimmunoprecipitation assay), 9 male and 2 female, with age at onset ranging from 65 to 85 years (mean: 75.2). AChR Abs titers ranged from 116 to 433 nM/L (mean: 217). There was no association with thymoma. All patients had generalized MG with prominent bulbar involvement. Two patients required intensive care unit monitoring. Plasmapheresis and/or intravenous immunoglobulin were necessitated in 9/11 patients. All patients were treated with prednisolone with prompt clinical response, while one received rituximab for refractory bulbar symptoms. The majority received concomitant non-steroidal immunosuppression. At the last follow-up, 9/11 patients had achieved a post-intervention status of minimal manifestations or better.

Conclusion: Patients in this serological subgroup present clinical and therapeutic characteristics of typical VLOMG patients. However, the unexpected high titer of AChR Abs raises concern about residual thymic lymphoid follicles, a possible but rare finding in LOMG. This could not be confirmed, as none of our patients underwent thymectomy. Another plausible explanation could be the presence of autoantibodies targeting multiple AChR subunits. The latter warrants additional analysis of Abs subunit specificity.

Medea, Bosisio Parini, Italy; [11]Neuromuscular and Rare Diseases Unit, Department of Neuroscience, Ospedale Maggiore Policlinico, Milan, Italy; [12]Section of Clinical Neurology, Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona, Verona, Italy; [13]Neurology Unit, Department of Neurosciences, University Hospital Santa Maria della Misericordia, Udine, Italy; [14]NeuroMuscular Omnicentre (NeMO) Trento, Villa Rosa Hospital, Pergine Valsugana, Italy; [15]Department of Neurosciences, University of Padua, Padua, Italy

Background and Aims: Pompe Disease is due to deficiency of the lysosomal enzyme acid alfa-glucosidase (GAA), with large phenotypic variability. An enzymatic replacement therapy (ERT) has been available since 2006, with different individual responses. Considering the new emerging therapies, it is important to collect information

on large patients' cohorts to define subgroups with homogeneous characteristics and their prognostic factors.

Methods: Fifteen Neuromuscular Centers, afferent to the Italian Myology Association (AIM), collected data from 90 LOPD patients (1–72 y, median 47) ERT-treated for 10 years; for 39 of them, data at 15 years were available.

Results: At baseline, 6MWT results were wide-ranging (60–814 m); 13/79 patients needed ventilatory support. FVC% values paralleled 6MWT results, with few exceptions. After 10 y, 6/77 patients had lost ambulation, and additional 3/30 after 15 years. Baseline 6MWT was <250 m in 8/9 of them. After 15 y, 9/27 patients were still stable, whereas 18 patients had worsened (66.6%). Age at start of therapy <18 y was a positive factor (85% stable after 15 y, against 7.31% treated aging >40 y). Five/32 patients (15.6%) with an initial FVC >80% started NIV after 10 y, compared to 21/34 (61.76%) with an initial FVC <80%. After 15 y, 16/39 patients (41.02%) were still ventilator-free.

Conclusion: Our results confirm the large variability of clinical course and ERT responses in LOPD patients, with about 30% patients stable after 15 years (most of them with an early-stage start of therapy), and a variable type and degree of decline in the others. A careful individual evaluation is requested in every patient when discussing the switch to alternative therapies.

EPV-055 | Fatigue and autonomic symptoms in chronic inflammatory demyelinating polyneuropathy – Pilot study

Ł. Rzepinski[1]; M. Zawadka-Kunikowska[2]
[1]*Department of Neurology, 10th Military Research Hospital and Polyclinic, Bydgoszcz, Poland;* [2]*Department of Human Physiology, Nicolaus Copernicus University Ludwik Rydygier*

EPV-056 | Young-onset dementia: Portrait of a tertiary outpatient clinic

M. Pereira Coutinho[1]; J. Durães[2]; M. Lima[2]; H. Gens[2]; D. Duro[2]; M. Almeida[3]; I. Baldeiras[3]; M. Tábuas-Pereira[2]; I. Santana[2]
[1]*Neurology Department, Centro Hospitalar Universitário Lisboa Central, Lisbon, Portugal;* [2]*Department of Neurology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal;* [3]*Centro de Neurociências e Biologia Celular da Universidade de Coimbra, Coimbra, Portugal*

EPV-057 | Alcoholism as a risk factor for frontal AD

M. Coelho[1]; I. Monteiro[1]; M. Lima[1]; J. Durães[1]; C. Bernardes[1]; P. Faustino[1]; D. Duro[1]; I. Baldeiras[2]; M. Almeida[3]; M. Tábuas-Pereira[1]; I. Santana[1]
[1]*Neurology Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal;* [2]*Neurochemistry laboratory, Center for Neuroscience and Cell Biology, Coimbra, Portugal;* [3]*Neurogenetics laboratory, Human Genetics at Center for Neuroscience and Cell Biology, Coimbra, Portugal*

EPV-058 | Association between cerebrovascular reactivity and CSF/plasma biomarkers in Alzheimer's disease

M. Di Donna[1]; M. Bagnato[2]; C. Bonomi[1]; C. Motta[1]; M. Diomedi[2]; A. Martorana[1]
[1]*Memory Clinic, Policlinico Tor Vergata, Rome;* [2]*Stroke Unit, Policlinico Tor Vergata, Rome*

EPV-059 | A rarity knocking on the clinic door – Ross syndrome

R. Oguntoye
Neurology, Queen Elizabeth Hospital, Birmingham, UK

EPV-060 | Effect of oral dimethyl fumarate treatment on orthostatic hypotension in multiple sclerosis patients

M. Gliniak[1]; M. Wnuk[2]; M. Marona[2]; K. Nowak[2]; A. Słowik[2]; M. Tutaj[2]
[1]*Department of Neurology, University Hospital in Krakow, Krakow, Poland;* [2]*Department of Neurology, Jagiellonian University in Krakow, Krakow, Poland*

EPV-061 | The effectiveness of dementia prevention programs: A systematic review and meta-analysis for 61,457 patients

A. Al Wssawi; H. Talib Hashim
University of Warith Al-Anbiyaa, College of Medicine

EPV-062 | Diagnosis of mild cognitive impairment in primary care in the era of plasma biomarkers and anti-amyloid therapies

M. Altuna; A. Estanga; M. García-Sebastián; M. Ecay-Torres; M. Tainta; C. López; J. Saldias; M. Cañada; A. Iriondo; P. Martínez-Lage
CITA-Alzheimer Foundation, Donostia, Spain

EPV-063 | Autonomic responses in electroconvulsive therapy: Understanding the neurophysiological basis of ejaculation

M. Le[1]; B. Carr[2]
[1]*College of Medicine, University of Florida, Gainesville, USA;* [2]*Department of Psychiatry, University of Florida, Gainesville, USA*

EPV-064 | Circulatory shock associated with left insular stroke and chronic steroid treatment

M. Russo; F. Dono; G. Polito; C. Ciprietti; S. Melchiorre; G. Patané; A. Pjeci; D. Calisi; S. Sensi
"G. d'Annunzio" University of Chieti-Pescara, Chieti, Italy

EPV-065 | Brain hemorrhage or edema in U.S. veterans with Alzheimer's disease prescribed antiplatelet and anticoagulant therapy

B. Mittler[1]; J. Reisman[2]; Y. Wang[3]; B. Aguilar[4]; R. Zhang[5]; A. Tahami Monfared[5]; Q. Zhang[5]; W. Xia[6]
[1]*Geriatric Research and Education and Clinical Center, VA South Texas Health Care, San Antonio, TX, USA;* [2]*Center for Healthcare Organization & Implementation, VA Bedford Healthcare System, Bedford, MA, USA;* [3]*Department of Applied Mathematics, Wentworth Institute of Technology, Boston, MA, USA;* [4]*The Bedford VA Research Corporation, Inc., Bedford, MA, USA;* [5]*Alzheimer's Disease and Brain Health, Eisai, Inc., Nutley, NJ, USA;* [6]*Department of Pharmacology, Physiology and Biophysics, Boston University Chobanian & Avedisian School of Medicine, Boston, MA, USA*

EPV-066 | More than just a transient memory loss: TGA as a first presentation of neurodegenerative disease

M. Kholodova[1]; T. Slobodin[2]; G. Sciacca[3]; O. Mamenko[4]; A. Matsko[5]; A. Afanasieva[6]
[1]*Department of Neurology and Neurosurgery, LLC "Dobrobut-Clinic", Kyiv, Ukraine;* [2]*Department of Neurology and Neurosurgery, LLC "Dobrobut-Clinic", Kyiv, Ukraine;* [3]*Department of Medical, Surgical Sciences and Advanced Technologies GF Ingrassia, University of Catania, Catania, Italy;* [4]*Department of Neurology and Neurosurgery, LLC "Dobrobut-Clinic", Kyiv, Ukraine;* [5]*Department of Neurology and Neurosurgery, LLC "Dobrobut-Clinic", Kyiv, Ukraine;* [6]*Department of Neurology and Neurosurgery, LLC "Dobrobut-Clinic", Kyiv, Ukraine*

EPV-067 | Factors affecting clinical improvement in patients diagnosed with possible normal pressure hydrocephalia

N. Yıldız Akbulut[1]; B. Özen Barut[1]; H. Düzkalır[2]; D. Özkaptan[3]; H. Günbey[2]
[1]*SBU Kartal Dr. Lutfi Kirdar Training and Research Hospital, Department of Neurology;* [2]*SBU Kartal Dr. Lutfi Kirdar Training and Research Hospital, Department of Radiology;* [3]*SBU Kartal Dr. Lutfi Kirdar Training and Research Hospital, Department of Psychology*

EPV-068 | The efficacy of a home-based, augmented reality dual-task platform for cognitive-motor training for elderly patients

S. Jung[1]; J. Park[2]; Y. Shim[3]; B. Yoon[4]
[1]*Department of Neurology, Hallym University Medical Center Kangnam Sacred Heart Hospital, Seoul, Republic of Korea;* [2]*Department of Rehabilitation Medicine, Eunpyeong St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea;* [3]*Department of Neurology, The Catholic University of Korea Eunpyeong St. Mary's Hospital, Seoul, Republic of Korea;* [4]*Department of Neurology, Konyang University Hospital, Konyang University College of Medicine, Daejeon, Republic of Korea*

EPV-069 | Clinical and autonomic characteristics in patients with postural tachycardia syndrome

S. Kang
Department of Neurology, College of Medicine, Jeju National University, Jeju, Republic of Korea

EPV-070 | Autonomic dysfunction in patients with Epilepsy

N. Rai[1]; S. Chabri[2]; R. Singh[3]; R. Joshi[4]
[1]*Department of Neurology AIIMS Bhopal;* [2]*Department of Neurology AIIMS Bhopal;* [3]*Department of Physiology AIIMS Bhopal;* [4]*Department of General Medicine AIIMS Bhopal*

EPV-071 | Effects of obstructive sleep apnea syndrome associated with aging: Preventing dementia – biomarker research

P. Guillot[1]; F. Roche[2]; N. Barth[3]; N. Perek[4]
[1]*Université Jean Monnet, Saint-Etienne, France;* [2]*CHU, Saint-Etienne, France;* [3]*Gérontopôle AURA, Saint-Etienne, France;* [4]*INSERM, U1059, SAINBIOSE, Université de Lyon, Saint-Etienne, France*

EPV-072 | Plasma ptau species, neuronal and glial biomarkers for evaluating Brain health in ageing

A. Pilotto[1]; A. Galli[1]; M. Bugada[1]; V. Quaresima[1]; C. Tolassi[1]; C. Trasciatti[1]; A. Rizzardi[1]; M. Parigi[2]; C. Tirloni[1]; S. Caratozzolo[1]; A. Benussi[1]; N. Ashton[3]; K. Blennov[4]; H. Zetterberg[5]; S. Giliani[2]; A. Padovani[1]
[1]*Neurology Unit, university of Brescia and ASST SPedali CIvili of Brescia, Brescia, Italy;* [2]*Nocivelli Institute, ASST SPedali CIvili of Brescia;* [3]*University of Gothenborg, GOthenborg, Sweden;* [4]*Clinical Neurochemistry Laboratory, MoeIndal, Sweden;* [5]*Ienberg Centre for Molecular and Translational Medicine, GOthenborg, Sweden*

EPV-073 | The clinical overlap between frontotemporal dementia (non-fluent variant PPA) and Corticobasal syndrome: A case report

M. Palchukovska[1]; A. Afanasieva[2]; T. Slobodin[3]
[1]*Department of Neurology, Shupyk National Healthcare University of Ukraine, Kyiv, Ukraine;* [2]*Department of Neurology and Neurosurgery, LLC "Dobrobut-Clinic", Kyiv, Ukraine;* [3]*Department of Neurology, Shupyk National Healthcare University of Ukraine, Kyiv, Ukraine*

EPV-074 | Is almería reaady for lecanemab?

R. Milán Pinilla; E. Guevara Sánchez; P. Olea Rodriguez; L. Andrade Zumárraga; M. Rodriguez Camacho; M. Iglesias Espinosa
Cognitive Care Unit, Neurology Department, Torrecárdenas University Hospital, Almería, Spain

EPV-075 | Diagnosis of functional cognitive disorder – Misguided by imaging findings, psychiatric and family history?

N. Žunič[1]; R. Berlot[2]
[1]*Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia;* [2]*Department of Neurology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

EPV-076 | Effect of treatment for head & neck tumor on autonomic nervous system

R. Singh[1]; A. Verma[2]; V. Gupta[2]; G. Behra[2]
[1]*Department of Physiology, All India Institute of Medical Sciences, Bhopal, India;* [2]*Department of Otorhinolaryngology & Head–Neck Surgery, AIIMS Bhopal, India*

EPV-077 | Correlation of gait characteristics to cognitive status during dual-task walking in elderly subjects of different ages

S. Radovanovic[1]; V. Markovic[2]; I. Stankovic[2]; N. Nedovic[3]
[1]*Institute for Medical Research, University of Belgrade, Belgrade, Serbia;* [2]*Neurology Clinic, Clinical Center of Serbia, Faculty of Medicine, University of Belgrade, Belgrade, Serbia;* [3]*College of Health Sciences, Academy of Applied Studies, Belgrade, Serbia*

EPV-078 | A single blind rct in india on effectiveness of adjunct cognitive stimulation therapy on cognitive outcomes in dementia

S. Bhowmik[1]; M. Chandra [2]; K. Anand[3]
[1]*Assistant Professor Neurology, AIIIMS Kalyani, Kolkata, India;* [2]*Prof and HOD Psychiatry, ABVIMS and Dr RML Hospital, New Delhi, India;* [3]*Prof and Ex-HOD Neurology, ABVIMS and Dr RML Hospital, New Delhi, India*

EPV-079 | A prenatal filamin a deficiency as a possible protective mechanism in Alzheimer's disease progression. A case study

T. Marusich; B. Hanseeuw; A. Ivanoiu
Institute of Neuroscience, Saint Luc University Hospital, Brussels, Belgium

EPV-080 | Cognitive deterioration between Alzheimer's dementia and Parkinson's disease dementia

S. Cankaya[1]; B. Yulug[1]; E. Ozdemir Oktem[1]; A. Ozsimsek[1]; D. Sayman[1]; R. Karaca[1]; C. Sayman[1]; U. Duran[1]; L. Hanoglu[2]
[1]*Department of Neurology, Alanya Alaaddin Keykubat University, Antalya, Turkey;* [2]*Research Institute for Health Sciences and Technologies (SABITA), Clinical Electrophysiology, Neuroimaging and Neuromodulation Laboratory, Istanbul Medipol University, Istanbul, Turkey*

EPV-081 | Dementia and associated caregiver family burden in a North Indian cohort: An observational study

K. Mahesh
Post Graduate Institute of Medical Education and Research, PGIMER

EPV-082 | The "claustrum sign" in covid-19 AND Alzheimer's disease: A case report

S. Orrego Molina[1]; M. García Alonso[2]; A. Esquivel[3]; M. Manzano Palomo[4]
[1]*Hospital Resident, Psychiatric Department, Universitary Hospital Infanta Leonor, Madrid, Spain;* [2]*Head of Nuclear Medicine Department, Universitary Hospital Getafe, Madrid, Spain;* [3]*3Head of Neurology Department, Universitary Hospital Infanta Leonor, Madrid, Spain;* [4]*Neurology Department, Universitary Hospital Infanta Leonor, Madrid, Spain*

EPV-083 | Longitudinal objective and self-reported cognitive function in subjective cognitive decline

S. Ryu[1]; C. Lee[2]; S. Ho[2]; Y. Hong[3]; J. Jeong[4]; K. Park[5]; S. Kim[6]; M. Wang[6]; S. Choi[7]; D. Yang[2]
[1]*Neurology, The Catholic University of Korea, Daejeon St Marys Hospital, Daejeon, Republic of Korea;* [2]*Neurology, The Catholic University of Korea, Seoul St. Mary's Hospital, Seoul, Republic of Korea;* [3]*Neurology, The Catholic University of Korea, Uijeongbu St. Mary's Hospital, Uijeongbu, Republic of Korea;* [4]*Neurology, Ewha Womans University Seoul Hospital, Ewha Womans University School of Medicine, Seoul, Republic of Korea;* [5]*Neurology, Gachon University Gil Hospital, Incheon, Republic of Korea;* [6]*Neurology, Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea;* [7]*Neurology, Inha University School of Medicine, Incheon, Republic of Korea*

EPV-084 | Drug-induced reversible cerebral vasoconstriction syndrome: A real-world evidence

S. Ben Mammou; B. Guillon; S. De Gaalon; P. Constant dit Beaufils
Nantes Université, CHU Nantes, Service de Neurologie, CNRS, INSERM, l'institut du thorax, Nantes, France

EPV-085 | Saccadic eye movement task can differentiate functional cognitive disorder from mild cognitive impairment

T. Wilcockson[1]; S. Roy[2]; T. Crawford[3]
[1]*School of Sport, Exercise and Health Sciences, Loughborough University, Loughborough, UK;* [2]*Department of Neurology, Leicester Royal Infirmary, Leicester, UK;* [3]*Department of Psychology, Lancaster University, Bailrigg, UK*

EPV-086 | Development of a brief intervention to address z-hypnotic overuse among older adults

T. Siddiqui[1]; M. Torheim Bjelkarøy[2]; T. Breines Simonsen[1]; J. Menichetti[1]; J. Gerwing[1]; C. Lundqvist[2]
[1]*Health Services Research Unit (HØKH), Akershus University Hospital, Lørenskog, Norway;* [2]*Health Services Research Unit (HØKH), Akershus University Hospital, Lørenskog, Norway and Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway*

EPV-087 | Alteration of blood biomarkers in Alzheimer's dementia with vascular lesions

T. Nakase; N. Tomita; Y. Takano; Y. Tatewaki; Y. Taki
Department of Aging Research & Geriatric Medicine, IDAC, Tohoku University

EPV-088 | Slow wave sleep and dementia: A systematic review and critical analysis

S. Tan[1]; C. Tang[1]; B. Nguyen[2]
[1]*Department of Psychiatry, Sengkang General Hospital, Singapore;* [2]*Duke NUS Medical School*

EPV-089 | Colour memory in mild cognitive impairment and Alzheimer's disease

V. Sutnikienė; G. Kaubrys
Clinic of Neurology and Neurosurgery, Institute of Clinical Medicine, Faculty of Medicine, Vilnius University, Vilnius, Lithuania

EPV-090 | Spectrum of vascular cognitive impairment according to the type of brain vascular damage

V. Ignatova[1]; A. Marazov[2]
[1]*Clinic of Neurology Multiprofile Hospital for Active Treatment – National Heart Hospital, Sofia, Bulgaria;* [2]*Institute of Biophysics and Biomedical Engineering Bulgarian Academy of Sciences Acad, Sofia, Bulgaria*

EPV-091 | TPS – Are there new perspectives in treatment of AD?

V. Rößner-Ruff; M. Ziegenbein; C. Penkov; J. Krieger; K. Friedrich; C. Disque; J. Michaelsen; C. Hauser; K. Höffgen; D. Clark
Wahrendorff Clinic, Großer Knickweg 6, Sehnde, Germany

EPV-092 | Potential applications of software supporting the early detection of cognitive disorders and dementia in diagnostics

Z. Gelencsér[1]; E. Simonová[2]; L. Varga[3]; M. Sátori[4]
[1]*NETIS Ltd., Budapest, Hungary;* [2]*ALSAD Medical, Budapest, Hungary; NETIS Ltd., Budapest, Hungary;* [3]*ALSAD Medical, Budapest, Hungary;* [4]*Szent János Hospital and North Buda Unified Hospitals, Budapest, Hungary*

EPV-093 | Efficacy and safety of gantenerumab in the treatment of Alzheimer's disease: A systematic review and meta-analysis

M. Sobral[1]; V. Soares[2]; O. Gonçalves[3]; V. Abreu[4]; L. Bendaham[5]; B. Batista[6]; M. Santos[7]
[1]*University of West Sao Paulo (UNOESTE), Presidente Prudente, Brazil;* [2]*Federal University of the Jequitinhonha and Mucuri Valleys (UFVJM), Diamantina, Brazil;* [3]*Federal University of Piauí (UFPI), Teresina, Brazil;* [4]*Medical School of Petropolis (UNIFASE – FMP), Rio de Janeiro, Brazil;* [5]*Federal University of Roraima (UFRR), Boa Vista, Brazil;* [6]*Restoration Hospital, Recife, Brazil;* [7]*University of the Plateau of Santa Catarina, Lages, Brazil*

EPV-094 | Digital biomarkers from diffusion MRI to monitor white matter abnormalities in Alzheimer's disease

M. Grange; J. Martini; A. Bezie; V. Perlbarg
BrainTale SAS, Strasbourg, France

EPV-095 | Correlation of hippocampal volume with memory impairment in Alzheimer's disease

V. Miloševi[1]; M. Malobabić[1]; E. Antić[1]; A. Aracki-Trenkić[2]; M. Živanović[2]; D. Stojanov[2]; J. Bašić[3]
[1]*Clinic of Neurology, University Clinical Center Niš;* [2]*Center for Radiology, University Clinical Center Niš;* [3]*Department of Biochemistry, Faculty of Medicine, University of Niš, Serbia*

EPV-096 | Pupillary light reflex testing may specify the location of visual tract lesions in patients with multiple sclerosis

R. Wang[1]; C. de Rojas Leal[2]; F. Canavese[1]; C. Möbius[1]; D. Lee[3]; R. Linker[3]; M. Hilz[1]
[1]*Department of Neurology, University of Erlangen-Nuremberg, Erlangen, Germany;* [2]*Department of Neurology, Hospital Universitario Virgen de La Victoria, Malaga, Spain;* [3]*Department of Neurology, University Hospital Regensburg, University of Regensburg, Regensburg, Germany*

EPV-097 | Cohort study of the effects of occupation and environmental tobacco smoke on Alzheimer's disease

L. Yang
Zhejiang Hospital

EPV-098 | Correlation of CSF index of blood–brain barrier with visual rating scale of brain MRI

Y. Shim[1]; B. Yoon[1]; S. Jung[2]
[1]*Department of Neurology, College of Medicine, The Catholic University of Korea;* [2]*Department of Neurology, Hallym University Medical Center Kangnam Sacred Heart Hospital, Seoul, Korea*

EPV-099 | Clinical, radiological and biomarker analysis of single center Creutzfeld-Jacob disease patients

Z. Kaya Güleç[1]; T. Çamoğlu[1]; Z. Yurttaş[1]; E. Keskin[1]; A. Arcan[2]; B. Türk[2]; F. Asan[2]; N. Uzun-Adatepe[2]; E. Dursun[1]; D. Gezen-Ak[1]
[1]*Institute of Neurological Sciences, Istanbul University-Cerrahpasa, Istanbul, Turkey;* [2]*Department of Neurology, Istanbul University-Cerrahpaşa, Cerrahpaşa Medical Faculty, Istanbul, Turkey*

EPV-100 | Clinical peripheral nerve examination in older adults with respect to risk factors and peripheral circulation

W. Bronge
Lund University, Division of Geriatrics

EPV-101 | Rare case of acute middle cerebral artery stroke with ipsilateral hemiplegia and uncrossed corticospinal tracts

E. Abi Fadel[1]; T. El Khoury[2]; A. Nassif[2]; S. Iskandar[1]; H. Al Khuder[1]; W. Ayoub[1]; M. El Dassouki[1]; A. Shatila[1]
[1]*Department of Neurology, Lebanese American University Medical Centre-Rizk Hospital, Beirut, Lebanon;* [2]*Department of Radiology, Lebanese American University Medical Centre-Rizk Hospital, Beirut, Lebanon*

EPV-102 | Evaluation of atrial cardiopathy in embolic stroke of undetermined source in elderly subjects with acute ischemic stroke

A. Narayan; S. Dey; D. Chakraborty; A. Ghosh
Apollo Multispeciality Hospitals Limited, Kolkata, India

EPV-103 | Post-transcatheter aortic valve implantation stroke: an analysis of risk factors, characteristics and clinical outcomes

E. Mariño[1]; A. Adán[1]; G. Galeote[2]; G. Ruiz-Ares[1]; C. Hervás[1]; E. de Celis[1]; O. Camejo[1]; S. Garcia[1]; A. Jurado[2]; R. Moreno[2]; B. Fuentes[1]; R. Rigual[1]
[1]*Department of Neurology and Stroke Center, Hospital La Paz Institute for Health Research-IdiPAZ (La Paz University Hospital-Universidad Autónoma de Madrid), Madrid, Spain;* [2]*Interventional Cardiology Section, Department of Cardiology, Hospital La Paz Institute for Health Research-IdiPAZ (La Paz University Hospital-Universidad Autónoma de Madrid), Madrid, Spain*

EPV-104 | Neurological findings in patients with organic acidemias

G. Aliyeva[1]; A. Karakiraz[4]; S. Özdemir[1]; A. Durmuş[2]; B. Ak[2]; Ş. Kılıç[2]; A. Selamioğlu[2]; C. Öney[3]; K. Özbilen[4]; H. Maraş Genç[3]; M. Balcı[2]; M. Karaca[2]; T. Gündüz[1]; N. Şirin İnan[1]; A. Öge[1]; G. Gökçay[2]; M. Kürtüncü[1]
[1]*Department of Neurology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey;* [2]*Division of Pediatric Nutrition and Metabolism, Istanbul University Faculty of Medicine, Istanbul University, Istanbul, Turkey;* [3]*Department of Pediatric Neurology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey;* [4]*Department of Ophthalmology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey*

EPV-105 | Carotid Eagle syndrome: A possible cause for undeterminated ischemic stroke cases

A. Gardin[1]; P. La Spina[1]; F. Grillo[1]; F. Giammello[2]; E. Nastro Siniscalchi[3]; S. Cicchiello[3]; K. Galletta[4]; F. Granata[4]; R. Musolino[1]; A. Toscano[1]

[1]Stroke Unit, Department of Clinical and Experimental Medicine, University Hospital of Messina, Italy; [2]International Doctorate in Translational Molecular Medicine and Surgery, Department of Biomedical, Dental, Morphological and Functional Imaging Sciences, University Hospital of Messina, Italy; [3]Maxillofacial Surgery Unit, Department of Biomedical and Dental Sciences, Morphological and Functional Images, University Hospital of Messina, Italy; [4]Neuroradiology Unit, Department of Biomedical, Dental Sciences, Morphological and Functional Images, University Hospital of Messina, Italy

EPV-106 | Acute recanalization therapy for ischemic stroke during pregnancy and puerperium

A. Richardt[1]; K. Aarnio[1]; A. Korhonen[1]; K. Rantanen[1]; L. Verho[2]; S. Curtze[1]; H. Laivuori[3]; M. Gissler[4]; M. Tikkanen[5]; P. Ijäs[1]

[1]Neurology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [2]Obstetrics and Gynecology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [3]Medical and Clinical Genetics, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; Institute for Molecular Medicine Finland, Helsinki Institute of Life Science, University of Helsinki, Helsinki, Finland; [4]Department of Knowledge Brokers, Finnish Institute for Health and Welfare, Helsinki, Finland; [5]Obstetrics and Gynecology, University of Helsinki, Helsinki, Finland

EPV-107 | Radiological eligibility of patients presenting with hyperdense MCA sign for mechanical thrombectomy

D. Lizzeik; C. Ibrahim; E. Tannouri; F. El Ghadban; M. Saad; W. Ayoub; H. Al Khuder; S. Iskandar; E. Abi Fadel; M. El Dassouki; A. Shatila; R. Ahdab

Gilbert and Rose-Marie Chagoury School of Medicine, Lebanese American University, Byblos, Lebanon

EPV-108 | The effect of anodal tDCS on post-stroke cognitive impairment in the acute phase: A pilot study

A. Yalcinkaya[1]; B. Yulug[2]; D. Sayman[2]; L. Hanoglu[1]; E. Ozdemir Oktem[2]; A. Ozsimsek[2]; S. Cankaya[2]; C. Sayman[2]

[1]Research Institute for Health Sciences and Technologies (SABITA), Clinical Electrophysiology, Neuroimaging and Neuromodulation Laboratory, Istanbul Medipol University, Istanbul, Turkey; [2]Department of Neurology, Alanya Alaaddin Keykubat University, Antalya, Turkey

EPV-109 | The early mobilization decision after an acute stroke: An umbrella review

C. Fernandes[1]; S. Bernardo-Castro[1]; J. André-Sousa[1]; C. Fernandes[1]; F. Silva[1]; A. Fonseca[2]; P. Castro[3]; E. Azevedo[3]; H. Donato[4]; J. Sargento-Freitas[1]

[1]Serviço de Neurologia, Unidade Local de Saúde de Coimbra, Coimbra, Portugal; [2]Serviço de Neurologia, Unidade Local de Saúde Santa Maria, Lisbon, Portugal; [3]Serviço de Neurologia, Unidade Local de Saúde São João, Porto, Portugal; [4]Documentation and Scientific Information Department, Unidade Local de Saúde de Coimbra, Coimbra, Portugal

EPV-110 | A 'salted pretzel' after a car accident

D. Santos Oliveira; E. Alves; J. Roriz

Neurology Department, Unidade Local de Saúde de Entre o Douro e Vouga, Santa Maria da Feira, Portugal

EPV-111 | The role of autophagy in the adaptation of neurons to chronic hypoxia

T. Baranich[1]; A. Gofman[3]; D. Voronkov[1]; D. Kharlamov[2]; P. Anufriev[1]; V. Glinkina[3]; V. Sukhorukov[1]

[1]Research Center of Neurology, Moscow, Russian Federation; Pirogov Russian National Research Medical University, Moscow, Russian Federation; [2]Scientific and Practical Center for Specialized Medical Care for Children, Moscow, Russian Federation; [3]Pirogov Russian National Research Medical University, Moscow, Russian Federation

EPV-112 | Mechanical thrombectomy in acute ischemic stroke: Predisposing factors for hemorrhagic transformation

D. Jakubowicz-Lachowska[1]; A. Mironczuk[1]; A. Milewska[2]; M. Bazylewicz[1]; A. Kulakowska[1]; J. Kochanowicz[1]
[1]*Department of Neurology, Medical University of Bialystok, Poland;* [2]*Department of Biostatistics and Medical Informatics, Medical University of Bialystok, Poland*

EPV-113 | Circadian effects on stroke outcomes after clot retrieval – An exploratory analysis

J. Donnelly[1]; C. Soo[2]; P. Barber[2]
[1]*Department of Neurology, Auckland City Hospital, New Zealand;* [2]*Department of Medicine, University of Auckland, New Zealand*

EPV-114 | Reperfusion therapy vs. conservative management in acute stroke patients with premorbid disability: Retrospective study

E. Dotto[1]; F. Pedroni[1]; M. Vabanesi[2]; R. Chieffo[2]; G. Giacalone[2]; G. Cutillo[1]; M. Orrico[2]; M. Bacigaluppi[2]; M. Filippi[1]; L. Roveri[2]
[1]*Department of Neurology, IRCCS San Raffaele Scientific Institute, Milan, Italy; Vita-Salute San Raffaele University, Milan, Italy;* [2]*Department of Neurology, IRCCS San Raffaele Scientific Institute, Milan, Italy*

EPV-115 | Markers of damage to the blood–brain barrier and brain in cerebral small vessel disease with cognitive impairments

M. Tsypushtanova; L. Dobrynina; A. Shabalina; K. Shamtieva; A. Makarova; M. Zabitova; Z. Gadzhieva; E. Gnedovskaya
Research Center of Neurology, Moscow, Russian Federation

EPV-116 | Carotid plaque MRI: Effects of plaque features on embolic complications and cognition after carotid artery stenting

O. Ozdemir[1]; A. Guler[2]; C. Eraslan[3]; C. Cınar[4]; I. Oran[4]
[1]*Department of Neurology, Buca Seyfi Demirsoy Hospital, İzmir, Turkey;* [2]*Department of Neurology, Ege University Hospital, İzmir, Turkey;* [3]*Department of Neuroradiology, Ege University Hospital, İzmir, Turkey;* [4]*Department of Invasive Radiology, Ege University Hospital, İzmir, Turkey*

EPV-117 | Decompressive craniectomy, for Whom? When? How Much?

O. Ozdemir[1]; A. Guler[2]; N. Celebisoy[2]; H. Sirin[2]; C. Eraslan[3]; E. Ozgiray[4]; T. Turhan[4]
[1]*Departmant of Neurology, Buca Seyfi Demirsoy Hospital, İzmir, Turkey;* [2]*Department of Neurology, Ege University Hospital;* [3]*Department of Neuroradiology, Ege University Hospital;* [4]*Department of Neurosurgery, Ege University Hospital, İzmir, Turkey*

EPV-118 | Precipitating factors in Moyamoya angiopathy, it's profile and implications: An experience from eastern India

S. Das; S. Dubey; B. Ray
Department of Neurology, Bangur Institute of Neurosciences, Institute of Post Graduate Medical Education and Research, Kolkata, India

EPV-119 | Acute incidental cerebral microinfarcts may predict ischemic stroke in patients with cancer

J. Naftali[1]; R. Barnea[1]; A. Leader[2]; R. Eliahou[3]; K. Pardo[1]; A. Tolkovsky[1]; V. Hasminski[2]; G. Rephaeli[1]; S. Bloch[4]; W. Saliba[5]; A. Wilf-Yarkoni[1]; E. Auriel[1]
[1]*Department of Neurology, Rabin Medical Center, Petach Tikva, Israel;* [2]*Department of Medicine, Hematology Service, Memorial Sloan Kettering Cancer Center, New York City, New York, USA;* [3]*Department of Radiology, Rabin Medical Center, Petach Tikva, Israel;* [4]*Department of Neurology, Carmael Medical Center;* [5]*Department of Community Medicine and Epidemiology, Lady Davis Carmel Medical Center*

EPV-120 | Acute incidental cerebral microinfarcts are common in patients with antiphospholipid syndrome

J. Naftali[1]; R. Barnea[1]; R. Eliahou[2]; W. Saliba[3]; S. Bloch[4]; A. Leader[1]; A. Wilf-Yarkoni[1]; E. Auriel[1]
[1]*Department of Neurology, Rabin Medical Center, Petach Tikva, Israel;* [2]*Department of Radiology, Rabin Medical Center, Petach Tikva, Israel;* [3]*Department of Community Medicine and Epidemiology, Lady Davis Carmel Medical Center;* [4]*Department of Neurology, Carmel Medical Center*

EPV-121 | The current profile of elderly Tunisian stroke patients

C. Khiari; E. Jarrar; A. Rekik; K. Jemai; S. Naija; A. Hassine; S. Ben Amor
Neurological Department of Sahloul-Sousse University Hospital, Tunisia

EPV-122 | Chronic cognitive deficits among aneurysmal subarachnoid hemorrhage survivors

E. Sagues Sese; D. Ojeda; C. Dier; E. Samaniego
University of Iowa Hospitals and Clinics

EPV-123 | Outcome predictors of posterior circulation ischemic stroke: A retrospective, single centre study

E. Rollo[1]; R. Calandrelli[2]; L. Tuzza[2]; G. Della Marca[3]; V. Brunetti[3]
[1]Department of Neurosciences, Università Cattolica del Sacro Cuore, Rome, Italy; [2]Radiology Unit, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy; [3]Neurology Unit, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy

EPV-124 | Gait disorders in cerebral small vessel disease: The role of cerebrospinal fluid flow and venous drainage impairment

L. Dobrynina; E. Bitsieva; A. Byrochkina; M. Tsypushtanova; A. Makarova; M. Zabitova; K. Shamtieva; Y. Akhmetshina; V. Trubitsyna
Research Center of Neurology, Moscow, Russian Federation

EPV-125 | CT perfusion in acute-onset global aphasia: A powerful tool to make a proper diagnosis

G. Furlanis[1]; E. Vincis[1]; G. Farina[2]; G. Prandin[1]; L. Mancinelli[1]; F. Palacino[1]; P. Caruso[1]; M. Naccarato[1]; M. Ukmar[3]; P. Manganotti[1]
[1]Clinical Unit of Neurology, Trieste University Hospital – ASUGI, Trieste, Italy; [2]Department of Medicine, Surgery and Health Sciences, Treiste University Hospital – ASUGI, Trieste, Italy; [3]Department of Radiology, Trieste University Hospital-ASUGI, Trieste, Italy

EPV-126 | Moyamoya presenting with tremor and bilateral symmetrical hyperintensities of the corticospinal tracts

E. Puci[1]; A. Quka[2]; A. Rroji[3]; F. Agalliu[1]; K. Elpenoria[4]; J. Tana[1]; J. Kruja[2]
[1]University of Medicine, Tirana; [2]Neurology Service, Mother Theresa Hospital; [3]Neuroradiology Service, Mother Theresa Hospital; [4]Memorial Hospital, Fier

EPV-127 | Neurodevelopmental disorders in pediatric patients with myotonic dystrophy type 1

E. Erokhina[1]; K. Shamtieva[2]; E. Melnik[3]; D. Vlodavets[1]
[1]Pirogov Russian National Research Medical University, Moscow, Russian Federation; [2]Lomonosov Medical Scientific and Educational Center of Moscow State University, Moscow, Russian Federation; [3]Russian Federation Research Centre for Medical Genetics, Moscow, Russian Federation

EPV-128 | Reversible cerebral vasoconstriction syndrome. Number of cases

E. Guevara Sánchez; A. Arjona Padillo; F. Gallo Pineda
Neurology Service, Torrecárdenas University Hospital, Almería, Spain

EPV-129 | Abstract withdrawn

EPV-130 | Endothelin-1 in embolic stroke of undetermined source patients with non-stenosing intracranial atherosclerotic plaques

F. Mazzacane[1]; B. Del Bello[1]; F. Ferrari[1]; E. Rognone[2]; S. Scaranzin[3]; C. Morandi[3]; M. Gastaldi[3]; A. Persico[4]; A. Pichiecchio[1]; A. Cavallini[4]
[1]Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; [2]Department of Neuroradiology, IRCCS Mondino Foundation, Pavia, Italy; [3]Neuroimmunology Research Unit, IRCCS Mondino Foundation, Pavia, Italy; [4]Department of Emergency Neurology and Stroke Unit, IRCCS Mondino Foundation, Pavia, Italy

EPV-131 | Double subclavian steal syndrome as manifestation of Erdheim-Chester

J. Finsterer
Neurology and Neurophysiology Centre Vienna

EPV-132 | What happens after transient global amnesia? A longitudinal population-based study

F. Gabriele[1]; M. Foschi[1]; F. De Santis[1]; D. Ciuffini[1]; F. Conversi[1]; E. Colangeli[2]; B. Orlandi[2]; F. De Santis[2]; R. Ornello[1]; S. Sacco[1]
[1]*Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy;* [2]*Stroke Unit and Neurology Unit, S.S. Filippo and Nicola Hospital, Avezzano, Italy*

EPV-133 | From 0 to 100 – Loop recorder implantation on stoke unit

F. Wagner; S. Brodoehl; C. Klingner; A. Günther; C. Geis; C. Klingner
Department of Neurology, Jena University Hospital, Germany

EPV-134 | Giant cell arteritis and inflammatory cerebral amyloid angiopathy – distinct or related diseases? A case report

F. Straeten; M. Koecke; L. Müller-Miny; A. Schmidt-Pogoda
Department of Neurology with Institute of Translational Neurology, Medical Faculty, University Hospital Münster, Germany

EPV-135 | Comparing ischemic strokes treated in extended and conventional times in the city of Pisa. A one-year outcomes analysis

G. Mignani[1]; N. Giannini[1]; M. Baldini[1]; R. D'Agliano[1]; M. Cosottini[2]; G. Orlandi[1]; G. Siciliano[1]; M. Mancuso[1]
[1]*Department of Neuroscience, University of Pisa, Pisa, Italy;* [2]*Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy*

EPV-136 | Increasing incidence of posterior reversible encephalopathy syndrome: 23-year experience in a third-level hospital

G. Cabañas Engenios; R. Sainz Amo; N. Mena García; R. Pastor González; M. Campos Jiménez; P. Garay Albizuri; B. Martínez García; D. Pérez Gil; I. Corral Corral
Department of Neurology, Ramón y Cajal University Hospital, Madrid, Spain

EPV-137 | Evaluation of the relationship of systemic inflammatory index with prognosis in patients with acute ischemic stroke

M. Bardakçı; M. Çetiner; E. Saygın Uysal; G. Akdağ; F. Akkoyun Arıkan; S. Canbaz Kabay
Department of Neurology, Kütahya Health Sciences University School of Medicine, Kütahya

EPV-138 | Do infarct volumes influence stroke heart syndrome (SHS) after mechanical thrombectomy (MT)?

G. Prandin; L. Mancinelli; F. Palacino; E. Vincis; G. Furlanis; P. Caruso; M. Naccarato; P. Manganotti
Clinical Unit of Neurology, Department of Medicine, Surgery and Health Sciences, University Hospital and Health Services of Trieste, ASUGI, University of Trieste, Trieste, Italy

EPV-139 | Niemann-Pick disease type C: Phenotypic variability

M. González Gómez[1]; M. Hernández Ramírez[1]; J. Villamor Rodríguez[1]; F. Sánchez García[1]; D. Barbero Jimenez[1]; A. Andrés Bartolomé[2]; G. Mateo Martínez[2]; J. Celi Celi[1]; M. Mas Serrano[1]
[1]*Neurology Department, Guadalajara University Hospital, Guadalajara, Spain;* [2]*Department of Neuropediatrics, Guadalajara University Hospital, Guadalajara, Spain*

EPV-140 | Internal carotid artery occlusion with stroke: Outcomes of emergent carotid endarterectomy and intravenous thrombolysis

R. Herzig[1]; S. Ostrý[2]; V. Kunešová[3]; A. Kondé[4]; M. Kovář[5]; R. Jura[6]; J. Fiksa[7]; P. Geier[8]; O. Škoda[9]; P. Vaško[10]
[1]Department of Neurology, Charles University Faculty of Medicine and University Hospital Hradec Kralove, Hradec Kralove, Czechia; [2]Department of Neurology, Ceske Budejovice Hospital, Ceske Budejovice, Czechia; [3]Cerebrovascular Research Program, International Clinical Research Center, Brno, Czechia; [4]Technical University of Ostrava, Faculty of Electrical Engineering and Computer Science, Ostrava, Czechia; [5]Department of Neurology, Na Homolce Hospital, Prague, Czechia; [6]Department of Neurology, University Hospital Brno, Brno, Czechia; [7]Department of Neurology, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czechia; [8]Department of Neurology, Pardubice Hospital – Hospital Pardubice Region, Inc., Pardubice, Czechia; [9]Department of Neurology, Jihlava Hospital, Jihlava, Czechia; [10]Department of Neurology, Third Faculty of Medicine, Charles University and Faculty Hospital Kralovske Vinohrady, Prague, Czechia

EPV-141 | Factors influencing the early neurological deterioration in intracranial branch atheromatous diseases

I. Deguchi; S. Fujiwara; N. Arai; T. Nakagami; R. Kimura; K. Oryu; K. Watanabe; Y. Kato; T. Hayashi; S. Takahashi; S. Suda
Department of Neurology and Cerebrovascular Medicine, Saitama Medical University International Medical Center

EPV-142 | Limb ischemia and ischemic stroke as a presentation of Kounis Syndrome

I. Del Pino Díaz; P. Guirado Ruiz; R. Calle Calle; I. Villegas Rodríguez
Department, Hospital Universitario San Cecilio, Granada, Spain

EPV-143 | Next generation sequencing and whole-exome sequencing of patients with spontaneous cervical artery dissections

I. Scala[1]; V. Trevisan[2]; P. Rizzo[1]; J. Di Giovanni[1]; S. Bellavia[1]; F. Colò[1]; S. Abruzzese[1]; F. Cerulli[1]; P. Concolino[3]; A. Minucci[4]; M. Monforte[5]; A. Broccolini[5]; C. Leoni[2]; G. Frisullo[5]
[1]Department of Neuroscience, Catholic University of Sacred Heart, Rome, Italy; [2]Rare Diseases Unit, Fondazione Policlinico Universitario Agostino Gemelli, IRCCS, Rome, Italy; [3]Clinical Chemistry, Biochemistry and Molecular Biology Operations (UOC), Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy; [4]Departmental Unit of Molecular and Genomic Diagnostics, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy; [5]Department of Neuroscience, Sensory Organs and Chest, Fondazione Policlinico Universitario Agostino Gemelli, IRCCS, Rome, Italy

EPV-144 | Factors influencing the outcome of stroke due to M1 occlusion of MCA

I. Kadi; M. Dimitrova
Clinic of Neurology, UMHATEM "N. I. Pirogov", Bulgaria

EPV-145 | Endovascular treatment of cerebral venous thrombosis: A multicentric study

J. Alonso[1]; E. Cañada[1]; C. Ramos[1]; C. Gómez-Escalonilla[2]; A. de Felipe[3]; P. Calleja[4]; P. de la Riva[5]; C. Tejero[6]; L. Llull[7]; S. Trillo[1]
[1]Neurology, Hospital Universitario de La Princesa, Madrid, Spain; [2]Neurology, Hospital Clínico San Carlos, Madrid, Spain; [3]Neurology, Hospital Universitario Ramón y Cajal, Madrid, Spain; [4]Neurology, Hospital Universitario, Madrid, Spain; [5]Neurology, Hospital Universitario Donostia, San Sebastián, Spain; [6]Neurology, Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain; [7]Neurology, Hospital Clínic de Barcelona, Barcelona, Spain

EPV-146 | Absence of headache in clinical presentation of cerebral venous thrombosis – a single center study of 105 cases

M. Janković; T. Švabić Međedović; P. Stanarčević; I. Berisavac; V. Pađen; M. Mijajlović; M. Ercegovac; N. Kresojević; M. Kovačević; D. R. Jovanović
Neurology Clinic, University Clinical Centre of Serbia, Belgrade, Serbia

EPV-147 | Secondary prevention of AF-related AIS: Deploying machine learning for robust validation and updating of CHA2DS2-VASc

J. Simon[1]; L. Krainski[2]; M. Karlinski[3]; M. Niewada[1]
[1]*Department of Experimental and Clinical Pharmacology, Medical University of Warsaw, Warsaw, Poland;* [2]*SGH Warsaw School of Economics, Warsaw, Poland;* [3]*2nd Department of Neurology, Institute of Psychiatry and Neurology, Warsaw, Poland*

EPV-148 | The ivy sign in patients with moyamoya syndrome associated with atherosclerotic occlusion of the middle cerebral artery

K. Jo
Gangneung Asan Hospital, University of Ulsan College of Medicine, Gangneung, Republic of Korea

EPV-149 | Persistent primitive trigeminal artery associated with agenesis of common carotid artery

K. Jo
Neurology, Gangneung Asan Hospital, University of Ulsan College of Medicine, Gangneung, Republic of Korea

EPV-150 | Histopathological analysis of thrombi obtained after mechanical thrombectomy. Project presentation

J. Romano[1]; J. Arnedo Fernández[2]; C. Chamorro Santos[3]; C. López Mesa[1]; Ó. Pérez Bustamante[3]; C. Moreno Franco[1]; R. Lorenzo López[1]; P. Jiménez Arco[1]; P. Casa Nova Leitao Moreira[1]; I. Pérez Ortega[1]; M. Fernandez Pérez[1]; J. Romero Fábrega[1]
[1]*Department of Neurology, Hospital Universitario Virgen de las Nieves, Granada, Spain;* [2]*Department of Statistics and Operations Research, Faculty of Science, University of Granada, Granada, Spain;* [3]*Department of Pathology, Hospital Universitario Virgen de las Nieves, Granada, Spain*

EPV-151 | Role and approach for assessment of nitric oxide bioavailability in cerebral small vessel disease

L. Dobrynina; K. Shamtieva; A. Shabalina
Research Center of Neurology, Moscow, Russian Federation

EPV-152 | Reversal of vision metamorphopsia due to cerebrovascular pathology: A single-center case series

A. Karamyan[1]; H. Tsatryan[2]; A. Kunz[1]; S. Pikija[1]
[1]*Department of Neurology, Christian Doppler University Hospital, Paracelsus Medical University of Salzburg, Salzburg, Austria;* [2]*Yerevan State Medical University, Yerevan, Armenia*

EPV-153 | Polypills and gender differences as tools to increase patients' compliance to secondary prevention of ischemic stroke

L. Martirosyan; S. Voskanyan; A. Papoyan; A. Madoyan; K. Kosyan; A. Ashugyan; K. Petrosyan
[1]*Department of General and Vascular Neurology, Saint Gregory the Illuminator Medical Center, Yerevan, Armenia*

EPV-154 | Impact of trimethylamine N-Oxide on stroke incidence and NOAF following STEMI: insights from gut microbiota metabolism

O. Knokneriene[1]; A. Aldujeli[2]; R. Unikas[2]; V. Tatarunas[2]; V. Skipskis[2]; A. Knokneris[3]
[1]*Department of Neurology, Seamen's Branch of Klaipeda University Hospital, Klaipeda, Lithuania;* [2]*Faculty of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania;* [3]*Department of Cardiology, Seamen's Branch of Klaipeda University Hospital, Klaipeda, Lithuania*

EPV-155 | Impact of combined inflammatory markers on increased risk of mortality after ischemic stroke in young subjects

L. Mbarek[1,2]; A. Jin[1,2]; Y. Pan[1,2]; Y. Jiang[1,2]; M. Xia[1,2]; Y. Wang[1,2]
[1]*Department of Neurology, Beijing Tiantan Hospital, Capital Medical University, Beijing, China;* [2]*China National Clinical Research Center for Neurological Diseases, Beijing Tiantan Hospital, Capital Medical University, Beijing, China*

EPV-156 | Comparison of troponin peak values between cerebral haemorrhages and untreated ischemic strokes

L. Mancinelli; G. Prandin; I. Scali; F. Palacino; E. Vincis; G. Furlanis; P. Caruso; M. Naccarato; P. Manganotti
Clinical Unit of Neurology, Department of Medicine, Surgery and Health Sciences, University Hospital and Health Services of Trieste, ASUGI, University of Trieste, Trieste, Italy

EPV-157 | Vasculitis with central nervous system involvement: A multicenter study

L. Santos[1]; I. Llera[1]; T. Montalvo[1]; J. Martínez[1]; J. Cebrian[1]; N. Barbero[1]; J. Fernández[1]; S. Pastor-Yvorra[2]
[1]*Neurology Service and Stroke Centre, Universitary Hospital Rey Juan Carlos;* [2]*Neurology Servicie, Universitary Hospital General de Villalba*

EPV-158 | Moyamoya disease and syndrome: A European centre experience

A. Neves[1]; P. Abreu[1]; P. Castro[1]; M. Carvalho[1]; A. Aires[1]; J. Guimarães[1]; L. Fonseca[2]; E. Azevedo[1]
[1]*Department of Neurology, Centro Hospitalar Universitário de São João, Porto, Portugal;* [2]*Department of Internal Medicine, Centro Hospitalar Universitário de São João, Porto, Portugal*

EPV-159 | High altitude-related factors may influence the stroke outcome: A pilot study from southern Armenia

L. Avetisyan[1]; L. Manutsyan[2]; S. Khachatryan[3]; N. Yeghiazaryan[4]
[1]*"Davidyants Polyclinics" Primary Healthcare Center, Yerevan, Armenia;* [2]*Goris Medical Center, Goris, Armenia;* [3]*Department of Neurology and Neurosurgery, National Institute of Health, Yerevan, Armenia;* [4]*Erebouni Medical Center, Yerevan, Armenia*

EPV-160 | Post-stroke neurogenic cardiac changes: A plea for extended cardiac monitoring

M. Manea[1]; I. Stoican[2]; I. Enache[2]; C. Ciulavu[2]; S. Tuta[1]; D. Dragos[3]
[1]*Neurology, Carol Davila University of Medicine and Pharmacy, National Institute of Neurology and Neurovascular Diseases, Bucharest, Romania;* [2]*Neurology, National Institute of Neurology and Neurovascular Diseases, Bucharest, Romania;* [3]*Internal Medicine, Carol Davila University of Medicine and Pharmacy, University Emergency Hospital, Bucharest, Romania*

EPV-161 | PAI mutation as a risk factor for large vessel occlusion – What is the best choice for treatment?

M. Cholakova
Nikolay Mihnev

EPV-162 | The role of inflammation in spontaneous cervicocephalic dissection: A comparative study and combined data analysis

I. Margarido[1]; B. Martins[1]; J. Sousa[2]; J. Ramos[3]; I. Mesquita[4]; L. Sampaio[2]; A. Costa[1]; P. Abreu[1]
[1]*Neurology Department, Centro Hospitalar Universitário de São João, Porto, Portugal;* [2]*Neuroradiology Department, Centro Hospitalar Universitário de São João, Porto, Portugal;* [3]*Neuroradiology Diagnostic Unit, Department of Imaging, Centro Hospitalar de Vila Nova de Gaia/ Espinho, Vila Nova de Gaia, Portugal;* [4]*Clinical Neurosciences and Mental Health Department, Faculty of Medicine, University of Porto, Porto Portugal*

EPV-163 | Stroke in hypertensive patients: Differences between young and very elderly patients

C. Fernandez-Moreno[1]; L. Castilla-Guerra[2]; M. De la Serna-Fito[1]; N. Guerrero-Carmona[1]
[1]*Department of Neurology, Hospital de Valme, Seville, Spain;* [2]*Department of Internal Medicina, Seville, Spain*

EPV-164 | Controversial endovascular approaches in childhood arterial ischemic stroke: A case report

M. Caccamo; D. Galotto; S. Grimaldi; N. Marrone; G. Milella; G. Falcicchio; A. Manni; S. Lamberti; M. Savarese; D. Mezzapesa; M. Petruzzellis; G. Defazio
Neurology Unit, Department of Translational Biomedicine and Neurosciences, University of 'Aldo Moro', Bari, Italy

EPV-165 | Predictors of good 1-year outcome in stroke patients post successful recanalization with initial poor functional status

M. Gielczynski[1]; P. Wrona[2]; D. Wrobel[4]; T. Popiela[3]; G. Kapral[4]; J. Staniszewska[4]; M. Derechowska[4]; A. Slowik[2]
[1]*Military Hospital, Krakow, Poland;* [2]*Department of Neurology, Jagiellonian University Medical College, Krakow, Poland,* [3]*Department of Radiology, Jagiellonian University Medical College, Krakow, Poland,* [4]*Student Scientific Group in Cerebrovascular Diseases, Jagiellonian University Medical College, Krakow, Poland*

EPV-166 | The role of the endothelium in the morphogenesis of changes blood vessels in cerebrovascular atherosclerosis

D. Mankovsky[1]; N. Chuiko[2]
[1]*State Institution "Heart Institute of the Ministry of Health of Ukraine";* [2]*Ivano-Frankivsk National Medical University*

EPV-167 | Thrombolysis in ischemic stroke due to cerebral small vessel disease: A case–control study

M. Miranda[1]; S. Galego[2]; A. Paiva Nunes[2]
[1]*Department of Neurology, Hospital de Cascais Dr. José de Almeida, Cascais, Portugal;* [2]*Unidade CérebroVascular, Hospital São José, Centro Hospitalar Lisboa Central, Lisbon, Portugal*

EPV-168 | Neurofeedback in patients with early cerebral small vessel disease

E. Novikova
Research center of Neurology, Moscow, Russian Federation

EPV-169 | Medical outcomes after ischemic stroke in an institutional cohort

G. Nacu; O. Grosu; S. Odobescu; L. Rotaru; G. Corcea; I. Moldovanu
The Diomid Gherman Institute of Neurology and Neurosurgery in Chișinău, Republic of Moldova

EPV-170 | Covert cerebrovascular disease in a stroke cohort

G. Nacu; O. Grosu; G. Corcea; I. Moldovanu
The Diomid Gherman Institute of Neurology and Neurosurgery in Chișinău, Republic of Moldova

EPV-171 | Young stroke patients: Modifiable risk factors and genetic scores

N. Mahmutbegovic; E. Mehmedika Suljic; A. Mehicevic
Neurology Clinic, Clinical Center of Sarajevo University, Sarajevo, Bosnia and Herzegovina

EPV-172 | Impact of lower extremity physical function on quality-of-life post-stroke: Findings from the MOBITEC-stroke study

M. Ryan[1]; R. Rössler[1]; N. Rommers[2]; L. Iendra[3]; E. Peters[1]; R. Kressig[1]; A. Schmidt-Trucksaess[4]; S. Engelter[1]; T. Hinrichs[4]; N. Peters[1]
[1]*University Department of Geriatric Medicine Felix Platter, University of Basel, Basel, Switzerland;* [2]*Department of Clinical Research, University of Basel, University Hospital Basel, Basel, Switzerland;* [3]*Department of Neurology and Stroke Center, University Hospital Basel and University of Basel, Basel, Switzerland;* [4]*Division of Sport and Exercise Medicine, Department of Sport, Exercise, and Health, University of Basel, Basel, Switzerland*

EPV-173 | Timing of hemorrhagic stroke in Almería (Spain)

P. Olea-Rodríguez; M. Martínez Salmerón; J. Fernández Pérez; P. Sánchez Martínez; A. Arjona Padillo; M. Iglesias Espinosa
Neurología, Hospital Universitario Torrecárdenas, Almería, España

EPV-174 | Vessel wall imaging in patients presenting with first ever stroke with intracranial atherosclerotic disease (ICAD)

S. Sen[1]; U. Chakbraborty[1]; S. Das[2]; B. Ray[3]; A. Biswas[4]
[1]*Post Doctoral Trainee, Department of Neuromedicine, Bangur Institute of Neurosciences, Kolkata, India;* [2]*Assistant Professor, Department of Radiology, IPGMER and SSKMH, Kolkata, India;* [3]*Professor and in charge stroke clinic, Department of Neuromedicine, Bangur Institute of Neurosciences, Kolkata, India;* [4]*Professor and Head of the Department, Department of Neuromedicine, Bangur Institute of Neurosciences, Kolkata, India*

EPV-175 | Utility of antiaggregation for primary prevention in patients with leukoaraiosis on MRI: A historical cohort study

P. Garrido Jiménez; S. López Anguita; A. Lorenzo Montilla; J. Rodríguez Quinchanegua; F. Valenzuela Rojas; M. Olmedilla González
Hospital Central de la Defensa "Gómez Ulla"

EPV-176 | Ischemic stroke from cerebral arteritis treated with anti-retroviral therapy in newly diagnosed HIV infection

F. Pedroni; G. Cutillo; M. Vabanesi; E. Dotto; N. Anzalone; F. Simionato; R. Chieffo; G. Giacalone; M. Filippi; L. Roveri
IRCSS San Raffaele Scientific Institute, Milan, Italy

EPV-177 | Ischemic stroke in atrial fibrillation: Difference between oral anticoagulant treated and treatment-naive patients

A. Canessa[1]; P. Mortola[1]; D. Sassos[2]; M. Del Sette[2]; I. Gandoglia[2]
[1]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, Italy; [2]Ospedale Policlinico San Martino – IRCCS, Genoa, Italy

EPV-178 | Inflammation markers, clinical and radiological parameters in acute ischemic stroke: A new composite prognostic score

P. Rizzo[1]; S. Bellavia[1]; I. Scala[1]; J. Di Giovanni[1]; G. Frisullo[2]
[1]UOC Neurology, Catholic University of Sacred Heart, Rome, Italy; [2]UOC Neurology, Fondazione Policlinico Universitario Agostino Gemelli, Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS), Rome, Italy

EPV-179 | Prevalence of electrolyte imbalance in patients with acute stroke: A systematic review and meta-analysis

P. Kumar
All India Institute of Medical Sciences, New Delhi, India

EPV-180 | Abstract withdrawn

EPV-181 | MicroRNAs predictive of carotid stenosis severity

A. Raskurazhev; P. Kuznetsova; A. Shabalina; A. Mazur; V. Annushkin; M. Tanashyan
Research Center of Neurology, Moscow, Russian Federation

EPV-182 | Cerebral venous thrombosis after lumbar puncture: About two cases

M. Mhiri; R. Guizani; R. Ben Dhia; N. Gouta; M. Frih-Ayed
Department of Neurology, Fattouma Bourguiba University Hospital, Monastir, Tunisia

EPV-183 | Non abducens cranial nerves involvement in cerebral venous sinus thrombosis

R. Smaoui; K. Moalla; N. Bouattour; N. Farhat; S. Daoud; S. Sakka; M. Damak; C. Mhiri
Neurology Department, Habib Bourguiba Hospital, Sfax, Tunisia

EPV-184 | Cerebral venous thrombosis and prothrombotic risk factors: A single-center experience from Tunisia

R. Smaoui; K. Moalla; S. Sakka; N. Bouattour; S. Daoud; N. Farhat; M. Damak; C. Mhiri
Neurology Department, Habib Bourguiba Hospital, Sfax, Tunisia

EPV-185 | Stroke prevention in atrial fibrillation: Is chronic anticoagulant therapy over-prescribed?

J. Rothrock[1]; R. Hart[2]
[1]Inova Health/University of Virginia, Fairfax, VA USA; [2]Stroke Research Program Population Health Research Institute Hamilton, Ontario, Canada

EPV-186 | The epidemiologic, clinical and etiological profile of young adult ischemic strokes in Morocco: About 57 cases

S. Saaf; Y. Mimouni; M. El Azhari; S. Lhassani; Z. El Yacoubi; M. Hakimi; A. Hazim; J. Aasfara; H. Ouhabi
Department of Neurology, Cheikh Khalifa University Hospital, Casablanca, Morocco

EPV-187 | Could reversing direct oral anticoagulants change the outlook for hemorrhagic strokes?

S. Palma; T. Santana; P. Laranjo; Pereira; M. Rodrigues
Garcia de Orta Hospital

EPV-188 | Early elevation of troponin levels in acute stroke

S. Lima; A. Costa; M. Mendes; R. Almendra; R. Raimundo; A. Matas
Department of Neurology, Unidade Local de Saúde de Trás-os-Montes e Alto Douro, Vila Real, Portugal

EPV-189 | Amaurosis fugax and ischemic stroke in a patient diagnosed with VEXAS syndrome

S. Sánchez Gamino; N. Bocero Hanan; A. Sarmiento Pita; P. Dodu; C. Martínez Tomás
Neurology Department, Hospital Regional Universitario de Málaga, Málaga, Spain

EPV-190 | Association between anemia and cerebral venous thrombosis

R. Smaoui; K. Moalla; N. Bouattour; S. Sakka; S. Daoud; N. Farhat; M. Damak; C. Mhiri
Neurology Department, Habib Bourguiba Hospital, Sfax, Tunisia

EPV-191 | Prolonged cardiac monitoring with textile wearable Holter technology in patients with ESUS stroke

S. Casanova[1]; H. Costa[1]; L. Paredes[2]; M. Rocha[1]; M. Veloso[1]; T. Gregório[2]; P. Barros[1]
[1]Neurology Department, Centro Hospitalar Vila Nova de Gaia/Espinho, Porto, Portugal; [2]Internal Medicine Department, Centro Hospitalar Vila Nova de Gaia/Espinho, Porto, Portugal

EPV-192 | Thrombophilia a significant cause of cerebral venous sinus thrombosis in East Africa: Retrospective review of 118 cases

T. Siika[1]; J. Sokhi[1]; S. Waa[2]; A. Mwirigi[3]; J. Shah[4]; D. Sokhi[1]
[1]Department of Medicine, Aga Khan University, Nairobi, Kenya; [2]Department of Radiology, Aga Khan University, Nairobi, Kenya; [3]Department of Oncology/Haematology, Aga Khan University, Nairobi, Kenya; [4]Department of Population Health, Aga Khan University, Nairobi, Kenya

EPV-193 | Impact of the TICI3 versus TICI2b reperfusion score to predict long-term good outcome following mechanical thrombectomy

T. Homa
Department of Neurology, University Hospital in Krakow, Poland

EPV-194 | Internal carotid artery dissection due to Eagle-syndrome: Can the toothpick in your neck cause a stroke?

T. Klail[1,2]; L. Sachs[3]; L. Panos[4]; O. Urban[4]; T. Siller[4]; W. Almiri[1]; S. Pilgram-Pastor[1]; R. Giger[3]; M. Müller[5]; F. Wagner[1]
[1]University Institute of Diagnostic and Interventional Neuroradiology, Inselspital – Bern University Hospital, Bern, Switzerland; [2]Faculty of Medicine, Masaryk University, Brno, Czechia, [3]Department of Head and Neck Surgery, Inselspital – Bern University Hospital, Bern, Switzerland; [4]Department of Neurology, Inselspital – Bern University Hospital, Bern, Switzerland; [5]Department of Emergency Medicine, Inselspital, Bern University Hospital, Bern, Switzerland

EPV-195 | Factors associated with early versus late hemorrhagic transformation in acute ischemic stroke

U. Chakraborty[1]; D. Mukherjee[1]; A. Mukherjee[2]; B. Ray[1]
[1]Department of Neurology, Bangur Institute of Neurosciences, IPGMER & SSKM Hospital, Kolkata, India; [2]Department of Neurology, North Bengal Medical College and Hospital, Siliguri, India

EPV-196 | Carotid web and atherosclerosis, double-trouble or double-face?

V. Tudisco[1]; L. Ferraù[1]; F. Giammello[2]; C. Dell'Aera[1]; M. Cotroneo[1]; A. Tessitore[3]; D. Vicari[3]; S. Vinci[3]; P. La Spina[1]; A. Toscano[1]
[1]*Stroke Unit, Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy;* [2]*Translational Molecular Medicine and Surgery, Department of Biomedical, Dental Science and Morphological and Functional Images, University of Messina, Messina, Italy;* [3]*Neuroradiology Unit, Department of Biomedical, Dental Science and Morphological and Functional Images, University of Messina, Messina, Italy*

EPV-197 | Improving written discharge communication in an acute stroke unit

W. Baber; L. Stark; M. Upcott; H. Shetty
Acute Stroke Unit, University Hospital of Wales, Cardiff, UK

EPV-198 | Therapeutic approach to non-COVID-19 cardioembolic stroke in the first year of the pandemic

A. Lučić Prokin[1]; M. Bogdanović[1]; Z. Božić[1]; D. Krtinić[2]; Ž. Živanović[1]
[1]*Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia;* [2]*Department for pharmacology and toxicology, Faculty of Medicine, University of Niš, Niš, Serbia*

EPV-199 | Evaluation of the quality of life and burden of caregivers of patients with stroke

A. Zouari EP Ben Amor; N. Bouattour; F. Kchaou; S. Daoued; S. Sakka; M. Dammak; C. Mhiri
Neurology Department, Habib Bourguiba University Hospital, Sfax, Tunisia

EPV-200 | Signal and biophysical models of diffusion MRI in assessing of cerebral small vessel disease progression

Z. Gadzhieva; L. Dobrynina; E. Kremneva; K. Shamtieva; A. Geints; A. Filatov; V. Trubitsyna; M. Krotenkova
Research Center of Neurology, Moscow, Russian Federation

EPV-201 | Long-term perspectives of COVID-19 neurological consequences in young out-patients and in-patients

V. Mishchenko; D. Kutikov; I. Nikishkova; O. Kutikov; Y. Kiziurina
Department of Brain Vascular Pathology and Rehabilitation, Institute of Neurology, Psychiatry and Narcology of the NAMS of Ukraine, Kharkiv, Ukraine

EPV-202 | Clinical and neuropsychological characterization of mild cognitive impairment in primary psychiatric disorders

M. Anselmi[1]; F. Menegon[1]; G. Decaroli[2]; F. De marchi[1]; C. Comi[2]; G. Tondo[2]
[1]*Neurology Unit, Department of Translational Medicine, University of Piemonte Orientale, Novara, Italy;* [2]*Neurology Unit, Department of Translational Medicine, S. Andrea Hospital, University of Piemonte Orientale, Vercelli, Italy*

EPV-203 | Suicide risk of patients with epilepsy and comorbid mental disorders

A. Bolshakova; N. Shova; V. Mikhailov
Department for the treatment of patients with epilepsy, V.M. Bekhterev National Medical Research Center for Psychiatry and Neurology, St. Petersburg, Russian Federation

EPV-204 | Efficacy of pharmacological interventions in fragile X syndrome: A network meta-analysis of randomised controlled trials

M. Muneer[1]; V. Suresh[2]; N. Joe[3]; M. Shamim[4]; R. Raj[5]; P. Gowda[3]; P. Pankaj[6]; T. Jha[7]; V. Krishna DV[8]; M. Hasan[9]; A. Khare[10]; K. Mehta[11]; P. Yadav[12]
[1]*Allama Iqbal Medical College, Lahore, Pakistan;* [2]*King George's Medical University, Lucknow, India;* [3]*St. John's Medical College, Bangalore, India;* [4]*Department of Pharmacology, All India Institute of Medical Science – Jodhpur;* [5]*Atal Bihari Vajpayee Institute of Medical Sciences and Dr. Ram Manohar Lohia Hospital, New Delhi, India;* [6]*All India Institute of Medical Sciences (AIIMS), New Delhi, India;* [7]*Medical College, Kolkata, India;* [8]*Institute of Medical Sciences, Banaras Hindu University, India;* [9]*Faculty of medicine, Al-Azhar university, Cairo, Egypt;* [10]*All India Institute of Medical Sciences, Gorakhpur, India;* [11]*Rajashree Chhatrapati Shahu Maharaj Government Medical College, Kolhapur;* [12]*Maulana Azad Medical College, New Delhi, India*

EPV-205 | Genetic causes of rare paediatric diseases with complex neurological phenotypes in the South Kazakhstan region

N. Yerkhojayeva[1]; N. Zharkinbekova[2]; R. Kaiyrzhanov[3]
[1]*Department of Medicine, International Kazakh-Turkish University, named after Kh.A.Yasawi, Turkestan, Kazakhstan;* [2]*Department of neurology, psychiatry, rehabilitation, and neurosurgery, South Kazakhstan medical academy, Shymkent, Kazakhstan;* [3]*Department of Neuromuscular Diseases, University College London, Queen Square, Institute of Neurology, London, UK*

EPV-206 | Information, support and guidance provided by the Finnish Epilepsy Association

T. Koskinen; V. Mäkitalo; P. Salminen; P. Sorjonen; V. Tarkiainen; A. Mikkola
Finnish Epilepsy Association

EPV-207 | Executive functions and its correlation to language deficits

S. Gjeci[1]; A. Quka[1]; E. Reka[2]; F. Dashi[1]; V. Skendo[3]; F. Elezi[1]
[1]*Department of Neurosciences, University of Medicine, Faculty of Medicine, Tirana, Albania;* [2]*Department of Neurology, Elbasan Hospital, Albania;* [3]*University Hospital Center Mother Teresa, Tirana, Albania*

EPV-208 | Neurocognitive and behavioral challenges in pediatric ASD and post-radiosurgery arteriovenous malformation

A. Sohel[1]; L. Katzell[2]; B. Carr[3]
[1]*University of Florida College of Medicine, Gainesville, FL, USA;* [2]*Department of Psychiatry and Behavioral Sciences, University of Texas at Austin, Austin, TX, USA;* [3]*Department of Psychiatry, University of Florida College of Medicine, Gainesville, FL, USA*

EPV-209 | Abstract withdrawn

EPV-210 | Clinical and Electrophysiological characteristics of COVE in the light of current ILAE criteria

B. Güleç[1]; M. Atacan Yaşgüçlükal[2]; D. Emre[1]; A. Elmalı[3]; Ö. Ertürk Çetin[4]; A. Demirbilek[1]
[1]*Department of Neurology, Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Istanbul, Turkey;* [2]*University of Health Sciences, Haseki Training and Research Hospital, Department of Neurology, Istanbul, Turkey;* [3]*Department of Neurology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey;* [4]*University of Health Sciences, Sancaktepe Şehit Prof. Dr. İlhan Varank Training and Research Hospital, Department of Neurology*

EPV-211 | Role of neurophysiology in scan-negative myelopathy

B. Madureira[1]; A. Brito da Silva[2]; C. Fry[2]; M. Baker[3]
[1]*Department of Neurology, Hospital Professor Dr. Fernando Fonseca, Lisbon, Portugal;* [2]*Department of Clinical Neurophysiology, Royal Victoria Infirmary, Newcastle-upon-Tyne, UK;* [3]*Translational and Clinical Research Institute Newcastle University*

EPV-212 | PPP2R1A-related neurodevelopmental disorder: The first Korean case with a novel variant of PPP2R1A and literature review

J. Lee[1]; J. Yoo[1]; S. Lee[1]; J. Lee[2]; E. Park[3]
[1]*Department of Laboratory Medicine, Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea;* [2]*Department of Radiology, Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea;* [3]*Department of Pediatrics, Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea*

EPV-213 | Detailed mechanisms of neuronal hyperexcitability induced by hyperventilation in electroconvulsive therapy

B. De[1]; B. Carr[2]
[1]*School of Medicine, University of California San Francisco, San Francisco, USA;* [2]*Department of Psychiatry, University of Florida, Gainesville, USA*

EPV-214 | Effect of concomitant medications on adverse event frequency, severity, and resolution in a cenobamate open-label trial

B. Steinhoff[1]; A. Gil-Nagel[2]; E. Alvarez-Baron[3]; J. Leach[4]; K. Thangavelu[5]; Y. Winter[6]; V. Villanueva[7]
[1]*Department for Adults, Kork Epilepsy Center, Kehl-Kork, Germany;* [2]*Department of Neurology, Hospital Ruber Internacional, Madrid, Spain;* [3]*Angelini Pharma España, Madrid, Spain;* [4]*Global Medical Department, Angelini Pharma S.p.A, Rome, Italy;* [5]*MeDaStats LLC, Tampa, FL, USA;* [6]*Mainz Comprehensive Epilepsy and Sleep Medicine Centre, Johannes Gutenberg-University, Mainz, Germany;* [7]*Refractory Epilepsy Unit, Neurology Service, Hospital Universitari i Politècnic La Fe, Valencia, Spain, Member of ERN Epicare*

EPV-215 | The assessment of subjective cognitive decline with major depressive disorder via montreal cognitive assessment (MoCA)

Ş. Çankaya[1]; A. Özşimşek[1]; E. Özdemir Öktem[1]; C. Sayman[2]; B. Yuluğ[1]
[1]*Department of Neurology, Alanya Alaaddin Keykubat University, Faculty of Medicine, Antalya, Turkey;* [2]*Department of Neurology, Alanya Training and Research Hospital, Antalya, Turkey*

EPV-216 | Hypoxia inducible factor 1 alpha (HIF-1A) – Biomarker of hypoxic cell suffering in children with status epilepticus

I. Calistru[1]; S. Hadjiu[1]; C. Calcîi[2]; O. Constantin[1]; E. Capestru[1]; I. Istratuc[2]; L. Feghiu[3]; S. Groppa[1]
[1]*State University of Medicine and Pharmacy Nicolae Testemițanu", Chisinau, Republic of Moldova;* [2]*Institute of Mother and Child Healthcare, Chisinau, Republic of Moldova;* [3]*National Epileptology Center, Chisinau, Republic of Moldova*

EPV-217 | Neonatal seizures – Etiological, clinical and electroencephalographic aspects

I. Calistru[1]; S. Hadjiu[1]; C. Calcii[2]; E. Capestru[1]; O. Constantin[1]; I. Istratuc[1]; L. Crivceanscaia[2]; S. Groppa[3]
[1]*Medical State University "Nicolae Testemițanu", Chisinau, Republic of Moldova;* [2]*Institute of Mother and Child Healthcare, Chisinau, Republic of Moldova;* [3]*National Epileptology Center, Chisinau, Republic of Moldova*

EPV-218 | International puzzle of needs & obstacles for the optimization of socio-cognitive assessment in neurocognitive disorders

C. Cerami[1]; C. Meli[2]; A. Panzavolta[1]; G. Funghi[2]; C. Festari[3]; T. Chatzikostopoulos[4]; C. Chicherio[5]; F. Clarence[6]; F. de Oliveira[7]; M. Filardi[8]; S. MacPherson[9]; J. Matias-Guiu[10]; L. Sacco[11]; A. Schild[12]; M. Sollberger[13]; M. Tabuas Pereira[14]; M. Tsolaki[4]; E. van der Berg[15]; S. Cappa[1]; G. Logroscino[8]; M. Bertoux[16]; F. Kumfor[17]; J. van den Stock[18]; M. Boccardi[19]; A. Dodich[2]
[1]*Scuola Universitaria di Studi Superiori IUSS di Pavia, Italy;* [2]*Centre for Mind/Brain Sciences, University of Trento, Rovereto, Italy;* [3]*IRCCS Istituto Centro San Giovanni di Dio Fatebenefratelli, Brescia, Italy;* [4]*Greek Association of Alzheimer's Disease and Related Disorders, Thessaloniki, Greece;* [5]*Memory Center, Geneva University Hospitals, Geneva, Switzerland;* [6]*Memory and Aging Centre, Fleni, Buenos Aires, Argentina;* [7]*Universidade Federal de São Paulo, São Paulo, Brazil;* [8]*Department of Translational Biomedicine and Neurosciences (DiBraiN), University of Bari Aldo Moro, Bari, Italy;* [9]*Department of Psychology, The University of Edinburgh, Edinburgh, UK;* [10]*Universidad Complutense de Madrid, Madrid, Spain;* [11]*Neuropsychological and Speech Therapy Unit, Neurocenter of Southern Switzerland, EOC, Lugano, Switzerland;* [12]*Universitätsklinikum Köln (AöR), Köln, Germany;* [13]*Memory Clinic, University Department of Geriatric Medicine FELIX PLATTER, Basel, Switzerland;* [14]*Memory Clinic, Neurology Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal;* [15]*Department of Neurology and Alzheimer Center Erasmus MC, Erasmus MC University Medical Center, Rotterdam, The Netherlands;* [16]*Lille Centre of Excellence for Neurodegenerative Diseases (LiCEND), Lille, France;* [17]*University of Sydney, School of Psychology, Sydney, NSW, Australia;* [18]*Neuropsychiatry, Leuven Brain Institute, KU Leuven, Leuven, Belgium;* [19]*German Centre for Neurodegenerative Diseases (DZNE), Rostock-Greifswald site, Rostock, Germany*

EPV-219 | Psychosocial vulnerability among patients living with Alzheimer's disease and frontotemporal dementia

A. Panzavolta[1]; A. Dodich[2]; M. Picascia[3]; M. Cotta Ramusino[3]; G. Perini[3]; C. Meli[2]; G. Funghi[2]; A. Costa[3]; C. Cerami[1]
[1]*University School for Advanced Studies IUSS, Pavia, Italy;* [2]*Center for Mind/Brain Sciences CIMeC, University of Trento, Rovereto, Italy;* [3]*IRCCS Mondino Foundation, Pavia, Italy*

EPV-220 | "Doctor, I can't follow a movie if all of the actresses are blonde"

C. Mercado Begara; L. Carazo Barrios; A. Morillas Pinteño; V. González Torres
Servicio de Neurología, Complejo Hospitalario de Jaén, España

EPV-221 | Brain health after COVID-19, pneumonia, myocardial infarction, and critical illness

C. Peinkhofer[1]; P. Zarifkar[1]; R. Christensen[2]; V. Nersesjan[2]; L. Fonsmark[3]; C. Merie[3]; A. Lebech[4]; T. Katzenstein[4]; L. Bang[5]; J. Kjærgaard[5]; P. Sivapalan[6]; J. Jensen[6]; M. Benros[2]; D. Kondziella[1]
[1]Department of Neurology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark; [2]Copenhagen Research Center for Biological and Precision Psychiatry, Mental Health Centre Copenhagen, Copenhagen University Hospital, Copenhagen, Denmark; [3]Department of Intensive Care, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark; [4]Department of Infectious Diseases, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark; [5]Department of Cardiology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark; [6]Section of Respiratory Medicine, Department of Medicine, Copenhagen University Hospital Herlev and Gentofte, Hellerup, Denmark

EPV-222 | Influence of preoperative nerve conduction studies on the outcome of carpal tunnel release surgery

P. Tan[1]; S. Tan[1]; L. Lee[1]; J. Gunasagaran[2]; S. Khoo[2]; C. Tan[1]
[1]Division of Neurology, Department of Medicine, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia; [2]Department of Orthopaedic Surgery, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia

EPV-223 | The serum proteome of post-acute COVID-19 Syndrome: Implications for cognition and neurodegeneration

G. Vavougios[1]; V. Stavrou[2]; D. Mysiris[2]; T. Mavridis[3]; K. Astara[2]; E. Pitaraki[2]; S. Boutlas[2]; E. Papayianni[2]; G. Tsirimona[2]; I. Dimeas[2]; S. Zarogiannis[4]; M. Ul Haq Katshu[5]; Z. Daniil[2]; G. Xiromerisiou[6]; G. D'Avossa[7]; S. Ganji[8]; T. Mishulin[8]; G. A. De Erausquin[9]; G. Hadjigeorgiou[1]; K. Gourgoulianis[2]
[1]Department of Neurology, Medical School, University of Cyprus, Nicosia, Cyprus; [2]Department of Respiratory Medicine, University of Thessaly, Larisa, Greece; [3]Department of Neurology, Tallaght University Hospital (TUH) / The Adelaide and Meath Hospital, Dublin, incorporating the National Children's Hospital (AMNCH), Dublin, Ireland; [4]Department of Physiology, University of Thessaly, Larisa, Greece; [5]Division of Psychiatry and Applied Psychology, University of Nottingham, Nottingham, UK; [6]Department of Neurology, University of Thessaly, Larisa, Greece; [7]School of Human & Behavioural, Sciences, Bangor University and BCHUB NHS Trust, Bangor, UK; [8]Astbury Centre for Structural Molecular Biology, School of Molecular and Cellular Biology, Faculty of Biological Sciences, University of Leeds, Leeds, LS2 9JT, UK; [9]Joe and Teresa Long School of Medicine University of Texas Heath San Antonio, USA

EPV-224 | Examining cognitive intra-individual variability in adults with and without HIV-associated neurocognitive disorder

D. Vance[1]; P. Fazeli[1]; J. Blake[2]; C. Collette[3]; K. Triebel[2]; A. Jacob[3]; V. Kamath[4]; V. Del Bene[2]
[1]School of Nursing, University of Alabama at Birmingham, Birmingham, Alabama, United States of America; [2]Department of Neurology, University of Alabama at Birmingham, Birmingham, Alabama, United States of America; [3]School of Medicine, Emory University, Atlanta, Georgia, United States of America; [4]The Johns Hopkins University School of Medicine, Balitmore, Maryland, United States of America

EPV-225 | Clinical utility of surface EMG for evaluation the effect of orthodontic treatment in patients with malocclusion

D. Tsakova[1]; V. Bogdanov[2]; M. Dinkova[2]
[1]Consulting and Diagnostic Department, Military Medical Academy, Sofia, Bulgaria; [2]Department of Orthodontics, Faculty of Dental Medicine, Medical University of Sofia, Sofia, Bulgaria

EPV-226 | Post-COVID-19 fatigue in the Moscow population: Prevalence and associated factors

G. Kustov[1]; D. Zhuravlev[1]; A. Razmakhnin[1]; A. Yakovlev[2]; M. Zinchuk[1]; R. Akzhigitov[1]; A. Guekht[3]
[1]*Moscow Research and Clinical Center for Neuropsychiatry, Moscow, Russian Federation;* [2]*Institute of Higher Nervous Activity and Neurophysiology of Russian Academy of Sciences, Moscow, Russian Federation;* [3]*Pirogov Russian National Research Medical University, Moscow, Russian Federation*

EPV-227 | Personality traits associated with suicidal ideation in patients with epilepsy

S. Popova[1]; M. Zinchuk[1]; G. Kustov[1]; D. Zhuravlev[1]; F. Rider[1]; A. Guekht[2]
[1]*Moscow Research and Clinical Center for Neuropsychiatry, Moscow, Russian Federation;* [2]*Pirogov Russian National Research Medical University, Moscow, Russian Federation*

EPV-228 | Exploring cognitive consequences: sNfL and sGFAP as biomarkers in post-COVID adults returning to work

D. Plantone[1]; A. Stufano[2]; D. Righi[1]; S. Locci[1]; I. Iavicoli[3]; P. Lovreglio[2]; N. De Stefano[1]
[1]*Department of Medicine, Surgery and Neuroscience University of Siena;* [2]*Department of Interdisciplinary Medicine, University of Bari Aldo Moro, Bari, Italy;* [3]*Department of Public Health, University of Naples Federico II, Naples, Italy*

EPV-229 | Modern possibilities for early diagnosis of cerebral disorders in children and adolescents with type 1 diabetes mellitus

D. Alidjanova
Department of Neurology, Pediatric Neurology and Medical Genetics, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

EPV-230 | tDCS improves empathy scores without affecting telepathic abilities

E. Ozdemir Oktem[1]; B. Yulug[1]; S. Cankaya[1]; A. Ozsimsek[1]; C. Sayman[1]; D. Sayman[1]; U. Duran[1]; A. Akturk[1]; H. Senturk[2]; L. Hanoglu[2]
[1]*Department of Neurology, Alanya Aladdin Keykubat University, Antalya, Turkey;* [2]*Research Institute for Health Sciences and Technologies (SABITA), Clinical Electrophysiology, Neuroimaging and Neuromodulation Laboratory, Istanbul Medipol University, Istanbul, Turkey*

EPV-231 | EEG calculator. A new tool for daily use in electroencephalography

E. Escario Méndez[1]; A. Escario Méndez[2]; M. Pintor Zamora[1]
[1]*clinical neurophysiology, Rey Juan Carlos University Hospital, Madrid, Spain;* [2]*CTO Madrija Consultoría S.L., Toledo, Spain*

EPV-232 | Measurement of olfactory impairment in Parkinson's disease patients and their relatives

E. Augste[1]; R. Holý[2]; J. Kozel[3]; P. Michalčová[3]; P. Bártová[4]; F. Strouhal[1]; D. Šalounová[1]; D. Školoudík[1]
[1]*Department of Clinical Neurosciences, Faculty of Medicine, University of Ostrava, Ostrava, Czechia;* [2]*Military University Hospital Prague, Department of Otorhinolaryngology and Maxillofacial Surgery, Prague, Czechia;* [3]*Center for Health Research, Faculty of Medicine, University of Ostrava, Ostrava, Czechia;* [4]*Neurology, University Hospital Ostrava, Ostrava, Czechia*

EPV-233 | Pneumocephalus and air embolism in COVID-19 interstizial pneumonia

F. Gargallo[1]; D. Colombo[2]; D. Bonardi[2]; L. Lorusso[1]; A. Tetto[1]; M. Vaccaro[1]; E. Tagliabue[1]; M. Di Stefano[1]; A. Formenti[1]; L. Airoldi[1]; P. Melzi[1]
[1]*Neurology and Stroke Unit Department, Leopoldo Mandic Hospital, Merate, Italy;* [2]*Respiratory Unit, IRCCS INRCA (Italian National Research Centre On Aging), Casatenovo, Italy*

EPV-234 | Epilepsy, antiseizure medications, and their relationship with music understanding

A. Fernández Cabrera[1]; P. Santamaría Montero[1]; J. García de Soto[2]; R. Pego Reigosa[2]; X. Rodríguez Osorio[1]
[1]*Hospital Universitario Lucus Augusti;* [2]*Hospital Universitario de Santiago de Compostela*

EPV-235 | The utility of EMG in the diagnosis of sciatica

I. Fettache; Y. Koubci; A. Khira; N. Slimani; W. Benzaghou; H. Bouzenada
Neurology Departement, the Central Hospital of the Army, Algeries, Algeria

EPV-236 | Epilepsy diagnostic clinic: First-year retrospective analysis

F. Assis Jacinto[1]; Â. Fonseca[1]; C. Cruto[2]; A. Ferreira[2]
[1]*Neurology Department, Hospital Pedro Hispano, Matosinhos, Portugal;* [2]*Neurophysiology Unit, Neurology Department, Hospital Pedro Hispano, Matosinhos, Portugal*

EPV-237 | COVID-19 vaccines and attributable risk of neurological disorders: A multicentre, case–control study (COVIVAX)

G. Mainini[1]; E. Pupillo[2]; E. Bianchi[2]; E. Beghi[2]; F. Pedrazzini[1]; A. Giglio[1]; E. Schilke[1]; M. Percetti[1]; C. Morotti Colleoni[1]; P. Calabresi[3]; G. Primiano[3]; G. Frisullo[3]; A. Padovani[4]; V. Cristillo[4]; A. Pilotto[4]; D. Arici[4]; S. Gipponi[4]; G. Tedeschi[5]; A. D'ambrosio[5]; R. Melisi[5]; A. Gallo[5]; A. Bisecco[5]; A. Salmaggi[6]; B. Simone[1]; C. Ferrarese[1]
[1]*Department of Medicine and Surgery, University of Milano Bicocca, Milano, Italy;* [2]*Dipartimento di Neuroscienze, Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milano, Italy;* [3]*Dipartimento di Neuroscienze, Organi di Senso e Torace, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy;* [4]*Spedali civili di Brescia, Brescia, Italy;* [5]*I Division of Neurology, Department of Advanced Medical and Surgical Sciences (DAMSS), University of Campania "Luigi Vanvitelli", Napoli, Italy;* [6]*Neurosciences Department, ASST Lecco, Italy*

EPV-238 | Gerstmann syndrome with acute/subacute and insidious onset: A systematic review with individual patient data analysis

G. Polito; M. Russo; S. Melchiorre; C. Ciprietti; P. Quintieri; M. Onofrj; A. Thomas; S. Sensi
Department of Neuroscience, Imaging and Clinical Sciences, University G. D'Annunzio of Chieti-Pescara, Chieti, Italy

EPV-239 | Unveiling PURA-related Syndrome: A case study of a newborn with hypotonia

G. Bruno[1]; S. Graziano[1]; L. D'Acunto[1]; A. Rubino[1]; A. Cristofano[2]; F. Acquaviva[3]; L. Masini[1]; A. Dolcini[4]; A. Varone[1]
[1]*Pediatric Neurology Unit, Department of Neurosciences, Santobono-Pausilipon Children's Hospital, Naples, Italy;* [2]*Pediatric Neuroradiology Unit, Department of Neurosciences, Santobono-Pausilipon Children's Hospital, Naples, Italy;* [3]*Mediical Genetics Unit, Department of Pediatrics, Santobono-Pausilipon Children's Hospital, Naples, Italy;* [4]*Intensive Care Unit, Department of Emergency, Santobono-Pausilipon Children's Hospital, Naples, Italy*

EPV-240 | Cross-cultural adaptation of TEA-CIFunciona for assessing functioning in children with autism through parental reporting

G. Janizello; L. De Oliveira; C. Gomes; S. Micaela Silva
Department of Postgraduate Studies in Rehabilitation Sciences, University Ninth of July, São Paulo, Brazil

EPV-241 | Evaluation of facial synkinesis with applied blink reflex test

J. Han[1]; E. Choi[2]
[1]*Department of Neurology, Veterans Health Service Center, Seoul, Republic of Korea;* [2]*Department of Neuropsychiatry, Evergreen Neuropsychiatry Clinic, Seoul, Republic of Korea*

EPV-242 | A single physical exercise imitating motor seizures increases the concentration of MMP-9 in the serum

J. Sielczak; M. Krawczyk; A. Cudna; I. Kurkowska-Jastrzębska
2nd Department of Neurology, Institute of Psychiatry and Neurology

EPV-243 | Psychiatric features in aceruloplasminemia: A systematic review and meta-analysis

I. Ketata; E. Ellouz
Neurology Department, University Hospital of Gabes, Gabes, Sfax University, Sfax, Tunisia

EPV-244 | Psychotic disorders: Inaugural manifestations of multiple sclerosis

I. Ghorbel; H. Derbali; M. Messelmeni; M. Mednini; I. Bedoui; M. Mansour; J. Zaouali; R. Mrissa
The Principal Military Hospital of Instruction of Tunis

EPV-245 | Chronic inflammatory demyelinating polyneuropathy after COVID-19 vaccination

E. Ehler[1]; I. Stetkarova[2]; M. Židó[2]; P. Kunc[3]
[1]*Neurological Department, Faculty of Health Studies, Pardubice University and Pardubice Regional Hospital, Pardubice, Czechia;* [2]*Department of Neurology, Third Faculty of Medicine, Charles University and Faculty Hospital Kralovske Vinohrady, Prague, Czechia;* [3]*Department of Neurology, Faculty of Medicine and University Hospital Hradec Kralove Charles University in Prague, Hradec Kralove, Czechia*

EPV-246 | Diagnostic accuracy in non-lesional, drug-resistant focal epilepsy and its impact on clinical management

J. Mayol; M. Grávalos; M. Quintana; S. López-Maza; D. Campos-Fernández; L. Abraira; E. Santamarina; M. Toledo
Epilepsy Unit, Neurology Department, Vall d'Hebron University Hospital, Barcelona, Spain

EPV-247 | Amyloid angiopathy – beyond cerebral hemorrhage

M. Rosa Andrade Ferreira[1]; M. Filipa Graça[1]; J. M. Ferreira Machado[1]; H. Silva[2]; M. Calejo[1]; A. Ferreira[1]; C. Cruto[1]
[1]*Department of Neurology, Unidade Local de Saúde de Matosinhos, Matosinhos, Portugal;* [2]*Neurophysiology Unit, Department of Neurology, Unidade Local de Saúde de Matosinhos, Matosinhos, Portugal*

EPV-248 | Using historical data to derive reference limits – A validation of the E-norms approach

Ø. Dunker[1]; T. Szczepanski[1]; P. Do[1]; T. Sand[2]; J. Jabre[3]; K. Nilsen[1]
[1]*Oslo University Hospital, Department of Neurology and Clinical Neurophysiology, Oslo, Norway;* [2]*Norwegian University of Science and Technology, Department of Neuromedicine and movement science, Trondheim, Norway;* [3]*Formerly, Department of Neurology, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA*

EPV-249 | Association of family history of epilepsy with demographic and clinical characteristics of patients

K. Wezyk[1]; M. Bosak[2]
[1]*Faculty of Health Sciences, Jagiellonian University Medical College, Krakow, Poland;* [2]*Department of Neurology, Faculty of Medicine, Jagiellonian University Medical College, Krakow, Poland*

EPV-250 | Allergic reactions to antiseizure medications in epilepsy patients: Prevalence, patterns, and implications

K. Wężyk[1]; M. Bosak[2]
[1]*Faculty of Health Sciences, Jagiellonian University Medical College, Krakow, Poland;* [2]*Department of Neurology, Faculty of Medicine, Jagiellonian University Medical College, Krakow, Poland*

EPV-251 | Transcranial magnetic stimulation of the supplementary motor area in children with Tourette syndrome and chronic tics

A. Mirzoyan; G. Zabrodzets; T. Charnukha; S. Kulikova
Republican Research and Clinical Center of Neurology and Neurosurgery, Minsk, Belarus

EPV-252 | Machine learning of cognitive trajectories in PD: Predicting STN-DBS impact with neuroimaging and clinical data

K. Balßuweit[1]; K. Gerner[2]; A. Barthel[1]; A. Schweinar[2]; F. Wagner[3]; H. Köhler[4]; A. Schmidt[4]; C. Gaser[4]; C. Klingner[3]; S. Brodoehl[3]
[1]*IZKF Graduate Program Experimental Medicine, Jena University Hospital, Jena, Germany;* [2]*Else Kröner Graduate School for Medical Students "JSAM", Jena University Hospital, Jena;* [3]*Department of Neurology, Jena University Hospital, Jena;* [4]*Biomagnetic Center, Jena University Hospital, Jena*

EPV-253 | The health status of newborns in patients with multiple sclerosis on the background of natalizumab therapy

S. Kotov; T. Yakushina; D. Yakushin; I. Shtang
Vladimirsky Moscow Regional Research Clinical Institute, Moscow

EPV-254 | Value of neuroinflammatory dysfunction of the blood–brain barrier in the development of drug-resistant epilepsy

S. Kravtsova[1]; Y. Zabrodskaya[1]; N. Paramonova[2]; A. Gerasimov[1]; D. Sitovskaya[1]; V. Nezdorovina[1]; S. Malyshev[1]; E. Skiteva[1]; K. Samochernykh[1]
[1]*Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation;* [2]*Sechenov Institute of Evolutionary Physiology and Biochemistry, Russian Academy of Sciences, St. Petersburg, Russian Federation*

EPV-255 | Features of physical activity in patients with epilepsy

S. Kravtsova; A. Koloteva; N. Dengina; G. Odintsova
Almazov National Medical Research Centre, St. Petersburg, Russian Federation

EPV-256 | Convulsive status epilepticus in an adult patient with Alexander disease: A case study

L. López Trashorras; A. Aldaz Burgoa; P. Abizanda Saro; N. Rodríguez Albacete; L. Franco Rubio; M. García Ruiz; J. Obregón Galán; P. Gutiérrez Bedia; A. Marcos Dolado; R. Ginestal López; E. López Valdés; P. Mayo Rodríguez
Department of Neurology of Hospital Clínico San Carlos

EPV-257 | Generative language models in medical education: An observational study of ChatGPT performance in neurology questions

M. Abdelazim Mohamed Awad Elkarim
Faculty of Medicine, University of Gezira, Wad Madani, Sudan

EPV-258 | Awareness and practice of febrile convulsions first aid among parents of convulsing children

Babiker Bakri; R. Asim Mohammed; R. Mursi Hamid; M. Jaber Amin
Alzaiem Alazhari university Faculty of Medicine, Khartoum, Sudan

EPV-259 | Electroencephalographam in acute ischemic stroke as a prediction tool for poststroke epilepsy

M. Adouania; M. Ben Mahmoud; S. Fray; H. Jamoussi; N. Ben Ali; M. Fredj
Neurology Department, Charles Nicole Hospital, Tunis, Tunisia

EPV-260 | Pregnenolone: A "Forgotten" marker and neurosteroid target in chronic fatigue

W. Maier-JansonJanson
Neurological Practise, Ravensburg, Germany

EPV-261 | The level of anxiety in patients with vestibular dysfunction

M. Mozheiko; I. Maryenko; A. Kleban; S. Likhachev
Republican Scientific and Practical Center for Neurology and Neurosurgery, Neurological department, Minsk, Belarus

EPV-262 | Low frequency photoparoxysmal response in Creutzfeldt-Jakob Disease

M. M. Roque[1]; S. Parreira[2]; M. Leal Rato[1]; F. Dourado Sotero[1]; A. Antunes[1]; L. Albuquerque[3]
[1]*Serviço de Neurologia, Departamento de Neurociências e Saúde Mental, ULS Santa Maria, Lisbon, Portugal;* [2]*Centro de Referência para Epilepsias Refractárias do HSM-CHULN, Portugal (Full Member of ERN EpiCARE);* [3]*Centro de Estudos Egas Moniz, Clínica Universitária De Neurologia, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal*

EPV-263 | Vanishing White Matter disease: Clinical heterogeneity by age of onset

M. Borrell-Pichot; T. Mederer-Fernandez; R. Sainz-Torres; G. Olmedo-Saura; M. Guasch-Jimenez; S. Martínez-Horta; J. Kulisevsky; J. Pérez-Pérez
Neurology department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

EPV-264 | Intracerebral hemorrhage (ICH) and epilepsy: A retrospective review

M. Hernandez Garcia; C. Hernandez Javier; G. González Toledo; D. García Alvarez; L. Iacampo Leiva; J. Rojo Aladro
Servicio de Neurología, Hospital Universitario de Canarias, La Laguna, Spain

EPV-265 | Minor neurological anomalies in patients with first-episode psychosis

E. Abouda[1]; I. Betbout[1]; M. Mhiri[2]; A. Abess[2]; A. Ben Haouala[1]; L. Gasab[1]; A. Mechri[1]; A. Mhalla[1]
[1]Psychiatry Department, Ffattouma Bourguiba University Hospital, Monastir, Tunisiade; [2]Neurology Department, Ffattouma Bourguiba University Hospital, Monastir, Tunisia

EPV-266 | DHDDS mutation: A rare cause of hyperkinetic movement disorders and epileptic encephalopathy in a 13-year-old girl

M. Krasteva
Clinic of Pediatric Neurology, University Pediatric Hospital, "Prof. Ivan Mitev", Sofia, Bulgaria

EPV-267 | Spatial navigation in primary age-related tauopathy and Limbic-predominant age-related TDP-43 encephalopathy

M. Laczó; Z. Svacova; H. Horakova; M. Vyhnalek; J. Hort; J. Laczó
Memory Clinic, Department of Neurology, Charles University, Second Faculty of Medicine and Motol University Hospital, Prague, Czechia

EPV-268 | Analytic visual information processing and cross modal illusions. Relevance for migraine research and therapy

M. Buonfiglio[1]; U. Quartetti[2]; M. Butera[2]; F. Di Sabato[1]; F. Brighina[2]
[1]Policlinico Umberto I, Sapienza Università di Roma, Dipartimento di Medicina Clinica, Roma; [2]Department of Biomedicine, Neuroscience and Advanced Diagnostics (BIND), University of Palermo, Italy

EPV-269 | Neuroimaging as a biomarker of comorbidities in children with cerebral palsy

M. Ben Hafsa[1]; H. Benrhouma[1]; T. Ben Younes[1]; M. Jamoussi[1]; A. Zioudi[1]; Z. Miladi[1]; H. Klaa[1]; I. Kraoua[1]; S. Nagi[2]; I. Ben Youssef-Turki[1]
[1]Department of Pediatric Neurology, LR18SP04, National Institute Mongi Ben Hmida of Neurology, Tunis-Tunisia; [2]Department of Neuroradiology, National Institute Mongi Ben Hmida of Neurology, Tunis-Tunisia

EPV-270 | MSL3 (Basilicata-Akhtar) syndrome: De-novo novel pathogenic variant of an ultra-rare genetic disorder

M. Yousaf[1]; M. Ghani[2]; D. Brock[2]
[1]Neurology, Dell Medical School, University of Texas at Austin, Austin, USA; [2]Neurology Department, University of Louisville School of Medicine, Louisville, USA

EPV-271 | The burden of treatment-resistant schizophrenia: A neurological concern?

A. Touiti; N. Kouki; C. Ben Said; I. Ghazeli; N. Bram
Forensic Psychiatry Department, Hospital Razi Manouba, Faculty of Medecine of Tunis, University Tunis el manar

EPV-272 | Dynamic study of neuropsychological complications arising as a result of the treatment of chronic lympholeukosis

R. Matmurodov[1]; G. Eshchanova[1]; J. Babadjanov[2]; M. Jumaboeva[3]
[1]Neurology, Tashkent medical academy, Tashkent, Uzbekistan; [2]Urganch Branch of Tashkent Medical Academy; [3]Multidisciplinary Medical Center of Khorezm region

EPV-273 | The efficacy and safety of cannabidiol (CBD) in pediatric patients with Dravet syndrome: A systematic review

N. Aderinto[1]; G. Olatunji[2]; E. Kokori[2]
[1]*Lautech Teaching Hospital;* [2]*University of Ilorin*

EPV-274 | Peculiarities of cognitive and emotional changes in patients with primary hypothyroidism in the early stages

S. Nilufar
Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

EPV-275 | Impact of obesity on elective spine surgeries during COVID-19 pandemics

N. Koruga[1]; A. Rončević[1]; A. Soldo Koruga[2]
[1]*Department of Neurosurgery, University Hospital Center Osijek, Croatia, Faculty of Medicine, University J.J. Strossmayer, Osijek, Croatia;* [2]*Department of Neurology, University Hospital Center Osijek, Croatia, Faculty of Medicine, University J.J. Strossmayer, Osijek, Croatia*

EPV-276 | Introduction to QEMG Analytics: A new way to visualize and interpret EMG and Near Fiber EMG data

O. Garnes-Camarena[1]; D. Stashuk[2]
[1]*Jimenez Diaz Foundation University Hospital, Madrid, Spain;* [2]*Systems Desing Engineering, University of Waterloo, Ontario, Canada*

EPV-277 | Minor/major malformations and neurodevelopmental outcomes in children prenatally exposed to LEV, LTG and CBZ monotherapy

Ö. Ertürk Çetin[1]; P. Algedik[2]; G. Akyüz[3]; R. Sürmeli[4]; Ü. Zanapalıoğlu[1]; G. Alev Saltak[5]; Ş. Güven[3]
[1]*Department of Neurology, University of Health Sciences, Sancaktepe Şehit Prof Dr İlhan Varank Training and Research Hospital, İstanbul, Turkey;* [2]*Department of Psychiatry, Haliç University Faculty of Medicine, İstanbul, Turkey;* [3]*Department of Pediatrics, University of Health Sciences, Sancaktepe Şehit Prof Dr İlhan Varank Training and Research Hospital, İstanbul, Turkey;* [4]*Department of Neurology, University of Health Sciences, Ümraniye Training and Research Hospital, İstanbul, Turkey;* [5]*Department of Speech and Language Theraphy, Istinye University, Faculty of Health Sciences, İstanbul, Turkey*

EPV-278 | Cognitive impairments – a symptom of post-COVID syndrome in the context of a global pandemic

M. Hristova[1]; R. Massaldjieva[2]; P. Atanassova[1]; L. Chervenkov[3]
[1]*Medical University of Plovdiv, Faculty of Medicine, Department of Neurology;* [2]*Medical University of Plovdiv, Faculty of Public Health, Department of Health Care Management;* [3]*Research Complex for Translational Neuroscience, Medical University of Plovdiv*

EPV-279 | Dyslexia: A word game to develop phonological awareness

A. Ribeiro[1]; A. Morgadinho[2]
[1]*Cercitejo, Cooperative for the Education and Rehabilitation of Disabled Citizens, Alverca, Portugal;* [2]*Department of Neurology, Hospital Garcia de Orta, Almada, Portugal*

EPV-280 | Auditory verbal memory in children with autism spectrum disorders

E. Gorobets; R. Gamirova; T. Mustakova; A. Toksubaeva
Kazan Federal University

EPV-281 | Serial organization of movements in children with autism spectrum disorders and in children with speech dysontogenesis

E. Gorobets; R. Gamirova; Y. Volskaya; O. Ivanova
Kazan Federal University

EPV-282 | Is fear experienced under virtual reality? An electrophysiology study under virtual reality conditions

R. Unkun; A. Ertorun; S. Yeni; A. Gündüz
Department of Neurology, İstanbul University-Cerrahpaşa, Cerrahpaşa Medical Faculty, İstanbul, Turkey

EPV-283 | Postural control anomalies and gait dysfunction in Tourette's syndrome: A systematic review

G. Guido[1]; G. Carlin[2]; F. Zeoli[3]; A. Sarnataro[4]
[1]*Department of Biomedical and Biotechnological Sciences, University of Catania;* [2]*University of Pavia, Pavia, Italy;* [3]*Catholic University of the Sacred Heart, Rome, Italy;* [4]*Department of Neuroscience and Reproductive Science and Odontostomatology, University of Naples "Federico II", Naples, Italy*

EPV-284 | B-cells cytokines activation in myelitis with predominant damage of lateral and posterior columns

A. Kozlova[1]; Z. Inessa[1]; A. Tukhvatulin[2]; R. Konovalov[1]; M. Zakharova[1]
[1]*Research Center of Neurology, Moscow;* [2]*The National Research Center for Epidemiology and Microbiology Named after Honorary Academician N.F. Gamaleya, Moscow*

EPV-285 | Risk factors for sudden unexpected death in epilepsy

S. Daoud; S. Sellami; R. Charfi; S. Sakka; N. Bouattour; K. Moalla; N. Farhat; M. Damak; C. Mhiri
Neurology Department and Research Laboratory LR12SP19, Habib Bourguiba University Hospital, Sfax, Tunisia

EPV-286 | The analysis of circadian rhythm of heart rate variability in patients with epilepsy

S. Daoud[1]; F. Kchaou[1]; R. Charfi[1]; A. Bahloul[2]; A. Haddar[3]; S. Sakka[1]; N. Bouaatour[1]; K. Moalla[1]; N. Farhat[1]; L. Abid[2]; K. Masmoudi[3]; M. Damak[1]; C. Mhiri[1]
[1]*Neurology Department, Habib Bourguiba University Hospital, Sfax, Tunisia;* [2]*Department of cardiology, Hedi Chaker University Hospital;* [3]*Department of Physiology and Functional Exploration, Habib Bourguiba Hospital, Tunisia*

EPV-287 | Radiological features of carpal tunnel syndrome in the patients with hereditary transthyretin amyloidosis

J. Oh[1]; Y. Min[2]; B. Kim[3]
[1]*Department of Neurology, Konkuk Univeristy Medical Center, Seoul, Korea;* [2]*Department of Neurology, Hallym University Medical Center, Kangnam Sacred Heart Hospital, Seoul, Korea;* [3]*Department of Neurology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea*

EPV-288 | The care of the aphasic patients: Experience from a stroke unit

S. Magno[1]; F. Ferrari[2]; F. Mazzacane[3]; E. Monti[4]; A. Costa[3]; A. Cavallini[2]
[1]*Department of Emergency Neurology and Stroke Unit, IRCCS Mondino Foundation, Pavia, Italy/Department of Brain and Behavioral Sciences, University of Pavia, Pavia Italy;* [2]*Department of Emergency Neurology and Stroke Unit, IRCCS Mondino Foundation, Pavia, Italy;* [3]*Center for Cognitive and Behavioral Disorders, C. Mondino National Neurological Institute and Department of Brain and Behavior, University of Pavia, Italy;* [4]*Department of Brain and Behavioral Sciences, University of Pavia, Pavia Italy*

EPV-289 | The developing cavernous sinus thrombosis in patients who underwent COVID-19

S. Khudayarova; G. Rakhmatullayeva; S. Said-Akhmadova
Neurology, Tashkent Medical Academy, Tashkent, Uzbekistan

EPV-290 | Optimizing diagnostics and treatment for epileptic encephalopathy with continuous spike and wave during sleep

S. Shokhimardonov; N. Tuychibaeva; S. Kuzieva
Neurology Department, Tashkent Medical Academy, Tashkent, Uzbekistan

EPV-291 | Unveiling neurophobia: Exploring factors among sudanese medical students and impact on neurology residency intentions

S. Mokhtar; E. Mohamedzain
Faculty of Medicine and Health Sciences, Gadarif University, Gadarif, Sudan

EPV-292 | Electrophysiological changes in pediatric spinal muscular atrophy: Results from an observational study

R. Sun
Graduate College of Tianjin Medical University

EPV-293 | Charles Bonnet syndrome as sequelae of occipital lobe infarct with hemorrhagic conversion: A case report

A. Sy; D. Gochioco
Department of Clinical Neurosciences, University of the East Ramon Magsaysay Memorial Medical Center, Quezon City, Philippines

EPV-294 | Specialized infrastructure in a tertiary hospital to administer disease modifying treatments in Alzheimer's disease

T. Nathan[1]; E. Ash[1]; E. Ash[2]; E. Ash[3]; D. Shir[1]; N. Trablus[1]; A. Bar-David[1]; G. Wolpe[1]; T. Shiner[1]; T. Shiner[2]; T. Shiner[3]; N. Bregman[1]; N. Bregman[2]; N. Bregman[3]
[1]Cognitive Neurology Unit, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; [2]Department of Neurology and Neurosurgery, Sackler School of Medicine, Tel Aviv University; [3]Sagol School of Neuroscience, Tel Aviv University, Tel Aviv, Israel

EPV-295 | Late-onset valproate-induced encephalopathy: An untoward possible event

T. Giannelli; D. Totaro; G. Ruta; F. Mazzeo; D. Paolicelli; G. Falcicchio
Department of Translational Biomedicine and Neuroscience (DiBraiN), University of Bari "Aldo Moro", Bari, Italy

EPV-296 | A rare case of megalencephaly-polymicrogyria-polydactyly-hydrocephaly syndrome with PIK3R2 mutation

T. Talıbov[1]; M. Inci[2]; P. Topaloğlu[2]; Z. Yapıcı[2]
[1]Department of Neurology, Istanbul Health and Technology University; [2]Department of Neurology, Istanbul Faculty of Medicine, Istanbul University

EPV-297 | Pediatric onset multiple sclerosis: A tertiary center experience

T. Talıbov[1]; M. İnci[2]; M. Eraksoy[2]; Z. Yapıcı[2]; P. Topaloğlu[2]
[1]Department of Neurology, Istanbul Health and Technology University; [2]Department of Neurology, Istanbul Faculty of Medicine, Istanbul University

EPV-298 | Repetitive transcranial magnetic stimulation in murine models of epilepsy: Methodological aspects and outcomes

V. Tseriotis[1]; D. Chlorogiannis[2]; P. Mavropoulos[3]; V. Kimiskidis[4]; S. Koukou[1]; G. Konstantis[3]; C. Pourzitaki[3]
[1]Department of Neurology, Agios Pavlos General Hospital of Thessaloniki, Thessaloniki, Greece; [2]Department of Radiology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; [3]Laboratory of Clinical Pharmacology, Aristotle University of Thessaloniki, Thessaloniki, Greece; [4]First Department of Neurology, AHEPA General Hospital of Thessaloniki, Thessaloniki, Greece

EPV-299 | Evoked potentials in the diagnosis of cognitive impairment syndromes after a cerebrovascular accident

W. Derkowski
Faculty of Health Sciences, University of Opole, Opole, Poland

EPV-300 | Impact of post-COVID-19 syndrome on self-perceived impairment of working memory

H. Crvenković[1]; S. Butković Soldo[3]; Z. Popović[3]; A. Soldo Koruga[3]; M. Vladetić[2]; D. Jančuljak[3]
[1]Faculty of Medicine, J.J. Strossmayer University of Osijek, Croatia; [2]Department for Neurology, University Hospital Center Osijek, Croatia; [3]Faculty of Medicine, J.J. Strossmayer University of Osijek, Croatia and Department for Neurology, University Hospital Center Osijek, Croatia

EPV-301 | Rheumatoid Arthritis triggered by Fremanezumab: The real-world side effects of the anti-CGRP migraine treatments

P. Almeida[1]; T. Videira[2]; A. Rocha[1]
[1]Neurology Department, Unidade Local de Saúde de Gaia e Espinho, Vila Nova de Gaia, Portugal; [2]Rheumatology Department, Unidade Local de Saúde de Gaia e Espinho, Vila Nova de Gaia, Portugal

EPV-302 | Searching for variants of the CACNA1A gene in migraine patients – Preliminary study

O. Szymanowicz[1]; M. Kapelusiak-Pielok[2]; W. Kozubski[2]; J. Dorszewska[1]
[1]Laboratory of Neurobiology, Department of Neurology, Poznan University of Medical Sciences, Poznan, Poland; [2]Chair and Department of Neurology, Poznan University of Medical Sciences, Poznan, Poland

EPV-303 | Leptomeningeal enhancement on brain MRI during an acute attack in a patient with familial hemiplegic migraine

L. Abdallah; A. Ashkenazi
Department of Neurology, Shaare Zedek Medical Center, Jerusalem, Israel

EPV-304 | Acute post traumatic idiopathic intracarnial hypertension-like syndrome associated with cerebral venous sinus stenosis

S. Shqair; A. Ashkenazi
Department of Neurology, Shaare Zedek Medical Center, Jerusalem, Israel

EPV-305 | Characterization of the interictal burden: A global view of migraine

A. Sánchez Huertas; M. Lorenzo Diéguez; L. Portocarrero Sánchez; J. Diáz de Terán
Neurology, Hospital Universitario La Paz, Madrid, Spain

EPV-306 | Real world practice study: Eptinezumab in patients with failure of at least four previous preventive treatments

A. Sánchez Huertas; L. Portorcarrero Sánchez; J. Díaz de Terán
Neurology, Hospital Universitario La Paz, Madrid, Spain

EPV-307 | OnabotulinmtoxinA as a promising treatment for primary trochlear headache: A case series

A. Jaimes; A. Gómez; O. Pajares; J. Rodriguez-Vico
Headache Unit, Neurology Department, Fundación Jiménez Díaz University Hospital

EPV-308 | Genetic insights into chronic migraine: New associations with polymorphisms in the genes ARG1, CES2, MOCS2 AND SLCO2B1

A. Yakubova; A. Rizvanov
Openlab "Gene and Cell Technologies", Kazan Federal University, Kazan, Russian Federation

EPV-309 | Efficacy and safety with cenobamate monotherapy conversion and dual therapy

Á. Sánchez-Guijo Benavente[1]; G. García Martín[1]; A. Barros Ruiz[1]; P. Cabezudo García[1]; Á. Sánchez Larsen[2]; P. Serrano Castro[1]
[1]*Neurology Department, Hospital Regional Universitario de Málaga;* [2]*Neurology Department, Hospital Universitario de Albacete*

EPV-310 | Recurrent thunderclap headaches: Diverse presentations in a single patient

A. Aldaz Burgoa; L. López Trashorras; N. Rodríguez Albacete; P. Abizanda Saro; L. Franco Rubio; J. Obregón Galán; P. Mayo Rodríguez; C. Gómez-Escalonilla Escobar; P. Simal Hernández; J. Egido Herrero; N. González García
Neurology, Hospital Clínico San Carlos, Madrid, Spain

EPV-311 | Assessment of response to botulinum toxin A in patients with trigeminal neuralgia: A case series study

A. Pereira[1]; L. Barbosa[1]; I. Macedo[2]; I. Alves[1]
[1]*Department of Neurology,Tâmega e Sousa Hospital Center, Penafiel, Portugal;* [2]*USF Hygeia, ACeS Tâmega III-Vale do Sousa Norte, Felgueiras, Portugal*

EPV-312 | Real-world effectiveness and safety of fremanezumab in migraine: 4th interim analysis of the Pan-European PEARL study

M. Ashina[1]; D. Mitsikostas[2]; F. Amin[3]; P. Kokturk[4]; C. Schankin[5]; G. Sahin[6]; P. Pozo-Rosich[7]; P. Dorman[8]; T. Nežádal[9]; I. Martins[10]; M. Sumelahti[11]; V. Ramirez Campos[12]; A. Ahn[12]; H. Akcicek[4]; C. Tassorelli[13]

EPV-334 | Headaches and nonalcoholic fatty liver disease: How much is obstructive sleep apnea syndrome to blame?

D. Georgescu[1]; D. Lighezan[1]; R. Buzas[1]; O. Ancusa[1]; C. Rosca[1]; I. Suceava[1]; M. Ionita[1]; D. Reisz[2]
[1]Department of Internal Medicine I, V Babes University of Medicine and Pharmacy, Timisoara, Romania; [2]Department of Neurosciences, V Babes University of Medicine and Pharmacy, Timisoara, Romania

EPV-335 | The physiotherapy and rehabilitation approaches in chronic tension-type headache

D. Onan[1]; H. Arıkan[2]; E. Ekizoğlu[3]; B. Taşdelen[4]; A. Özge[5]; P. Martelletti[6]
[1]Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Yozgat Bozok University, Yozgat, Turkey; [2]Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Tokat Gaziosmanpasa University, Tokat, Turkey; [3]Department of Neurology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey; [4]Department of Biostatistics and Medical Informatics, Mersin University School of Medicine, Mersin University, Mersin, Turkey; [5]Department of Neurology, Algology and Clinical Neurophysiology, Mersin University School of Medicine, Mersin, Turkey; [6]School of Health Sciences, Unitelma Sapienza University, Rome, Italy

EPV-336 | Deep Brain Stimulation of the Ventral Tegmental Area (VTA) in refractory chronic cluster headache: Two case reports

D. Moraleja[1]; V. Obach Irimia[2]; D. Asín[1]; D. Ramis[1]; T. Marco[1]; A. Anton[3]; M. Sosa[1]; S. Fernandez-Fernandez[1]; N. Fabregat[1]; T. Topczesky[4]; P. Roldan[4]; V. Obach Baurier[1]
[1]Neurology Department, Hospital Clinic, Barcelona, Spain; [2]Faculty of Medicine, University of Barcelona, Barcelona, Spain; [3]Radiology Department, Hospital Clinic, Barcelona, Spain; [4]Neurosurgery Department, Hospital Clinic, Barcelona, Spain

EPV-337 | Genetic testing in adolescents with epilepsy

M. Babunovska[1]; M. Velkoska[2]; B. Adjami[3]; I. Isjanovski[4]; B. Boskovski[1]; I. Kuzmanovski[1]; D. Plaseska Karanfilska[5]; E. Cvetkovska[1]

[1]University Clinic of Neurology, Faculty of Medicine, Ss. Cyril and Methodius University, Skopje, North Macedonia; [2]General Hospital Borka Taleski, Prilep, North Macedonia; [3]City General Hospital 8 September, Skopje, North Macedonia; [4]University Clinic for Eye diseases, faculty of medicine, Ss. Cyril and Methodius, Skopje, N.Macedonia; [5]Research Centre for Genetic Engineering and Biotechnology Georgi D Efremov, Macedonian Academy of Sciences and Arts, Skopje, North Macedonia

EPV-338 | The role of BDNF during cluster headache attack

B. Holmuratova; N. Rashidova

Tashkent Medical Academy, Department of Neurology

EPV-339 | Prognostic value of interictal EEG pattern in the control of generalized epilepsy

M. Ahmed Hammad[1]; A. Alemam[2]; I. AlAhmar[2]; A. Mounir[2]

[1]University of Sadat City, Sadat City, Egypt, [2]Faculty of medicine, Menoufya University, Neurology, Shebin Elkom, Egypt

EPV-340 | Mind the change: Possibility of de novo psychogenic nonepileptic seizures after epilepsy surgery

E. Çakar[1]; K. Karadeniz[1]; B. Türk[1]; S. Yağcı-Kurtish[2]; G. Sağlam[2]; M. Delil[1]; S. Yeni[1]; M. Uzan[3]; Ç. Özkara[1]

[1]Department of Neurology, Faculty of Medicine, Istanbul University-Cerrahpasa; [2]Department of Psychiatry, Faculty of Medicine, Istanbul University-Cerrahpasa; [3]Department of Neurosurgery, Faculty of Medicine, Istanbul University-Cerrahpasa

EPV-341 | Flunarizine in migraine prophylaxis: The Turkish clinical experience

D. Ertem[1]; F. İlik[2]; M. İlik[3]

[1]Department of Neurology, Silivri Anadolu Hospital, Istanbul, Turkey; [2]Department of Neurology, KTO University, Medical Faculty, Konya, Turkey; [3]Department of Neurosurgery, Ozel Buyuksehir Hospital, Konya, Turkey

EPV-342 | The role of gasser ganglion block and radiofrequency ablation in cluster headache

M. İlik[1]; F. İlik[2]; D. Ertem[3]

[1]Department of Neurosurgery, Ozel Buyuksehir Hospital, Konya, Turkey; [2]Department of Neurology, KTO University, Medical Faculty, Konya, Turkey; [3]Department of Neurology, Silivri Anadolu Hospital, Istanbul, Turkey

EPV-343 | Mortality of status epilepticus in the intensive care unit from emergency institute from Chișinău

M. Vasilieva[1]; R. Racila[1]; C. Munteanu[2]; N. Gorincioi[3]; D. Ciolac[1]; I. Plesca[2]; V. Chiosa[2]; S. Groppa[2]

[1]Nicolae Testemitanu State University of Medicine and Pharmacy, Laboratory of Neurobiology and Medical Genetics, Chisinau, Republic of Moldova; [2]Nicolae Testemitanu State University of Medicine and Pharmacy, Department of Neurology no. 2, Chisinau, Republic of Moldova; [3]Institute of Emergency Medicine, Clinical Department of Neurology, Epileptology and Internal Disease, Chisinau, Republic of Moldova

EPV-344 | Super-refractory status epilepticus: Precipitating factors in a susceptible patient

M. Filipa Graça[1]; M. Andrade Ferreira[1]; L. Ribeiro[1]; A. Ferreira[1]; S. Moreira[1]; F. Assis Jacinto[1]; C. Batista[2]; C. Cruto[1]; S. França[1]

[1]Department of Neurology, Hospital Pedro Hispano, Matosinhos, Portugal; [2]Neurophysiology Laboratory, Hospital Pedro Hispano, Matosinhos, Portugal

EPV-345 | Long-term efficacy and safety data about cenobamate use in focal epilepsy: A single centre real-world experience

F. Mazzeo; D. Graziani; T. Giannelli; D. Paolicelli; G. Defazio; G. Falcicchio

Department of Translational Biomedicine and Neuroscience (DiBraiN), University of Bari "Aldo Moro", Bari, Italy

EPV-346 | Epilepsy risks for cognitive decline and their prevention

G. Kiteva-Trenchevska

Clinical Center "Mother Teresa", Medical Faculty, University "Ss Cyril and Methodius", Skopje, N. Macedonia

EPV-347 | VNS and cenobamate: A therapeutic alliance for drug-resistant epilepsy?

G. Pauletto[1]; A. Nilo[2]; P. Vergobbi[3]; E. Lamon[3]; S. D'Auria[4]; E. Osanni[5]; M. Vavla[5]; L. Verriello[1]; M. Valente[3]; P. Bonanni[5]
[1]*Neurology Unit, Head–Neck and Neurosciences Department, Santa Maria della Misericordia University Hospital, Udine, Italy;* [2]*Clinical Neurology Unit, Head–Neck and Neurosciences Department, Santa Maria della Misericordia University Hospital, Udine, Italy;* [3]*Department of Medicine (DMED), University of Udine, Udine, Italy;* [4]*Neurosurgery Unit, Head–Neck and Neurosciences Department, Santa Maria della Misericordia University Hospital, Udine, Italy;* [5]*Epilepsy and Neurophysiology Unit, IRCCS E. Medea, Conegliano (TV), Italy*

EPV-348 | Long-term perampanel effectiveness in generalized epilepsy as add-on therapy with 1 or 2 antiseizure medications

G. Di Mauro[1]; F. Operto[2]; N. Canas[3]; R. Renna[4]; F. Dainese[5]; M. Fernandes[1]; N. Mercuri[1]; C. Liguori[1]
[1]*Department of Medicine of Systems, University of Rome Tor Vergata, Rome, Italy;* [2]*Child and Adolescent Neuropsychiatry Unit, Department of Medicine, Surgery and Dentistry, University of Salerno, Salerno, Italy;* [3]*Epilepsy and Sleep Unit; Neurology Department, Hospital da Luz Torres Hospital, Lisbon, Portugal;* [4]*Neurological Clinic and Stroke Unit, "A. Cardarelli" Hospital, Naples, Italy;* [5]*Clinical Neurophysiology Unit, Clinical Neurology, DIDAS Department, Padua, Italy*

EPV-349 | Factors associated with excessive daytime sleepiness in patients with focal epilepsy

L. Atabekyan[1]; E. Balian[1]; H. Hovakimyan[1]; N. Yeghiazaryan[2]; S. Khachatryan[1]
[1]*Somnus Sleep And Movement Disorders Clinic;* [2]*Department Neurology and Neurosurgery National Institute of Health*

EPV-350 | An unexpected cause of epileptic seizures – Fahr's syndrome

H. Goldstein; L. Popa; S. Petrescu; H. Nicolae; V. Tiu; A. Daneasa; M. Popa; B. Azamfirei; L. Bica; S. Brita; C. Panea
Elias Emergency University Hospital

EPV-351 | Down syndrome and epilepsy

H. Abbashar; A. Hussein; A. Siddig; A. Abdelhaleem; A. Abbasher; M. Abbasher; S. Hamednalla; Z. Shihab; A. Algamal; A. Elamin; M. Abdulla; M. Mustafa
Neurology, Daoud Researsh Group, Cairo, Egypt

EPV-352 | Pre-implantation scalp EEG can predict VNS efficacy in children

I. Dolezalova
Brno Epilepsy Center, Departments of Neurology and Neurosurgery, St. Anne's University Hospital and Medical Faculty of Masaryk University, Brno, Czechia

EPV-353 | Genetic epilepsy and CDKL5 mutation: Case report

I. Istratuc
"Nicolae Testemitanu" State University of Medicine and Pharmacy

EPV-354 | The effect of antiepileptic therapy on bone metabolism: Intermediate results

I. Trukhina; N. Sivakova; I. Abramova; V. Rybasova; L. Lukina; V. Mikhailov; G. Mazo
V.M. Bekhterev National Medical Research Center for Psychiatry and Neurology, Saint-Petersburg, Russian Federation

EPV-355 | Impulsivity in episodic cluster headache

J. Cajape Mosquera; B. Del Moral Sahuquillo; M. Almeida Zurita; D. Cheli Gracia; J. Rodriguez Montolío; S. Santos Lasaosa
Neurology Service, Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain

EPV-356 | BHV-7000, a novel Kv7 potassium channel activator, demonstrates dose-dependent pharmacodynamic effects on EEG parameters

J. Lerner[1]; B. Awsare[1]; H. Sevinsky[1]; E. Ashbrenner[1]; R. Killingsworth[1]; R. Kendrick[2]; E. Vereycken[3]; N. Colenbier[3]; C. Neuray[3]; P. van Mierlo[3]; J. Slater[4]; D. Wyatt[5]; I. Qureshi[1]; S. Dworetzky[1]; M. Bozik[1]
[1]Biohaven Pharmaceuticals; [2]Certara, Inc; [3]Epilog, Clouds of Care NV; [4]Stratus; [5]Syneos Health

EPV-357 | Migraine burden associated with triptan treatment satisfaction from the 2022 European National Health & Wellness Survey

M. Lewis[1]; A. Jenkins[2]; J. Cirillo[3]; K. Hygge Blakeman[4]; L. Abraham[2]; J. Brown[1]
[1]Real World Evidence, Pfizer, New York, NY, USA; [2]HTA, Value & Evidence, Pfizer, Tadworth, UK; [3]HTA, Value & Evidence, Pfizer, New York, NY, USA; [4]Global Medical Affairs, Pfizer, Stockholm, Sweden

EPV-358 | Epilepsy in Alzheimer Disease; a late-stage complication or an integral part of Alzheimer Disease phenotype?

A. Kalyvas[1]; A. Efthymiou[1]; M. Lima[1]; K. Tzimourta[2]; P. Ioannidis[1]; N. Grigoriadis[1]; T. Afrantou[1]
[1]2nd Neurology Department, AHEPA University General Hospital, Thessaloniki, Greece; [2]Department of Electrical & Computer Engineering, University of Western Macedonia, Kozani, Greece

EPV-359 | Validation of the self-assessment cognitive tool "Test Your Memory" (TYM) for people with epilepsy (PWE)

K. Vizjak Sterman
Department of Neurology, University Clinical Centre Maribor, Slovenia

EPV-360 | Drug resistance predictive utility of age of onset and cortical imaging abnormalities in epilepsy

K. Alare; B. Ogungbemi; A. Fagbenro; B. Adetunji; O. Owonikoko; T. Omoniyo; H. Jagunmolu; A. Kayode; S. Afolabi
Department of Medicine, Ladoke Akintola University of Technology, Ogbomoso, Nigeria

EPV-361 | Beneficial effect of Cenobamate in patients treated with vagus nerve stimulation for drug resistant epilepsy

L. Hogeveen[1]; A. Meurs[1]; A. Mertens[1]; R. Raedt[1]; F. Dewaele[2]; J. Vandersteene[2]; S. Gadeyne[1]; K. Kristl[1]; P. Boon[1]
[1]4BRAIN, Department of Neurology, Ghent University Hospital, Belgium; [2]Department of Neurosurgery, Ghent University Hospital, Belgium

EPV-362 | The effect of GLP-1 agonists on idiopathic intracranial hypertension

N. Lev[1]; E. Elefant[2]
[1]Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [2]Department of Neurology, Meir Medical Center Kfar Saba, Israel

EPV-363 | Headache patients' characteristics and management at the emergency department

E. Elefant; N. Lev
Department of Neurology, Meir Medical Center, Kfar Saba Faculty of Medicine, Tel Aviv University, Israel

EPV-364 | Ophthalmoplegic neuropathy, a rare cause of headache

L. Franco Rubio; P. Abizanda Saro; A. Aldaz Burgoa; L. López Trashorras; N. Rodríguez Albacete; P. Mayo; M. Malaret Segurado; J. Ortega Macho; A. Maruri Pérez; P. Gutiérrez Bedia; J. Obregón Galán
Neurology, Hospital Clínico San Carlos, Madrid, Spain

EPV-365 | Lacrimal neuralgia: An unusual cranial neuralgia

L. Franco Rubio; N. Rodríguez Albacete; A. Aldaz Burgoa; P. Abizanda Saro; L. López Trashorras; N. González García
Hospital Clínico San Carlos, Madrid, Spain

EPV-366 | Deep ear pain: A case report of nervus intermedius neuralgia

L. Franco Rubio; N. Rodríguez Albacete; L. López Trashorras; A. Aldaz Burgoa; P. Abizanda Saro; N. González García
Hospital Clínico San Carlos, Madrid, Spain

EPV-367 | Effectiveness of fremanezumab for the preventive treatment of migraine up to 12 months: PEARL Italian interim analysis

L. Iannone[1]; A. Russo[2]; M. Allena[3]; C. Altamura[4]; A. Doretti[5]; G. Viticchi[6]; S. Zuppone[7]; P. Kokturk[8]; M. Cepparulo[7]
[1]Headache Center and Clinical Pharmacology Unit, Careggi University Hospital, Florence, Italy; [2]Department of Advanced Medical and Surgical Sciences, Headache Centre, University of Campania "Luigi Vanvitelli", Naples, Italy; [3]Headache Science and Neurorehabilitation Center, IRCCS C. Mondino Foundation, Pavia, Italy; [4]Fondazione Policlinico Universitario Campus Bio-Medico, Via Alvaro del Portillo, Rome, Italy; [5]Department of Neurology, IRCCS Istituto Auxologico Italiano, Milan, Italy; [6]Neurological Clinic, Marche Polytechnic University, Ancona, Italy; [7]Teva Italia Srl, Milan, Italy; [8]Teva Netherlands B.V., Amsterdam, The Netherlands

EPV-368 | Treatment profile of adult patients diagnosed with Epilepsia Partialis Continua in a tertiary care hospital

A. Luque-Ambrosiani; A. Ortega Ruiz; A. Castela Murillo; M. Morales Martínez; C. Arenas Cabrera
Neurology Department, Virgen del Rocio University Hospital, Seville, Spain

EPV-369 | Experience with cenobamate in drug-resistant patients in a general neurology practice of a secondary hospital

D. Cerdán Santacruz; C. Gómez López de San Román; M. Capra; M. Vargas Cobos; L. Caballero Sánchez; I. Bermejo Casado; P. Guerrero Becerra; G. Suárez Fernández; A. Castrillo Sanz; A. Mendoza Rodríguez; C. Tabernero Garcia
General Hospital of Segovia, Neurology

EPV-370 | Status epilepticus as a presentation of inflammatory amyloid angiopathy. Clinical case

M. Afkir Ortega[1]; A. Campos Villegas[1]; E. García Carrasco[2]; A. Gómez González[1]; M. Mañez Sierra[1]
[1]Department of Neurology, Hospital Virgen de la Victoria (Málaga); [2]Department of Radiology, Hospital Virgen de la Victoria (Málaga)

EPV-371 | Recurrent syncope during migraine attacks

M. Dias da Costa; B. Nunes Vicente; F. Dourado Sotero; I. Pavão Martins
Neurology, Department of Neurosciences and Mental Health, Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisbon, Portugal

EPV-372 | MRI defined structural etiology across lobar diagnoses in focal epilepsy

M. Kovacevic[1]; D. Sokic[1]; A. Ristic[1]; I. Berisavac[1]; M. Ercegovac[1]; O. Milicevic[2]; N. Vojvodic[1]
[1]Neurology Clinic, Clinical Center of Serbia, Faculty of Medicine, Univeristy of Belgrade; [2]Faculty of Medicine, Univeristy of Belgrade

EPV-373 | Seizure and non-seizure outcomes in generalized epilepsy patients: 24-month results from the CORE-VNS

M. Boffini[1]; A. Suller-Marti[2]; R. Verner[1]; M. Keezer[3]; A. Andrade[2]; M. Veilleux[4]; K. Myers[5]; G. Giannicola[1]; J. Burneo[6]; M. DIbue[1]; P. Roncon[1]
[1]LivaNova PLC (or a Subsidiary), Houston, TX; [2]Department of Clinical Neurological Sciences, Schulich School of Medicine and Dentistry, Western University, London, Ontario, Canada and Department of Pediatrics, Schulich School of Medicine and Dentistry, Western University, London, Ontario; [3]Department of Neurosciences and School of Public Health, Université de Montréal, Montreal, Quebec, Canada, [4]Department of Neurology and Neurosurgery, Montreal Neurological Institute and Hospital, Montreal, Quebec, Canada; [5]Research Institute of the McGill University Medical Center, Montreal, Quebec, Canada; [6]Department of Clinical Neurological Sciences, Schulich School of Medicine and Dentistry, Western University, London, Ontario, Canada and Department of Epidemiology and Biostatistics, Schulich School of Medicine and Dentistry, Western University, London, Ontario

EPV-374 | "Double cortex syndrome" due to DCX gene mutation: A rare cause of distonic seizures

R. Matrullo; A. Giordano; F. Scotto Di Clemente; R. De Micco; G. Tedeschi; A. Tessitore
Università degli Studi della Campania "Luigi Vanvitelli", Napoli, Italy

EPV-375 | Neurological and ethical implications of rising botched executions in the U.S.

A. Sohel[1]; M. Polestino[2]; B. Carr[3]
[1]College of Medicine, University of Florida, Gainesville, Fl, USA; [2]College of Liberal Arts and Science, University of Florida, Gainesville, Fl, USA; [3]Department of Psychiatry, University of Florida College of Medicine, Gainesville, Fl, USA

EPV-376 | Unusual case of postictal cutaneous manifestation of generalized tonic–clonic seizure

E. Abi Fadel; H. Al Khuder[1]; M. Bou Karroum[2]; S. Iskandar[1]; W. Ayoub[1]; A. Shatila[1]; M. El Dassouki[1]
[1]Department of Neurology, Lebanese American University Medical Center-Rizk Hospital, Beirut, Lebanon; [2]Gilbert and Rose-Marie Chagoury School of Medicine, Lebanese American University, Byblos, Lebanon

EPV-377 | Long-term patient retention rates with cenobamate in patients with different epilepsy aetiologies

M. Toledo[1]; J. Leach[2]; E. Alvarez-Baron[3]; K. Thangavelu[4]; C. Brandt[5]
[1]Hospital Universitari Vall d'Hebron Passeig Vall d'Hebron, Barcelona, Spain; [2]Global Medical Department, Angelini Pharma S.p.A, Rome, Italy; [3]Angelini Pharma España, Madrid, Spain; [4]MeDaStats LLC, Tampa, FL, USA; [5]Bethel Epilepsy Centre, Mara Hospital, Bielefeld, Germany

EPV-378 | Investigation of clinical characteristics and outcome of first-ever status epilepticus patients in a single center

N. Aydinli; B. Türk; M. Delil; S. Yeni; Ç. Özkara
Department of Neurology, Istanbul University-Cerrahpasa, Istanbul, Turkey

EPV-379 | Assessment of Toll-like receptor 4 (TLR4) biomarker in children with epilepsy

O. Constantin[1]; C. Calcii[2]; L. Feghiu[3]; E. Capestru[1]; I. Calistru[1]; S. Hadjiu[1]; S. Groppa[3]
[1]State University of Medicine and Pharmacy "Nicolae Testemițanu"; [2]Mother and Child Institute; [3]National Epileptology Center, Chisinau, Republic of Moldova

EPV-380 | Disrupted sleep architecture is associated with poor cognitive performance in adult patients with temporal lobe epilepsy

O. Tikhonova; A. Turchinets; F. Rider
Moscow Research and Clinical Center for Neuropsychiatry, Moscow, Russian Federation

EPV-381 | VNS and cenobamate: A potential new run against Ultra-refractory focal lesional epilepsy?

O. Pardeo; G. Atanasio; F. Lamanna; C. Martellino; A. Labate
Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy

EPV-382 | One-year follow-up experience of epilepsy and electroencephalography in a rural center

Ö. Kizek
Gumushane State Hospital

EPV-383 | Efficacy of erenumab in patients with chronic migraine: A prospective single-center study

P. Garay Albízuri; D. Pérez Gil; B. Martínez García; A. Llanes Ferrer; G. García Alcántara; C. García Moreno; J. Masjuan; B. Zarza Sanz
Department of Neurology, Hospital Ramón y Cajal, Madrid

EPV-384 | Dealing with disclosure of risk for Parkinson's disease: A population-based pilot study

P. Mahlknecht[1]; S. Leiter[1]; C. Horlings[1]; K. Schwarzovà[1]; I. Egner[1]; H. Stockner[1]; K. Marini[1]; K. Seppi[1]; W. Poewe[1]; O. HeBA Consortium[2]
[1]*Department of Neurology, Innsbruck Medical University, Innsbruck, Austria;* [2]*Healthy Brain Ageing (HeBA) consortium investigators*

EPV-385 | Efficacy of rimegepant for the acute treatment of migraine in women from China and South Korea

S. Yu[1]; Y. Sun[2]; Y. Liu[3]; Y. Zou[4]; Q. Zhao[5]; Z. Lu[2]
[1]*Chinese PLA General Hospital, Beijing, China;* [2]*Pfizer (China) Research and Development Co., Ltd, Shanghai, China;* [3]*Pfizer Inc., Beijing, China;* [4]*Pfizer Inc., Shanghai, China;* [5]*Pfizer Inc., Chengdu, China*

EPV-386 | Sustained efficacy of rimegepant for the acute treatment of migraine in adults from China and South Korea

S. Yu[1]; Y. Sun[2]; Y. Liu[3]; Q. Zhao[4]; Y. Zou[5]; Z. Lu[2]
[1]*Chinese PLA General Hospital, Beijing, China;* [2]*Pfizer (China) Research and Development Co., Ltd, Shanghai, China;* [3]*Pfizer Inc., Beijing, China;* [4]*Pfizer Inc., Chengdu, China;* [5]*Pfizer Inc., Shanghai, China*

EPV-387 | Clearing the shadows on CGRP antibodies and photophobia in migraine management

R. Costa[1]; G. Rodrigues[2]; A. Costa[1]
[1]*Neurology Department, Centro Hospitalar Universitário de São João, Porto, Portugal;* [2]*Faculdade de Medicina da Universidade do Porto, Porto, Portugal*

EPV-388 | Efficacy of eptinezumab in patients with refractory chronic migraine: Is it worth it?

P. Dodu; D. Rodriguez Garcia; C. Algar Ramirez; V. Castro Sanchez
Department of Neurology, Málaga's Regional and Universitary Hospital, Málaga, Spain

EPV-389 | Mortality in people with epilepsy with alcohol withdrawal seizures

F. Rider[1]; A. Turchinets[1]; A. Yakovlev[2]; W. Hauser[3]; A. Guekht[4]
[1]*Moscow Research and Clinical Center for Neuropsychiatry, Moscow, Russian Federation;* [2]*Moscow Research and Clinical Center for Neuropsychiatry, Institute of Higher Nervous Activity and Neurophysiology of Russian Academy of Sciences, Moscow, Russian Federation;* [3]*Gertrude H. Sergievsky Center, Columbia University, New York, USA;* [4]*Moscow Research and Clinical Center for Neuropsychiatry, Pirogov Russian National Research Medical University, Moscow, Russian Federation*

EPV-390 | Electrophysiological examination of the "switch off lateralization" pattern

S. Özdemir; İ. İlgezdi Kaya; M. Özcan; A. Elmalı; N. Bebek
Department of Neurology, Istanbul University Istanbul Faculty of Medicine, Istanbul, Turkey

EPV-391 | Two cases of focal onset seizures with amygdala enlargement

H. Kaleagasi[1]; A. Ozgur[2]; U. Topbas[1]
[1]*Department of Neurology, Mersin University School of Medicine;* [2]*Department of Radiology, Mersin University School of Medicine*

EPV-392 | Socioeconomic disparities in clinical trials in attention deficit hyperactivity disorder and autism spectrum disorder

S. Marti; L. Weber; A. Zmutt; A. Chan; R. Hoepner
Department of Neurology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland

EPV-393 | Evaluation of predictors of response to anti-CGRP monoclonal antibodies

V. Mendes Ferreira; G. Cabral; M. Serôdio; A. Caetano; M. Viana-Baptista
Neurology Department, Hospital de Egas Moniz, Lisbon, Portugal

EPV-394 | S-EEG guided thermocoagulation as a therapeutic option in drug-resistant epilepsy associated to ulegyria

V. Anciones Martín[1]; M. Sánchez Horvath[2]; A. Moreno Estébanez[1]; Í. Garamendi Ruiz[1]; P. de Ceballos Cerrajería[1]; L. Galbarriatu Gutiérrez[3]; M. Ruiz de Gopegui Ruiz[3]; A. Lagüela Alonso[1]; A. Rebollo Pérez[1]; V. Fernández Rodríguez[1]; L. Fernández Llarena[1]; C. Valido Reyes[1]; M. Martínez Seijas[1]; Á. López Prado[1]; í. Pomposo Gaztelu[3]; B. Mateos Goñi[4]; A. Rodríguez Antigüedad[1]; A. Marinas Alejo[1]

[1]Department of Neurology, Cruces University Hospital; [2]Department of Neurophysiology, Cruces University Hospital; [3]Department of Neurosurgery, Cruces University Hospital; [4]Department of Neuroradiology, Cruces University Hospital

EPV-395 | Demographic description and analysis of difficulty in accessing advanced resources in a small population

V. Pérez Navarro[1]; M. Cegarra Clares[1]; M. García Pérez-Carlos[1]; R. Ramírez Toledo[1]; A. González Romero[1]; M. Cánovas Iniesta[2]; M. Lozano Caballero[3]; B. Palazón Cabanes[3]; M. Navarro Lozano[3]; G. García Egea[2]; P. Herrero Bastida[4]; L. Ibañez Gabarrón[5]; P. Arnaldos Illán[5]; Á. Valero López[5]; C. Sánchez García[5]; F. Martínez García[5]; M. Llorente Iniesta[5]

[1]Neurology Service, Reina Sofía University Hospital, Murcia; [2]Neurology Service, Virgen del Castillo Hospital, Yecla; [3]Neurology Service, Lorenzo Guirao Hospital, Cieza; [4]Neurology Service, Rafael Méndez Hospital, Lorca; [5]Neurology Service, Virgen de la Arrixaca University Hospital, Murcia

EPV-396 | Research of the effect of melatonin on cell viability and SLC7A11 in glioblastoma cell line

V. Tunçbilek Akın[1]; N. Turgut[1]; B. Batar[2]; B. Yıldırım[3]

[1]Neurology Department, Tekirdağ Namık Kemal University, Tekirdağ, Turkey; [2]Medical Biology Department, Tekirdağ Namık Kemal University, Tekirdağ, Turkey; [3]Tumor Biology and Immunology Department, ekirdağ Namık Kemal University, Tekirdağ, Turkey

EPV-397 | Non-convulsive-status-epilepticus related to leptomeningeal carcinomatosis mimicking a stroke: A first case-description

V. Laterza; L. Mumoli; A. Fratto; A. Colosimo; A. Clodomiro; E. Le Piane; R. Iannacchero; T. Tallarico; G. Frontera; A. Luccisano; D. Pirritano; M. Pantusa; D. Bosco

Institute of Neurology, Department of Neurosciences, Presidio Ospedaliero "Pugliese", AOU "Renato Dulbecco", Catanzaro, Italy

EPV-398 | Causal errors in brain injury prognostication

W. Choi[1]; M. Young[2]

[1]Warren Alpert Medical School of Brown University; [2]Department of Neurology, Massachusetts General Hospital

EPV-399 | The efficacy of GON and LON blockage for chronic migraine treatment in patients with multiple sclerosis

Y. Beckmann[1]; C. Uzunköprü[2]

[1]İzmir Katip Çelebi University, School of Medicine, Department of Neurology; [2]İzmir Katip Çelebi University, School of Medicine, Department of Neurology

EPV-400 | Headache profile of patients seen in neurology consultations at HASSAN II Hospital in Morocco

Y. Zakaria; E. Boumahra; N. Kissani; M. Chraa

[1]Neurology Department, Mohamed VI Hospital University, Marrakesh, Morocco

EPV-401 | Rupture of an infected gastric artery aneurysm during treatment of Listeria monocytogenes meningitis

K. Inoue[1]; K. Yoshitaka[1]; A. Tamagake[1]; R. Ono[1]; A. Yasaka[1]; M. Otomo[1]; K. Tsukita[1]; G. Watanabe[1]; G. Yunome[2]; H. Rikimaru[3]; A. Sato[3]; Y. Suzuki[1]

EPV-402 | Demographic and clinical characteristics of patients with Parkinson's disease in South Region of Kazakhstan

S. Abdraimova; N. Zharkinbekova
Department of Neurology, South Kazakhstan Medical Academy, Shymkent, Kazakhstan

EPV-403 | Association between Parkinson's disease and environment in south region of Kazakhstan

S. Abdraimova; N. Zharkinbekova
Department of Neurology, South Kazakhstan Medical Academy, Shymkent, Kazakhstan

EPV-404 | Functional mapping of cortical areas involved in affect discrimination using intracranial EEG

A. Kalina[1]; M. Kajsova[1]; P. Marusic[1]; P. Jezdik[2]; J. Hammer[1]
[1]*Department of Neurology, Second Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czechia;* [2]*Department of Measurement, Faculty of Electrical Engineering, Czech Technical University, Prague, Czechia*

EPV-405 | Respiratory failure (RF) in acquired motor neuron diseases (MND): Our experience with ventilatory support (VS)

G. González Toledo; A. Bartolomé Yumar; P. Helena; H. Maria José; L. Marcial; Ismael Naim; R. Jose
Hospital Universitario de Canarias, San Cristóbal de La Laguna/Spain

EPV-406 | Post-partum onset of probable motor neuron disease in a young female

A. Ghiuta; M. Docan; E. Marin; B. Toron; L. Zurini; A. Arbune; A. Hanganu; A. Dulamea
Neurology, Fundeni Clinical Institute, Bucharest, Romania

EPV-407 | Complex clinical conundrum: Tuberculous meningoencephalitis in a patient with concurrent HIV and SARS-CoV-2 infection

A. Resiga; A. Ribigan; M. Moldovan; I. Vasiliu; S. Stefan; F. Antochi
Department of Neurology, University Emergency Hospital Bucharest, Bucharest, Romania

EPV-408 | Capnocytophaga canimorsus meningoencephalitis secondary to a canine bite

Á. Bonelli Franco[1]; D. Landaeta Chinchilla[1]; J. Rojas Marcos Rodríguez de Quesada[2]; P. Nieto González[1]; J. Cebrián Escudero[1]; T. Montalvo Moraleda[1]; N. Barbero Bordallo[1]
[1]*Integrated Neurology Department of Rey Juan Carlos University Hospital, Infanta Elena University Hospital and Villalba University Hospital;* [2]*Internal Medicine Department of Rey Juan Carlos University Hospital*

EPV-409 | Language as the working model of human mind

A. Dube
Department of Physiology, S.M.S. Medical College and Attached Hospitals, Jaipur

EPV-410 | Gene mutation TBK1: A case report

A. Gómez González; C. Neurología; J. Pinel Ríos; M. Máñez Sierra; P. Carbonell Corvillo
Hospital Universitario Virgen de la Victoria

EPV-411 | Beyond movement: A comparative study between PD and ET using NMSQ

A. Fonseca; M. Lima; M. Seco; M. Calejo; P. Salgado
Neurology Department, Hospital Pedro Hispano, ULS-Matosinhos, Portugal

EPV-412 | Neurological examination of patients with movement disorders via telemedicine: A systematic review

E. Angelopoulou; D. Kontaxopoulou; E. Stanitsa; S. Fragkiadaki; E. Smaragdaki; K. Vourou; C. Koros; J. Papatriantafyllou; L. Stefanis; S. Papageorgiou
Department of Neurology, Eginition University Hospital, Athens, Greece

EPV-413 | Striatal dopamine transporter imaging correlates of neuropsychiatric symptoms in Progressive Supranuclear Palsy

A. Bougea; C. Koros; A. Simitsi; N. Papagiannakis; R. Antonelou; I. Pachi; C. Chrysovitsanou; Stefanis
1st Department of Neurology, Eginition Hospital, National and Kapodistrian University of Athens, Athens, Greece

EPV-414 | Singin training in people with Parkinson's disease: A feasibility study

A. Trinchillo[1]; E. Marcuzzo[2]; F. Cucinotta[1]; F. Morgante[1]; L. Ricciardi[1]
[1]*Neuroscience and Cell Biology Institute, Neuromodulation and Motor Control Section, St George's University of London, London, UK;* [2]*Neurology Unit, Movement Disorders Division, Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona, Verona, Italy*

EPV-415 | Assessment of autonomic dysfunction in Parkinson's disease: Electrophysiological insights and daily life implications

B. Taşdelen; M. Çolak Atmaca; G. Baran; Ü. Zanapalıoğlu; Ö. Ertürk Çetin; P. Bekdik
Neurology Clinic, Sancaktepe Şehit İlhan Varank Training and Research Hospital, İstanbul, Turkey

EPV-416 | Integrative neurobiology of akathisia: Dissecting the role of basal ganglia and neurotransmitter systems

B. De[1]; B. Carr[2]
[1]*School of Medicine, University of California San Francisco, San Francisco, USA;* [2]*Department of Psychiatry, University of Florida, Gainesville, USA*

EPV-417 | Amyotrophic lateral sclerosis: Blood brain barrier permeability and phagocytosis

D. Baranov; S. Kiryukhina; S. Labunskiy; V. Podsevatkin; N. Kolmykova
Ogarev Mordovia State University, Saransk, Russian Federation

EPV-418 | Continuous subcutaneous infusion with apomorphine or levodopa/carbidopa in Parkinson's disease: A systematic review

E. Assis[1]; J. Limongi[2]
[1]*Department of Medicine, Baltic Federal University, Kaliningrad, Russian Federation;* [2]*Department of Neurology, University of São Paulo, São Paulo, Brazil*

EPV-419 | Deep brain stimulation in early stage Parkinson's disease: A systematic review and meta-analysis of randomized studies

E. Assis[1]; M. Reis[2]; F. Machado[3]; A. Almeida[4]; J. Limongi[5]
[1]*Department of Medicine, Baltic Federal University, Kaliningrad, Russian Federation;* [2]*Department of Medicine, National University of Rosario, Rosario, Argentina;* [3]*Department of Medicine, State University of Southwest Bahia, Bahia, Brazil;* [4]*Department of Medicine, Federal University of Mato Grosso, Mato Grosso, Brazil;* [5]*Department of Neurology, University of São Paulo, São Paulo, Brazil*

EPV-420 | Persisting cerebral vasculitis after bacterial meningitis. Report of two unusual cases

C. Villar Rodriguez[1]; D. Villagrán-Sancho[1]; M. Salgado Irazabal[1]; P. Franco Perejón[1]; A. Fernandez Panadero[1]; E. Rivas Infante[2]; M. Bernal Sanchez-Arjona[1]
[1]*Neurology and Neurophysiology Department, Virgen del Rocio University Hospital, Sevilla, Spain;* [2]*Pathological Anatomy Department, Virgen del Rocio University Hospital, Sevilla, Spain*

EPV-421 | ADHD – A differential diagnosis for mild cognitive impairment in the adult

C. Gonçalves[1]; M. Saraiva[2]
[1]*Hospital Egas Moniz;* [2]*Hospital Fernando Fonseca*

EPV-422 | Possible H.parainfluenzae endocarditis with embolic stroke in a patient with patent foramen ovale – mimicking meningitis

C. Gavancho; M. Pimenta; M. Cazola; J. Rosa
Neurology Department, Hospital de São José, Unidade Local de Saúde São José, Lisbon, Portugal

EPV-423 | Peripheral immune response pattern in a cohort of REM sleep behavior disorder patients

N. Papagiannakis[1]; A. Simitsi[1]; A. Bougea[1]; R. Antonelou[1]; I. Pachi[1]; I. Beratis[2]; S. Fragkiadaki[1]; D. Kontaxopoulou[1]; E. Sfikas[1]; C. Chrysovitsanou[1]; E. Angelopoulou[1]; M. Bregianni[3]; K. Lourentzos[3]; V. Constantinides[1]; G. Velonakis[4]; V. Prassopoulos[5]; C. Potagas[1]; S. Papageorgiou[1]; A. Bonakis[3]; L. Stefanis[1]; C. Koros[1]
[1]1st Department of Neurology, Eginition Hospital, National and Kapodistrian University of Athens, Greece; [2]Deree, The American College of Greece; [3]2nd Department of Neurology, Attikon Hospital, National and Kapodistrian University of Athens, Greece; [4]Research Unit of Radiology, 2nd Department of Radiology, Medical School, National and Kapodistrian University of Athens, "Attikon" University General Hospital, Athens, Greece[5]Nuclear Medicine Unit, IASO hospital, Athens, Greece

EPV-424 | Anterior opercular syndrome in an immunocompetent elderly caused by herpes simplex encephalitis

C. Kiew; G. Ng
Department of Neurology, National Neuroscience Institute, Singapore

EPV-425 | A case of a stroke-like onset of ALS in a patient with TBK1 mutation

C. Meoni; C. Carlesi; F. Bianchi; L. Becattini; L. Fontanelli; B. Giovannini; G. Vadi; G. Siciliano
Department of Clinical and Experimental Medicine, Neurological Clinic, University of Pisa

EPV-426 | Down the rabbit hole

C. Mercado Begara; L. Carazo Barrios; A. Morillas Pinteño; V. González Torres
Servicio de Neurología, Complejo Hospitalario de Jaén, España

EPV-427 | A case of HIV leucoencephalopathy during the COVID-19 pandemic

C. Herghelegiu[1]; N. Marginean[1]; L. Dumitrescu[1]; B. Nitu[2]; E. I. Davidescu[1]; B. O. Popescu[1]
[1]"Carol Davila" University of Medicine and Pharmacy, Faculty of Medicine, Clinical Neuroscience Department, Bucharest, Romania; Colentina Clinical Hospital, Neurology Department, Bucharest, Romania; [2]Neuroaxis Clinic, Bucharest, Romania

EPV-428 | Deceptive mimicry: Neurobrucellosis masquerading as primary angiitis of the central nervous system

D. Araújo; A. Militão; G. Bonifácio; J. Alves
Department, Hospital São Bernardo, CHS, Setubal, Portugal

EPV-429 | Intraventricular colistin in the treatment of healthcare-associated ventriculitis acinetobacter baumannii in an infant

D. Casasola; L. Precelyn
Tondo Medical Center

EPV-430 | Episodes of paroxysmal movements as an atypical presentation of a diffuse glioma

A. Garcia Maruenda; I. Martin Sobrino; M. Nieto Palomares; P. Gomez Ramirez; J. Cabello; R. Ibañez; J. Vaamonde Gamo
Department of Neurology, Ciudad Real, Spain

EPV-431 | Headache rounds: A headache in an immunosuppressed individual

M. Tandon[1]; C. Richardson[1]; D. Mendoza-Cervantes[2]; J. Malone[1]
[1]University of Pittsburgh Medical Center (UPMC), Pittsburgh, PA, USA; [2]University of Pittsburgh School of Medicine

EPV-432 | Clinically assessed walking capacity versus real-world walking performance in people with Parkinson's disease

E. Bianchini[1]; C. Hansen[3]; D. Rinaldi[1]; M. Alborghetti[1]; S. Galli[1]; L. De Carolis[1]; P. Pacilio[1]; F. Pontieri[1]; N. Vuillerme[2]
[1]Department of Neuroscience, Mental Health and Sensory Organs (NESMOS), Sapienza University of Rome, Rome, Italy; [2]AGEIS, Université Grenoble Alpes, Grenoble, France; [3]Department of Neurology, Kiel University, Kiel, Germany

EPV-433 | Asymmetry of DAT SPECT imaging in Parkinson's Disease according to REM sleep behavior onset

C. Cicero; S. Tabbì; R. Garofalo; A. Luca; G. Mostile; G. Donzuso; M. Zappia; A. Nicoletti
Department of Medical, Surgical Sciences and Advanced technologies G.F. Ingrassia, Section of Neurosciences, University of Catania, Catania, Italy

EPV-434 | Quantitative EEG in Parkinson's disease: When REM sleep behavior disorder onset really matters

R. Terranova[1]; C. Cicero[1]; R. Garofalo[1]; S. Tabbì[1]; A. Luca[1]; G. Mostile[1]; L. Giuliano[1]; G. Donzuso[1]; G. Sciacca[1]; M. Malaguti[2]; M. Zappia[1]; A. Nicoletti[1]
[1]Department of Medical, Surgical Sciences and Advanced technologies G.F. Ingrassia, Section of Neurosciences, University of Catania, Catania, Italy; [2]Department of Neurology, Ospedale Santa Chiara, Trento, Italy

EPV-435 | Lower limb dystonia only during down the stairs: A rare task-specific dystonia

E. Benevento; G. Palermo; E. Unti; R. Ceravolo
Neurology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

EPV-436 | A case of SCA17 presentation in a young woman from Sri Lanka

E. Benevento; J. Pasquini; G. Palermo; R. Ceravolo
Neurology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

EPV-437 | Effectiveness and safety of using monoclonal antibodies against migraine in patients with a comorbid disorder

E. Colombo[1]; A. Doretti[1]; D. Ungaro[1]; S. Pierro[2]; M. Sodano[1]; G. Demirtzidis[1]; V. Silani[2]; N. Ticozzi[2]; S. Messina[1]
[1]Department of Neurology, Istituto Auxologico Italiano, IRCCS, Milan, Italy; [2]Department of Pathophysiology and Transplantation, University of Milan, Italy

EPV-438 | Possible non-pharmacological interventions for fatigue among Parkinson's disease patients

M. Elkhooly[1]; M. Ismail[2]
[1]Department of Neurology, Southern Illinois University School of Medicine, Springfield, IL, USA; Department of Neurology, Wayne State university, Detroit, MI, USA; Department of Neurology and Psychiatry, Minia University, Minia, Egypt; [2]Department of Neurology and Psychiatry, Minia University, Minia, Egypt

EPV-439 | Are three times too many? Effect of repeated interruptions and restarts of erenumab treatment

E. Parreira; R. Pinheiro
Neurology Department, Hospital Prof Dr Fernando Fonseca, Amadora, Portugal

EPV-440 | The correlation between migraine and patent foramen ovale: An analysis in a group of patients at Berat Hospital, Albania

E. Rraklli[1]; O. Cibuku[2]; A. Bileri[3]; J. Ranxha[3]
[1]Regional Hospital of BERAT, ALBANIA; [2]American Hospital, Tirana, Albania; [3]Regional Hospital of Berat, Albania

EPV-441 | Visual snow syndrome in patients with migraine: Clinical features. Comparative analysis

E. Sokolov[1]; A. Nurmeeva[1]; A. Pyatkov[2]; A. Sergeev[1]
[1]Department of Neurology and Neurosurgery, Sechenov University; [2]Department of Neurophysiology, Sechenov University

EPV-442 | Refinement of patient criteria in the selection process for STN-DBS in PD: An exploration of exclusionary factors

F. Repas Barbosa; D. Costa; J. Damásio; N. VIla-Chã; L. Botelho; S. Cavaco; V. Sá Pinto; A. Mendes
Centro Hospitalar Universitário de Santo António

EPV-443 | Abstract withdrawn

EPV-444 | Lyme neuroborreliosis: An unexpected cause of isolated abducens palsy

G. Filisetti[1]; D. Vecchio[1]; P. Naldi[1]; C. Comi[2]; R. Cantello[1]
[1]Department of Translational Medicine, University of Piemonte Orientale, Neurology Unit, Azienda Ospedaliero-Universitaria Maggiore della Carità, Novara, Italy; [2]Department of Translational Medicine, University of Piemonte Orientale, Neurology Unit, S. Andrea Hospital, Vercelli, Italy

EPV-445 | EBV complicating neuroborreliosis infection diagnosis in a female case with facial palsy

E. Georgopoulou; I. Kyriakopoulos; A. Kalaentzis; E. Anastasiadi; A. Kaliontzoglou
Neurology Department, General Hospital of Rhodes, Dodecanese, Greece

EPV-446 | Stroke-mimicking hemiplegia as a presenting symptom of Listeria encephalitis in an immunocompromised patient

G. Adamo[1]; A. Tonon[2]; C. Palestini[2]; R. L'Erario[2]
[1]Department of Neuroscience, Hospital of Padua, Padua, Italy; [2]Department of Neurology, Hospital of Venice, Venice, Italy

EPV-447 | Clinical and neurophysiological follow-up of adult type III Spinal Muscular Atrophy patients treated with nusinersen

G. Libelli[1]; E. Siena[2]; A. Nuredini[1]; S. Romano[1]; P. Anceschi[1]; A. D'Orsi[1]; I. Allegri[3]; E. Chierici[3]; E. Saccani[3]
[1]Unit of Neurology, Department of Medicine and Surgery, University of Parma, Parma, Italy; [2]Neurology Unit, Department of General and Specialized Medicine, Hospital of Vaio, Fidenza, Italy; [3]Neurology Unit, Department of General and Specialized Medicine, University Hospital of Parma, Parma, Italy

EPV-448 | Prokineticin-2 is highly expressed in colonic mucosa of early Parkinson's disease patients

G. Palermo[1]; G. Bellini[1]; F. Rettura[2]; C. Ippolito[3]; L. Fontanelli[4]; C. Pellegrini[3]; D. Frosini[4]; C. Lambiase[2]; N. Bernardini[3]; R. Ceravolo[1]
[1]Center for Neurodegenerative diseases – Parkinson's disease and Movement disorders, Unit of Neurology, University of Pisa, Pisa, Italy; [2]Gastrointestinal Unit, Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy; [3]Unit of Histology and Embryology, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; [4]Neurology Unit, Department of Clinical and Experimental Medicine, AOUP, Pisa, Italy

EPV-449 | Daily and night functioning improvement in pharmacoresistant migraine patients treated with anti CGRP/R mAbs

G. Procopio; L. Curto; E. Ferrari; A. Di Chirico; L. Becattini; A. Pascazio; G. Siciliano; F. Baldacci; S. Gori
Department of Clinical and Experimental Medicine, Neurological Clinic, University of Pisa,

EPV-450 | Unravelling the complexity: A rare case of multiple sclerosis and amyotrophic lateral sclerosis and a literature review

P. Gklinos; D. Tzavella; A. Daponte; E. Anagnostou; V. Zouvelou; M. Rentzos
1st Neurology Department, Eginition Hospital, National and Kapodistrian University of Athens, Athens, Greece

EPV-451 | Challenge in diagnosing spinal muscular atrophy with childhood onset

G. Piccirilli[1]; A. Nanni[1]; G. Milella[1]; P. Lasorella[1]; A. Fraddosio[1]; I. Ladisa[2]; F. Cacace[2]; D. Paolicelli[1]; E. D'Errico[1]
[1]*Neurology Unit, Department of Translational Biomedicine and Neurosciences (DiBraiN), University of Bari – Italy;* [2]*Physical Medicine and Rehabiltation Unit, Department of Translational Biomedicine and Neurosciences (DiBraiN), University of Bari – Italy*

EPV-452 | Rimegepant effectiveness and tolerability as acute migraine treatment (GAINER): A real-world multicentric Italian study

G. Vaghi[1]; R. De Icco[1]; L. Iannone[2]; A. Burgalassi[2]; M. Corrado[1]; E. De Matteis[3]; F. De Santis[3]; C. Fasano[2]; E. Piella[4]; M. Romozzi[5]; G. Sebastianelli[6]; G. Avino[7]; S. Cevoli[8]; G. Coppola[6]; G. Dalla Volta[9]; A. Granato[10]; E. Mampreso[11]; R. Ornello[3]; F. Pistoia[3]; I. Rainero[12]; M. Trimboli[13]; A. Russo[14]; M. Valente[15]; C. Vollono[16]; C. Tassorelli[1]
[1]*Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; Headache Science & Neurorehabilitation Center, IRCCS Mondino Foundation, Pavia, Italy;* [2]*Headache Centre and Clinical Pharmacology Unit, Careggi University Hospital Florence, Florence, Italy;* [3]*Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, Italy;* [4]*Department of Neurosciences "Rita Levi Montalcini", University of Torino, Torino, Italy;* [5]*UOC Neurologia, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy;* [6]*Sapienza University of Rome Polo Pontino ICOT, Department of Medico-Surgical Sciences and Biotechnologies, Latina, Italy;* [7]*Ospedale di Prato Santo Stefano, Prato, Italy;* [8]*IRCCS Istituto delle Scienze Neurologiche Bologna, Bologna, Italy;* [9]*Headache Centre of Istituto clinico città di Brescia (gruppo SAN DONATO), Brescia, Italy;* [10]*Azienda Ospedaliero-Universitaria di Trieste, Trieste, Italy;* [11]*Headache Centre, Neurology – Euganea Health Unit, Padua, Italy;* [12]*Headache Center, Department of Neuroscience, University of Torino, Torino, Italy;* [13]*Centro Interaziendale Cefalee, Azienda Ospedaliero-Universitaria Renato Dulbecco, Catanzaro, Italy;* [14]*Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, Italy;* [15]*Azienda Sanitaria Universitaria Friuli Centrale, Presidio Ospedaliero Santa Maria della Misericordia, Udine, Italy;* [16]*Department of Neurosciences, Università Cattolica del Sacro Cuore, Rome, Italy*

EPV-453 | Follow-up of Nusinersen treatment in pregnancy and related considerations

Z. Grosz; V. Zsumbera; N. Töreki; L. Szabó; Á. Palásti; E. Ripszam; M. Molnár
Institute of Genomic Medicine and Rare Disorders, Semmelweis University

EPV-454 | Effects of the testosterone and estradiol hormones on the clinical course of cluster headache

G. Nurmakhammatova[1]; B. Holmuratova[2]; N. Rashidova[2]
[1]*Tashkent Medical Academy, treatment faculty;* [2]*Tashkent Medical Academy, Neurology department*

EPV-455 | Median nerve ultrasonography in Parkinson's disease: A systematic review and meta-analysis

H. Atwan[1]; A. Abdelaziz[2]; H. Ayman Kassem[3]; M. A. Eltobgy[4]; M. Gamal[1]; N. Yahia Ebaid[5]
[1]*Faculty of Medicine, Assiut University, Assiut, Egypt;* [2]*Faculty of Medicine, Al-Azhar University, Cairo, Egypt;* [3]*Faculty of Medicine, Ain Shama University, Cairo, Egypt;* [4]*Kasr Al Ainy School of Medicine, Cairo university, Cairo, Egypt;* [5]*Radiology Department, Faculty of Medicine, Zagazig University, Sharqia, Egypt*

EPV-456 | Dramatic improvement of cerebral toxoplasmosis: An illustrative case from Mozambique

H. Buque[1]; P. Manjate[2]; N. Arroz[1]; E. Rosales[1]; L. Bacallau[1]; H. Nzwalo[3]; H. Nzwalo[5]; M. Sidat[4]
[1]*Neurological Department, Central Hospital of Maputo, Mozambique;* [2]*Internal Medicine department, Maputo Central Hospital, Mozambique;* [3]*Faculty of Medicine and Biomedical research, University of Algarve, Portugal;* [4]*Faculty of Medicine, Eduardo Mondlane University, Mozambique;* [5]*Algarve Biomedical Sciences Research Institute, Portugal*

EPV-457 | Cerebral toxoplasmosis presenting with confusion and headache: A case of study

I. Korucu[1]; T. Karakoyun Alpay[2]
[1]*Department of Neurology, Mardin Training and Research Hospital, Mardin, Turkey;* [2]*Department of Neurology, Faculty of Medicine, Tekirdag Namik Kemal University, Tekirdag, Turkey*

EPV-458 | Myeloradiculitis revealing an infection with the hepatitis B virus

I. Ghorbel; H. Derbali; I. Bedoui; M. Mednini; M. Messelmeni; M. Mansour; J. Zaouali; R. Mrissa
The Principal Military Hospital of Instruction of Tunis

EPV-459 | Observational pilot study on the efficacy of anti CGRP antibodies on quality of sleep and depression

V. Drago[1]; M. Algozzino[2]; R. Vecchio[1]
[1]*U.O.S.D. Neurologia Ospedale Muscatello di Augusta, Siracusa Italy;* [2]*Dipartimento di Psicologia Clinica Università Kore Enna, Italy*

EPV-460 | Focal status epilepticus secondary to convexity subarachnoid hemorrhage due to infective endocarditis

I. Rosa[1]; I. Bartolomé[1]; O. Brengaret[1]; C. Brenlla[1]; G. Cuervo[2]; X. Urra[1]; A. Doncel-Moriano[1]
[1]*Neurology Department, Hospital Clínic, Barcelona, Spain;* [2]*Infectious Diseases Department, Hospital Clínic, Barcelona, Spain*

EPV-461 | Nummular headache: Demographics and clinical response in a case series

I. Owrang Calvo; C. Morales Hernández; M. Lobato González; A. Bartolomé Yumar
Servicio de Neurología, Hospital Universitario de Canarias, La Laguna, España

EPV-462 | FaceLessInjection ParadigmStudy (FLIPAS) with onabotulinum toxin type A for chronic migraine

J. Rodriguez-Vico; A. Jaimes-Sanchez; A. Gomez-García; O. Pajares-Pascual
Headache Unit, Neurology Department, Hospital Fundación Jiménez Díaz, Madrid, Spain

EPV-463 | A rare location; Report of a case of tuberculoma in the cavernous sinus

F. Sánchez García; M. Hernández Ramírez; J. Villamor Rodríguez; M. González Gómez; D. Barbero Jiménez
Neurology, Guadalajara University Hospital, Guadalajara, Spain

EPV-464 | Meningoradiculitis with involvement of the seventh nerve during Mediterranean spotted fever: A case report

F. Kchaou; K. Moalla; H. Hadj Kacem; N. Farhat; N. bouaatour; M. Damak; S. Sakka; C. Mhiri
Neurology Department, Habib Bourguiba University Hospital, Sfax, Tunisia

EPV-465 | Hemorrhagic reversible cerebral vasoconstriction syndrome caused by adrenaline and corticoids after an allergic reaction

M. Córdova Infantes; K. Jiménez Ureña; M. Páramo Camino; N. Guerrero Carmona; J. Pinedo Córdoba; A. Cienfuegos Fernández; M. Fernández Recio
Neurology Deparment, University Virgen de Valme Hospital, Seville, Spain

EPV-466 | Granulation amebic encephalitis: Diagnostic and therapeutic challenges through a case report from Morocco

K. Belaidi; N. Kissani
Neurology Department, University Hospital of Mohamed VI, Marrakesh, Morocco

EPV-467 | Computed tomography predictors of post-stroke aphasia recovery in the acute period of ischemic stroke

S. Kotov; V. Zenina; M. Shcherbakova; E. Stepanova
Vladimirsky Moscow Regional Research Clinical Institute, Moscow

EPV-468 | Presentation of a multiphasic HaNDL syndrome patient, case present report and literature review

K. Pozsegovits[1]; K. Boór[1]; Z. Arányi[2]
[1]*Albert Schweitzer Hospital, Department of Neurology, Hatvan, Hungary;* [2]*Semmelweis University, Department of Neurology, Budapest, Hungary*

EPV-469 | Exploring the relationship between fatigue and disease severity: Insights from ALS-FRS-r in ALS population

L. Becattini[1]; F. Bianchi[2]; E. Del Prete[2]; C. Carlesi[2]; L. Fontanelli[3]; C. Meoni[1]; G. Vadi[1]; G. Siciliano[1]
[1]*University of Pisa, Department of Clinical and Experimental Medicine, Neurological Clinic;* [2]*Azienda Ospedaliera-Universitaria Pisana, Department of Clinical and Experimental Medicine, Neurological Clinic;* [3]*Health Science Interdisciplinary Center, Sant'Anna School of Advanced Studies, Pisa*

EPV-470 | Anti-CGRP monoclonal antibodies reduce workplace disability

L. Bartole; A. Granato; G. Garascia; P. Manganotti
Neurology Unit, Headache Centre, Department of Medicine, Surgical and Health Sciences, ASUGI, University Hospital of Trieste, Italy

EPV-471 | Cauda Equina syndrome due to varicella zoster virus infection: In relation to two clinical cases

L. López Trashorras; L. Franco Rubio; P. Abizanda Saro; A. Aldaz Burgoa; N. Rodríguez Albacete; M. García Ruiz; M. Lara González; E. López Valdés; A. Marcos Dolado; R. Ginestal López; A. Fernández Revuelta
Department of Neurology of Hospital Clínico San Carlos

EPV-472 | The relationship of food components with the number of days with headache per month by patients with migraine

M. Afanasev; L. Dobrynina; A. Belopasova; M. Gubanova
Department of Neurology, Russian Research Centre of Neurology, Moscow, Russian Federation

EPV-473 | Treatment of hypnic headache: A single centre experience

M. Abu-Lafi; A. Avi Ashkenazi
Neurology Department, Sharee Zedek Medical Centre, Jerusalem, Israel

EPV-474 | Differences in neural activations between active and passive numerical symbol processing in large-scale brain networks

M. Kajsova; A. Kalina; P. Marusic; J. Hammer
Department of Neurology, Second Faculty of Medicine, Charles University, Motol University Hospital, Prague, Czechia

EPV-475 | Rimegepant for acute migraine treatment across BMI categories: Pooled analysis of 4 phase 3 randomised clinical trials

M. Sánchez del Río[1]; T. Fullerton[2]; G. Pixton[2]; A. Chan[3]
[1]*Neurology Department, Clínica Universidad de Navarra, Madrid, Spain;* [2]*Pfizer Inc, Groton, CT, USA;* [3]*Pfizer Healthcare Ireland, Dublin, Ireland*

EPV-476 | Impact of personal traits on language preference by bilinguals

S. Tukaiev[1]; J. Alves Ferreira[2]; M. Makarchuk[3]; I. Zyma[4]
[1]*Taras Shevchenko National University of Kyiv, Educational Scientific Institute of High Technologies, Kyiv, Ukraine;* [2]*Faculty of Medicine, University of Coimbra, Coimbra, Portugal;* [3]*Taras Shevchenko National University of Kyiv, Educational and Scientific Centre "Institute of Biology and Medicine", Kyiv, Ukraine;* [4]*Taras Shevchenko National University of Kyiv, Educational and Scientific Centre "Institute of Biology and Medicine", Kyiv, Ukraine*

EPV-477 | Orthonasal olfactory blockage determines the neural reorganization in the brain: First minutes

S. Tukaiev[1]; I. Zyma[2]; J. Alves Ferreira[3]
[1]*Taras Shevchenko National University of Kyiv, Educational Scientific Institute of High Technologies, Kyiv, Ukraine;* [2]*Taras Shevchenko National University of Kyiv, Educational and Scientific Centre "Institute of Biology and Medicine", Kyiv, Ukraine;* [3]*Faculty of Medicine, University of Coimbra, Coimbra, Portugal*

EPV-478 | Central mechanisms of neural reorganization under short-term olfactory deprivation

S. Tukaiev[1]; J. Alves Ferreira[2]; I. Zyma[3]
[1]*Taras Shevchenko National University of Kyiv, Educational Scientific Institute of High Technologies, Kyiv, Ukraine;* [2]*Faculty of Medicine, University of Coimbra, Coimbra, Portugal;* [3]*Taras Shevchenko National University of Kyiv, Educational and Scientific Centre "Institute of Biology and Medicine", Kyiv, Ukraine*

EPV-479 | Failure in migraine treatment with monoclonal antibodies after a positive initial response

N. Bocero Hanan; L. Rodríguez; P. Gallego; S. Sánchez; M. Castro
Neurology, Hospital Regional Universitario Málaga, Malaga, Spain

EPV-480 | Gender differences in idiopathic intracranial hypertension

N. Karli; G. Mesut; S. Alizade; E. Oguz-Akarsu
Department of Neurology, Faculty of Medicine, Bursa Uludag University, Bursa

EPV-481 | Analysis of a series of cases of neuroborreliosis in Northern Spain

P. Siso Garcia[1]; P. Zunzunegui Arroyo[2]; A. Criado Anton[2]; D. Fuentes Castañon[2]; A. Garcia Rua[1]; M. Alvarez Alvarez[1]; A. Sanchez Rodriguez[1]; S. Fernandez Menendez[2]
[1]Department of Neurology, HUCAB, Spain; [2]Department of Neurology, HUCA, Spain

EPV-482 | Efficacy of eptinezumab in patients with migraine reporting psychiatric comorbidities

P. Pozo-Rosich[1]; C. Tassorelli[3]; L. Boserup[4]; S. Awad[4]; X. Lee[4]; J. Ailani[5]
[1]Vall d'Hebron University Hospital, Barcelona, Spain; [3]University of Pavia National Institute of Neurology Foundation, Pavia, Italy; [4]H. Lundbeck A/S, Copenhagen, Denmark; [5]Georgetown University Hospital, Washington, DC, USA

EPV-483 | Psychiatric comorbidities and dizziness in migraine

P. Amarasena; M. Villar-Martinez; R. Wilcha; J. Hoffman; P. Goadsby
Wolfson Sensory Pain and Regeneration Centre, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, UK

EPV-484 | Unusual cause of secondary headache. A case report and literature review

S. Dodaj[1]; R. Uruci[2]; E. Roci[2]; J. Kruja[3]
[1]Neurology Service, "Mother Teresa" University Hospital Center, Tirana, Albania; [2]Neurovascular Service, "Mother Teresa" University Hospital Center, Tirana, Albania; [3]Head of Neurology Service, "Mother Teresa" University Hospital, Tirana, Albania

EPV-485 | Phylogenetic elucidation and philosophical inquiry into the Claustrum's implications in mammalian consciousness

R. Grace[1]; D. Nolasco[2]; B. Carr[3]
[1]University of Florida College of Medicine, Gainesville, USA; [2]University of Florida Department of Psychiatry, Gainesville, USA; [3]University of Florida College of Medicine & Department of Psychiatry, Gainesville, USA

EPV-486 | A concept of viral etiogenesis of amyotrophic lateral sclerosis (ALS) in historical development

R. Kanarkowski
University of Warsaw, Warsaw, Poland

EPV-487 | Amyotrophic lateral sclerosis – The most recent advances in understanding of pathogenesis and treatment (2023)

R. Kanarkowski
University of Warsaw, Warsaw, Poland

EPV-488 | The effect of the psychiatric co-morbidities of migraine on medical university students: A cross-sectional study

R. Widaa Taha[1]; A. Widaa Taha[2]; Jaber Amin[2]; H. Ibrahim Awadal[1]
[1]Faculty medicine, University of Khartoum, Khartoum, Sudan; [2]Faculty of Medicine, Alzaiem Alazhari University, Khartoum, Sudan

EPV-489 | Surviving the abyss: The diagnostic challenge of a case of herpetic encephalitis

M. Hernández Ramírez; M. González Gómez; J. Villamor Rodríguez; F. Sánchez García; J. Celi Celi
Department of Neurology, Guadalajara Universitary Hospital, Guadalajara, Spain

EPV-490 | Imaging and laboratory characteristics of case series diagnosed with probable sporadic Creutzfeldt-Jakob disease

A. Fırat[1]; S. Alizada[1]; R. Çakmur[1]; İ. Öztura[1]; N. Karabay[2]; D. Öz[1]
[1]*Dokuz Eylul University, Department of Neurology;* [2]*Dokuz Eylul University, Department of Radiology*

EPV-491 | Severe encephalitis after surgical resection of a posterior fossa hemangioblastoma

S. Ştefan[1]; F. Antochi[1]; D. Iacob[2]; P. Ioan[1]; M. Moldovan[1]; A. Ribigan[1]; D. Teleanu[3]
[1]*Department of Neurology, Bucharest University Emergency Hospital, Bucharest, Romania;* [2]*Department of Infectious Diseases, Bucharest University Emergency Hospital, Bucharest, Romania;* [3]*Department of Neurosurgery, Bucharest University Emergency Hospital, Bucharest, Romania*

EPV-492 | Case Report: A rare case of Neurosyphilis presenting with seizures and psychotic symptoms

S. Dirkeç; S. Üstün Özek; E. Ünal; C. Örken
Department of Neurology, Prof. Dr. Cemil Taşcıoğlu City Hospital, Istanbul, Turkey

EPV-493 | Prospective study on the main side effects of the different antibodies against CGRP used in the prevention of migraine

S. Navarro Conti; M. Portillo Rivero; I. Lorite Fuentes; L. Cobo Roldan; M. Recio Bermejo
Neurology Department, Hospital Universitario Reina Sofía, Córdoba, Spain

EPV-494 | Treacherous Lyme disease presented as a progressive lumbosacral plexopathy

M. Kholodova[1]; A. Matsko[1]; T. Slobodin[1]; O. Mamenko[1]; G. Sciacca[2]; A. Afanasieva[1]
[1]*Department of Neurology and Neurosurgery, LLC "Dobrobut-Clinic", Kyiv, Ukraine;* [2]*Department of Medical, Surgical Sciences and Advanced Technologies GF Ingrassia, University of Catania, Catania, Italy*

EPV-495 | Short-term psychodynamic psychotherapy as chronic migraine preventive therapy: Responders and predictive factors

S. Ruggiero[1]; A. Viganò[2]; B. Petolicchio[2]; M. Toscano[2]; R. Di Giambattista[3]; M. Altieri[2]; E. Gillieron[3]; V. Di Piero[2]
[1]*Università degli Studi di Napoli 'Luigi Vanvitelli';* [2]*Università degli Studi di Roma 'La Sapienza';* [3]*IREP 'Istituto delle Ricerche Europee in Psicoterapia Psicoanalitica'*

EPV-496 | The contribution of ACC to task regulation: A prospective study in patients with frontal lobe stroke

J. Oerlemans[1]; R. Alejandro[2]; D. Hemelsoet[1]; P. Boon[1]; C. Holroyd[2]; V. De Herdt[1]
[1]*Department of Neurology, Ghent University Hospital, Ghent, Belgium;* [2]*Department of Experimental Psychology, Ghent University, Ghent, Belgium*

EPV-497 | FIG4-associated disease: An aggressive amyotrophic lateral sclerosis phenotype

V. Mendes Ferreira; A. Caetano; L. Santos; M. Fernandes
Neurology Department, Hospital de Egas Moniz, Lisbon, Portugal

EPV-498 | Clinical presentation of polyradiculoneuropathy revealing a neurological tuberculosis infection

Y. Zakaria; S. Benlamkadam; N. Kissani; M. Chraa
Neurology Department, Mohamed VI Hospital University, Marrakesh, Morocco

EPV-499 | Headache and papilledema in IIH: An early integrated multidisciplinary management favors better outcome

G. Carlucci[1]; M. Di Cristinzi[1]; A. Repice[2]; C. Fasano[1]; L. Massacesi[1]
[1]*Department of Neurosciences, University of Florence;* [2]*Department of Neurology II, Careggi University Hospital, Florence, Italy*

EPV-500 | Varicella zoster reactivation presented as pseudotumor cerebri in a young immunocompetent patient: A case report

I. Martín Sobrino; L. Quirós Illán; M. Nieto Palomares; A. García Maruenda; P. Gómez Ramírez
[1]*Neurology Department, General University Hospital of Ciudad Real*

EPV-501 | A diagnostic model for Parkinson's disease based on anoikis-related genes

Y. Bao
Department of Neurology, Shanghai East Hospital, School of Medicine, Tongji University, Shanghai, China

EPV-502 | Efficacy and safety of efgartigimod in acute phase of neuromyelitis optica spectrum disorders: A case report

Z. Li[1]; Q. Xu[2]; J. Huang[3]; Q. Zhu[4]; X. Yang[1]; M. Zhang[1]; S. Zhang[1]; S. Huang[1]; G. Yu[1]; P. Zheng[1]; X. Qin[1]; J. Feng[1]
[1]*Department of Neurology, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China;* [2]*Department of Neurology, Xuanwu Hospital Capital Medical University, Beijing, China;* [3]*958th Hospital of the People's Liberation Army, Chongqing, China;* [4]*Department of radiology, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China*

EPV-503 | Wilson's disease: Clinical presentations and treatment outcomes

S. Bildirici; C. Isiklar; R. Tiras; S. Ucler
Prof. Dr. Cemil Tascioglu City Hospital, Istanbul, Turkey

EPV-504 | The whistle-smile reflex in Parkinson's disease

A. Martini[1]; G. Paparella[1]; A. Grandolfo[1]; D. Costa[1]; D. Birreci[1]; L. Balestrucci[1]; M. De riggi[1]; L. Angelini[1]; M. Passaretti[1]; A. Cannavacciuolo[2]; M. Bologna[1]
[1]*Department of Human Neurosciences, Sapienza, University of Rome, Rome, Italy;* [2]*IRCCS Neuromed, Pozzilli, IS, Italy*

EPV-505 | Dysphagia in synucleinopathies: Preliminary data of a retrospective study

A. Furia; A. Incensi; S. Parisini; G. Rizzo; R. Liguori; V. Donadio
IRCCS Istituto delle Scienze Neurologiche di Bologna, UOC Clinica Neurologica, Bologna, Italy

EPV-506 | Infoflex impact: Accelerating MS care through digital innovation

A. Straukiene; J. Grundy; F. Moxon; S. Hughes
Torbay and South Devon NHS Foundation Trust

EPV-507 | A decade with Duodopa®: Boon or bane?

A. Rodríguez-Vallejo; D. Alonso-Modino; J. De León-Machín; J. Lorenzo-Brito; E. Rojas-Pérez
Neurology Department, University Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain

EPV-508 | Altered domain-specific striatal functional connectivity in patients with Parkinson's disease with urinary dysfunction

S. Aloisio[1]; R. De Micco[1]; N. Piramide[1]; F. Di Nardo[1]; G. Caiazzo[1]; M. Siciliano[2]; M. Cirillo[1]; A. Russo[1]; G. Tedeschi[1]; F. Esposito[1]; A. Tessitore[1]
[1]*Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Napoli;* [2]*Neuropsychology Laboratory, Department of Psychology, University of Campania "Luigi Vanvitelli", Caserta, Italy*

EPV-509 | Sphingosine-1-phosphate receptor modulators induced lymphopenia – selectivity matters?

J. Alves[1]; M. Soares[2]; P. Faustino[2]; I. Gomes[2]; J. Sequeira[2]; C. Capela[2]; F. Ladeira[2]
[1]*Department of Neurology, Unidade Local de Saúde Arrábida EPE, Setúbal, Portugal;* [2]*Multiple Sclerosis Center (CRI EM), Unidade Local de Saúde São José, Lisbon, Portugal*

EPV-510 | Central nervous system demyelination related to ustekinumab treatment

A. Cordeiro[1]; D. Marques[2]; M. Grunho[1]; F. Antunes[1]
[1]*Department of Neurology, Hospital Garcia de Orta, Almada, Portugal;* [2]*Department of Neuroradiology, Hospital Garcia de Orta, Almada, Portugal*

EPV-511 | Kinematic signature of rigidity during passive upper limb mobilization in patients with Parkinson's disease

A. Cannavacciuolo[1]; M. De Riggi[2]; A. Martini[2]; D. Birreci[2]; D. Costa[2]; L. Angelini[2]; S. Grandolfo[2]; M. Passaretti[2]; G. Paparella[1]; G. Paparella[2]; M. Bologna[1]; M. Bologna[2]
[1]*IRCCS Neuromed, Pozzilli, IS, Italy;* [2]*Department of Human Neurosciences, Sapienza, University of Rome, Rome, Italy*

EPV-512 | Online education yields significant gains in physicians' knowledge of biosimilars for multiple sclerosis

A. Stan[1]; T. Barras[1]; S. Sørensen[2]
[1]*Medscape LLC, New York, New York, USA;* [2]*Danish Multiple Sclerosis Center, Department of Neurology, Copenhagen University Hospital, Rigshospitalet Copenhagen, Denmark*

EPV-513 | Tongue tremor as the main finding on neurological examination

B. Teixeira[1]; C. Correia[2]; R. Valério[3]; A. Castro[1]; C. Oliveira[1]; I. Carrilho[2]
[1]*Neurology, Unidade Local de Saúde Entre-Douro e Vouga;* [2]*Neuropediatrics, Centro Materno-Infantil do Norte;* [3]*Pediatrics, Centro Hospitalar de Leiria*

EPV-514 | Evaluation of non motor symptoms in GBA Parkinson patients in Albania

E. Basha; E. Ranxha
Neuroscience Department, UHC "Mother Theresa" Tirana, Albania

EPV-515 | Clinical and neuroimaging features of a series of patients with diabetic striatopathy

B. Barreto[1]; S. Vedor[2]; C. Correira[1]; B. Martins[1]; A. Fernandes[1]; P. Abreu[1]; C. Soares[1]
[1]*Neurology Department, Centro Hospitalar Universitário de São João, E.P.E., Porto, Portugal;* [2]*Neuroradiology Department, Centro Hospitalar Universitário de São João, E.P.E., Porto, Portugal*

EPV-516 | Epidemiological aspects of Parkinson's disease in a population of southern Algeria. Dr. Bellagh Houria

B. Houria; B. Abd El Karim
Medecine Department, a south Algerian hospital, Algeria

EPV-517 | Subnetwork effects of subthalamic deep brain stimulation during voluntary spiral drawing in Parkinson's disease

Á. Berki[1]; H. Ding[2]; M. Palotai[1]; L. Halász[3]; L. Erőss[3]; G. Fekete[4]; L. Bognár[4]; P. Barsi[5]; A. Kelemen[1]; B. Jávor-Duray[1]; M. Muthuraman*[2]; G. Tamás*[1]
[1]*Department of Neurology, Semmelweis University, Budapest, Hungary;* [2]*Department of Neurology, Julius-Maximilians-Universität of Würzburg, Würzburg, Germany;* [3]*National Institute of Clinical Neurosciences, Budapest, Hungary;* [4]*Department of Neurosurgery, University of Debrecen, Debrecen, Hungary;* [5]*Department of Neuroradiology, Medical Imaging Centre, Semmelweis University, Budapest, Hungary*

EPV-518 | Siponimod from fingolimod direct switch in patients transitioning in secondary progressive multiple sclerosis

A. Bianco; T. Guerra; R. Vitobello; F. Oggiano; P. Iaffaldano
Department of Translational Biomedicines and Neurosciences-DiBraiN, University of Bari Aldo Moro

EPV-519 | Comorbidity in multiple sclerosis: An Albanian population-based study on disease demographics

M. Xhelili[1]; J. Kruja[2]
[1]*Regional Hospital Center "Shefqet Ndroqi", Albania;* [2]*MD, PhD, FEAN, UHC "Mother Teresa", Neurology Service, Tirana, Albania*

EPV-520 | Impact assessment of rTMS with stabilometric training on neurocognitive function in progressive multiple sclerosis

A. Buniak; S. Likhachev; M. Dymkouskaya
Neurological Department, Republican Research and Clinical Center of Neurology and Neurosurgery, Minsk, Belarus

EPV-521 | Cognitive impairment and pulvinar volume alterations in MS patients

B. Yulug[1]; E. Ozdemir Oktem[1]; D. Sayman[1]; S. Cankaya[1]; A. Ozsimsek[1]; C. Sayman[1]; A. Yalcinkaya[2]; L. Hanoglu[2]
[1]Department of Neurology, Alanya Alaaddin Keykubat University, Antalya, Turkey; [2]Research Institute for Health Sciences and Technologies (SABITA), Clinical Electrophysiology, Neuroimaging and Neuromodulation Laboratory, Istanbul Medipol University, Istanbul, Turkey

EPV-522 | Is tremor in blepharospasm a manifestation of dystonia or a separate disease?

Č. Jovanović; I. Petrović; N. Dragašević Mišković; M. Svetel
Neurology Clinic, University Clinical Center of Serbia

EPV-523 | Writer's cramp: Our experience in North Tenerife

C. Hernández Javier; M. Hernández García; M. Fernández Sanfiel; M. Crespo Rodríguez; M. Lobato González; A. Bartolmé Yumar; I. Owrang Calvo; S. Del Águila Romero; M. Millet Oval1; J. Rojo Aladro
Complejo Hospitalario Universitario de Canarias

EPV-524 | Acute disseminated encephalomyelitis associated with whipple disease

C. Coclitu; C. Chambon; M. Vaillant; O. Casez
CHU Grenoble Alpes, France

EPV-525 | Acquired demyelinating syndromes-Anti MOG antibodies associated with presence of CSF OCB-case series

C. Coclitu; S. Viguier; M. Vaillant; O. Casez
CHU Grenoble Alpes, Grenoble, France

EPV-526 | Prevalence non-motor symptoms in adult Northern Thai patients with primary focal or segmental dystonia

C. Wantaneeyawong[1]; O. Udomsirithamrong[2]; K. Wattana[3]; K. Thiankhaw1[1]; A. Soontornpun[1]; N. Sirimaharaj[1]; A. Nudsasarn[3]; C. Teekaput[1]; S. Tanprawate[1]
[1]Division of Neurology, Department of Internal Medicine, Faculty of Medicine, Chiang Mai University; [2]Nakornping Hospital; [3]The Northern Neuroscience Center, Faculty of Medicine, Chiang Mai University

EPV-527 | Gene expression of inflammatory markers in multiple sclerosis disease modifying therapies

C. Adan Diaz[1]; R. Luque Huertas[2]; R. Piñar Morales[1]; F. Barrero Hernández[1]; E. Gonzalez Rey[3]
[1]Clínico San Cecilio Huniversitary Hospital, Granada, Spain; [2]Maimonides Biomedical Research Institute, Cell Biology, Physiology and Immunology, Córdoba, Spain; [3]Institute of Parasitology and Biomedicine Lopez-Neyra (IPBLN), CSIC, Granada, Spain

EPV-528 | Risk factors for disease progression in patients with multiple sclerosis

C. Uzunköprü[1]; S. Cengiz[2]; Y. Beckmann[3]
[1]İzmir Katip Çelebi University, School of Medicine, Department of Neurology; [2]İzmir Katip Çelebi University, School of Medicine, Department of Neurology; [3]İzmir Katip Çelebi University, School of Medicine, Department of Neurology

EPV-529 | Exploring the spectrum of saccadic intrusions in essential tremor

C. Terravecchia[1]; G. Mostile[1]; A. Rufa[2]; R. Terranova[1]; C. Chisari[1]; A. Salerno[1]; A. Luca[1]; G. Donzuso[1]; C. Cicero[1]; M. Zappia[1]; A. Nicoletti[1]
[1]Department of Medical, Surgical Sciences and Advanced Technologies "G.F. Ingrassia", University of Catania, Catania, Italy; [2]Eye tracking and Visual Application Lab (EVA Lab), Department of Medicine, Surgery and Neurosciences, University of Siena, Siena, Italy

EPV-530 | Nutritional status and mediterranean diet adherence in paediatric multiple sclerosis

C. Di Monaco[1]; A. Carotenuto[1]; E. Scarpato[2]; M. Serra[2]; A. Esposito[1]; M. Moccia[1]; A. Staiano[1]; V. Brescia Morra[1]; C. Mandato[3]; R. Lanzillo[1]
[1]*Department of Neurosciences, Reproductive and Odontostomatological Sciences, Federico II University, Naples, Italy;* [2]*Department of Translational Medical Sciences-Section of Pediatric, University Federico II, Naples, Italy;* [3]*Pediatrics Section, Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", University of Salerno, Baronissi, Salerno, Italy*

EPV-531 | Atypical progression of motor symptoms in facio-scapulo-humeral dystrophy: Clinical worsening or overlap?

D. Calisi; M. De Rosa; M. Onofrj; S. Sensi
Department of Neuroscience, Imaging and Clinical Sciences, Gabriele d'Annunzio University of Chieti and Pescara, Chieti, Italy

EPV-532 | Transcranial alternating current stimulation of the cerebellum in cervical dystonia

D. Costa[1]; D. Birreci[1]; M. Passaretti[1]; A. Cannavacciuolo[1]; D. Colella[1]; L. Angelini[1]; G. Paparella[1]; A. Guerra[2]; A. Berardelli[1]; M. Bologna[1]
[1]*Department of Human Neurosciences, Sapienza, University of Rome, Rome, Italy;* [2]*Parkinson and Movement Disorder Unit, Study Center on Neurodegeneration (CESNE), Department of Neuroscience, University of Padua, Padua, Italy*

EPV-533 | Comparative study of alpha-fetoprotein in Parkinson's disease and vascular parkinsonism

D. Akramova; G. Rakhimbaeva; T. Bobomuratov; B. Ibodov
Tashkent Medical Academy

EPV-534 | A case of neuromyelitis optica spectrum disorder with paroxysmal dyskinesia

O. Ozdemir[1]; A. Yuceyar[2]
[1]*Departmant of Neurology, Buca Seyfi Demirsoy Hospital, İzmir, Turkey;* [2]*Department of Neurology, Ege University Hospital, İzmir, Turkey*

EPV-535 | Lingual dystonia induced by speaking: Case series and literature review

R. İsmayılov[1]; Y. Değirmenci[1]; Y. Değirmenci[2]
[1]*1Neurology Clinic, İstanbul Health and Technology University Şişli Kolan International Hospital, İstanbul, Turkey;* [2]*Department of Neurology, İstanbul Health and Technology University Medical Faculty, İstanbul, Turkey*

EPV-536 | RBD unmasked: LRRK2 and the prodromal path to Parkinson's disease

S. Datta; N. Ghosh; B. Chakraborty; M. Acharya
Indian Institute of Technology

EPV-537 | Dimethyl fumarate in relapsing–remitting multiple sclerosis: A study on patient satisfaction and treatment efficacy

D. Cetinkaya Tezer; I. Gungor Dogan; E. Uludasdemir; M. Turkkol; S. Demir
University of Health Science, Sehit Prof. Dr. Ilhan Varank Sancaktepe Training and Research Hospital, Department of Neurology

EPV-538 | How can I assess my patients with Parkinson's disease during a busy clinic day?

E. Madrigal[1]; J. Miranda[1]; G. Gámez-Leyva[1]; A. García[2]; S. Calvo[2]; L. Simon[2]; J. Rivadeneyra[2]; P. Martínez[3]; P. Mir[3]; D. Santos[4]; E. Cubo[1]
[1]*Department of Neurology, University Hospital of Burgos (Spain);* [2]*University Hospital of Burgos, Research Unit, Spain;* [3]*CIBERNED Spain;* [4]*Complejo Hospitalario Universitario de A Coruña (Spain), Departmente¡ of Neurology*

EPV-539 | A man with dystonia and novel sequence variant in KMT2B

E. Benjaminsen[1]; A. Simonsen[1]; M. Karlberg[1]; S. Lothe[3]; G. Braathen[3]
[1]*Department of Neurology, Nordland Hospital, Bodø, Norway;* [3]*Department of Medical Genetics, Telemark Hospital, Skien, Norway*

EPV-540 | Expert report: Evaluation of efficacy and efficiency between safinamide and rasagiline

E. Morales García[1]; F. Pérez Errazquin[1]; M. Gómez Heredia[1]; N. García-Agua Soler[2]; A. García Ruiz[2]
[1]*Movement Disorders Unit, Neurology Department, Virgen de la Victoria University Hospital, Málaga, Spain;* [2]*Clinical Therapeutics and Pharmacology Department, Faculty of Medicine, University of Málaga, Málaga, Spain*

EPV-541 | Cognition in patients with spinocerebellar ataxia type 1 and type 2

F. Colucci[1]; A. Gozzi[1]; S. Stefanelli[2]; E. Contaldi[3]; P. Antenucci[1]; D. Gragnaniello[2]; M. Pugliatti[1]; M. Sensi[2]
[1]*Department of Neuroscience and Rehabilitation, University of Ferrara, Ferrara, Italy;* [2]*Department of Neuroscience and Rehabilitation, Azienda Ospedaliero-Universitaria S. Anna, Ferrara, Italy;* [3]*Centro Parkinson e Parkinsonismi ASST Gaetano Pini-CTO Milan Italy*

EPV-542 | Uncovering the impact of deep brain stimulation on blood-based biomarkers in Parkinson's disease

F. Sanmartino[1]; F. Cano-Cano[1]; Á. Cruz-Gómez[1]; E. Lozano-Soto[1]; J. Riqué[3]; L. Forero[2]; G. Rubio-Esteban[2]; R. Espinosa-Rosso[4]; R. Rashid-López[2]; J. González-Rosa[1]

EPV-687 | Factors related to willingness to childbearing in women with MS

S. Nabavi[1]; Z. Emamipoor[2]; L. Amini[2]; H. Haqqani[2]

[1]Department of brain and cognitive sciences, Royan Institute for Stem cell Biology and Technology, Royan, Iran, ACCR, Iran; [2]Iran University of Medical Sciences

EPV-688 | Fatigue and pain in people with multiple sclerosis: Discriminator factor analysis

S. Nabavi[1]; M. heidari[2]; M. akbarfahimi[2]; G. Taghizade[2]; I. Lajevardi[2]
[1]*Department of Regenerative Biomedicine, Royan Institute for Stem Cell Biology and Technology, Royan, Iran, ACECR, Tehran, Iran;* [2]*Department of occupational therapy, School of Rehabilitation Science, Iran University of Medical Science, Tehran, Iran*

EPV-689 | Prodromal headache in optic neuritis with anti-myelin oligodendrocyte glycoprotein antibodies

A. Sikkal; S. Bellakhdar; G. Hjiej; H. Khattab; K. Haddouali; H. Elotmani; B. Elmoutawakil; M. Rafai
Service de Neurologie – Explorations Neurophysiologiques, CHU Ibn Rochd, Casablanca – Maroc

EPV-690 | Two-year longitudinal monitoring of corticospinal tract integrity in relapsing remitting multiple sclerosis

M. Rogic Vidaković[1]; S. Pavelin[2]; A. Bralić[3]; N. Režić Mužinić[4]; A. Markotić[4]; J. Šoda[5]; A. Mastelić[4]; K. Dolić[3]; A. Ćurković Katić[2]
[1]*Laboratory for Human and Experimental Neurophysiology, Department of Neuroscience, School of Medicine, University of Split, Split, Croatia;* [2]*Department of Neurology, University Hospital of Split, Split, Croatia;* [3]*Department of Interventional and Diagnostic Radiology, University Hospital of Split, Split, Croatia;* [4]*Department of Medical Chemistry and Biochemistry, School of Medicine, University of Split, Split, Croatia;* [5]*Signal Processing, Analysis, Advanced Diagnostics Research and Education Laboratory (SPAADREL), Department for Marine Electrical Engineering and Information Technologies, Faculty of Maritime Studies, University of Split, Split, Croatia*

EPV-691 | Experience with cladribine in multiple sclerosis patients in Montenegro: A national cohort study

S. Bojovic; S. Perunicic; L. Radulovic; B. Vujovic; J. Erakovic; D. Milikic; Z. Idrizovic; S. Vujovic; S. Gluscevic; M. Debeljevic; M. Dajevic; M. Roganovic; A. Gucci; S. Martinovic
Clinic for Neurology, Clinical Center of Montenegro, Podgorica, Montenegro

EPV-692 | Experience with natalizumab in multiple sclerosis patients in Montenegro: A national cohort study

S. Bojovic; L. Radulovic; S. Perunicic; D. Milikic; B. Vujovic; J. Erakovic; M. Debeljevic; Z. Idrizovic; S. Gluscevic; S. Vujovic; M. Dajevic; M. Roganovic; A. Gucci; S. Martinovic
Clinic for Neurology, Clinical Center of Montenegro, Podgorica, Montenegro

EPV-693 | Efficacy and safety of two therapeutic strategies in a multiple sclerosis population of Afro-Caribbean descent

T. David[1]; H. Chuamont[1]; P. Cabre[2]
[1]*Service de Neurologie, CHU Guadeloupe, Pointe à Pitre, Guadeloupe;* [2]*Service de Neurologie, CHU Martinique, Hôpital Pierre-Zobda-Quitman, Fort de France, Martinique*

EPV-694 | The effect of ocrelizumab on the risk and outcome of Covid-19 infection in patients with multiple sclerosis

S. Todorovic[1]; S. Vojinovic[2]; D. Savic[2]; D. Aleksic[3]
[1]*Clinic of Neurology, University Clinical Center of Nis, Serbia;* [2]*Clinic of Neurology, University Clinical Center of Nis, Serbia; Faculty of Medicine, University of Nis, Serbia;* [3]*Faculty of Medical Sciences, University of Kragujevac, Serbia*

EPV-695 | Epidemiology, clinical course and characteristics of MS in the Fergana region

Y. Musaeva; E. Yulchiev; T. Axunova; U. Abdullazizova
Tashkent Medical Academy, Neurology Department, Fergana, Uzbekistan

EPV-696 | Long term management with cladribine tabs: What to expect? Real-world clinical outcomes for years 1 and 2 in Greece

V. Deligianni; E. Kouremenos; O. Sideri; I. Spanou; K. Kournis; N. Skarli; C. Toilos
251 Air Force General Hospital, Athens, Greece

EPV-697 | Relationship between kappa light chain level and demyelinating lesion localization in SPMS

İ. Acir; H. Erdoğan; E. Eyüboğlu; V. Yayla
Bakırkoy Dr. Sadi Konuk Research and Training Hospital Neurology Clinics, Istanbul, Turkey

EPV-698 | Evaluation of the impact of autonomic dysfunction on the quality of life in multiple sclerosis patients

M. Göbel; İ. Acır; E. Dinç Polat; V. Yayla
Bakırkoy Dr. Sadi Konuk Research and Training Hospital Neurology Clinics, Istanbul, Turkey

EPV-699 | Association between multiple sclerosis and epilepsy

V. Danielius; L. Norkutė; R. Balnytė
Neurology Department, Lithuanian University of Health Sciences, Kaunas, Lithuania

EPV-700 | Utility of routine MRI in patients with multiple sclerosis (pwMS) on disease modifying therapies (DMTs)

C. Watanabe[1]; A. Lim[1]; A. Stenton[1]; D. Pearson[2]; E. Tallantyre[2]
[1]*Cardiff University School of Medicine;* [2]*University Hospital of Wales*

EPV-701 | Long-term follow up of patients with late-onset Pompe disease, treated with Enzymatic Replacement Therapy

G. Witkowski[1]; M. Konopko[2]; R. Rola[1]; D. Ryglewicz[1]; H. Sienkiewicz-Jarosz[2]
[1]*Department of Neurology, Military Institute of Aviation Medicine, Warsaw, Poland;* [2]*I-st Department of Neurology, Institute of Psychiatry and Neurology, Warsaw, Poland*

EPV-702 | SQSTM1 Pro392Leu presenting as a corticobasal syndrome

C. Bernardes[1]; A. Morgadinho[1]; A. Freire Gonçalves[1]; D. Duro[1]; M. Lima[1]; J. Durães[1]; I. Baldeiras[2]; I. Santana[1]; M. Almeida[2]; M. Tábuas-Pereira[1]
[1]*Neurology Department, Coimbra University Hospital Centre;* [2]*Center for Neuroscience and Cell Biology*

EPV-703 | Exploring genetics associated with Parkinson's disease in deep brain stimulation outcomes

A. Fernandes[1]; C. Soares[1]; J. Massano[1]; A. Oliveira[1]; R. Araújo[1]; C. Chamadoira[2]; M. Rito[2]; C. Reis[3]; C. Silveira[4]; J. Lima[5]; C. Sousa[5]; M. José Rosas[1]
[1]*Serviço de Neurologia, Centro Hospitalar Universitário de São João EPE, Porto, Portugal;* [2]*Serviço de Neurocirurgia, Centro Hospitalar Universitário de São João EPE, Porto, Portugal;* [3]*Serviço de Neurorradiologia, Centro Hospitalar Universitário de São João EPE, Porto, Portugal;* [4]*Serviço de Psiquiatria, Centro Hospitalar Universitário de São João EPE, Porto, Portugal;* [5]*Serviço de Neuropsicologia, Centro Hospitalar Universitário de São João EPE, Porto, Portugal*

EPV-704 | Diagnostic uncertainty in neurology: How much eludes diagnosis

A. Aguilar Monge; C. Ortega Hiraldo; A. Gomez Gonzalez; M. Vicente Dominguez; V. Delgado Gil
Neurology, Hospital Universitario Virgen de la Victoria, Málaga, Spain

EPV-705 | Formulation and standardization of frontotemporal lobar degeneration database in North Macedonia

A. Angelova[1]; K. Aleksovska[2]; G. Novotni[1]; M. Pendarovska[1]; S. Iloski[3]; I. Jacheva[4]
[1]*Department of Cognitive Neurology and Neurodegenerative Diseases, University Clinic of Neurology, Skopje, North Macedonia;* [2]*Scientific Department, European Academy of Neurology;* [3]*General Hospital Ohrid;* [4]*Public Health Institution Vinica*

EPV-706 | Lambert-Eaton myasthenic syndrome in a Sicilian cohort of patients: A clinico-neurophysiological and therapeutic study

A. Pugliese[1]; A. Barbaccia[1]; F. Biasini[1]; O. Musumeci[1]; S. Messina[1]; A. Toscano[2]; C. Rodolico[1]
[1]*Clinical and Experimental Medicine Department, University of Messina, Messina, Italy;* [2]*European Reference Network-NeuroMuscular Disease, Messina, Italy*

EPV-707 | A rare mutation in autossomic recessive spinocerebellar ataxia type 10

A. Aldomiro
Department of Neurology, Hospital de São Bernardo, Setúbal, Portugal

EPV-708 | Gene therapy approach for metachromatic leukodystrophy using recombinant adeno-associated virus encoding human Arsa gene

A. Mullagulova; A. Shaimardanova; V. Solovyeva; Y. Mukhamedshina; A. Yakubova; A. Rizvanov
Openlab "Gene and Cell Technologies", Kazan Federal University, Kazan, Russian Federation

EPV-709 | Evaluation of behavioural problems in the VISION-DMD study of vamorolone vs prednisone in Duchenne muscular dystrophy

E. Henricson[1]; A. de Vera[2]; M. Leinonen[2]; P. Clemens[3]; M. Guglieri[4]; N. Truba[5]; E. Hoffman[6]
[1]University of California, Davis, Sacramento, CA, USA; [2]Santhera Pharmaceuticals (Switzerland) Ltd, Pratteln, Switzerland; [3]University of Pittsburgh, Pittsburgh, PA, USA; [4]Newcastle University and Newcastle Hospitals NHS Foundation Trust, Newcastle upon Tyne, UK; [5]Nationwide Children's Hospital, Columbus, OH, USA; [6]ReveraGen BioPharma, Rockville, MD, USA

EPV-710 | Usefulness and feasibility of a self-monitoring diary for management and follow-up of patients with myasthenia gravis

A. Nuredini[1]; F. Stragliati[1]; P. Anceschi[1]; S. Romano[1]; G. Libelli[1]; A. D'Orsi[1]; I. Allegri[2]; E. Chierici[2]; E. Saccani[2]
[1]Unit of Neurology, Department of Medicine and Surgery, University of Parma, Parma, Italy; [2]Neurology Unit, Department of General and Specialized Medicine, University Hospital of Parma, Parma, Italy

EPV-711 | Cognitive impairment associated to bladder dysfunction and ataxia

Á. Morales Lahoz; J. Pelegrina Molina; I. del Pino Díaz; M. Serrano Jiménez
Neurology, Hospital Universitario Clínico San Cecilio, Granada, Spain

EPV-712 | Extending the spectrum: Elderly-onset vanishing white matter disease

A. Fonseca; C. Duque
Neurology Department, Hospital Pedro Hispano, ULS-Matosinhos, Portugal

EPV-713 | Canvas and sleep disorders: A prospective cross-sectional study

A. Funcis; S. Rossi; F. Madia; G. Dalla Zanna; G. Silvestri; V. Brunetti
Institute of Neurology, Catholic University of the Sacred Heart, Rome

EPV-714 | Prevalence of diabetic neuropathy in type 2 diabetes patients and its impact on quality of life in Pakistan

M. Bashir[1]; N. Ghouri[2]
[1]Indus Hospital and Health Network; [2]Indus Hospital and Health Network

EPV-715 | Diagnostic challenges in diplopia, ophthalmoplegia and Parkinsonism: A case report associated with POLG mutation

O. Akan[1]; B. Yaralıoğlu[1]; B. Kılboz[1]; G. Ünverengil[2]; G. Yunisova[3]; P. Oflazer[3]
[1]Department of Neurology, University of Health Sciences, Prof. Dr. Cemil Tascioglu City Hospital, Istanbul, Turkey; [2]Department of Pathology, Istanbul University Faculty of Medicine, Istanbul, Turkey; [3]Department of Neurology, Koc University Hospital, Istanbul, Turkey

EPV-716 | Multiple sclerosis in Albania: A 20 year-old history

M. Xhelili[1]; J. Kruja[2]
[1]UHC "Mother Teresa", University of Medicine, Faculty of Medicine, Neurology Service, Tirana, Albania; [2]UHC "Mother Teresa", Neurology Service, Tirana, Albania

EPV-717 | Rituximab in myastenia gravis: A single center experience

C. Erra; F. Tuccillo; D. Ricciardi; B. De Martino; A. Fasolino; F. Habetswallner
AORN A. Cardarelli, Neurophysiology Unit, Naples Italy

EPV-718 | Use of goal attainment scaling to identify relevant central nervous system domains in myotonic dystrophy type 1

C. Ferrari Aggradi[1]; A. Zanolini[2]; G. Colacicco[2]; J. Casiraghi[2]; V. Sansone[1]
[1]*Department of Neurology, University of Milan, Milan, Italy;* [2]*Department of Neurorehabilitation, NeMO Clinical Center, Milan, Italy*

EPV-719 | Sudden-onset adult-onset Alexander disease and the concept of GFAP toxicity

C. Guerreiro[1]; F. Godinho[1]; J. Freixo[2]; J. Oliveira[2]; J. Rosa[2]
[1]*Neurology Department, Centro Hospitalar Universitário Lisboa Central, Lisbon, Portugal;* [2]*Center for Predictive and Preventive Genetics, Molecular Cell Biology Institute, Porto, Portugal*

EPV-720 | Impact of HLADRB1 alleles on clinical and neuroimaging profile in hellenic pediatric onset multiple sclerosis patients

C. Skarlis[1]; N. Markoglou[2]; M. Gontika[3]; A. Artemiadis[4]; M. Pons[5]; M. Dalakas[6]; G. Chrousos[7]; M. Anagnostouli[8]
[1]*Research Immunogenetics Laboratory, First Department of Neurology, School of Medicine, National and Kapodistrian University of Athens, Aeginition University Hospital, Athens, Greece;* [2]*First Department of Neurology, School of Medicine, National and Kapodistrian University of Athens, Aeginition University Hospital;* [3]*Penteli Children's Hospital, Attiki, Greece;* [4]*Neurology Department, Cyprus University, Cyprus;* [5]*First Department of Pediatrics, School of Medicine, National and Kapodistrian University of Athens, Aeginition University Hospital, Athens, Greece;* [6]*Neuroimmunology Laboratory, Department of Pathophysiology School of Medicine, National and Kapodistrian University of Athens, Clinical Neuroimmunology and Neuromuscular Diseases Department, Thomas Jefferson University Philadelphia, USA;* [7]*University Research Institute of Maternal, Child and Child Health Precision Medicine, Clinical and Translational Research Unit in Endocrinology, National and Kapodistrian University of Athens, Greece, UNESCO Chair in Adolescent Health and Medicine;* [8]*Multiple Sclerosis and Demyelinating Diseases Unit, Center of Expertise for Rare Demyelinating and Autoimmune Diseases of CNS, First Department of Neurology, School of Medicine, National and Kapodistrian University of Athens, NKUA, Aeginition University H*

EPV-721 | Meningitis mortality: A retrospective and observational study on Brazilian epidemiology

C. Rech; C. Fernandes; C. de Almeida Rodrigues
Universidade Estadual do Oeste do Paraná

EPV-722 | Different posology due to synthetic protein allergy during eculizumab therapy in a patient with myasthenia gravis

C. Uzunköprü[1]; Y. Beckmann[2]
[1]*İzmir Katip Çelebi University, School of Medicine, Department of Neurology;* [2]*İzmir Katip Çelebi University, School of Medicine, Department of Neurology*

EPV-723 | Comprehensive analysis of functional neurological disorders over a decade: Insights from a cohort study

C. Correia[1,2]; B. Medeiros[1,3]; R. Araújo[1,4]; J. Massano[1,4]; C. Soares[1,4]
[1]*Neurology Department, Centro Hospitalar Universitário de São João, E.P.E., Porto, Portugal;* [2]*Medicine Department, Faculty of Medicine, University of Porto, Porto, Portugal;* [3]*Neurology Department, Hospital do Divino Espírito Santo, E.P.E., Ponta Delgada, Açores, Portugal;* [4]*Clinical Neuroscience and Mental Health Department, Faculty of Medicine, University of Porto, Porto, Portugal*

EPV-724 | Ocular myasthenia gravis: Determining the predictive factors of secondary generalisation

W. Ong; P. Gengadharan; J. Tan; C. Tan
Neurology Unit, Department of Medicine, Faculty of Medicine, Universiti Malaya, Kuala Lumpur, Malaysia

EPV-725 | L-dopa-responsive Parkinsonism and down-beat nystagmus as first manifestation of SCA27B. A new red flag?

D. López Domínguez; B. Alemany Perna; R. Ferrer Tarres
Ataxia Unit, Josep Trueta Hospital, Girona, Spain

EPV-726 | Eculizumab in refractory generalized Myasthenia Gravis: A single center 1 year experience

D. Ricciardi; F. Tuccillo; C. Erra; A. Fasolino; B. De Martino; F. Habetswallner
UOC Neurofisiopatologia – AORN Cardarelli, Naples, Italy

EPV-727 | Myasthenia gravis control: Evolution over eight years of follow-up and patient characteristics

D. Reyes-Leiva[1]; A. Carbayo[1]; A. Vesperinas[1]; L. Querol[1]; M. Pujades-Rodriguez[2]; R. Rojas-Garcia[1]; E. Cortés-Vicente[1]
[1]Neuromuscular Disease Unit, Hospital de la Santa Creu i Sant Pau e IIB Sant Pau, Barcelona, Spain; [2]UCB Pharma, Brussels, Belgium

EPV-728 | Epilepsy in relation to a case of a new variant in DLG4-related synaptopathy

D. Rodriguez Garcia; C. Algar; R. Dodu; P. Cabezudo Garcia; P. Serrano Castro; G. Garcia Martin
Servicio de Neurología, Hospital Regional Universitario de Málaga, Málaga, Spain

EPV-729 | Descriptive study of Guillain-Barre syndrome in the health area of the Guadalajara Hospital (Spain)

J. Villamor Rodríguez; M. Hernández Ramírez; M. González Gómez; F. Sánchez García; J. Celi Celi; D. Barbero Jiménez
Department of Neurology, Guadalajara, Spain

EPV-730 | Unraveling Isaacs Syndrome: A rare case of acquired neuromyotonia

D. Valente; H. Machado; C. Félix; J. Raposo
Neurology Department, Centro Hospitalar Universitário do Algarve, Faro, Portugal

EPV-731 | The role of TGFbeta-1 and VEGFA gene in the development of cerebrovascular disorders in obesity

F. Shermukhamedova; F. Muratov; A. Ismatov
Department of Neurology, Tashkent Medical Academy, Tashkent, Uzbekistan

EPV-732 | CANVAS family in Turkey: A report of five cases in one family

G. Baskan; N. Celebisoy; F. Gokcay
Ege University Medical School Department of Neurology

EPV-733 | The role of IL1beta C3953T gene polymorphism in post-infectious encephalopathy

K. Duve; S. Shkrobot
I. Horbachevsky Ternopil National Medical University

EPV-734 | Titin variants of uncertain significance and myopathy

D. Cruz; M. Fortuna Baptista; M. Schön; M. Oliveira Santos
Neurology Service, Neurosciences and Mental Health Department, Hospital de Santa Maria, CHULN, Lisbon, Portugal

EPV-735 | Potential genetic markers of multiple sclerosis in multi-incident Libyan families

E. Darmun; M. Al-Griw
Genetics and Histology Department, Faculty of Medicine, University of Tripoli, Libya

EPV-736 | Prevalence of psychiatric disorders in a neurofibromatosis 1 adult cohort

E. Vanore[1]; G. Miele[1]; N. Setola[1]; F. Napolitano[1]; C. Santoro[2]; M. Melone[1]
[1]Center for Neurofibromatosis & Rare Diseases and Inter University Center for Research in Neurosciences, Department of Advanced Medical and Surgical Sciences, 2nd Division of Neurology, University of Campania Luigi Vanvitelli, Napoli, Italy; [2]Department of Women's and Children's Health and General and Specialized Surgery, University of Campania "Luigi Vanvitelli", Napoli, Italy

EPV-737 | A case of lissencephaly-9 caused by a novel mutation in the MACF1 gene

E. Belyaeva; L. Minaycheva; V. Sivokha; Y. Yakovleva; M. Lopatkina; E. Fonova; A. Sivtsev; A. Zarubin; N. Babushkina; I. Lebedev
Research Institute of Medical Genetics, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk, Russian Federation

EPV-738 | CHCHD2 and DNAJC6 double gene mutation in an Italian patient with early-onset Alzheimer's disease

F. Menegon[1]; F. Vignaroli[1]; L. Corrado[2]; F. De Marchi[1]; S. Daffara[3]; F. Caushi[2]; S. D'Alfonso[2]; C. Comi[4]; G. Tondo[4]
[1]*Department of Translational Medicine, University of Piemonte Orientale, Neurology Unit, Azienda Ospedaliero-Universitaria Maggiore della Carità, Novara, Italy;* [2]*Department of Health Sciences, University of Piemonte Orientale, Novara, Italy;* [3]*Biology Unit, Sant'Andrea Hospital, Vercelli, Italy;* [4]*Department of Translational Medicine, University of Piemonte Orientale, Neurology Unit, Sant'Andrea Hospital, Vercelli, Italy*

EPV-739 | Mitochondrial encephalopathy due to the novel compound heterozygous variants c.182C > T and c.446A > AG in NARS2

J. Finsterer[1]; S. Mehri[2]
[1]*Neurology and Neurophysiology Center Vienna;* [2]*University of Monastir*

EPV-740 | Secondary symptomatic dystonia with a genetic cause

G. Braathen[1]; K. Tveten[1]; S. Øygarden[2]; E. Dahl[2]
[1]*Department of Medical Genetics, Telemark Hospital, Skien, Norway;* [2]*Department of Neurology, Telemark Hospital, Skien, Norway*

EPV-741 | Defining the demographic and clinical characteristics of sleepy patients with myotonic dystrophy type 1 (DM1)

G. Colacicco[1]; F. Manacorda[1]; B. Andrea[2]; S. Stano[2]; A. Lizio[1]; J. Casiraghi[1]; D. Elisa[1]; M. Gualandris[1]; A. Cima[1]; E. Roma[1]; E. Carraro[1]; A. Zanolini[1]; P. Vitali[3]; M. Zanardo[3]; R. Zuccarino[2]; F. Sardanelli[3]; V. Sansone[1]
[1]*NeMO Omnicenter, Neurorehabilitation Unit, University of Milan, Italy;* [2]*NeMO Omnicenter, Trento, Italy;* [3]*Department of Radiology, Research Hospital Policlinico San Donato, Milan, Italy*

EPV-742 | Beyond ALS: A case of facial onset sensory and motor neuronopathy (FOSMN)

G. Pederzoli; G. Regonesi; L. Stanzani; A. Giglio; S. Lazzari; M. Frigo; F. Da Re; G. Stefanoni; I. Appollonio; C. Ferrarese
Department of Neurology, Fondazione IRCCS San Gerardo dei Tintori, School of Medicine and Surgery, Milan Center for Neuroscience, University of Milano-Bicocca, Monza, Italy

EPV-743 | Eculizumab versus rituximab for refractory acetylcholine receptor-positive generalized myasthenia gravis

H. Durmus; A. Cakar; Y. Gülşen Parman
Department of Neurology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey

EPV-744 | Insight into inter-individual phenotypic differences in Korean patients with 16p11.2 deletion

J. Han
Dajeon St. Mary's Hospital, The Catholic University of Korea

EPV-745 | Significance of light kappa chains in patients with seronegative myasthenia gravis (MG)

H. Pilsová; M. Týblová; P. Nytrová; I. Nováková; A. Tesař; M. Andělová; M. Jakubíková
Neurological Clinic, General Faculty Hospital, Prague, Czechia

EPV-746 | Endovascular thrombectomy complications due to vascular frailty in a patient with ACTA2 mutation

I. Albajar[1]; J. Equiza[1]; E. Garmendia[2]; P. Iruzubieta[1]; J. Larrea[2]; J. Marta[1]; G. Arenaza[2]; F. Gonzalez[1]; M. Alonso-Lacabe[2]; G. Nuñez[1]; A. Lüttich-Uroz[2]; M. Martinez de Albeniz – Zabaleta[1]; P. De la Riva[1]
[1]*Neurology, Donostia University Hospital;* [2]*Radiology, Donostia University Hospital*

EPV-747 | Clinical and genetic features of CANVAS: A single centre cohort experience

I. Arena[1]; G. Falcone[1]; M. Porcino[1]; C. Usbergo[1]; A. Tessa[2]; F. Santorelli[2]; O. Musumeci[1]
[1]*Unit of Neurology and Neuromuscular Disorders, Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy;* [2]*Molecular Medicine and Neurogenetics, IRCCS Fondazione Stella Maris, Pisa, Italy*

EPV-748 | "Eyes wide shut": The challenging diagnosis of botulism – a case report

I. Bermejo Casado; C. Gómez López de San Román; M. Capra Remedi; M. Vargas Cobos; L. Caballero Sánchez; D. Cerdán Santacruz; A. Castrillo Sanz; A. Mendoza Rodríguez; C. Tabernero García; G. Suárez
Neurology Department, Segovia General Hospital, Segovia, Spain

EPV-749 | Phenotype variations within a family with Col4A1 mutation

I. Del Pino Díaz; P. Guirado Ruiz; Á. Morales Lahoz; I. Villegas Rodríguez
Neurology Department, Hospital Universitario San Cecilio, Granada, Spain

EPV-750 | A comprehensive review of neurological adverse events linked to mRNA Covid-19 vaccines

K. Khalimova; N. Rashidova; J. Salimjonov
Department of Neurology and Medical Psychology, Tashkent Medical Academy, Tashkent, Uzbekistan

EPV-751 | Hemorrhagic transformation in ischemic stroke after intravenous thrombolysis

J. Celi Celi[1]; M. Hernández Ramírez[1]; J. Villamor Rodríguez[1]; J. Campaña Naranjo[2]
[1]*Neurology Department, Guadalajara Universitary Hospital;* [2]*UNED*

EPV-752 | Who should undergo thymectomy in non-thymomatous Myasthenia Gravis? Results from the Swedish Myasthenia Gravis Register

J. Wu[1]; M. Petersson[2]; A. Dufva[2]; F. Fang[1]; F. Piehl[2]; S. Brauner[2]
[1]*Unit of Integrative Epidemiology, Institute of Environmental Medicine (IMM), Karolinska Institutet, Stockholm, Sweden;* [2]*Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden*

EPV-753 | Late onset progressive external ophthalmoplegia caused by recessive MYH2-related myopathy

J. Fernandes[1]; D. Gabriel[1]; A. Gonçalves[2]; M. E Oliveira[2]; R. Santos[2]; A. Sousa[3]
[1]*Neurology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal;* [2]*Molecular Genetics Laboratory, Department of Laboratory Genetics, Centro de Genética Médica Jacinto Magalhães, Centro Hospitalar Universitário de Santo António, Porto, Portugal;* [3]*Neurophysiology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal*

EPV-754 | A novel FHL1 variant associated with adult-onset myopathy in a Portuguese family

J. Fernandes[1]; J. Moura[1]; R. Lobato[2]; A. Gonçalves[3]; E. Vieira[3]; R. Santos[3]; M. Pinto[4]; R. Taipa[4]; A. Sousa[5]
[1]*Department of Neurology, Centro Hospitalar Universitário de Santo António, Porto, Portugal;* [2]*Department of Neurology, Unidade Local de Saúde do Alto Minho, Viana do Castelo, Portugal;* [3]*Molecular Genetics Laboratory, Serviço de Genética Laboratorial, Centro de Genética Médica Jacinto Magalhães, Centro Hospitalar Universitário de Santo António, Porto, Portugal;* [4]*Portuguese Brain Bank, Centro Hospitalar Universitário de Santo António, Porto, Portugal;* [5]*Department of Neurophysiology, Centro Hospitalar Universitário de Santo António, Porto, Portugal*

EPV-755 | Frequency and characteristics of intravenous immunoglobulin-associated headache

J. Moniz Dionísio[1]; S. Delgado[1]; E. Silva[1]; M. Fernandes[2]; B. Madureira[1]; P. Neves[1]; L. Santos[3]; A. Caetano[3]; P. Pereira[2]; S. Cruz[1]
Neurology Department – Hospital Prof. Doutor Fernando Fonseca, Amadora, Portugal; [2]*Neurology Department – Hospital Garcia de Orta, Almada, Portugal;* [3]*Neurology Department – Centro Hospitalar Lisboa Ocidental, Portugal*

EPV-756 | Mitochondrial dysfunction in phosphaturic mesenchymal tumor-induced myopathy and various clinical presentations of PMT

A. Kim[1]; D. Lee[2]; J. Sung[2]
[1]*Chungbuk National University Hospital;* [2]*Seoul National University Hospital*

EPV-757 | Navigating the enigma: Idebenone efficacy discrepancy in DNAJC30-associated mitochondrial disease

K. Chojnowski[1]; K. Dzwilewski[1]; M. Krygier[1]; M. Mazurkiewicz-Bełdzińska[1]
[1]*Department of Developmental Neurology, Medical University of Gdansk, Gdansk, Poland*

EPV-758 | Prediction of refractory myasthenia gravis based on response to treatment within the first year from diagnosis

S. Kim; H. Han
Department of Neurology, Severance Hospital, Yonsei University College of Medicine

EPV-759 | Ends of the PNPLA6-spectrum: Report of 2 cases

L. Santos Sánchez de las Matas; C. Ordás Bandera; B. Álvarez Mariño; J. Martínez Ramos; Á. Bonelli Franco; D. Landaeta Chinchilla; I. Llera López; N. Barbero Bordallo; A. Querejeta Coma
Neurology Department, Hospital Universitario Rey Juan Carlos, Madrid, Spain

EPV-760 | Boucher-Neuhauser syndrome; A novel missense mutation in the PNPLA6 gene in two siblings

A. Liampas[1]; P. Nicolaou[2]; C. Votsi[2]; A. Georghiou[2]; K. Christodoulou[2]; G. Tanteles[3]; M. Pantzaris[1]
[1]*Neuroimmunology Department, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus;* [2]*Neurogenetics Department, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus;* [3]*Medical Genetics Department, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus*

EPV-761 | Mitochondrial disorders are associated with morphological neuromuscular junction defects

L. Lessard[1]; E. Girard[2]; N. Streichenberger[3]; C. Acquaviva[4]; C. Pagan[4]; F. Bouhour[1]; P. Petiot[1]; L. Schaeffer[2]
[1]*Service d'Electroneuromyographie et de pathologies neuromusculaires, Hôpital Neurologique Pierre Wertheimer, Hospices Civils de Lyon, France;* [2]*INMG-PGNM, UMR CNRS 5261 – INSERM U1315, Université Lyon 1, Lyon, France;* [3]*Département d'Anatomo-Pathologie, Groupement Hospitalier Est, Hospices Civils de Lyon, Lyon, France;* [4]*Service de Biochimie et Biologie Moléculaire – Unité Pathologies Héréditaires du Métabolisme, Hospices Civils De Lyon, Lyon, France*

EPV-762 | Metabolic defects as a potential therapeutic target in Type 1 Myotonic Dystrophy

L. Lessard[1]; M. Weiss-Gayet[1]; S. Ben Larbi[1]; A. Ravel-Chapuis[2]; J. Courchet[1]; D. Furling[3]; L. Gallay[4]; R. Mounier[1]
[1]*INMG PGNM – CNRS UMR 5261-INSERM U1315 – Université Claude Bernard Lyon 1, Lyon, France;* [2]*Department of Cellular and Molecular Medicine, Éric Poulin Centre for Neuromuscular Disease, Faculty of Medicine, University of Ottawa, Ottawa, Canada;* [3]*Association Institut de Myologie, Centre de Recherche en Myologie – INSERM – Sorbonne Université, Paris, France;* [4]*Laboratoire "Cell Therapy & Musculoskeletal Disorders", Département de Chirurgie Orthopédique, Hôpital Universitaire et Faculté de Médecine, Genève, Suisse*

EPV-763 | Impending myasthenic crisis successfully treated with ravulizumab

L. Lymperopoulos[1]; I. Tatouli[2]; E. Strataki[1]; D. Tzavella[1]; S. Kontogiannis[2]; V. Zouvelou[1]
[1]*1st Neurology Department, National and Kapodistrian University of Athens, Greece Eginitio Hospital, ERN EURO-MND;* [2]*Department of Clinical Therapeutics, Alexandra Hospital, High-Dependency Unit, National and Kapodistrian University of Athens, Greece*

EPV-764 | Epilepsy phenotype in KCNK4-related neurodevelopmental syndrome: A novel case and literature review

M. Krygier[1]; W. Talaśka-Liczbik[1]; A. Walczak[2]; M. Rydzanicz[2]; S. Ziętkiewicz[3]; R. Płoski[2]; M. Mazurkiewicz-Bełdzińska[1]
[1]*Department of Developmental Neurology, Medical University of Gdansk, Gdansk, Poland;* [2]*Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland;* [3]*Intercollegiate Faculty of Biotechnology, University of Gdansk, Gdansk, Poland*

EPV-765 | External respiration parameters in neuromuscular (NMD) patients with repeat expansion diseases

E. Malhina[1]; Y. Rushkevich[1]; S. Likhachev[1]; A. Gusina[2]; O. Haliyeyskaya[1]
[1]*Republican Scientific and Practical Center of Neurology and Neurosurgery, Minsk, Belarus;* [2]*Republican Scientific and Practical Center "Mother and Child", Minsk, Belarus*

EPV-766 | Malignant catatonia or neuroleptic malignant syndrome: When in doubt, same approach?

M. Capra; C. Gómez López de San Román; M. Vargas Cobos; D. Cerdán Santacruz; L. Caballero Sánchez; A. Castrillo Sanz; A. Mendoza Rodríguez; I. Bermejo Casado
Neurology, Hospital General de Segovia, Segovia, España

EPV-767 | Dropped head: Myasthenia gravis or Parkinsonism? The role of neurophysiology

M. Mangiardi[1]; M. Alessandro[2]; M. Marano[2]; C. Colosimo[3]; L. Marsili[4]
[1]*Department of Stroke Unit San Camillo-Forlanini Hospital, Rome, Italy;* [2]*Department of Neurology Campus Biomedico University Hospital, Rome Italy;* [3]*Department of Neurology, Santa Maria University Hospital, Terni, Italy;* [4]*Gardner Family Center for Parkinson's Disease and Movement Disorders, Department of Neurology, University of Cincinnati, Cincinnati, OH, USA*

EPV-768 | Evaluation of cognitive decline, depression and subclinical atherosclerosis in patients with atrial fibrillation

M. Militaru[1]; D. Lighezan[2]; A. Militaru[2]
[1]*Department of Neuroscience, Discipline of Neurology II, Victor Babes University of Medicine and Pharmacy Timisoara, Municipal Emergency Hospital Timisoara, Timisoara/Romania;* [2]*Department of Internal Medicine I, Discipline of Medical Semiology I, Victor Babes University of Medicine and Pharmacy Timisoara, Municipal Emergency Hospital Timisoara, Timisoara, Romania*

EPV-769 | Coexistence of hereditary spastic paraplegia and sodium chanel myotonia in a family

M. Castelló-López; J. De León Hernández; J. Alonso Pérez
Department of Neurology, Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain

EPV-770 | Rituximab in acethylcholine receptor antibody-positive myasthenia gravis: A Slovenian single centre experience

M. Baruca Grad[1]; L. Leonardis[1]; A. Horvat Ledinek[2]; U. Rot[2]; S. Šega Jazbec[2]
[1]*Institute of Clinical Neurophysiology, University Medical Centre Ljubljana, Ljubljana, Slovenia;* [2]*Department of Neurology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

EPV-771 | Cancer frequency and type in myotonic dystrophy, FSHD, and OPMD

N. Bareja; M. Vytopil; J. Srinivasan; M. Ghasemi
Department of Neurology, Lahey Hospital and Medical Center, Burlington, MA, USA

EPV-772 | The impact of nusinersen in adult spinal muscular atrophy type III beyond the central nervous system

M. Fortuna Baptista[1]; A. Pronto-Laborinho[2]; T. Freitas[2]; M. de Carvalho[1]; M. Oliveira Santos[1]
[1]*Serviço de Neurologia, Departamento de Neurociências e Saúde Mental, Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa-Norte, Lisbon, Portugal;* [2]*Instituto de Fisiologia, Instituto de Medicina Molecular João Lobo Antunes, Centro de Estudos Egas Moniz, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal*

EPV-773 | Vanishing white matter disease in adulthood

A. Montalvo[1,2,3]; R. Rodrigues[1]; M. Schön[1]; Â. Dias[4]; C. Morgado[4]; F. Dourado Sotero[1,2]; A. Antunes[1,2]; L. Albuquerque[1,2]
[1]*Serviço de Neurologia, Departamento de Neurociências e Saúde Mental, Unidade Local de Saúde Santa Maria, Lisbon, Portugal;* [2]*Centro de Estudos Egas Moniz, Clínica Universitária de Neurologia, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal;* [3]*Instituto de Fisiologia, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal;* [4]*Serviço de Imagiologia Neurológica, Departamento de Imagiologia, Unidade Local de Saúde Santa Maria, Lisbon, Portugal*

EPV-774 | Generalized myasthenia gravis case series: Patients with myasthenia gravis switching from eculizumab to ravulizumab

K. Morita[1]; G. Watanabe[1]; A. Yasaka[1]; A. Tamagake[1]; S. Watanabe[1]; M. Arai[2]; K. Tsukita[1]; Y. Suzuki[1]
[1]*Department of Neurology, National Hospital Organization Sendai Medical Center;* [2]*Department of Internal Medicine, Tome Citizen Hospital*

EPV-775 | Novel case of longitudinally complete spinal cord lesion with proposed "Ram" sign

M. Yousaf[1]; L. Hanbali[2]; M. Brown[2]
[1]*Neurology Department, University of Texas at Austin, Austin, USA;* [2]*Neurology Department, University of Louisville School of Medicine, Louisville, USA*

EPV-776 | The complex connection between myasthenia gravis and its association to depression

O. Mihalache[1]; C. Vilciu[1]; D. Petrescu[2]; C. Petrescu[3]; A. Ciobanu[3]; M. Draghici[1]
[1]*Department of Neurology, Fundeni Clinical Institute, Bucharest, Romania;* [2]*Department of Neurology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania;* [3]*Department of Psychiatry, Prof. Dr. Alexandru Obregia Clinical Hospital of Psychiatry, Bucharest, Romania*

EPV-777 | The modified Neurological Impairment Scale to measure neurologic severity and complexity in acute setting

A. Padovani; I. Mattioli; T. Comunale; A. Pilotto
Neurology Unit, University of Brescia and ASST SPedali CIvili of Brescia, Brescia, Italy

EPV-778 | Understanding epilepsy stigma: Rural and urban female patients in a developing nation

P. Poonia; I. Ahuja; S. Gupta
Department of Medicine, Government Medical College & Hospital, Chandigarh, India

EPV-779 | Management of presymptomatic juvenile patients with Late-Onset Pompe Disease

M. Porcino; O. Musumeci; I. Arena; C. Usbergo; C. Rodolico; A. Toscano
Clinical and Experimental Medicine Department, University of Messina, Messina, Italy

EPV-780 | Use onasemnogene abeparvovec for treatment spinal muscular atrophy

V. Koroleva; L. Shchougareva
Children's City Multidisciplinary Clinical Specialized Center of High Medical Technologies, St. Petersburg, Russian Federation

EPV-781 | Asymptomatic/paucisymptomatic creatine kinase elevation in the neuromuscular disorders outpatient setting

R. Costa; I. Margarido; G. Nadais; F. Silveira; L. Braz; M. Pinto
Department of Neurology, Centro Hospitalar Universitário de São João, Oporto, Portugal

EPV-782 | Immune checkpoint inhibitor – Induced neuromuscular adverse events: Clinical findings and management of two cases

R. Louka[1]; G. Tsironis[2]; C. Charalambous[2]; E. Fotiou[2]; A. Artemiades[3]; G. Vavougios[3]; P. Bargiotas[3]; S. Kalampokini[3]; P. Ioannides[1]; R. Chirmpaki[1]; C. Argyropoulou[1]; S. Lambrianides[4]; E. Manolis[5]; R. Theologou[1]; P. Neofytou[1]; E. Agkastinioti[1]; L. Achilleos[1]; A. Liampas[1]; G. Hadjigeorgiou[3]; P. Zis[3]
[1]*Department of Neurology, Nicosia General Hospital, Nicosia, Cyprus;* [2]*Department of Medical Oncology, Bank of Cyprus Oncology Centre, Nicosia, Cyprus;* [3]*Medical School, University of Cyprus, Cyprus;* [4]*Apollonion Private Hospital, Nicosia, Cyprus;* [5]*Department of Intensive Care Unit, Nicosia General Hospital, Nicosia, Cyprus*

EPV-783 | Whole-exome-sequencing in cerebellar ataxia: Broadening the clinical and treatment spectrum

R. Manso Calderón; J. Vizcaya; M. Ravelo; A. González; M. Sevillano
Neurology Deparment, Hospital Clínico Universitario, Salamanca, Spain

EPV-784 | Efgartigimod in AChR-Ab positive myasthenia gravis: A 2-year experience

R. Frangiamore[1]; E. Rinaldi[1]; F. Vanoli[1]; F. Andreetta[1]; S. Bonanno[1]; L. Maggi[1]; R. Mantegazza[1]; C. Antozzi[1]; R. Arnaboldi[2]; A. Pinna[2]
[1]*UOC Neurology 4 – Neuroimmunology and Neuromuscular Diseases Unit, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy;* [2]*argenx Italy, s.r.l., Milan, Italy*

EPV-785 | Neuromuscular immune-related adverse events of checkpoint inhibitors. A case series at a hospital in Argentina

R. Sanjinez Arana
Adult Neurology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

EPV-786 | Complete inhibition of the classical complement pathway with IM-101, a novel anti-C5 antibody, in a Phase I study

S. Lee[1]; H. Jun[2]; K. Kim[1]; K. Yi[1]; M. Choi[1]; J. Seo[1]; D. Wyatt[5]; I. Lee[1]; Y. Hong[1]; S. Sohn[3]; I. Joo[4]; X. Pan[1]; D. Kim[1]
[1]*ImmunAbs, Inc., Seoul, Republic of Korea;* [2]*ImmunAbs USA, Inc., Irvine, USA;* [3]*Department of Neurology, Seran General Hospital, Seoul, Republic of Korea;* [4]*Department of Neurology, Ajou University School of Medicine, Suwon, Republic of Korea;* [5]*Syneos Health, Miami, USA*

EPV-787 | Ocular myasthenia gravis mimics

S. Palma; C. Alves; P. Pereira
Garcia de Orta Hospital

EPV-788 | Autoimmune thrombocytopenia in a patient with generalised Myasthenia Gravis in treatment with Eculizumab: A case-report

A. Sarnataro; N. Cuomo; M. Campanile; G. Puorro; A. Marsili; C. Pane; F. Saccà
Department of Neurosciences and Reproductive Sciences and Odontostomatology, University of Naples "Federico II", Naples, Italy

EPV-789 | Thymoma-associated autoimmune diseases responsive to efgartigimod: A case report

J. Song[1]; Y. Chen[1]; D. Yue[2]; S. Luo[1]; C. Zhao[1]
[1]*Huashan Rare Disease Center and Department of Neurology, Huashan Hospital, Shanghai Medical College, National Center for Neurological Disorders, Fudan University, Shanghai, China;* [2]*Department of Neurology, Jing'an District Center Hospital of Shanghai, Fudan University, Shanghai, China*

EPV-790 | Facial diplegia as a prominent symptom in sporadic Inclusion Body Myositis

S. Xirou; C. Papadopoulos; K. Aravantinou; V. Zouvelou; G. Papadimas
First Department of Neurology, Eginiteio Hospital, National and Kapodistrian University, Athens, Greece

EPV-791 | Expanding the phenotype of Filamin C-related myopathies

S. Xirou; C. Papadopoulos; A. Liverezas; G. Papadimas
Department of Neurology, Eginition Hospital, National and Kapodistrian University of Athens, Greece

EPV-792 | Cerebellar ataxia with neuropathy and vestibular areflexia syndrome (CANVAS) presenting as asymmetrical neuropathic pain

S. Kalampokini[1]; C. Ioannou[1]; A. Anagiotos[2]; C. Deltas[3]; G. Papagrigoriou[3]; C. Polydorou[3]; G. Konstantinou[3]; K. Stefanou[3]; P. Bargiotas[1]; G. Vavougios[1]; A. Artemiadis[1]; G. Hadgigeorgiou[1]; P. Zis[1]
[1]*Medical School, University of Cyprus and Department of Neurology, Nicosia General Hospital, Nicosia, Cyprus;* [2]*Department of Otolaryngology, Nicosia General Hospital, Nicosia, Cyprus;* [3]*Center of Excellence in Biobanking and Biomedical Research, University of Cyprus*

EPV-793 | Efficacy and safety of steroids for chronic subdural hematoma: A systematic review and meta-analysis

T. Fadlalla Ahmad[1]; M. Shafique[2]
[1]*Ahfad University for Woman;* [2]*Jinnah Sindh Medical University*

EPV-794 | Clinical variability in desminopathies: Description of two families

G. Vadi[1]; F. Torri[1]; L. Fontanelli[1]; L. Becattini[1]; S. Loprieno[1]; G. Alì[2]; A. Torella[3]; V. Nigro[3]; G. Cenacchi[4]; R. Costa[4]; G. Ricci[1]; G. Siciliano[1]
[1]*Neurology Unit, Department of Neuroscience, University of Pisa;* [2]*Anatomic Pathology Section, Department of Surgical, Medical, Molecular Pathology and Critical Area, University di Pisa University;* [3]*Medical Genetics and Cardiomyology Unit, Department of Precision Medicine, Università degli Studi della Campania "Luigi Vanvitelli", Napoli, Italy;* [4]*Department of Biomedical and Neuromotor Sciences, University of Bologna*

EPV-795 | Respiratory course in a population of patients with facioscapulohumeral dystrophy: A retrospective study

V. Patisso[1]; C. Ferrari Aggradi[1]; E. Carraro[2]; E. De Mattia[2]; E. Roma[2]; M. Croci[2]; A. Lizio[2]; V. Sansone[1]
[1]*Department of Neurology, University of Milan, Milan, Italy;* [2]*Department of Neurorehabilitation, NeMO Clinical Center, Milan, Italy*

EPV-796 | Quality of life in patients with different neuromuscular diseases from the same cultural background

V. Ivanovic[1]; Z. Vukojevic[2]; V. Viric[1]; I. Bozovic[1]; S. Peric[1]
[1]*Neurology Clinic, University Clinical Center of Serbia, University of Belgrade, Faculty of Medicine, Belgrade, Serbia;* [2]*Clinic of Neurology, University Clinical Center of Republic of Srpska, Faculty of Medicine, University of Banja Luka, Banja Luka, Republic of Srpska, Bosnia and Herzegovina*

EPV-797 | The Swedish Myasthenia Gravis registry: A nationwide, population-based high coverage registry

W. Wu[1]; M. Petersson[1]; A. Eriksson-Dufva[2]; F. Piehl[2]; S. Brauner[2]
[1]*Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden;* [2]*Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden & Department of Neurology, Karolinska University Hospital, Stockholm, Sweden*

EPV-798 | Efgartigimod in immune-checkpoint inhibitor induced myasthenia gravis, myocarditis and myositis: A case report

L. Duan; X. Fang; L. Ren; Y. Yuan
Department of Critical Care Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

EPV-799 | 'Like mother like daughter' A rare late-onset ataxia case: Spinocerebellar ataxia type 36

Z. Kaya Güleç[1]; Ö. Öztop Çakmak[2]; N. Başak[3]; S. Ertan[2]
[1]*Institute of Neurological Sciences, Istanbul University-Cerrahpasa, Istanbul, Turkey;* [2]*Department of Neurology, Koc University Faculty of Medicine, Istanbul, Türkiye;* [3]*Suna and Inan Kiraç Foundation, Neurodegeneration Research Laboratory, KUTTAM, School of Medicine, Koç University, Istanbul, Turkey*

EPV-800 | Long-term hospital readmission after non traumatic subarachnoid hemorrhage in a population-based study

C. Ragaglini[1]; M. Foschi[1]; F. Santis[1]; F. Conversi[1]; E. Colangeli[2]; R. Ornello[1]; S. Sacco[1]
[1]*Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, Italy;* [2]*Department of Neurology and Stroke Unit of Avezzano-Sulmona, ASL 1 Avezzano-Sulmona-L'Aquila, L'Aquila, Italy*

EPV-801 | Theranostic CEST-enhanced thermoresponsive hydrogel drug delivery system for postsurgical treatment of glioblastoma

C. Zhuang[1]; R. Wu[2]
[1]*Department of Radiology, First Affiliated Hospital, Shantou University Medical College, Shantou, China;* [2]*Department of Radiology, Second Affiliated Hospital, Shantou University Medical College, Shantou, China*

EPV-802 | Myasthenia gravis and systemic lupus erythematosus, a rare but important association regarding diagnosis and treatment

A. Maruri; V. Cid-Izquierdo; C. Ribacoba; J. Ortega; P. Gutierrez-Bedia; M. Malaret; J. Obregon; A. Marcos-Dolado; E. Lopez-Valdes; R. Ginestal
Department of Neurology, Hospital Clínico San Carlos, Madrid, Spain

EPV-803 | Anti-IgLON5 disease: A challenging diagnosis

A. Quka[1]; A. Kuqo[1]; S. Likaj[2]; E. Laci[2]; J. Kruja[1]
[1]*Department of Neurology, University Hospital Center Mother Teresa, Tirana, Albania;* [2]*Faculty of Medicine, University of Medicine, Tirana, Albania*

EPV-804 | The unexpected clinical course of NMOSD

A. Kuqo[1]; E. Reka[2]; B. Qazimllari[3]; A. Rroji[4]; J. Kruja[1]
[1]*University Hospital Center "Mother Theresa" Neurology Service, Tirana, Albania;* [2]*Regional Hospital Center of Elbasan, Neurology Service, Albania;* [3]*Regional Hospital Center of Saranda, Neurology Service, Albania;* [4]*University Hospital Center "Mother Theresa" Neuroimaging Service, Tirana, Albania*

EPV-805 | Antineuronal antibodies for CASPR2 identified in two elderly men undergoing dementia investigations

A. Freitas-Huhtamäki[1]; A. Gardner[1]; N. Maryola Danes[1]; J. Theorell[1,2]
[1]*Center for Infectious Medicine, Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden;* [2]*Department of Neurology, Karolinska University Hospital, Stockholm, Sweden*

EPV-806 | Anti-HMGCR Ab myopathy treated with IVIG infusions: A case series

A. Favero; A. Sartori; A. Bratina; P. Manganotti
Clinical Unit of Neurology, School of Neurology, Department of Medicine, Surgery and Health Sciences, University Hospital and Health Services of Trieste, ASUGI, University of Trieste, Trieste, Italy

EPV-807 | CLOCC secondary to chronic treatment with metronidazole

A. Sánchez Rodríguez; A. García Rúa; M. Alvarez Alvarez; P. Siso García
Neurology/Hospital of Cabueñes/Gijon/Spain

EPV-808 | Overlapping and distinguishing neuroimaging features of the CNS demyelinating disorders: MS, NMOSD, and MOGAD

B. Güleç; E. Everest; A. Çam; M. Tütüncü; U. Uygunoglu; A. Siva
Department of Neurology, Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Istanbul, Turkey

EPV-809 | Assessing the impact of early de-escalation in aggressive multiple sclerosis: Clinical outcomes and functional capacity

B. Taşdelen; Ş. Ocak; İ. Güngör Doğan; D. Çetinkaya Tezer; S. Demir
Neurology Clinic, Sancaktepe Sehit Prof. Dr. Ilhan Varank Research and Training Hospital, İstanbul, Turkey

EPV-810 | Dimethyl fumarate vs. teriflunomide: Comparing effects on physical and psychological parameters in MS treatment

B. Taşdelen; D. Çetinkaya Tezer; İ. Güngör Doğan; S. Demir
Neurology Clinic, Sancaktepe Şehit İlhan Varank Training and Research Hospital, İstanbul, Turkey

EPV-811 | Disease activity in NMOSD and MOGAD patients during SARS-CoV-2 vaccination

O. Brengaret[1]; D. Escudero[1]; J. Cabrera[1]; E. Fonseca[1]; S. Llufriu[1]; E. Martinez-Hernandez[1]; M. Guasp[1]; T. Armangué[1]; A. Hernando[1]; M. Artola[1]; M. Aldea[2]; A. Vilella[2]; R. Ruiz[3]; Y. Blanco[1]; A. Saiz[1]; M. Sepúlveda[1]
[1]*Neuroimmunology and Multiple Sclerosis Unit of Hospital Clinic de Barcelona, Neuroimmunology Program, IDIBAPS, and Universitat de Barcelona; Spain;* [2]*Department of Preventive Medicine and Epidemiology, Hospital Clinic de Barcelona, Spain;* [3]*Department of Immunology, Hospital Clinic de Barcelona, Spain*

EPV-812 | Toxic multifocal leukoencephalopathy associated with cocaine use: Differential diagnosis

C. Hurtado-Alcázar; M. Carrasco-García; C. Santillana-Ávila; R. Piñar-Morales; C. Creus-Fernández; F. Barrero-Hernández
Department of Neurology, San Cecilio Universitary Hospital, Granada, Spain

EPV-813 | Clinical and immunologic spectrum of GQ1b syndrome in a third-level centre

C. Villar Rodriguez; D. Villagran-Sancho; F. Gomez Fernandez; I. Rojas-Marcos

Department of Neurology and Neurophysiology, Virgen del Rocio University Hospital, Sevilla, Spain

EPV-814 | Increased central obesity correlates with physical activity and food processing in multiple sclerosis

G. Thévoz[1]; N. Phillips[2]; J. Rebeaud[1]; P. Lim-Dubois-Ferriere[1]; A. Revaz[1]; A. Gauthier-Jaques[1]; M. Théaudin[1]; R. Du Pasquier[1]; S. Panda[3]; T. Collet[4]; C. Pot[1]

[1]Laboratories of Neuroimmunology, Center for Research in Neuroscience and Service of Neurology, Department of Clinical Neurosciences, Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland; [2]Service of Endocrinology, Diabetology, Nutrition and Therapeutic Education, Geneva University Hospitals (HUG), Geneva, Switzerland; [3]Salk Institute for Biological Studies, La Jolla, CA, USA; [4]Diabetes Centre, Faculty of Medicine, University of Geneva, Geneva, Switzerland

EPV-815 | Multiple sclerosis and headache: A possible link?

C. Borges; A. Marques; S. Lima; J. Gabriel; A. Matas

Serviço de Neurologia, Centro Hospitalar de Trás-os-Montes e Alto Douro

EPV-816 | Limbic encephalitis in patient with Crohn's disease

C. Guerreiro[1]; J. Ferreira[1]; M. Cazola[2]; S. Rosa[3]; F. Godinho[1]; J. Rosa[1]

[1]Neurology Department, Centro Hospitalar Universitário Lisboa Central, Lisbon, Portugal; [2]Neurology Department, Clínica Sagrada Esperança, Luanda, Angola; [3]Neuroradiology Department, Centro Hospitalar Universitário Lisboa Central, Lisbon, Portugal

EPV-817 | Pseudotumoral lesion as onset in multiple sclerosis

C. Martínez-Coeg[1]; P. Cacabelos-Perez[1]; M. Lustres-Perez[1]; E. Rodriguez-Castro[1]; M. Alberte-Woodward[1]; A. Mosqueira-Martinez[2]; J. Del-Rio-Garma[3]; J. Garcia-de-Soto[1]; J. Pouso-Diz[1]; A. Minguillon-Pereiro[1]; C. Sempere-Navarro[1]; M. Lorenzo-Garcia[1]; S. Fernandez-Fraile[1]

[1]Neurology Department, Hospital Clínico Universitario de Santiago de Compsotela, Santiago de Compostela, Spain; [2]Radiology Department, Hospital Clínico Universitario de Santiago de Compostela, Santiago de Compostela, Spain; [3]Hematology Department, Hospital Clínico Universitario de Santiago de Compostela, Santiago de Compostela, Spain

EPV-818 | Anti-LGI1 encephalitis as a possible paraneoplastic manifestation of Langerhans cell histiocytosis: A case report

D. Cerne[1]; F. Massa[1]; S. Morbelli[2]; L. Roccatagliata[3]; G. Rebella[4]; F. Villani[5]; F. Bozzano[6]; A. Uccelli[1]; L. Benedetti[7]; C. Cabona[5]

[1]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, Italy; [2]Department of Medical Sciences, University of Turin, Italy; [3]Department of Health Sciences (DISSAL), University of Genoa, Genoa, Italy; [4]Neuroradiology Unit, IRCCS Ospedale Policlinico San Martino, Genoa, Italy; [5]Division of Neurophysiology and Epilepsy Centre, IRCCS Ospedale Policlinico San Martino, Genova, Italy; [6]Autoimmunity Laboratory, IRCCS Ospedale Policlinico San Martino, Genova, Italy; [7]IRCCS, Ospedale Policlinico San Martino, Genoa, Italy

EPV-819 | Multifocal toxic leucoencephalopathy due to cocaine

D. Barbero Jiménez[1]; J. Villamor Rodríguez[1]; M. Gonzalez Gomez[1]; F. Gonzalez gomez[1]; J. Celi Celi[1]; M. Barbero Jiménez[2]

[1]Department of Neurology, Hospital Universitario de Guadalajara, Guadalajara, Spain; [2]Department of Oncology, Hospital Universitario del Prado, Talavera de la Reina, Spain

EPV-820 | A case of cerebral venous thrombosis in MOGAD: Causal or casual association?

D. Tedeschi[1]; O. Marsico[1]; E. Ferlazzo[1]; A. Pascarella[1]; S. Gasparini[1]; L. Manzo[2]; V. Bova[2]; V. Dattola[2]; I. Garreffa[2]; S. Calabrò[2]; A. Mammi'[2]; V. Cianci[2]; U. Aguglia[1]

[1]Institute of Neurology, Department of Medical and Surgical Sciences, Magna Græcia University, Catanzaro, Italy; [2]Regional Epilepsy Center, Great Metropolitan Bianchi-Melacrino-Morelli Hospital", Reggio Calabria, Italy

EPV-821 | Rare case of juvenile Lupus with neuromyelitis optica spectrum disorder presenting as area postrema syndrome

S. Kapur[1]; A. Deshpande[2]
[1]*Asian Rheumatology Center, Warangal, India;* [2]*Vinayaka Neurology Center, Warangal, India*

EPV-822 | Progressive aphasia as presenting symptom of anti-NMDAR encephalitis (A-NMDAE) and pancreatic tumour: A case report

A. Garcia Maruenda; I. Martin Sobrino; P. Gomez Martinez; M. El Harmochi Daoud; A. Sánchez Gómez; A. Hernandez Gonzalez
Department of Neurology, Ciudad Real, Spain

EPV-823 | Sensitivity and specificity of FL-CBA versus IFA for NMO-IgG detection in neuromyelitis optica patients

I. Gungor Dogan[1]; M. Yigit[2]; D. Cetinkaya Tezer[1]; O. Gulactı[2]; B. Tasdelen[1]; S. Ayhan[2]; I. Tekdemir[2]; C. Uzunkopru[3]; M. Yetkin[4]; M. Tutuncu[5]; S. Demir[1]
[1]*University of Health Sciences, Sancaktepe Sehit Prof Dr Ilhan Varank Training and Research Hospital, Department of Neurology, Istanbul, Turkey;* [2]*Gen Immun Laboratory, Istanbul, Turkey;* [3]*Katip Celebi University, Ataturk Training and Research Hospital, Izmir, Turkey;* [4]*Erciyes University, Department of Neurology, Kayseri, Turkey;* [5]*Istanbul University, Cerrahpaşa Faculty of Medicine, Department of Neurology, Istanbul, Turkey*

EPV-824 | Anti-neurofascin186-related neuropathy mimics Miller-Fisher syndrome: A case report

E. Baroncelli[1]; M. Bellucci[1]; C. Castellano[1]; E. Mobilia[2]; A. Lechiara[2]; G. Pesce[2]; C. Cabona[3]; L. Roccatagliata[4]; A. Schenone[1]; L. Benedetti[3]
[1]*Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI), University of Genoa, Genoa, Italy;* [2]*IRCCS Ospedale Policlinico San Martino, Laboratory of Autoimmunology, Genoa, Italy;* [3]*Ospedale Policlinico San Martino, IRCCS, Genoa, Italy;* [4]*Department of Health Sciences (DISSAL), University of Genoa, Genoa, Italy*

EPV-825 | Changes on EEG before the development of epilepsy

E. Eralieva[1]; K. Dzholboldieva[2]; B. Koulov[3]
[1]*Neurosurgery, Osh City Clinical Hospital, Osh, Kurgyzstan;* [2]*Neurology, Osh Regional Children Hospital, Osh, Kyrgyzstan;* [3]*Neurology, Kyrgyz-Russian Slavic University, Bishkek, Kyrgyzstan*

EPV-826 | Efficacy and safety of biologic agents in neuromyelitis optica spectrum disorder. A systematic review and meta-analysis

F. S. Alqahtani[1]; M. Asiri[1]; W. Alwabel[1]; Z. M. Alqahtani[1]; A. E Alghamdi[1]; S. Almarwan[1]; H. Alshaikh[1]; A. Althagafi[1]; A. Alshakhs[2]; H. Alsulami[1]; A. Abulaban[1]
[1]*College of Medicine, King Saud Bin Abdulaziz University for Health Sciences, Saudi Arabia – King Abdullah International Medical Research Center, Saudi Arabia;* [2]*King Faisal University, Alahsa, Saudi Arabia*

EPV-827 | Seasonal variation in myasthenia gravis incidence

S. Falso[1]; P. Zara[2]; S. Marini[1]; M. Puci[3]; E. Sabatelli[4]; G. Sotgiu[2]; M. Marini[1]; G. Spagni[5]; A. Evoli[1]; P. Solla[2]; R. Iorio[4]; E. Sechi[2]
[1]*Department of Neuroscience, Catholic University of the Sacred Heart; Rome, Italy;* [2]*Neurology Unit, University Hospital of Sassari; Sassari, Italy;* [3]*Clinical Epidemiology and Medical Statistics Unit, University Hospital of Sassari; Sassari, Italy;* [4]*Neurology Unit, Fondazione Policlinico Universitario Agostino Gemelli IRCCS; Rome, Italy;* [5]*German Center for Neurodegenerative Diseases (DZNE) Berlin; Berlin, Germany*

EPV-828 | Orbital inflammatory syndrome: Case series and review of literature

F. D'Anna; M. Risi; M. Cirillo; A. Tessitore; A. Bisecco
Department of Advanced Medical and Surgical Sciences – University of Campania "Luigi Vanvitelli"

EPV-829 | Immunotherapy and stroke: A case report

M. García Huguet; R. Ferrer Tarrer; C. Vera Cáceres; I. Saurina; C. Martínez; J. Serena; J. Álvarez-Cienfuegos; M. Terceño Izaga; S. Bashir; Y. Silva Blas
Department of Neurology, University Hospital Doctor Josep Trueta, Girona

EPV-830 | Assessment of clinical prognosis in autoimmune encephalitis: Girona Score

G. Álvarez Bravo[1]; G. Guglielmini[1]; A. Gifreu Fraixinó[1]; A. Boix Lago[1]; A. Quiroga Varela[2]; L. Ramió Torrentà[2]
[1]*Unit of Neuroimmunology and Multiple Sclerosis of Girona;* [2]*Neurodegeneration and Neuroinflammation Research Group, Girona Biomedical Research Institute (IDIBGI)*

EPV-831 | Autoimmune encephalitis-like malignant brain tumor: Case report and systematic review of the literature

G. Cereda[1]; F. Deleo[2]; C. Pastori[2]; R. Di Giacomo[2]; G. Didato[2]; E. Corsini[3]; E. Ciusani[3]; F. Doniselli[4]; E. Visani[2]; F. Villani[5]; M. de Curtis[2]; A. Stabile[2]

EPV-837 | An unexpected turn: Vertigo as the only telltale symptom of cerebellar hemangioblastoma

M. González Gómez; M. Hernández Ramírez; J. Villamor Rodríguez; F. Sánchez García; J. Celi Celi; M. González Sánchez
Department of Neurology, Guadalajara Universitary Hospital, Guadalajara, Spain

EPV-838 | Neurological toxicity associated with immune checkpoint inhibitors: A case series study

P. Hernández Vitorique; M. Mañez Sierra; J. Pinel Rios; M. Afkir Ortega; M. Vicente Domínguez; P. Carbonell Corvillo
Neurology, Hospital Virgen de la Victoria, Málaga, Spain

EPV-839 | Neuromyelitis optica spectrum in the elderly: About four cases

I. Ghorbel; H. Derbali; M. Mednini; D. Hadjkacem; M. Mansour; J. Zaouali; R. Mrissa
The Principal Military Hospital of Instruction of Tunis

EPV-840 | Immune checkpoint inhibitor-related neuromuscular toxicity: An observational monocentric study

I. Florean[1]; M. Dentoni[1]; D. Iacono[2]; M. Cinausero[2]; M. Fabris[3]; M. Valente[1]; A. Vogrig[1]
[1]Clinical Neurology, Department of Medicine (DMED), University of Udine, Udine, Italy; [2]Department of Oncology, Azienda Sanitaria Universitaria Friuli Centrale (ASU FC), Presidio Ospedaliero Santa Maria della Misericordia, Udine, Italy; [3]Laboratory of Immunopathology, Institute of Clinical Pathology, Department of Laboratory Medicine, University Hospital of Udine, Udine, Italy

EPV-841 | NMDAR-Ab spectrum disorders: A new entity? An unusual case of recurring inflammatory transverse myelitis

J. Perugini[1]; F. Pasini[1]; C. Costa[1]; G. Giussani[2]; S. Creta[2]
[1]ASST Ospedale Metropolitano di Niguarda, Milano, Italia; [2]ASST Valtellina e alto Lario

EPV-842 | Descriptive analysis of autoimmune encephalitis. A case series

J. Cajape Mosquera; B. Del Moral Sahuquillo; E. Muñoz Farjas; E. Bellosta Diago
Neurology Service, Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain

EPV-843 | Epidemiological, clinical, therapeutic and functional differences between adults and children in ADEM

J. Alcalá Torres[1]; C. Santos Martín[1]; C. Amarante Cuadrado[1]; M. González Arbizu[1]; R. Simón de las Heras[2]; N. Núñez Enamorado[2]; A. Gómez López[3]; A. Camacho Salas[2]
[1]Department of Neurology, Hospital Universitario 12 de Octubre, Madrid; [2]Section of Pediatric Neurology, Hospital Universitario 12 de Octubre, Madrid (Spain); [3]Department of Neurology, Hospital Universitario Rey Juan Carlos, Móstoles (Madrid)

EPV-844 | Imaging pattern might be different in dementia patients of positive brain amyloid PET with depression

T. Lee; Y. Wang; N. Peng
Department of Nuclear Medicine, Taipei Veterans General Hospital, Taipei, Taiwan

EPV-845 | Motor symptoms in anti-Hu paraneoplastic syndrome

J. Lopes[1]; J. Cabrera-Maqueda[2]; R. Samões[1]; J. Navarro-Otano[3]; Y. Blanco[2]; E. Martínez-Hernández[2]
[1]Neurology Department, Centro Hospitalar Universitário de Santo António, Porto, Portugal; [2]Neuroimmunology and Multiple Sclerosis Unit Hospital Clinic Barcelona, Fundació de Recerca Clínic Barcelona-IDIBAPS, Barcelona, Spain; [3]Neurology Department, Hospital Clinic Barcelona, Fundació de Recerca Clínic Barcelona-IDIBAPS, Barcelona, Spain

EPV-846 | The importance of early immunotherapy in anti-LGI1 encephalitis: Case report and systematic review of the literature

J. Villamor Rodríguez; D. Barbero Jiménez; M. Hernández Ramírez; M. González Gómez; F. Sánchez García; M. Mas Serrano
Department of Neurology, Guadalajara, Spain

EPV-847 | Neurosyphilis mimicking limbic encephalitis – A case report

K. Teo; A. Jiang; Y. Goh; K. Yip; J. Boey; A. Hui
Department of Neurology, Ng Teng Fong General Hospital

EPV-848 | Prognostic risk factors and clinical characterization of Susac's syndrome

L. Fuchs[1]; I. Vigiser[2]; H. Kolb[2]; K. Regev[2]; D. Zur[3]; Z. Habot-Wilner[3]; Y. Oron[4]; V. Furer[5]; O. Elkayam[5]; N. Shimon[6]; M. Hellmann[7]; I. Lotan[7]; E. Auriel[7]; A. Wilf-Yarkoni[7]; A. Karni[2]
[1]Faculty of Medicine, Tel Aviv University; [2]Neuroimmunology and MS unit, Neurology Institute, Tel Aviv Sourasky Medical Center; [3]Division of Ophthalmology, Tel Aviv Sourasky Medical Center; [4]Department of ENT, Tel Aviv Sourasky Medical Center; [5]Department of Rheumatology, Tel Aviv Sourasky Medical Center; [6]Department of Neurology, Shamir Medical Center; [7]Department of Neurology, Rabin Medical Center

EPV-849 | Immunophenotyping of lymphocytes in patients with multiple sclerosis who interrupted natalizumab therapy

S. Kotov; Y. Belova; Y. Chuksina; I. Vasilenko
Vladimirsky Moscow Regional Research Clinical Institute, Moscow

EPV-850 | MRI factors predictive of progression from clinically isolated syndrome (CIS) to multiple sclerosis (MS)

N. Lakri; Y. Koubci; H. Bouzenada
Central Hospital of Army, Algiers, Algeria

EPV-851 | Therapeutic challenge: Anquilosant spondylitis and concomitant multiple sclerosis

L. Santos Sánchez de las Matas[1]; P. Nieto González[2]; J. Martínez Ramos[1]; C. González Ávila[2]; L. Rubio Flores[3]; A. Gómez López[1]; S. Pastor Yborra[3]
[1]Department of Neurology, Hospital Universitario Rey Juan Carlos, Madrid, Spain; [2]Department of Neurology, Hospital Infanta Elena, Madrid, Spain; [3]Department of Neurology, Hospital General de Villalba, Madrid, Spain

EPV-852 | Not every serpinginous lesion is an arteriovenous malformation

L. Caballero Sánchez; C. Gómez López de San Román; M. Capra Remedi; M. Vargas Cobos; D. Cerdán Santacruz; I. Bermejo Casado; A. Castrillo Sanz; A. Mendoza Rodríguez
General Hospital of Segovia

EPV-853 | Quantification of the pyramidal tract pathology in highly active multiple sclerosis using diffusion tensor MRI

A. Peshkin[1]; G. Toniya[2]; E. Stepanova[2]; V. Lizhdvoy[1]; S. Kotov[1]
[1]Department of Neurology, MRSRCI, Moscow, Russian Federation; [2]Radiology Department, MRSRCI, Moscow, Russian Federation

EPV-854 | Cerebral vascular lesions in moldovan Parkinson's cohort

L. Rotaru[1]; T. Plescan[2]; O. Nicolenco[1]; S. Odobescu[1]; I. Moldovanu[1]; S. Groppa[3]
[1]"Diomid Gherman" Institute of Neurology and Neurosurgery, Chisinau, Republic of Moldova; [2]Medpark International Hospital, Chisinau, Republic of Moldova; [3]"Nicolae Testemitanu" State Medical and Pharmaceutical University, Chisinau, Republic of Moldova

EPV-855 | A novel use and dramatic efficacy of ofatumumab for seronegative autoimmune encephalitis: A case report

H. Guo
Department of Neurology, Shaanxi Provincial People's Hospital, Xi'an, Shaanxi, China

EPV-856 | Characterizing cross presenting dendritic cells in CNS border compartments using a murine model of multiple sclerosis

L. Müller-Miny; J. Wolbert; D. Schafflick; F. Straeten; H. Wiendl; G. Meyer zu Hörste
Department of Neurology with Institute of Translational Neurology, University Hospital Münster, Münster, Germany

EPV-857 | Cotard's Syndrome as manifestation of autoimmune encephalitis

L. Cobo Roldán; A. Rodríguez Martín
Department of Neurology, Hospital Universitario Reina Sofía, Córdoba, Spain

EPV-858 | Falcotentorial meningioma: Clinical manifestations and management approach. A case report

L. Quiros Illan[1]; I. Martin Sobrino[1]; A. Franco Salinas[3]; P. Nieto Palomares[2]; A. Garcia Maruenda[2]; S. Carrasco[1]; M. Muñoz Pasadas[1]
[1]Neurology Department, Hospital Santa Barbara, Puertollano, Spain; [2]Neurology Department, Hospital General Universitario Ciudad Real, Spain; [3]Neurology Department, Hospital Virgen de Mar, Madrid, Spain

EPV-859 | Recurrent facial palsy as the sole neurological manifestation in Behcet disease (BD)

L. Quiros Illan[1]; M. Muñoz Pasadas[1]; S. Carrasco[1]; A. Franco Salinas[1]; I. Martin Sobrino[2]
[1]*Hospital Santa Barbara;* [2]*Hospital General Universitario de Ciudad Real*

EPV-860 | Cerebral air embolism after an endoscopic procedure: An infrequent cause of ischaemic stroke

M. Gonzalez[1]; J. Alcala[1]; C. Santos[1]; C. Amarante[1]; L. Ibañez[2]; A. Herrero[1]
[1]*Department of Neurology, 12 De Octubre University Hospital, Madrid, Spain;* [2]*Department of Radiology, 12 De Octubre University Hospital, Madrid, Spain*

EPV-861 | Central diabetes insipidus, optic neuropathy and cerebral venous thrombosis in a young male: A rare CNS mishmash

V. Singh; S. Chouksey; A. Jain; R. Chaurasia
Department of Neurology, Institute of Medical Sciences, Banaras Hindu University, Varanasi, India

EPV-862 | New strategies in the diagnosis of ischemic stroke in women in Dagestan

K. Manysheva
Department of nervous diseases, medical genetics and neurosurgery, Dagestan State Medical University, Makhachkala, Russian Federation

EPV-863 | Case report: Repeated late-onset neutropenia after ofatumumab treatment in a patient with multiple sclerosis

M. Protopapa; M. Schraad; L. Steenken; V. Fleischer; S. Bittner
Department of Neurology, Focus Program Translational Neuroscience (FTN), and Immunotherapy (FZI), Rhine-Main Neuroscience Network (rmn2), University Medical Center of the Johannes Gutenberg University, Mainz, Germany

EPV-864 | Combined central and peripheral demyelination: A small case series

M. Pereira[1]; J. Moura[1]; M. Cardoso[2]; E. Santos[1]
[1]*Neurology Department, Centro Hospitalar Universitário do Porto (CHUdSA), Porto, Portugal;* [2]*Neurophysiology Department, Centro Hospitalar Universitário do Porto (CHUdSA), Porto, Portugal*

EPV-865 | Polymorphisms/gene variations in hemostasis-related genes in patients with ischemic stroke

M. Martínez Salmerón[1]; L. Amaya Pascasio[1]; P. Olea Rodríguez[1]; C. Velázquez de Castro[2]; F. Rodríguez Sánchez[2]; A. Arjona Padillo[1]; A. Rodríguez Sánchez[3]; P. Martínez Sánchez[4]
[1]*Stroke Centre, Department of Neurology, Torrecárdenas University Hospital, Almería, Spain;* [2]*Laboratory Services, Torrecárdenas University Hospital, Almería, Spain;* [3]*Fundación para la Investigación Biosanitaria de Andalucía Oriental (FIBAO), Torrecárdenas University Hospital, Almería, Spain;* [4]*Faculty of Health Science, Health Research Center (CEINSA), University of Almería, Spain, Stroke Centre, Department of Neurology, Torrecárdenas University Hospital, Almería, Spain*

EPV-866 | Posterior circulation stroke (PCS) mimics. When the Head CT misleads the diagnosis

M. Hernandez Garcia; C. Hernandez Javier; D. García Alvarez; M. Lobato Gonzalez; A. Bartolome Yumar; J. Rojo Aladro
Servicio de Neurología, Hospital Universitario de Canarias

EPV-867 | Hypomyelinating leukodystrophy with TUBB4A mutation and concominant mutation in the Spast gene, a case report

M. Lima; D. Parissis; N. Grigoriadis; P. Ioannidis
B' Department of Neurology, AHEPA University General Hospital of Thessaloniki, Aristotle University of Thessaloniki, Thessaloniki, Greece

EPV-868 | Transcranial brain sonography characteristics of neurosarcoidosis

M. Jeremić; M. Ždraljević; A. Radojičić; A. Tomić; M. Mijajlović
Department for Cerebrovascular Diseases, Neurology Clinic, Clinical Center of Serbia, Belgrade, Serbia

EPV-869 | Central and peripheral neurological involvement in MPO-ANCA-associated vasculitis: A diagnostic case report

M. Vicente Domínguez; C. Ortega Hidalgo; P. Hernández Vitorique; F. Pinel Rios; P. Carbonell Corvillo
Department of Neurology, University Hospital Virgen de la Victoria, Málaga, Spain

EPV-870 | A young woman with neuromyotonia, NMOSD, MG and SLE: Looking for tolerance

M. Marini[1]; S. Marini[1]; S. Falso[1]; J. Morroni[2]; R. Iorio[1]
[1]Department of Neuroscience, Università Cattolica del Sacro Cuore, Rome, Italy; [2]Neurology Unit, IRCCS Fondazione Policlinico Universitario A. Gemelli, UOC di Neurologia – Rome, Italy

EPV-871 | SNCA expression in synucleinopathies

M. Andreev; N. Abramycheva; A. Protopopova; A. Protsenko; E. Fedotova
Research Center of Neurology, Moscow, Russian Federation

EPV-872 | Norepinephrine inhibits monocyte-induced Th17-/Th1-immune response in multiple sclerosis

M. Melnikov; O. Belousova; A. Lopatina
Federal Center of Brain Research and Neurotechnologies of the Federal Medical-Biological Agency of Russian Federation

EPV-873 | Imaging predictive factors of outcome after intravenous thrombolysis in acute ischemic stroke

E. Smaoui; K. Moalla; N. Farhat; S. Sakka; S. Daoud; N. Bouattour; M. Damak; C. Mhiri
Department of Neurology, Habib Bourguiba University Hospital, Sfax, Tunisia

EPV-874 | Is COVID-19 mRNA vaccination related with autoimmune thrombotic thrombocytopenia with cerebral sinus thrombosis?

J. Baik[1]; H. Ma[2]
[1]Department of Neurology, Inje University Sanggye Paik hospital, Seoul, Republic of Korea; [2]Department of Neurology, Hallym University Sacred Heart hospital, Anyang, Republic of Korea

EPV-875 | Advanced age guillain Barre syndrome case

M. Cam; B. Güler
Canakkale Onsekiz Mart University

EPV-876 | Thalamic asymmetry in multiple sclerosis

N. Ramezani[1]; F. Davanian[1]; S. Naghavi[2]; R. Riahi[3]; G. Zandieh[1]; S. Danesh-Mobarhan[1]; F. Ashtari[1]; V. Shaygannejad[1]; M. Sanayei[4]; I. Adibi[1]
[1]Isfahan Neurosciences Research Center, Isfahan University of Medical Sciences, Isfahan, Iran; [2]Department of Neurology, School of Medicine, Isfahan University of Medical Sciences, Isfahan, Iran; [3]Department of Epidemiology and Biostatistics, School of Public Health, Isfahan University of Medical Sciences, Isfahan, Iran; [4]School of Cognitive Sciences, Institute for Research in Fundamental Sciences (IPM), Tehran, Iran

EPV-877 | Decades lost: Metachromatic leukodystrophy masquerading as a psychiatric disorder

N. Jucevičiūtė[1]; G. Pšemeneckienė[1]; R. Traberg[2]; R. Jonikas[2]; R. Ugenskienė[2]
[1]Department of Neurology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Department of Genetics and Molecular Medicine, Hospital of Lithuanian University of Health Sciences Kaunas Clinics, Kaunas, Lithuania

EPV-878 | Hypertrophic pachymeningitis (HP): A diagnostic and therapeutic challenge. Two cases reports

P. Gómez Ramírez; I. Martín Sobrino; M. Nieto Palomares; A. García Maruenda; M. El Harmochi Daoud; A. Sánchez Gómez; L. Quirós Illán; A. Mateos Romero; P. Otero Fernández; A. Hernández González; M. Del Real Francia
Department of Neurology, Ciudad Real, Spain

EPV-879 | A MRI-based radiomics-clinical machine learning model for predicting radiation-induced temporal lobe injury

L. Wang[1]; J. Zhou[1]; T. Qiu[1]; Y. Zhu[2]; B. Sun[3]; G. Yang[4]; S. Huang[1]; X. He[1]; L. Wu[1]

[1]Department of Radiation Oncology, The Affiliated Cancer Hospital of Nanjing Medical University, Jiangsu Cancer Hospital, Jiangsu Institute of Cancer Research, Nanjing, China; [2]Department of Radiation, The Affiliated Cancer Hospital of Nanjing Medical University, Jiangsu Cancer Hospital, Jiangsu Institute of Cancer Research, Nanjing, China; [3]Department of Radiation Oncology, School of Medicine, Washington University in St. Louis, St. Louis, America; [4]Key Laboratory of Computer Network and Information Integration, Southeast University, Nanjing, China

EPV-880 | HHV-6 associated transverse myelitis: A case report and literature review

C. Isiklar; S. Bildirici; C. Orken

Prof. Dr. Cemil Tascioglu City Hospital, Istanbul, Turkey

EPV-881 | Myasthenia gravis and acute immune-mediated polyneuropathy. Simultaneous onset and diagnosis

M. Martínez Palicio; P. Pinzón Benavides; P. Rozas Fernández; A. Cordero Novo; D. Alonso Vallín; R. Suarez Moro; M. Sánchez-Suárez López

Neurology, Hospital de Cabueñes, Gijón, España

EPV-882 | Association of serum albumin levels with outcome in intravenous immunoglobulin–treated Guillain-Barre syndrome

S. Sen[1]; B. Ray[2]; A. Biswas[3]

[1]Department of Neuromedicine, Bangur Institute of Neurosciences; [2]Department of Neuromedicine, Bangur Institute of Neurosciences; [3]Bangur Institute of Neurosciences

EPV-883 | Off-label rituximab use for neurological indications; observational data to assist with prescribing decisions

P. Murphy; A. Kondratiuk; A. Scalfari

Imperial College Healthcare NHS Trust

EPV-884 | Neuroimaging and management controversials of Spontaneous Intracranial Hypotension (SIH): Description of 4 cases

P. Mahiques Ochoa; M. Warken Miralles; P. Ros Arlanzón; L. Ruiz-Escribano Menchén

Neurology, Hospital General Universitario Doctor Balmis, Alicante, Spain

EPV-885 | Limbic encephalitis with anti Ma2 antibodies, associated with immunotherapy in renal cancer

P. Pinzón Benavides; A. Jimeno Hermoso; M. Martínez Palicio; D. Alonso Vallina; A. Cordero Novo; P. Rozas Fernández

Neurology Department, Cabueñes University Hospital, Gijón, Spain

EPV-886 | Neuroimaging to enhance neurological diagnosis in Uzbekistan

A. Radjapov; Y. Madjidova; N. Xusenova; A. Bijanova; A. Ernazarov

Tashkent Pediatric Medical Institute

EPV-887 | Cognitive teleRehabilitation in patients with Encephalitis of AutoIMmune etiology: CoRe-AIM study

R. Barnabei[1]; S. Bernini[2]; S. Bottiroli[1]; M. Scucchi[1]; P. Businaro[3]; S. Masciocchi[3]; S. Scaranzin[3]; C. Morandi[3]; S. Gasverde[4]; F. Deleo[5]; S. Beretta[6]; D. Franciotta[3]; M. Gastaldi[3]

[1]Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; [2]Dementia Research Center, IRCCS Mondino Foundation, Pavia, Italy; [3]Neuroimmunology Research Unit, IRCCS Mondino Foundation, Pavia, Italy; [4]Department of Neurology, Ospedale Civile Ciriè, Torino, Italy; [5]Epilepsy Unit, IRCCS Istituto Neurologico Carlo Besta, Milano, Italy; [6]Department of Neuroscience, Università degli Studi di Milano Bicocca, Milano, Italy

EPV-888 | Refractory anti-nmdar encephalitis: Paradigm shift required in the treatment

S. Nair[1]; E. M. Koshy[1]; D. Kannoth[2]; D. Kandikonda[2]

[1]Department of Pharmacy Practice, Amrita School of Pharmacy, Amrita Vishwa Vidyapeetham, AIMS Health Sciences Campus, Kochi, Kerala, India; [2]Department of Neurology, Amrita Institute of Medical Science and Research Centre, Amrita Vishwa Vidyapeetham, AIMS Health Sciences Campus, Kochi, Kerala, India

EPV-889 | Vocal cord palsy in late adulthood as a sign of recessive spinocerebellar ataxia type 10

C. Santillana Ávila; R. Calle Calle; M. Carrasco García; C. Hurtado Alcázar; R. Piñar Morales
Neurology, Hospital Clínico San Cecilio, Granada, Spain

EPV-890 | Immune-checkpoint inhibitor-associated encephalitis: Case series in a tertiary hospital

S. García-Bellido Ruiz[1]; D. Pérez Rangel[1]; G. Velilla Alonso[2]
[1]*Neurology Department, Hospital Universitario 12 de Octubre, Madrid, Spain;* [2]*Neuro-Oncology Unit, Hospital Universitario 12 de Octubre, Madrid, Spain*

EPV-891 | Neurological and neuropsychological correlates of Klippel-Feil syndrome

S. Melchiorre; M. Russo; G. Polito; C. Ciprietti; M. Santilli; S. Sensi
Department of Neuroscience, Imaging and Clinical Sciences, University G. D'Annunzio of Chieti-Pescara, Chieti, Italy

EPV-892 | Commercial volumetric and lesion segmentation MRI tools in Multiple Sclerosis (MS)

E. Schilke; M. Frigo; M. Fusco; D. Cereda; C. Balducci; G. Cavaletti
Neurology Department, Fondazione IRCCS San Gerardi dei Tintori, Monza, Italy

EPV-893 | The significance of immunohistochemical expression of mesothelin in meningiomas

S. Pavelin[1]; K. Bečić[2]; E. Marušić[3]; D. Jandrić Bečić[4]
[1]*Clinical Department for Neurology, Split University Hospital, Split, Croatia;* [2]*Department for Pathology and Citology, General Hospital Šibenik, Šibenik, Croatia;* [3]*Clinical Department for Pediatrics, Split University Hospital, Split, Croatia;* [4]*Department for Anesthesiology, Reanimatology and Intensive care, General Hospital Šibenik, Šibenik, Croatia*

EPV-894 | Clinical-genetic phenotype in Bulgarian patients with ALS and mutation in NEK1 gene

T. Angelov[1]; T. Chamova[1]; T. Todorov[2]; S. Ormandzhiev[2]; A. Todorova[3]; D. Devos[4]; I. Tournev[5]
[1]*Clinic of Nervous Diseases, University Hospital "Alexandrovska", Department of Neurology, Medical University of Sofia, Bulgaria;* [2]*Genetic Medical Diagnostic Laboratory "Genica", Sofia, Bulgaria;* [3]*Genetic Medical Diagnostic Laboratory "Genica", Sofia, Bulgaria; Department of Medical Chemistry and Biochemistry, Medical University of Sofia, Bulgaria;* [4]*Department of Medical Pharmacology, Lille Neuroscience & Cognition, CHU Lille, France;* [5]*Clinic of Nervous Diseases, University Hospital "Alexandrovska", Department of Neurology, Medical University of Sofia, Bulgaria; Department of Cognitive Science and Psychology, New Bulgarian University, Sofia, Bulgaria*

EPV-895 | Temporal lobe glioblastoma: An uncommon mimic of autoimmune limbic encephalitis

V. Floris; P. Zara; P. Solla; E. Sechi
Department of Neurology, Sassari

EPV-896 | ERLIN 2 mutations in an Italian series of patients: Phenotypic and genetic variability

V. Gioiosa[1]; E. Cioffi[1]; A. Petrucci[2]; F. Santorelli[3]; A. Tessa[3]; C. Casali[1]
[1]*Department of Medico-Surgical Sciences and Biotechnologies, University of Rome Sapienza, Latina, Italy;* [2]*Department of Neurology and neurophysiopathology, Azienda Ospedaliera San Camillo Forlanini, Rome, Italy;* [3]*IRCCS Stella Maris Foundation, Calambrone, Pisa, Italy*

EPV-897 | Neuroimaging profile in a cohort of Brazilian cadasil patients

V. Carvalho Neri[1]; R. Lettieri[2]; K. Lobo[2]; S. Machado[3]; T. Gomes[2]; B. Mothe[2]; A. Carvalho[2]; C. Pandino[2]; C. Cardoso[4]; A. Goes[5]
[1]*Neurology Department, Hospital da Lagoa, Rio de Janeiro/Brazil;* [2]*Neurology, Faculdade de Medicina de Campos, Rio de Janeiro/ Brazil;* [3]*Biology Department, Universidade Estadual do Norte Fluminense Darcy Ribeiro-Uenf, Campos dos Goytacazes/Brazil;* [4]*Neurology Department, Hospital UNIMED, Campos dos Goytacazes/Brazil;* [5]*Neurology Post Graduate Program, Universidade Federal do Estado do Rio de Janeiro-UNIRIO, Rio de Janeiro/Brazil*

EPV-898 | Auditory neuropathy and optic atrophy, linked with FDXR gene mutations

V. Fonseca; M. Saianda Duarte; J. Correia; A. Arraiolos; T. Lampreia; J. Vale
Neurology Service, Hospital Beatriz Angelo, Lisbon, Portugal

EPV-899 | Structural changes of the brain in patients with Wilson's disease according to MR tomography and MR spectroscopy

I. Voloshyn-Haponov
Department of Neurology, Psychiatry, Narcology and Medical Psychology, V.N. Karazin Kharkiv National University, City Kharkiv, Ukraine

EPV-900 | Early-onset amyloid angiopathy

A. García Rúa; M. Álvarez Álvarez; P. Siso García; A. Sánchez Rodriguez; J. González Ardura
Neurology, Hospital Universitario de Cabueñes, Gijón, España

EPV-901 | Isolated recurrent sixth nerve palsy: Could it be a presentation of microscopic polyangiitis?

R. Cagigal; A. Mendes
Unidade de Saúde Local Gaia/Espinho

EPV-902 | Clinical effects of virtual reality training and tDCS for upper limb function in paediatric brain injury: A RCT protocol

A. Cerezo-Zarzuelo[1]; F. Sanchez-Cuesta[2]; M. Moreno-Verdu[3]; M. Rios-Lago[4]; B. Gavilan-Agusti[5]; J. Romero-Muñoz[2]
[1]*Psychology PhD Program, Universidad Nacional de Educación a Distancia (UNED), Madrid, Spain;* [2]*Brain Injury and Movement Disorders Neurorehabilitation Group (GINDAT), Institute of Life Sciences, Francisco de Vitoria University, Spain;* [3]*Brain, Action and Skill Laboratory (BAS-Lab), Institute of Neuroscience (Cognition and Systems Division), UC Louvain, Woluwe-Saint-Laimbert, Belgium;* [4]*Department of Basic Psychology II. School of Psychology, Universidad Nacional de Educación a Distancia (UNED), Madrid, Spain;* [5]*Brain Damage Unit, Beata Maria Ana Hospital, Madrid, Spain*

EPV-903 | Jaw drop in leptomeningeal metastasis

A. Gottiparthy[1]; A. Zahid[1]; E. Burns[2]; I. Tremont-Lukats[3]
[1]*Stanley Appel Department of Neurology, Houston Methodist Hospital;* [2]*Mary and Ron Neal Cancer Center, Houston Methodist Hospital;* [3]*Kenneth R. Peak Brain and Pituitary Tumor Center, Houston Methodist Hospital*

EPV-904 | Effect of transcranial magnetic stimulation on functional outcome of patients with incomplete spinal cord injury

A. Hassanen
Faculty of Physical Therapy, Egyptian Chinese University

EPV-905 | Papilledema and other neurological signs due to an atypical cause. A case report

A. Lagüela; V. Anciones; A. Rebollo; V. Fernández; L. Fernández; C. Valido; M. Martínez; Á. López; M. Freijo; A. Rodríguez-Antigüedad; A. Durán; J. Losada
Neurology Department, Cruces University Hospital

EPV-906 | Magnetic resonance imaging correlates of challenging gait condition in multiple sclerosis

M. Albergoni[1]; E. Marabese[1]; A. Meani[1]; E. Pagani[1]; P. Valsasina[1]; P. Preziosa[2]; M. Rocca[2]; M. Filippi[3]
[1]*Neuroimaging Research Unit, Division of Neuroscience, IRCCS San Raffaele Scientific Institute, Milan, Italy;* [2]*Neuroimaging Research Unit, Division of Neuroscience, and Neurology Unit, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy;* [3]*Neuroimaging Research Unit, Division of Neuroscience, Neurology Unit, Neurorehabilitation Unit, and Neurophysiology Service, IRCCS San Raffaele Scientific Institute, Milan, Italy; and Vita-Salute San Raffaele University, Milan, Italy*

EPV-907 | Combination of different NIBS treatments for upper limb recovery in stroke. A systematic review

A. Lerín Calvo[1]; D. Rodríguez Martínez[1]; J. Bernal Jiménez[2]; S. Lerma Lara[3]; R. Ferrer Peña[3]
[1]Clínica Neuron Madrid Río, Madrid, Spain; [2]Faculty of Health Sciences, Universidad de Castilla la Mancha, Talavera de la Reina, Toledo, Spain; [3]Departamento de Fisioterapia, Centro Superior de Estudios Universitarios La Salle, Universidad Autónoma de Madrid, Aravaca, Madrid, Spain

EPV-908 | Limited effect of the rehabilitation training on post-injury spinal cord recovery

T. Ageeva; E. Davletshin; D. Sabirov; A. Timofeeva; E. Plotnikova; A. Rizvanov; A. Yakubova; Y. Mukhamedshina
Openlab "Gene and Cell Technologies", Kazan Federal University, Kazan, Russian Federation

EPV-909 | When it seems to be SMART and it is not. The dark side of radiotherapy

A. Oliveira; T. Jesus; P. Grilo; S. Costa; C. Barroso
Department of Neurology, Hospital de Vila Franca de Xira, Lisbon, Portugal

EPV-910 | Atypical debut of multifocal primary central nervous system lymphoma: A case report

A. Aldaz Burgoa; L. López Trashorras; L. Franco Rubio; P. Abizanda Saro; N. Rodríguez Albacete; R. Ginestal López; E. López Valdés; A. Marcos Dolado
Neurology, Hospital Clínico San Carlos, Madrid, Spain

EPV-911 | Autoimmune-encephalitis mimics: Red flags on a case resulting a glioblastoma multiforme

Á. Morales Lahoz; M. Serrano Jiménez; M. Carrasco García; I. del Pino Díaz; R. Calle Calle; R. Piñar Morales
Neurology, Hospital Universitario Clínico San Cecilio, Granada, Spain

EPV-912 | Redefining the superficial peroneal nerve: Stimulation technique, normal values, and clinical significance

A. Sreij; A. Ezzedine; H. Doumiati; R. Sawaya
American University of Beirut Medical Center – Beirut, Lebanon

EPV-913 | Development of rehabilitation potential and restoration of motor function in ischemic stroke

B. Bakhriev
Tashkent State stomotological Institute

EPV-914 | Hypothetical neurological impacts of exceeding auditory thresholds in transcranial magnetic stimulation

B. De[1]; B. Carr[2]
[1]School of Medicine, University of California San Francisco, San Francisco, USA; [2]Department of Psychiatry, University of Florida, Gainesville, USA

EPV-915 | Adapting LIMOS for stroke patients: Validating a patient-reported measurement in brazilian outpatient rehabilitation

B. Monteiro[1]; A. Silva[1]; G. Leandro[1]; E. Baldi[1]; B. Ottinger[2]; T. Vanbellingen[2]; S. Silva[1]
[1]University Nove de Julho, Sao Paulo, SP, Brazil; [2]Neurology and Neurorehabilitation Center, Lucerne, Switzerland

EPV-916 | The characterization of selected brain injury factors and cytokines in the CSF among RRMS patients

R. Adamczyk[1]; N. Morawiec[1]; G. Mamak[1]; S. Boczek[1]; D. Brzęk[1]; N. Trędota[1]; P. Walocha[1]; Z. Czuba[2]; M. Błachut[3]; W. Bartman[1]; M. Adamczyk-Sowa[1]
[1]Department of Neurology, Faculty of Medical Sciences in Zabrze, Medical University of Silesia in Katowice, Zabrze, Poland; [2]Department of Microbiology and Immunology, Faculty of Medical Sciences in Zabrze, Medical University of Silesia in Katowice, Zabrze, Poland; [3]Clinical Department of Psychiatry, Faculty of Medical Sciences in Zabrze, Medical University of Silesia in Katowice, Katowice, Poland

EPV-917 | Central nervous system vasculitis in inflammatory Bowel disease: A rare cause of stroke

C. Algar Ramírez; P. Dodu; D. Rodriguez García; J. Lopez Madrona
Department of Neurology, Hospital Regional de Málaga, Málaga, Spain

EPV-918 | The SECONDs index score to assess consciousness fluctuations in acute patients with severe brain injury

M. Khosravi[1]; P. Fritz[1]; M. Vitello[1]; E. Szymkowicz[1]; P. Cardone[1]; A. Regnier[1]; F. Petit[2]; C. Martial[1]; C. Beaudart[3]; A. Thibaut[1]; O. Gosseries[1]; C. Aubinet[1]
[1]*Coma Science Group, GIGA Consciousness, University of Liège, Belgium;* [2]*Intensive Care Units, University Hospital of Liège, Belgium;* [3]*Department of Biomedical Sciences, Faculty of Medicine, NAmur Research Institute for LIfe Sciences, Belgium*

EPV-919 | The impact of aerobic exercise on cognitive function in individuals with multiple sclerosis

S. Albayrak[1]; F. Bilek[2]; C. Demir[1]
[1]*Department of Neurology, School of Medicine, Fırat University, Elazığ, Turkey;* [2]*Department of Geriontology, Fethiye Faculty of Health Sciences, Muğla Sıtkı Koçman University, Muğla, Turkey*

EPV-920 | Exploring the efficacy of art therapy for cognitive improvement in dementia: A systematic review

C. Gabriel Fernandes; C. Keiti Rech; C. Frederico de Almeida Rodrigues
Universidade Estadual do Oeste do Paraná – UNIOESTE, Campus de Francisco Beltrão, Paraná, Brazil

EPV-921 | WEBINO syndrome (Wall-Eyed Bilateral Internuclear Ophthalmoplegia): A case report

C. Nieva Sánchez; A. García Díaz; A. Freixa Cruz; L. Pérez Girona; M. Paul Arias; D. Vázquez García
Neurology, Arnau de Vilanova University Hospital, Lleida, Spain

EPV-922 | Eosinophilic granulomatosis with polyangiitis mimicking chronic inflammatory demyelinating polyneuropathy: A case report

D. Totaro; G. Ruta; T. Giannelli; G. Falcicchio; A. Introna; D. Paolicelli; G. Defazio
The Department of Translational Biomedicine and Neuroscience (DiBraiN) – University of Bari "Aldo Moro"

EPV-923 | Nonsense-mediated decay (NMD) as a shared peripheral immune dysregulation process across neurological disease

G. Vavougios[1]; E. Agkastinioti[1]; E. Christou[1]; A. Liampas[1]; P. Neofytou[1]; R. Louka[1]; R. Theologou[1]; T. Doskas[2]; R. Chirmpaki[1]; C. Argyropoulou[1]; P. Ioannidis[1]; S. Kalambokini[1]; L. Panos[1]; P. Zis[1]; A. Artemiadis[1]; P. Zis[1]; G. Hadjigeorgiou[1]
[1]*Department of Neurology, Medical School, University of Cyprus, Nicosia, Cyprus;* [2]*Athens Naval Hospital, Athens, Greece*

EPV-924 | Expanding the horizon of paraneoplastic disorders: New intracellular antibody for progressive cerebellar degeneration

D. Rodriguez Garcia; C. Algar Ramirez; R. Dodu; P. Cabezudo Garcia; N. Ciano Petersen; P. Serrano Castro
Servicio de Neurología, Hospital Regional Universitario de Málaga, Málaga, Spain

EPV-925 | Bilateral horizontal diplopia of rare etiology: Paraneoplastic syndrome due to Anti-Ri

D. Barbero Jimenez[1]; J. Villamor Rodríguez[1]; J. Celi Celi[1]; M. Gonzalez Gómez[1]; F. Sanchez García[1]; M. Barbero Jiménez[2]
[1]*Departament of Neurology, Hospital Universitario de Guadalajara, Guadalajara, Spain;* [2]*Department of Oncology, Hospital Universitario Nuestra Señora del Prado, Talavera de la Reina, Spain*

EPV-926 | Rehabilitation of young children with epilepsy: Opportunities and safety

E. Bukreeva[1]; P. Sokolov[1]; E. Sergeenko[1]; A. Krapivkin[1]; D. Kharlamov[1]; O. Laisheva[2]
[1]*Scientific and Practical Center for Specialized Care for Children, Moscow, Russian Federation;* [2]*Pirogov Russian National Research Medical University, Moscow, Russian Federation*

EPV-927 | Neurodevelopmental therapy for cerebral palsy: A systematic review of systematic reviews

A. Samir; A. Abdelghany
Faculty of Physical Therapy, Cairo University, Giza, Egypt

EPV-928 | Vasculitic sensory motor peripheral neuropathy (ANCA-associated vasculitis) in juvenile primary Sjögren's syndrome

S. Kapur[1]; A. Deshpande[2]
[1]Asian Rheumatology Center, Warangal, India; [2]Vinayaka Neurology Center, Warangal, India

EPV-929 | Left–right reversal of vision metamorphopsia caused by cerebellar glioma: A case report

E. Karakoleva[1]; A. Firozvi[2]; E. Shamim[3]
[1]Pennsylvania State University College of Medicine, Hershey, PA, USA; [2]William and Mary University, Williamsburg, VA, USA; [3]Mid-Atlantic Permanente Research Institute, Rockville, MD, USA

EPV-930 | Features differentiated treatment for pain in adults with complex regional pain syndrome (CRPS)

E. Bakhtereva; N. Terehov; E. Leiderman; T. Ryabkova
Yekaterinburg Medical Research Center for Prophylaxis and Health Protection in Industrial Workers, Yekaterinburg, Russian Federation

EPV-931 | Unveiling erdheim chester disease enigma: Case report and literature review

A. Díaz-Alba[1]; E. Sarmiento-Lizárraga[2]; T. Ori-Guy[2]; R. Lugo-Sánchez[2]; S. Ramirez-Andrade[1]; V. García-Navarro[1]; J. Paz-Gutierrez [1]
[1]Instituto Neurológico de Guadalajara, Zapopan, Mexico; [2]Monterrey Institute of Technology and Higher Education, Zapopan, Mexico

EPV-932 | NeuroGPT; is it really an AI capable of diagnosing and treating patients in neurology? A view through 72 patients

A. Fernández Cabrera[1]; J. García de Soto[2]; P. Santamaría Montero[1]; R. Pego Reiglosa[1]
[1]Hospital Universitario Lucus Augusti, Lugo, Spain [2]Hospital Universitario de Santiago de Compostela, Santiago, Spain

EPV-933 | Idiopathic intracranial hypertension following abortion complicated with acute anaemia – a case report

F. Repas Barbosa; L. Silva; J. Alves; J. Heitor Pinto; I. Laranjinha
Centro Hospitalar Universitário de Santo António

EPV-934 | Phenotypic spectrum of a series of temporally and spatially close cases of Guillain-Barré syndrome

G. Baso[1]; C. Ferrari Aggradi[1]; G. Furciniti[1]; S. Mambriani[1]; D. Iacobucci[1]; D. Saccomanno[1]; D. Velardo[1]; S. Corti[2]; G. Comi[2]
[1]Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; [2]Department of Pathophysiology and Transplantation, University of Milan; Neurology Unit – Foundation IRCCS Ca′ Granda – Department of Neuroscience and Mental Health, Milan, Italy

EPV-935 | Acute neurological complications following taxane chemotherapy in gastric adenocarcinoma: A case report

G. Ruta; D. Totaro; T. Giannelli; A. Fallacara; A. Introna; G. Falcicchio; D. Paolicelli; G. Defazio
Department of Translational Biomedicine and Neuroscience (DiBraiN) – University of Bari "Aldo Moro"

EPV-936 | Relaxation effects of environment of "the Way of Tea" on the autonomic nervous system

H. Minami; T. Nakamura
Department of Neurology, Hamamatsu University Graduate School of Medicine, Hamamatsu, Japan

EPV-937 | The AUREUS project (Austrian Rehabilitation Exchange with Uzbekistan) in Uzbekistan

S. Jabborova[1]; M. Yakutkhan[2]
[1]*Севара Жаббарова – Ташкентский Педиатрический медицинский институт, Ташкент Богишамол 230;* [2]*Маджидова Якутхон – ТашПМИ, Богишамол 230*

EPV-938 | Prospective and quantitative evaluation of gait and stance in patients with acute vertigo and dizziness

H. Hadzhikolev[1]; K. Möhwald[1]; A. Zwergal[1]; P. Jaufenthaler[1]; K. Jahn[2]; M. Wuehr[1]
[1]*German Center for Vertigo and Balance Disorders, DSGZ, University Hospital, LMU Munich, Germany;* [2]*Schön Klinik, Department of Neurology, Bad Aibling, Germany*

EPV-939 | Diabetes and anemia during aceruloplasminemia: Systematic review and meta-analysis

I. Ketata; E. Ellouz
Neurology Department, University Hospital of Gabes, Sfax University, Sfax, Tunisia

EPV-940 | Alameda, an opportunity for at-home neurologic rehabilitation (NR)-interim data collection results

P. Ioan[1]; A. Ribigan[1]; A. Sorici[2]; L. Bajenaru[2]; A. Florea[2]; F. Antochi[1]
[1]*Emergency University Hospital Bucharest;* [2]*Politehnica University Bucharest*

EPV-941 | Changes of emotional and neurophysiological status in cardiac surgery patients after multitasking cognitive training

O. Razumnikova[1]; I. Tarasova[2]; O. Trubnikova[2]
[1]*Novosibirsk State Technical University, Russian Federation;* [2]*Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation*

EPV-942 | Repeating CSF flow cytometry as a diagnostic strategy: Meningeal lymphomatosis secondary to follicular lymphoma

J. Alcalá Torres[1]; M. González Arbizu[1]; G. Ramos Moreno[2]; I. Zamanillo Herreros[2]; C. Santos Martín[1]; C. Amarante Cuadrado[1]; A. Herrero San Martín[1]
[1]*Department of Neurology, Hospital Universitario, Madrid;*
[2]*Department of Hematology, Hospital Universitario, Madrid*

EPV-943 | An unusual clinical case of metastasis in spinal nerves roots

J. Marly; M. Hernández Ramírez; J. Villamor Rodríguez; D. Barbero Jiménez
Neurology Deparment, Guadalajara Universitary Hospital

EPV-944 | A case of intractable hiccups caused by hemangioblastoma of the fourth ventricle

J. Kim; J. Woo
Neurology, Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Republic of Korea

EPV-945 | The effectiveness of cognitive training using virtual reality for patients with initial cognitive impairment

K. Shamtieva; V. Dubas; A. Valeeva; V. Zelentsova; T. Peters
Medical Research and Educational Center of Moscow State University named after M.V. Lomonosov

EPV-946 | Comparison US evaluated muscle thickness and echogenicity between control and stroke patients with spasticity

H. Kang; H. Kim; W. Choi
Department of Physical Medicine and Rehabilitation, VHS Medical Center, Seoul, Republic of Korea

EPV-947 | Outcome measures in the rehabilitation of children with autism: A systematic review aligned with the CIF

L. Oliveira; G. Janizello; S. Silva; C. Gomes
Postgraduate in Rehabilitation Sciences, Universidade Nove de Julho, São Paulo, Brazil

EPV-948 | Assessing neurological manifestations in mucopolysaccharidoses type-III: Outcomes from a scoping review

L. Nunes Campos[1]; A. Sabino Romagnoli[1]; D. Fernandez-Guzman[1]; F. Fernandez Zelcer[2]; C. Stegmann[1]; C. Argüelles[1]; L. Sosa[1]; J. Stegmann[1]; A. Gerk[1]
[1]Rare Diseases Community, Buenos Aires, Argentina; [2]Facultad de Filosofía y Letras, Universidad de Buenos Aires, Buenos Aires, Argentina

EPV-949 | Exploring neurological symptoms in mucopolysaccharidoses type VI: A scoping review

L. Nunes Campos[1]; A. Gerk[1]; S. Kundu[2]; F. Fernandez Zelcer[3]; C. Stegmann[1]; C. Argüelles[1]; L. Sosa[1]; J. Stegmann[1]
[1]Rare Diseases Community, Buenos Aires, Argentina; [2]McGill University, Montreal, Canada; [3]Facultad de Filosofía y Letras, Universidad de Buenos Aires, Buenos Aires, Argentina

EPV-950 | Evaluating neurological symptoms in mucopolysaccharidoses type VII: Results from a scoping review

L. Nunes Campos[1]; A. Gerk[1]; S. Kundu[2]; F. Fernandez Zelcer[3]; C. Stegmann[1]; C. Argüelles[1]; L. Sosa[1]; J. Stegmann[1]
[1]Rare Diseases Community, Buenos Aires, Argentina; [2]McGill University, Montreal, Canada; [3]Facultad de Filosofía y Letras, Universidad de Buenos Aires, Buenos Aires, Argentina

EPV-951 | Otolaryngologic presentation of giant cell arteritis (GCA)

L. Caballero Sánchez; C. Gómez López de San Román; M. Capra; M. Vargas Cobos; D. Cerdán Santacruz; I. Bermejo Casado; A. Castrillo Sanz; A. Mendoza Rodríguez
General Hospital of Segovia

EPV-952 | Acute polyneuropathy (APN) as a debut of Sjogren's syndrome (SS): Two cases and a review

L. Gonzalez Fernandez[1]; J. Molina Gil[2]
[1]Neurology, Cabueñes University Hospital, Gijón, Spain; [2]Neurology, Valle del Nalón Hospital, Riaño, Spain

EPV-953 | Tuberculous papillitis, the "great imitator" of ocular disease

L. Costa[1]; R. Silva[2]; S. Gomes[3]; I. Amorim[3]; A. Santos[3]; G. Cação[1]; C. Almeida[2]; C. Machado[3]
[1]Neurology Department, Unidade Local de Saúde do Alto Minho; [2]Ophthalmology Department, Unidade Local de Saúde de Braga; [3]Neurology Department, Unidade Local de Saúde de Braga

EPV-954 | Advanced perspectives for the diagnosis of Parkinson's and Alzheimer's disease through machine learning techniques

A. Malvaso[1]; S. Panarese[2]; M. Catalano[3]; M. Migliore[4]; D. Caligiore[5]
[1]IRCCS Mondino Foundation, Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy; Computational and Translational Neuroscience Laboratory, Institute of Cognitive Sciences and Technologies, National Research Council, Rome, Italy; [2]Dipartimento di Biologia e Biotecnologie, Sapienza Università di Roma, Rome, Italy; Computational and Translational Neuroscience Laboratory, Institute of Cognitive Sciences and Technologies, National Research Council, Rome, Italy; [3]Dipartimento di Biologia, Università degli studi di Roma Tor Vergata Rome, Italy; [4]Institute of Biophysics, National Research Council, Palermo, Italy; Dipartimento di Biologia e Biotecnologie, Sapienza Università di Roma, Rome, Italy; [5]Computational and Translational Neuroscience Laboratory, Institute of Cognitive Sciences and Technologies, National Research Council, Rome, Italy

EPV-955 | Association between neuropsychiatric SLE and a Positive HLA-B51 antigen – Coincidence or clinical correlation?

M. Moldovan; A. Ribigan; A. Resiga; C. Argintaru; F. Antochi
Neurology Department, Emergency University Hospital, Bucharest, Romania

EPV-956 | Central neurocytoma: Casuistry of a tertiary center

M. Dias da Costa[1]; P. Faustino[2]; R. Roque[1]
[1]Neurology, Department of Neurosciences and Mental Health, Unidade Local de Saúde Santa Maria, Lisbon, Portugal; [2]Neurology, Unidade Local de Saúde São José, Lisbon, Portugal

EPV-957 | What is essential is invisible to the eye

M. Capra; C. Gómez López de San Román; M. Vargas Cobos; D. Cerdán Santacruz; L. Caballero Sánchez; A. Castrillo Sanz; A. Mendoza Rodríguez; I. Bermejo Casado
Neurology, Hospital General de Segovia, Segovia, Spain

EPV-958 | Targeting subclinical motor and cognitive impairment in patients with early onset multiple sclerosis: RELIABLE study

M. Betti[1]; E. Portaccio[1]; G. Pasquini[2]; F. Gerli[2]; C. Niccolai[2]; S. Dalla Bella[2]; U. Kihlbom[3]; K. Bywall[4]; A. Kalron[5]; R. Aloni[6]; S. Martin[4]; A. Achiron[7]; M. Amato[8]
[1]University of Florence, Department of Neurofarba, Florence, Italy; [2]IRCCS Fondazione Don Carlo Gnocchi, Florence, Italy; [3]Stockholm Centre for Health Care Ethics (CHE), LIME, Karolinska Instutet, Sweden; [4]Centre for Research Ethics & Bioethics (CRB), Uppsala University, Sweden; [5]Department of Physical Therapy, School of Health Professions, Faculty of Medicine and Sagol School of Neuroscience, Tel-Aviv University, Tel-Aviv, Israel; Multiple Sclerosis Center, Sheba Medical Center, Tel-Hashomer, Israel; [6]Department of Psychology, Ariel University, Ariel, Israel; Multiple Sclerosis Center, Sheba Medical Center, Tel-Hashomer, Israel; [7]Multiple Sclerosis Center, Sheba Medical Center, Tel-Hashomer, Israel; Neurology Department, Sheba Medical Center, Tel-Hashomer, Israel; Sackler School of Medicine, Tel-Aviv University, Tel Aviv, Israel; [8]University of Florence, Department of NEUROFARBA, Florence, Italy; IRCCS Fondazione Don Carlo Gnocchi, Florence, Italy

EPV-959 | Is it possible to challenge a neurologist brain with Artificial Intelligence?

M. Tosi; N. Maiorana; A. Priori
"Aldo Ravelli" Research Center for Neurotechnolgy and Experimental Brain Therapeutics, Department of Health Sciences, San Paolo University Hospital, University of Milan, Milan, Italy

EPV-960 | Parkinsonism, dystonia and vertical gaze palsy: A case report of an anti Ma2 paraneoplastic syndrome

E. Smaoui; S. Sakka; R. Smaoui; K. Moalla; S. Daoud; N. Bouattour; M. Damak; C. Mhiri
Department of Neurology, Habib Bourguiba University Hospital, Sfax, Tunisia

EPV-961 | Botulinum toxin A therapy in patients with post-stroke spasticity

M. Kramárik[1]; E. Minks[1]; M. Baláž[2]
[1]First Department of Neurology, St. Anne's University Hospital Brno, Czechia; [2]Faculty of Medicine, Masaryk University, Brno, Czechia

EPV-962 | Focal seizures in non-ketotic hyperglycaemia

A. Montalvo[1,2,3]; M. M Roque[1]; B. Nunes Vicente[1]; M. Leal Rato[1,4]; F. Dourado Sotero[1,2]; A. Antunes[1,2]; L. Albuquerque[1,2]
[1]Serviço de Neurologia, Departamento de Neurociências e Saúde Mental, Unidade Local de Saúde Santa Maria, Lisbon, Portugal; [2]Centro de Estudos Egas Moniz, Clínica Universitária de Neurologia, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal; [3]Instituto de Fisiologia, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal; [4]Instituto de Farmacologia e Neurociências, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal

EPV-963 | Designing and deploying an innovative stroke rehabilitation system via the ReInsult mobile app

M. Bakhramov; Y. Madjidova; B. Bakhriev; S. Jabborova; Z. Abdullayev
Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

EPV-964 | Electromagnetic treatment of patients with motor deficits after a stroke

M. Al-Zamil[1]; N. Mansur[2]
[1]Department of Physiotherapy of Peoples' Friendship University of Russia, Moscow, Russian Federation; [2]Department of Physiotherapy of Peoples' Friendship University of Russia, City Clinical Hospital named after V. V. Vinogradov, Moscow, Russian Federation

EPV-965 | Isolated seizure secondary to embolic ischemic stroke: Libman-Sacks endocarditis debut, in unknown autoimmune diseases

P. Gómez Ramírez; I. Martín Sobrino; M. Nieto Palomares; A. García Maruenda; M. El Harmochi Daoud; A. Sánchez Gómez; L. Quirós Illán; A. Hernández González
Department of Neurology, Ciudad Real, Spain

EPV-966 | Establishing an integrated Neurorehabilitation service for children with long-term neurological condition

Z. Ng[1]; L. Tan[2]; N. Shaik Mohamed Shafi'ee[3]; A. Alia[4]; W. Leo[5]; J. Teo[1]; T. Yeo[1]; D. Chan[1]
[1]Department of Pediatrics, Neurology Service, KK Women's and Children's Hospital, Singapore; [2]Division of Nursing, Nursing Specialist Services, KK Women's and Children's Hospital, Singapore; [3]Division of Allied Health Specialties, Occupational Therapy Service, KK Women's and Children's Hospital, Singapore; [4]Division of Allied Health Specialties, Physiotherapy Department, KK Women's and Children's Hospital, Singapore; [5]Division of Allied Health Specialties, Speech Language Therapy Service, KK Women's and Children's Hospital, Singapore

EPV-967 | Secondary central nervous system vasculitis: A series of 21 patients

S. Sellami; N. Farhat; H. Haj Kacem; N. Bouattour; K. Moalla; S. Daoud; S. Sakka; M. Damak; C. Mhiri
Neurology Department and Research Laboratory LR12SP19, Habib Bourguiba University Hospital, Sfax, Tunisia

EPV-968 | Using artificial intelligence in diagnostics of neurological diseases

O. Heorhiu; Y. Solodovnikova; A. Son
Department of Neurology and Neurosurgery, Odesa National Medical University, Odesa, Ukraine

EPV-969 | Examining neurological manifestations in Bardet-Biedl syndrome: Insights from a scoping review

O. Pintos[1]; L. Nunes Campos[1]; I. Rudzinski[1]; S. Curto[1]; S. Maximowicz[1]; A. Gerk[1]; F. Fernandez Zelcer[2]; C. Stegmann[1]; C. Argüelles[1]; J. Stegmann[1]
[1]Rare Diseases Community, Buenos Aires, Argentina; [2]Facultad de Filosofía y Letras, Universidad de Buenos Aires, Buenos Aires, Argentina

EPV-970 | Anti-Yo antibody-mediated paraneoplastic cerebellar degeneration syndrome with pathological neuroimaging

M. Martínez Palicio; P. Pinzón Benavidez; A. Cordero Novo; D. Alonso Vallín; P. Rozas Fernández; R. Suarez Moro; M. Sánchez-Suarez López; J. Granda Méndez; M. Álvarez Álvarez
Neurología, Hospital Universitario Cabueñes, Gijón, España

EPV-971 | Indian perspective of patients with peripheral neuropathies receiving Gabapentinoid – A cross-sectional study

P. Agarwal[1]; M. Khalse[2]; P. Deshmukh[3]; K. Patel[4]
[1]Principle Director and Head Neurology Max Super specialty Hospital, Delhi; [2]Medical Affairs, Lupin Limited; [3]Medical Affairs, Lupin Limited; [4]Medical Affairs, Lupin Limited

EPV-972 | Artificially induced Mismatch-Training (AIM) and its impact on effective motor learning

P. Arndt[1]; H. Am Ende[2]; A. Oppermann[1]; H. Köhler[3]; A. Schmidt[3]; S. Brodoehl[4]; C. Klingner[4]; F. Wagner[4]
[1]IZKF Graduate Program Experimental Medicine, Jena University Hospital, Jena, Germany; [2]Else Kröner Graduate School for Medical Students „JSAM", Jena University Hospital, Jena, Germany; [3]Biomagnetic Center, Jena University Hospital, Jena, Germany; [4]Department of Neurology, Jena University Hospital, Jena, Germany

EPV-973 | Neurological manifestations of thrombotic thrombocytopenic purpura (TTP): Diagnostic and therapeutic difficulties

M. Nieto Palomares; M. El Harmochi Daoud; I. Martín Sorbrino; A. García Maruenda; P. Gómez Ramírez; A. Sánchez Gómez; A. Hernández González; M. Del Real Francia
Neurology Department, Hospital General Universitario de Ciudad Real, Ciudad Real, Spain

EPV-974 | rTMS as part of complex neurorehabilitation affecting motor symptoms in patients with Parkinson's

P. Lambeva; P. Bozhinov
Medical Center Galileo, Pleven, Bulgaria

EPV-975 | Aseptic meningitis associated with hyperalgic radiculitis – difficulties in establishing the diagnosis

C. Profirescu; M. Martoiu; S. Petrescu; C. Panea
Elias Emergency and University Hospital, Bucharest

EPV-976 | Role of anti-neural antibodies in paraneoplastic neurological syndromes: A cohort study

R. García Yu; G. Zmork Martínez; P. López-Grueiro Valcarce; A. García Leal; M. Fernández-Fournier Fernández; A. Tallón Barranco; L. Lacruz Ballester
Neurology, La Paz University Hospital, Madrid, Spain

EPV-977 | Neurological complications of graft-versus-host disease

R. Rodrigues[1]; C. Santos Silva[1,2]; C. Serrão[1]; D. Cruz[1]; M. Oliveira Carvalho[1]; V. Rodrigues[3]; J. Lacerda[4]; M. Oliveira Santos[1,2]
[1]Neurology, Department of Neurosciences and Mental Health, Unidade Local de Saúde de Santa Maria, Centro Hospitalar Universitário Lisboa-Norte, Lisbon, Portugal; [3]Internal Medicine, Medicine Department, Unidade Local de Saúde de Santa Maria, Centro Hospitalar Universitário Lisboa-Norte, Lisbon, Portugal; [4]Haematology and Bone Marrow Transplantation, Oncology Department, Unidade Local de Saúde de Santa Maria, Centro Hospitalar Universitário Lisboa-Norte, Lisbon, Portugal

EPV-978 | Intraparenchymal hematomas as a manifestation of posterior reversible encephalopathy syndrome: About a case

S. Saaf; Y. Mimouni; S. Lhassani; Z. El Yacoubi; M. El Azhari; M. Hakimi; J. Aasfara; A. Hazim; H. Ouhabi
Department of Neurology, Cheikh Khalifa University Hospital, Casablanca, Morocco

EPV-979 | Impairment based aphasia therapy: Impact on grammar in patients with post stroke non-fluent aphasia

S. Alizada[1]; A. Ozcan Vural[2]; V. Ozturk[1]; G. Kuruoğlu[2]
[1]Department of Neurology, Dokuz Eylul University; [2]Department of Linguistics, Dokuz Eylul University

EPV-980 | Multiple cranial neuropathy in atypical Ramsay-Hunt syndrome mimicking vertebral artery dissection: A case report

A. Saraceno[1]; L. Mumoli[2]; E. Fratto[1]; V. Laterza[1]; A. Fratto[2]; E. Colosimo[2]; D. Pirritano[2]; A. Clodomiro[2]; T. Tallarico[2]; A. Lucisano[2]; E. Le Piane[2]; M. Pantusa[2]; R. Iannacchero[2]; G. Frontera[2]; D. Bosco[2]
[1]Institute of Neurology, Department of Medical and Surgical Sciences, University Magna Graecia of Catanzaro, Italy; [2]Institute of Neurology, Department of Neurosciences, Presidio Ospedaliero "Pugliese", AOU "Renato Dulbecco", Catanzaro, Italy

EPV-981 | A potential aggravating factor in reversible posterior leukoencephalopathy syndrome

S. Ștefan; F. Antochi; P. Ioan; M. Moldovan; A. Ribigan
Department of Neurology, Bucharest University Emergency Hospital, Bucharest, Romania

EPV-982 | Adopting telehealth solutions for multiple sclerosis (MS) patients: Utilization trends and readiness assessment

F. Zare[1]; R. Rahimi[2]; H. Zehtab Hashemi[3]; L. Faghani[4]; G. Ghaedi[5]; S. Nabavi[6]
[1]Department of Laboratory Medicine, Faculty of Medical sciences, Gorgan Branch, Islamic Azad University, Gorgan, Iran; [2]Department of Medical Informatics, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran; [3]Department of Health Informatics, Smart University of Medical Sciences, Tehran, Iran; [4]Arya group for treatment and research for multiple Sclerosis, Tehran, Iran; [5]Psychiatry Department, Mostafa medical center, Shahed University, Tehran, Iran; [6]Regenerative Medicine Department, MS and Neurology Group, Royan institute for stem cell biology and Technology, Tehran, Iran

EPV-983 | To study Ophthalmic artery hemodynamics in patients with Optic Neuritis vs Ischemic Optic Neuropathy vs controls

N. Sharma
PGIMER Chandigarh, India

EPV-984 | Safety and efficacy of ofatumumab during one-year treatment: A multicentre study

S. Pastor-Yvorra[1]; L. Santos[2]; C. González[3]; A. Gómez[2]; E. Sturla[2]; J. Martínez[2]; P. Nieto[2]
[1]Neurology Department, Hospital General Universitario de Villalba; [2]Neurology Department, Hospital General Universitario Rey Juan Carlos; [3]Neurology Department, Hospital General Universitario Infanta Elena

EPV-985 | Sanskrit Vedic Chants intervention provides beneficial behavioral and biological changes in Autistic spectral disorders

S. Narayan
Department of Neurology, JIPMER, Pondicherry, India

EPV-986 | Investigating the effect of anti-meningococcal vaccine in patients on Eculizumab therapy

S. Marini[1]; G. Gyamfi-Brobbey[2]; S. Falso[1]; E. Sabatelli[1]; M. Marini[1]; R. Borrow[2]; R. Iorio[3]
[1]Università Cattolica del Sacro Cuore, Rome, Italy; [2]Vaccine Evaluation Unit, UK Health Security Agency, Manchester Royal Infirmary, Manchester, UK; [3]IRCCS Fondazione Policlinico A. Gemelli, Rome, Italy

EPV-987 | Long-term EEG reveals distinct variability patterns in epilepsy after autoimmune encephalitis

S. Neidhart; O. Kohnen; L. Imbach
Swiss Epilepsy Center, Zurich, Switzerland

EPV-988 | Effect of ascites paracentesis on cognitive performance in patients with hepatic encephalopathy

I. Straka[1]; M. Komlosi[2]; M. Mikusiakova[1]; P. Valkovic[1]
[1]2nd Department of Neurology, Faculty of Medicine, Comenius University Bratislava, Slovakia; [2]3rd Department of Internal Medicine, Faculty of Medicine, Comenius University Bratislava, Slovakia

EPV-989 | The effectiveness of prosthetic and exoskeleton control through brain-computer interfaces in rehabilitation

T. Cristina[1]; M. Mendes[2]
[1]Federal University of Pernambuco; [2]Uninabuco

EPV-990 | Long-term effect of COVID on the brain: A systemic review and meta-analysis

T. Elboraay[1]; H. Elsaeed AboElfarh[2]; M. Elmallahy[3]; H. Ahmed Aboeldahab[4]; L. Said Mansour[5]; M. Elsayed[1]; O. El sayed Rageh[3]; A. Khaled Abd Eltawab[6]; S. F Mohamed[7]; M. A. Ebada[8]
[1]Faculty of Medicine Zagazig University, Egypt; [2]Neurology Department, Faculty of Medicine, Mansoura University, Egypt; [3]Faculty of Medicine Tanta University, Egypt; [4]Clinical Research Department, Al-Gomhoria General Hospital,MoHP, Egypt; [5]Faculty of Medicine and Internal Medicine Resident at Damanhour Teaching Hospital, Egypt; [6]Urology Department Sednawy Health Insurance Hospital, Egypt; [7]Alexandria Faculty of Medicine, Egypt; [8]Egyptian Fellowship Board of Neurology, Cairo, Egypt

EPV-991 | Ophthalmoplegic migraine – A longitudinal interventional follow up study from Indian subcontinent

D. Trivedi[1]; D. Kiran[2]; D. Datta[1]; D. Shobhana[1]
[1]Department of Neurology, Institute of Neuroscience Kolkata, India; [2]Calcutta National Medical College, Kolkata, India

EPV-992 | Steeplechase: Challenges in using published repository data

U. Karadkar[1]; C. Hammerer[2]; W. Struhal[2]
[1]Center for Interdisciplinary Research on Aging and Care, University of Graz, Graz, Austria; [2]Karl Landsteiner University of Health Sciences, Department of Neurology, University Hospital Tulln, Tulln, Austria

EPV-993 | A rare case of pachymeningitis in the context of Lymphoplasmacyte-rich, grade 1 en plaque meningioma

E. Koumasopoulos[1]; A. Daponte[1]; G. Velonakis[2]; C. Zorzos[3]; N. Georgakoulias[4]; V. Zouvelou[1]; M. Rentzos[1]
[1]*First Department of Neurology, Aeginition Hospital, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece;* [2]*Radiology Research Unit, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece;* [3]*Pathology Department, "George Gennimatas" General Hospital of Athens, Athens, Greece;* [4]*Department of Neurosurgery, Athens General Hospital "Georgios Gennimatas," Athens, Greece*

EPV-994 | VOC-ALS: A smartphone-based app for VOiCe analysis in amyotrophic lateral sclerosis (ALS) patients

V. Iuzzolino[1]; M. Spisto[2]; L. Verde[3]; I. De Falco[4]; G. Sannino[4]; R. Dubbioso[1]
[1]*Department of Neurosciences, Reproductive Sciences and Odontostomatology, University of Naples "Federico II", Naples, Italy;* [2]*Department of Psychology of the University of Campania "Luigi Vanvitelli", Caserta, Italy;* [3]*Department of Mathematics and Physics of the University of Campania "Luigi Vanvitelli", Caserta, Italy;* [4]*National Research Council of Italy (CNR), Institute for High-Performance Computing and Networking (ICAR), Naples, Italy*

EPV-995 | Posterior reversible encephalopathy syndrome (PRES) a rare presentation of granulomatosis with polyangiitis

V. Mendes Ferreira; F. Serrazina; A. Caetano; M. Fernandes
Neurology Department, Hospital de Egas Moniz, Lisbon, Portugal

EPV-996 | Development of a self-help digital intervention for functional cognitive disorder (Mementum)

V. Cabreira[1]; L. Frostholm[2]; J. Stone[1]; A. Carson[1]
[1]*Centre for Clinical Brain Sciences, University of Edinburgh, Edinburgh, UK;* [2]*Department of Clinical Medicine, Aarhus University Hospital, Aarhus, Denmark*

EPV-997 | Rehabilitation approach for treatment of children with ASD

T. Voloshyn
KIRC

EPV-998 | Clinical global impression in assessing IVIg response in CIDP patients: Learnings from the PRISM study

Y. Rajabally[1]; R. Ouaja[2]; E. Nobile-Orazio[3]
[1]*Aston University, UK;* [2]*LFB;* [3]*IRCCS Humanitas Clinical Institute, Milan*

EPV-999 | Beyond the norm: Ischemic stroke in Behcet's disease about two cases

Y. Boubaker; M. Mhiri; R. Ben Dhia; N. Gouta; M. Frih-Ayed
Department of Neurology, Fattouma Bourguiba University Hospital, Monastir, Tunisia

EPV-1000 | A prospective study to screen for cochleo-vestibular disorders in individuals with multiple sclerosis

Y. Zakaria[1]; A. Zantaoui[2]; N. Kissani[1]; M. Chraa[1]
[1]*Neurology Department, Mohamed VI Hospital University, Marrakesh, Morocco;* [2]*ENT-Neck and Head Surgery Department, University Medical Center Mohammed VI, Marrakech, Morocco*

EPV-1001 | Brief intervention as a general method to address prescription or non-prescription medication misuse

M. Torheim Bjelkarøy[1]; T. Ghazal Siddiqui[1]; T. Breines Simonsen[1]; S. Ma[2]; J. Gjerstad[3]; C. Lundqvist[4]
[1]*Health Services Research, Akershus University Hospital;* [2]*University of Oslo, Campus Akershus University Hospital;* [3]*Department of Research & Development in Mental Health, Akershus University Hospital;* [4]*Health Services Research, Akershus University Hospital and Inst.Clin.Med, University of Oslo, Norway*

EPV-1002 | Dermatomal contact heat evoked potentials in non-myelopathic degenerative cervical spinal cord compression

A. Betik[1]; E. Vlckova[1]; Z. Kadanka jr.[1]; M. Nemec[1]; L. Joppekova[1]; T. Horak[1]; Z. Kadanka[1]; H. Magda[1]; J. Bednarik[1]
[1]*Department of Neurology, University Hospital Brno, Brno, Czechia; Faculty of medicine, Masaryk University, Brno, Czechia*

EPV-1003 | Botulinum toxin A for neuropathic pain – A systematic review and meta-analysis

A. Datta Gupta
University of Adelaide

EPV-1004 | Headache after surgical sealing of cerebrospinal fluid leaks in patients with spontaneous intracranial hypotension

A. Scutelnic[1]; A. Lüthi[1]; I. Stöckli[1]; L. Justus[1]; B. Bracher[1]; A. Klein[1]; N. Slavova[1]; E. Morel[1]; F. Riederer[1]; T. Doborcky[2]; E. Piechowiak[2]; C. Jesse[3]; C. Ulrich[3]; R. Schär[3]; C. Schankin[1]
[1]Department of Neurology, Inselspital, University Hospital, University of Bern, Bern, Switzerland; [2]Institute of Diagnostic and Interventional Neuroradiology, Inselspital, University Hospital and University of Bern, Bern, Switzerland; [3]Department of Neurosurgery, Inselspital Bern University Hospital and University of Bern, Bern, Switzerland

EPV-1005 | Education needs in palliative care and ACP of Italian residents in neurology: An online survey

A. Bombaci[1]; F. Di Lorenzo[2]; E. Pucci[3]; A. Solari[4]; S. Veronese[5]
[1]"Rita Levi Montalcini" Department of Neuroscience, University of Turin, Turin, Italy; [2]IRCCS Fondazione Santa Lucia, Rome, Italy; [3]UOC Neurologia – AST-Fermo, Fermo, Italy; [4]Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy; [5]Fondazione FARO ETS, Turin, Italy

EPV-1006 | Reversible cerebral vasoconstriction syndrome: Diagnosis and treatment monitoring with transcranial ultrasound

A. Pes; C. Baracchini
Neurology Department, Hospital of Padua, Italy University of Padua School of Medicine – Italy

EPV-1007 | Surgical vs conservative management of chronic sciatica (> 3 months) due to lumbar disc herniation

A. Hammed[1]; C. Tanislav[1]; A. Al-Qiami[2]; H. Alsalhi[3]; A. Alzawahreh[4]; A. Almansi[5]; M. Masoud[6]; W. Habra[1]
[1]Department of Geriatrics and Neurology, Diakonie Hospital Jung Stilling Siegen, Germany; [2]Faculty of Medicine, Kassala University, Kassala, Sudan; [3]Faculty of Medicine, The Hashemite University, Zarqaa, Jord; [4]Faculty of medicine, The Hashemite University, Zarqa, Jordan; [5]Prince Hamza Hospital, Amman, Jordan; [6]Faculty of Medicine, Al-Azhar University Damietta, Egypt

EPV-1008 | Cytotoxic lesion of corpus callosum due to thermogenic supplement

H. Im; J. Lee
Department of Neurology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea/Seoul, Republic of Korea

EPV-1009 | Segmental spinal myoclonus: An unusual presentation of spinal dural arteriovenous fistula

Á. Camero Piñatel[1]; C. Valderrama Martín[1]; P. Tomás Muñoz[2]; M. Molina Haro[1]; F. Escamilla Sevilla[1]
[1]Department of Neurology, Virgen de las Nieves University Hospital, Granada, Spain; [2]Department of Neuroradiology, Virgen de las Nieves University Hospital, Granada, Spain

EPV-1010 | Fluctuating paraparesis due to spinal vascular micromalformation, a case report

A. Campos Villegas; A. Aguilar Monge; M. Afkir Ortega; A. Gómez Gonzalez; A. Guzmán Tellez; M. Mañez Sierra
Neurologia, Hospital Universitario Virgen de la Victoria, Málaga, España

EPV-1011 | Objective pain assessment in lower back pain: Integrating clinical treatment and biochemical markers

A. Kulyk; A. Payenok; B. Zadorozhna
Department of Neurology and Neurosurgery FPGE, Danylo Halytsky Lviv National Medical University, Lviv, Ukraine

EPV-1012 | Potential involvement of the mechanosensitive channel Piezo1 in regulating axonal regeneration after spinal cord injury

A. Li; Y. Liang; W. Yu; H. Guo; H. Liu; Y. Li; Y. Xu; P. Yu
Guangdong-Hong Kong-Macau Institute of CNS Regeneration, Jinan University, Guangzhou, Guangdong, China

EPV-1013 | Longitudinally extensive transverse myelitis, thinking beyond

M. Angela; L. Lidia Binela; R. Paula; M. Alba
Neurology, Hospital Joan XXIII, Tarragona, Spain

EPV-1014 | Improving palliative care in Parkinson's Disease: A Case on subcutaneous apomorphine infusion for patient comfort

M. Auffret
Manon Auffret: France Développement Electronique (FDE), Monswiller, France; Institut des Neurosciences Cliniques de Rennes (INCR), Rennes, France; Behavior & Basal Ganglia Research Unit, CIC-IT, CIC1414, Pontchaillou University Hospital, & University

EPV-1015 | Risk Factors affecting the therapeutic effect of botulinum toxin A on chronic migraine: A retrospective study

B. Medeiros[1]; M. Andrade[2]; I. Andrade[3]; R. Dias[4]; M. Pinto[5]; A. Costa[4]
[1]Neurology Department, Hospital do Divino Espírito Santo, E.P.E., Açores, Portugal; [2]Faculty of Medicine, University of Porto, Porto; [3]Department of Physical Medicine and Rehabilitation, Centro de Medicina de Reabilitação de Alcoitão, Cascais, Portugal; [4]Clinical Neuroscience and Mental Health Department, Faculty of Medicine, University of Porto, Porto, Portugal; [5]Neurology Department, Centro Hospitalar Universitário de São João, E.P.E., Porto, Portugal

EPV-1016 | Clinical deterioration secondary to corticosteroid: Uncovering spinal dural arteriovenous fistula, a great imitator

C. Algar Ramírez; Á. Sánchez-Guijo Benavente; A. Sarmiento Pita; A. Maestre Martínez
Department of Neurology, Hospital Regional Universitario de Málaga, Málaga, Spain

EPV-1017 | Ultrahigh-dose methylcobalamin's impact on clinical outcomes in amyotrophic lateral sclerosis: Meta-analysis

C. Moura[1]; L. Campos[2]; O. Rocha[3]; C. Pupe[1]
[1]Universidade Federal Fluminense; [2]Faculdade de Ciências Médicas, Universidade de Pernambuco, Recife, Pernambuco, Brazil; [3]Universidade Federal do Piauí, Teresina, Piauí, Brazil

EPV-1018 | Clinical outcomes of patients with chronic immune-mediated neuropathies treated with subcutaneous immunoglobulin

C. Tan
Neurology Unit, Department of Medicine, Faculty of Medicine, Universiti Malaya, Kuala Lumpur, Malaysia

EPV-1019 | The electrophysiological evaluation of replacement therapy on small fiber neuropathy due to B12 deficiency

D. Agircan[1]; N. Bal[1]; T. Gesoglu-Demir[1]; A. Gocmen[2]; O. Ethemoglu[1]
[1]Department of Neurology, Harran Faculty of Medicine, Harran University, Sanliurfa, Turkey; [2]Department of Neurology, Sanliurfa Training and Research Hospital, Sanliurfa, Turkey

EPV-1020 | Patient reported outcomes in a 2-week randomized trial of a central muscle relaxant in acute low back pain with sciatica

L. Dabasi[1]; K. Dénes[1]; B. Dobi[2]; N. Tegze[1]; Z. Arány[1]; A. Csillik[1]; A. Kelemen[1]; B. István[3]; D. Bereczki[1]
[1]Department of Neurology, Semmelweis University, Budapest, Hungary; [2]HUN-REN SU Neuroepidemiological Research Group, Budapest, Hungary; [3]Cortex Pharma Services, Budapest, Hungary

EPV-1021 | Fibrocartilaginous embolism as a rare condition of acute paraplegia

D. Cerdán Santacruz; C. Gómez López de San Román; M. Capra; M. Vargas Cobos; L. Caballero Sánchez; I. Bermejo Casado; A. Castrillo Sanz; A. Mendoza Rodríguez
Hospital Complex of Segovia, Neurology

EPV-1022 | Lack of neuro-palliative services adversely affects motor neurone disease patients in Kenya: An illustrative case series

D. Sokhi[1]; E. Kamadi[1]; L. Barasa[1]; M. Wendo[1]; H. Ekea[1]; J. Hooker[1]; J. Weru[2]
[1]*Department of Medicine, Aga Khan University, Nairobi, Kenya;* [2]*Department of Oncology/Haematology, Aga Khan University, Nairobi, Kenya*

EPV-1023 | Peripheral nervous system dysfunction in systemic autoimmunity: A clinical insight

N. Blidaru[1]; A. Tanasoiu[1]; A. Constantinescu[1]; S. Neculai[1]; D. Tulba[2]; B. Popescu[3]
[1]*Department of Neurology, Colentina Clinical Hospital, Bucharest;* [2]*Carol Davila" University of Medicine and Pharmacy, Bucharest;* [3]*Department of Molecular Medicine, "Victor Babeș" National Institute of Pathology, Bucharest*

EPV-1024 | Psychological distress as a chronification factor for headache

G. Oxana; E. Calugareanu; L. Rotaru; I. Moldovanu
Diomid Gherman Institute of Neurology and Neurosurgery, Chisinau, The Republic of Moldova

EPV-1025 | Effect of tofacitinib and adalimumab in patients with rheumatoid arthritis with signs of central sensitization

E. Filatova[1]; A. Karateev[1]; A. Potapova[1]; S. Morozova[2]; E. Polishchuk[1]; E. Luchikhina[3]; V. Amirdzhanova[1]; E. Zotkin[1]; A. Lila[1]
[1]*VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation;* [2]*Scientific Center of Neurology, Moscow, Russian Federation;* [3]*Moscow Regional Scientific Research Clinical Institute n.a. M.F. Vladimirsky, Moscow, Russian Federation*

EPV-1026 | Which are the factors affecting the topography of nitrous oxide-induced neurological complications?

E. Solé Cruz[1]; E. Fortanier[1]; F. Hilezian[2]; A. Maarouf[2]; C. Boutiere[2]; S. Demortiere[2]; A. Rico[2]; E. Delmont[1]; J. Pelletier[2]; S. Attarian[1]; B. Audoin[2]
[1]*Reference Center for Neuromuscular Diseases and ALS, La Timone University Hospital, APHM, Marseille, France;* [2]*Inflammatory Neurology Department, La Timone University Hospital, APHM, Marseille, France*

EPV-1027 | Head injury in the city of Helsinki: The HEAD Helsinki study – design, rationale and patient characteristics

J. Kinnunen[1]; J. Satopää[2]; I. Marinkovic[1]; H. Isokuortti[3]; M. Patronen[4]; O. Halminen[5]; O. Raassina[6]; R. Autio[7]; Ö. Tanzer[8]; R. Vataja[8]; J. Parkkola[9]; P. Randen[10]; M. Pystynen[10]; M. Kuisma[10]; M. Lehto[11]; J. Haukka[12]; M. Linna[5]; J. Putaala[1]; M. Niemelä[2]
[1]*Department of Neurology, University of Helsinki, Helsinki University Hospital, Helsinki, Finland;* [2]*Department of Neurosurgery, University of Helsinki, Helsinki University Hospital, Helsinki, Finland;* [3]*Department of Intensive Care, University of Helsinki, Helsinki University Hospital, Helsinki, Finland;* [4]*Statistics Finland, Helsinki, Finland;* [5]*Department of Industrial Engineering and Management, Aalto University, Espoo, Finland;* [6]*Department of Radiology, University of Helsinki, Helsinki University Hospital, Helsinki, Finland;* [7]*Department of Radiology, Vaasa Central Hospital, Vaasa, Finland;* [8]*Department of Psychiatry, University of Helsinki, Helsinki University Hospital, Helsinki, Finland;* [9]*Apotti Oy, Electronic social and health record provider, Helsinki, Finland;* [10]*Department of Emergency Medicine & Services, University of Helsinki, Helsinki University Hospital, Helsinki, Finland;* [11]*Department Internal Medicine, University of Helsinki, Helsinki University Hospital, Helsinki, Finland;* [12]*Department of Public Health, Clinicum, University of Helsinki, Finland*

EPV-1028 | Mortality of head injury in the city of Helsinki: The HEAD Helsinki study

J. Kinnunen[1]; J. Satopää[2]; I. Marinkovic[1]; H. Isokuortti[3]; M. Patronen[4]; O. Halminen[5]; O. Raassina[6]; R. Autio[7]; Ö. Tanzer[8]; R. Vataja[8]; J. Parkkola[9]; P. Randen[10]; M. Pystynen[10]; M. Kuisma[10]; M. Lehto[11]; J. Haukka[12]; M. Linna[5]; J. Putaala[1]; M. Niemelä[2]

EPV-1032 | Facial quantitative sensory testing in patients with trigeminal neuralgia

K. Shin; J. Eun

Department of Neurology, Haeundae-Paik Hospital, Inje University, Busan, Korea

EPV-1033 | Post-operative infection in Unilateral Biportal Endoscopy (UBE): A systematic review and meta-analysis

H. Hashim[1]; G. Hasan[2]; A. Al-Obaidi[3]

[1]University of Warith Al-Anbiyaa, College of Medicine; [2]Royal Private Hospital; [3]University of Baghdad, College of Medicine

EPV-1034 | Tetraplegia reversed with a simple neck collar: A case of spontaneous spinal epidural haematoma

M. González Gómez; M. Hernández Ramírez; J. Villamor Rodríguez; F. Sánchez García; D. Barbero Jiménez; J. Celi Celi; M. Mas Serrano
Neurology Department, Guadalajara University Hospital, Guadalajara, Spain

EPV-1035 | Variations in the atlantoaxial joint anatomy detected by computer tomography in control subjects

H. Peltonen[1]; K. Berghem[2]; O. Rebekka[3]; J. Honkaniemi[4]
[1]Department of Psychiatry, Tampere University Hospital, Tampere, Finland; [2]Department of Radiology, Tampere University Hospital, Tampere, Finland; [3]Department of Neurology and Rehabilitation, Tampere University Hospital, Tampere, Finland; [4]Department of Neurology, Tampere University Hospital, Tampere, Department of Neurology, Vaasa Central Hospital, Vaasa and University of Turku, Turku, Finland

EPV-1036 | Fatal posterior reversible encephalopathy syndrome associated with atypical presentation Guillain-Barré syndrome

I. Del Pino Díaz; Á. Morales Lahoz; A. Dengra Maldonado; M. Carrasco García; R. Calle Calle
Neurology Department, Hospital Universitario San Cecilio, Granada, Spain

EPV-1037 | Noninvasive deep brain stimulation

T. Riis; B. Mickey; J. Kubanek
University of Utah

EPV-1038 | Polyradiculoneuropathy following bariatric surgery – A clinical insight and review

J. Diniz[1]; I. Bernardo[1]; R. Sousa[1]; C. Bernardes[2]; Ú. Martins[1]
[1]Serviço de Medicina Física e de Reabilitação, Unidade Local de Saúde do Tâmega e Sousa, Penafiel, Portugal; [2]Serviço de Neurologia, Unidade Local de Saúde de Coimbra, Coimbra, Portugal

EPV-1039 | Carotid Free-Floating Thrombus case series diagnosed by duplex ultrasonography: Treatment options and risk of recurrence

J. Álvarez-Cienfuegos; C. Vera Cáceres; R. Ferrer Tarrés; M. García Huguet; I. Saurina Navarro; C. Martínez Follana
Hospital Universitari de Girona Dr. Josep Trueta

EPV-1040 | Cefepime-induced neurotoxicity: An underestimated cause of in-hospital complications

K. Petrosyan
Department of General and Vascular Neurology, Saint Gregory the Illuminator Medical Center, Yerevan, Armenia

EPV-1041 | Correlation between hyperechogenicity of substantia nigra and olfactory dysfunction in patients with Parkinson's disease

J. Kozel[1]; E. Augste[1]; P. Michalčová[1]; P. Bártová[2]; D. Šalounová[1]; D. Školoudík[1]
[1]Centre for Health Research, Faculty of Medicine, University of Ostrava, Ostrava, Czechia; [2]Neurology, University Hospital Ostrava, Ostrava, Czechia

EPV-1042 | Stylohyoid syndrome (Eagle's syndrome): A case report

T. Makeeva
Pain Management Center, Klinika Gorod Zdorovia, Voronezh, Russian Federation

EPV-1043 | Isolated conus medullaris demyelinating lesion following anti-TNF-α therapy

L. Quiros Illan[1]; I. Martin Sobrino[2]; P. Nieto Palomares[2]; A. Garcia Maruenda[2]; A. Franco Salinas[3]; S. Carrasco[1]; M. Muñoz Pasadas[1]
[1]Neurology Department, Hospital Santa Barbara, Puertollano, Spain; [2]Neurology Department, Hospital General Universitario Ciudad Real, Spain; [3]Neurology Department, Hospital Sanitas Virgen del Mar, Madrid, Spain

EPV-1044 | Pregnenolone deficiency in fibromyalgia syndrome (FMS) – A diagnostic marker and potential therapeutic target?

W. Maier-Janson
Neurological Practise, Ravensburg, Germany

EPV-1045 | Characteristics of sleep and REM sleep without atonia in a group of patients affected by PANS

P. Congiu[1]; A. Gagliano[2]; M. Mascia[3]; L. Tamburrino[1]; M. Figorilli[1]; R. Ferri[4]; M. Puligheddu[1]
[1]Sleep Disorders Center, Department of Medical Sciences and Public Health, University of Cagliari; [2]Section of Neuroscience & Clinical Pharmacology, Department of Biomedical Sciences, University of Cagliari, Cagliari, Italy; Child & Adolescent Neuropsychiatry Unit, "Azienda Ospedaliera Brotzu" Hospital Trust, Cagliari, Italy, Cagliari, Italy; [3]UOC Neurology, AOU Cagliari, Cagliari; [4]Oasi Research Institute – IRCCS, Troina, Italy

EPV-1046 | Electrodiagnostic testing and prognosis of Guillain Barré syndrome – A case series

M. Almeida; F. Gomes; A. Alferes; A. Matos; A. Geraldo; L. Almendra; L. Negrão
Neurology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

EPV-1047 | Evidence of partial response to Safinamide in chronic patients with Parkinson's disease-related pain

M. Moreno-Verdú[1]; Y. González-Zamorano[2]; J. Herreros-Rodríguez[3]; V. Gómez-Mayordomo[4]; A. Méndez[5]; J. Romero[1]
[1]Brain Injury and Movement Disorders Neurorehabilitation Group (GINDAT), Francisco de Vitoria University, Spain; [2]Department of Physical Therapy, Occupational Therapy, Physical Medicine and Rehabilitation, Rey Juan Carlos University, Spain; [3]Department of Neurology, University Hospital Infanta Leonor, Spain; [4]Neuroscience Institute, Vithas La Milagrosa, Spain; [5]Department of Neurology, University Hospital 12 de Octubre, Spain

EPV-1048 | Evidence for independent pathways of fatigue and pain in people with Parkinson's disease-related pain?

M. Moreno-Verdú[1]; Y. González-Zamorano[2]; J. Herreros-Rodríguez[3]; A. Hurtado-Martínez[1]; A. Lerín-Calvo[4]; J. Romero[1]
[1]Brain Injury and Movement Disorders Neurorehabilitation Group (GINDAT), Francisco de Vitoria University, Spain; [2]Department of Physical Therapy, Occupational Therapy, Physical Medicine and Rehabilitation, Rey Juan Carlos University, Spain; [3]Department of Neurology, University Hospital Infanta Leonor, Spain; [4]Department of Physiotherapy, CSEU La Salle, Universidad Autónoma de Madrid, Spain

EPV-1049 | Improving cost effectiveness of IVIG in immune mediate peripheral neuropathies in the Maltese Islands

M. Bonello; M. Vella; S. Micallef; C. Vella
Department of Neurosciences, Mater Dei Hospital, Malta

EPV-1050 | Laughing gas lament: The neurological impact of recreational nitrous oxide inhalation

M. Docan[1]; E. Marin[2]; A. Hanganu[2]; A. Arbune[1]; M. Marian[2]; A. Ghiuță[1]; B. Toron[1]; L. Zurini[1]; A. Dulămea[2]
[1]Neurology, Fundeni Clinical Institute, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

EPV-1051 | Clinical relevance of Neutrophil-to-Lymphocyte Ratio in Guillain-Barré Syndrome

A. Ellouze[1]; S. Mejdoub[1]; A. Trigui[2]; N. Farhat[2]; S. Feki[1]; W. Ben moallem[1]; M. Dammak[2]; H. Hachicha[1]
[1]Immunology Laboratory, Habib Bourguiba University Hospital, Sfax, Tunisia; [2]Neurology Department, Habib Bourguiba University Hospital, Sfax, Tunisia

EPV-1052 | Sovateltide (IRL-1620) enhances motor function and reduces hyperalgesia in a rodent model of spinal cord injury

OPR-116 | Auricular vagal nerve stimulation in patients with mild cognitive impairment due to Alzheimer's disease

A. Broncel[1]; M. Krawczyk[1]; T. Ben David[1]; J. Konopacki[1]; E. Ben-Menachem[2]
[1]*Neuromedical, Clinical Research Department, Lodz, Poland;* [2]*Department of Clinical Neuroscience Sahlgren Academy Gotebrog University, Goteborg, Sweden*

Background and Aims: The study was conducted on patients diagnosed with mild cognitive impairment (MCI) due to Alzheimer's disease (AD). Auricular transcutaneous vagal nerve stimulation (atVNS) was applied using the VGuard device, which was specifically designed to minimize stimulation side effects and was applied only during sleep, a period characterized by higher activity of the vagal nerve.

Methods: The study was a randomized, double-blind, placebo-controlled trial conducted in a group of 51 patients with AD, 35 patients in the treatment arm and 16 patients in the placebo arm. The study consisted of a 12 week treatment period, with an extension of an additional 12 week period for 20 patients. After the extension period, stimulation was terminated. 15 patients underwent cognitive evaluation after an additional 24 weeks.

Results: The study showed statistically significant cognitive improvement between placebo and active treatment arms with $p < 0.01$ in the ADAS-COG, as well as improvements in Mini Mental Status Examination (MMSE), Color Trial Test (CTT) and Verbal Memory Probing (VMP). Cognitive improvement observed in the 15 patients during the stimulation period returned to baseline values after 24 weeks of no treatment.

Conclusion: The results of this randomized, doubled-blind, placebo-controlled study demonstrate that atVNS using the Vguard device significantly improved cognition in patients with MCI due to AD and may represent an effective therapeutic approach in delaying the conversion of MCI into initial stages of AD.

Disclosure: The study was co-financed by the European Funds under Priority Axis I: Research, development, and commercialization of knowledge of the Regional Operational Programme of the Lodz Voivodeship Poland for the years 2014-2020. Project nr RPLD.01.02.02-10-0067/17-00.

OPR-117 | Opioids and dementia; nationwide Danish population-based study

N. Pourhadi[1]; J. Janbek[1]; C. Gasse[2]; T. Laursen[3]; G. Waldemar[1]; C. Jensen-Dahm[1]
[1]*Danish Dementia Research Centre, Department of Neurology, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark;* [2]*Department of Affective Disorders, Aarhus University Hospital Psychiatry, Aarhus, Denmark;* [3]*National Centre for Register-Based Research, Aarhus University, Aarhus, Denmark*

Background and Aims: Opioid use has been associated with short-term adverse effects on cognition, but long-term studies on opioid-associated risk of dementia are lacking. We assessed associations between cumulative non-cancer opioid use and risk of age-related all-cause dementia.

Methods: Using national Danish registries, we conducted a nationwide nested case–control study within a cohort of 1,872,854 individuals aged 60–75 years, without dementia, cancer, or opioid addiction followed from 2000–2020. By incidence-density-matching, each dementia case was matched to five controls. Use of opioids was evaluated from redeemed prescriptions translated into total standardized doses (TSD). Conditional logistic regression yielded adjusted incidence rate ratios (IRR).

Results: During follow-up, 93,638 individuals developed dementia. Opioid exposure up to 90 TSDs was not associated with increased dementia risk. Use of more than 90 TSDs was associated with an increased dementia risk occurring before age 90 years with indication of a dose–response pattern. IRR of dementia occurring at age 60–69 years was 1.28 (1.16–1.41) for 91–200 TSDs of opioid use. Corresponding IRRs for ages 70–79 years and 80–89 years at dementia diagnosis were 1.16 (1.10–1.21) and 1.09 (1.04–1.14), respectively. Associations persisted in individuals with specified chronic non-cancer pain diagnoses and with exclusive use of weak opioids.

Conclusion: Opioid use up to 90 TSDs did not show increased dementia risk. Exposure to more than 90 TSDs was associated with a slightly increased dementia risk, also with use of weak opioids only and among individuals with chronic non-cancer pain. Further studies are needed to determine if these findings represent causality between opioid use and dementia.

Disclosure: Nothing to disclose.

OPR-118 | **The diagnostic value of transcranial ultrasound in Swedish parkinsonism patients: A retrospective cohort study**

M. Stiehm[1]; C. Nilsson[2]
[1]*Department of Neurology, Skåne University Hospital, Malmö, Sweden;* [2]*Department of Clinical Sciences, Lund University & Department of Neurology, Skåne University Hospital, Lund, Sweden*

Background and Aims: Although transcranial ultrasound (TU) assessing hyperchogenic substantia nigra (SN+) as biomarker for Parkinson's disease (PD) has been introduced elsewhere, the clinical relevance and validity in a Swedish population is still unknown.
Methods: From 2013 to 2017, 75 patients with parkinsonism have been examined by TU to be able describing the SN+ status in relation to PD, atypical parkinsonian disorders (APS) and essential tremor (ET) and aimed for a long follow-up (FU) to be sure about the correct final diagnosis.
Results: In 2024, we found a mean FU time of 95 months. The initial diagnosis was changed in 36 cases (47%). 4% ($n = 3$) had no transcranial bone window necessary for TU and were excluded. 41 of 56 true PD-patients and 2 of the 16 non-PD patients had the SN+ finding ($p < 0.001$). Sensitivity and accuracy were low (73% and 76%, respectively) whereas specificity and the positive predictive value were higher (87.5 and 95.3%, respectively). The study's limitations were small sample size, single center data, retrospective design, no interrater comparison due to only one sole sonographer, unknown reliability and a cut-off value only validated for discrimination between PD and healthy controls.

Table 1

Baseline characteristics

Variable	All (n=75)
	Demographics
Age, mean	66 (range 43-88)
Women/men, no.	29/46
	Time variables
FU duration, months	95
Symptomduration prior visit, months	18
Time from 1st visit to TU examination, months	8
	Medical
Change of diagnosis during FU, no. (%)	36 (47)
PET and/or SPECT, no.	27
Died during FU, no.	23
Dementia during FU, no.	19

Baseline characteristics of study population.

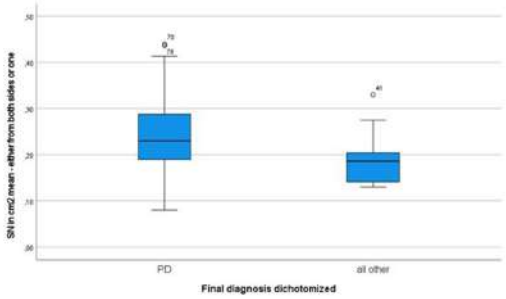
Table 2: Hyperechogenicity of Substantia Nigra vs. Final Diagnosis

	PD (no.)	Non-PD (no.)	All (no.)	p
SN+	41	2	43	*<0.001*
Normal SN	15	14	29	*<0.001*
	56	16	72	*<0.001*

Numbers of patients with positive/negative test results in the study population (cross tabulation).

Conclusion: We conclude TU possibly being a valuable add-on tool in PD diagnostics in our patient population because SN+ has a high probability to support a diagnosis already in the early stage of disease. TU seems not being suitable as single first-line diagnostics due to unsatisfactory sensitivity and accuracy. More studies are needed, especially on TU reproducibility and head-to-head studies comparing TU and PET/SPECT.

Figure 1: Boxplots of mean SN-size (cm^2) vs. final diagnosis (p 0.05)



Size of Substantia Nigra in PD- and non-PD patients.

Disclosure: Thanks to The Husbands Stoltz Foundation, Malmö and The Elsa Schmidt Foundation, Lund for research grants and special thanks to Our experienced PD nurse Eva Berg The participating patients.

OPR-119 | Long-term findings of N-acetyl-L-leucine for Niemann-Pick disease type C

T. Bremova-Ertl[1]; U. Ramaswami[2]; M. Rohrbach[3]; M. Brands[4]; T. Foltan[5]; M. Gautschi[6]; P. Gissen[7]; F. Gowing[8]; A. Hahn[9]; S. Jones[10]; R. Kay[11]; L. Arash-Kaps[12]; T. Background and Aims: The IB1001-301 clinical trial was a Phase II, double-blind, randomized, placebo-controlled trial comparing N-acetyl-L-leucine (NALL) with placebo for the treatment of neurological signs and symptoms in Niemann-Pick disease type C (NPC) after 12 weeks. The primary Scale for the Assessment and Rating of Ataxia (SARA) endpoint was reduced −1.97 points with NALL and −0.60 with placebo ($p < 0.001$). Extended follow-up data were obtained in an open-label Extension Phase (EP) to evaluate the long-term, neuroprotective effects of NALL for NPC.

Methods: Patients received treatment with orally administered NALL 2–3 times per day. The primary endpoint was the modified 5-domain NPC Clinical Severity Scale (5-Domain NPC-CSS) (range 0–25 points; lower score representing better neurological status). Comparisons were made to the expected annual trajectory of disease decline established in published natural history studies. Exploratory endpoints included the 17-domain NPC-CSS (excluding hearing) and SARA.

Results: 54 patients aged 5–67 years were treated in the EP. After 12 months, the mean (±SD) change from baseline on the 5-domain NPC-CSS was −0.115 (±2.60) and 1.5 ± 3.1 in the historical cohort (mean difference 1.56; 95% Confidence Interval, 0.31–2.92; $p < 0.017$), a 108% reduction in annual disease progression. The result of the 17-domain NPC-CSS was supportive of the primary analysis and the improvements in neurological status demonstrated in the Parent Study's primary SARA endpoint were sustained over the long-term follow-up.

Conclusion: In NPC, treatment with NALL after 1 year was associated with a statistically and clinically significant reduction in disease progression and consistent with a neuroprotective, disease-modifying effect.

Disclosure: Tatiana Bremova-Ertl received speaker's honoraria and consultancy fees from Actelion, Sanofi-Genzyme and Zevra as well as blinded video-rater fees from Intrabio.

OPR-120 | Alterations in BDNF and plasmin-related proteins are associated with regional brain atrophy in alpha-synucleinopathies

Z. Nedelska; F. Angelucci; B. Manova; F. Olejko; A. Katonova; J. Hort

Second Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czechia

Background and Aims: Plasmin is serine protease acting in tissue and synaptic remodeling, inflammation regulation and modulation of neurotrophic factors, and is regulated by activating tissue plasminogen activator (tPA), and by inhibiting plasminogen activator inhibitor-1 (PAI-1). Brain derived neurotrophic factor (BDNF) is abundant neurotrophin. Their levels and associations with regional brain atrophy in alpha-synucleinopathies (PD, DLB and MSA) are unclear.

Methods: Serum levels of tPA, PAI-1, BDNF and their ratios were investigated in 34 DLB, 12 MSA and 11 PD patients compared to 11 cognitively unimpaired controls, evaluated including brain MRI. Protein serum concentrations were quantified using ELISA and compared across the groups. Regional brain atrophy was measured using automated algorithm FreeSurfer v7.0 and associations with protein serum levels were assessed using false discovery rate.

Results: Adjusting for age, we showed dysregulated plasmin synthesis by differences in PAI-1 among groups ($p < 0.001$): PD ($p = 0.027$) and especially MSA ($p < 0.001$) patients showed higher levels of PAI-1 vs controls. PAI-1 differed in DLB vs MSA ($p = 0.008$). BDNF levels were higher in DLB ($p < 0.001$), PD ($p < 0.001$) and MSA ($p = 0.012$) vs controls, and PAI-1/BDNF ratio differed in MSA vs DLB ($p = 0.008$). PAI-1 and PAI-1/BDNF ratio levels were inversely associated with regional brain atrophy in several brain regions including cholinergic basal forebrain nuclei volume, posterior cingulate, retrosplenial, parahippocampal cortical thickness and nucleus accumbens, hippocampal, basal ganglia and brainstem volumes ($p < 0.05$).

Conclusion: Plasmin system and BDNF are altered in alpha-synucleinopathies. Increased BDNF levels may suggest compensatory mechanism. Plasmin system and BDNF may be explored as a therapeutic targets in these neurodegenerations.

Disclosure: Nothing to disclose.

Late breaking news 2

OPR-121 | Single-cell analysis of anti-BCMA CAR T cell therapy in patients with central nervous system autoimmunity

C. Qin[1]; M. Zhang[1]; L. Zhou[1]; M. Dong[1]; W. Wang[2]; S. Cai[2]; C. Li[3]; D. Wang[3]; B. Bu[1]; D. Tian[1]; W. Wang[1]

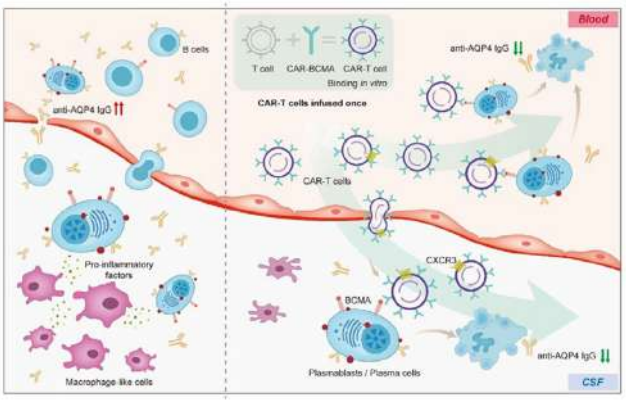
[1]*Department of Neurology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China;* [2]*Nanjing IASO Biotechnology Co., Ltd., Nanjing, China;* [3]*Department of Hematology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*

Background and Aims: Chimeric antigen receptor (CAR) T cell immunotherapy for the treatment of neurological autoimmune diseases is promising, but CAR T cell kinetics and immune alterations following treatment are poorly understood.

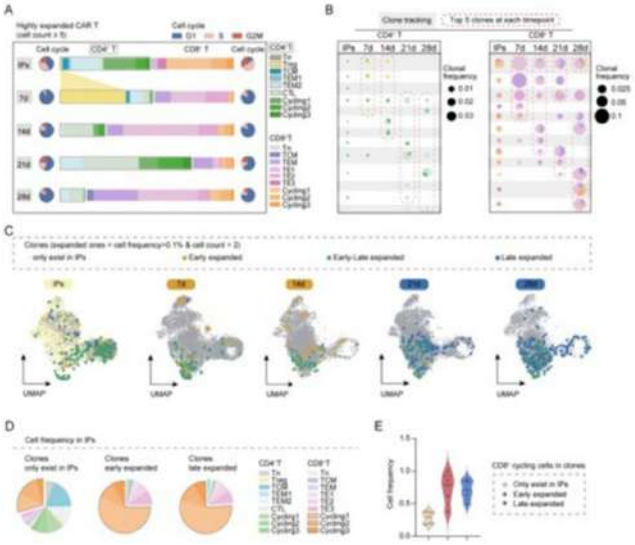
Methods: We performed single-cell multi-omics sequencing of paired cerebrospinal fluid (CSF) and blood samples from patients with neuromyelitis optica spectrum disorder (NMOSD) treated with anti-B cell maturation antigen (BCMA) CAR T cells.

Results: Proliferating cytotoxic-like CD8+ CAR T cell clones were identified as the main effectors in autoimmunity. Anti-BCMA CAR T cells with enhanced features of chemotaxis efficiently crossed the blood–CSF barrier, eliminated plasmablasts and plasma cells in the CSF, and suppressed neuroinflammation. The CD44-expressing early memory phenotype in infusion products was potentially associated with CAR T cell persistence in autoimmunity. Moreover, CAR T cells from NMOSD patients displayed distinctive features of suppressed cytotoxicity compared with those from hematological malignancies.

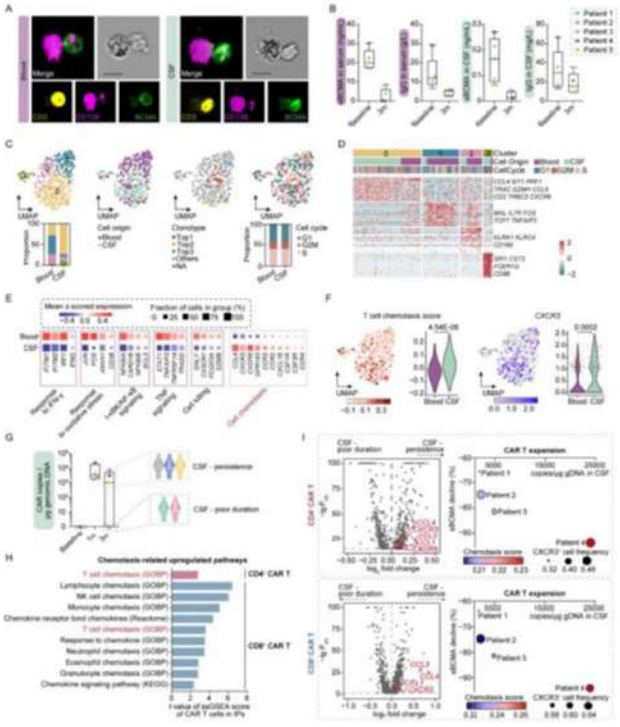
Conclusion: These data provide mechanistic insights into CAR T cell function in patients with neurological autoimmune disease.



CAR T cells reversed immune dysfunction in the CSF of NMOSD patients.



Clonal kinetics of CAR T cells in patients with NMOSD.



Properties associated with CAR T cell infiltration into CSF.

Background and Aims: As patients after severe acute brain injury (SABI) typically lack decisional capacity, families and clinicians in the ICU share prognostic uncertainty and treatment decisions. Our study aims to compare the impact of prognostic scoring on decisions from the patients, families and ICU clinicians' perspectives.
Methods: Families, physicians and nurses responded to a survey on treatment decisions for SABI patients in the ICU with a GCS < 12 after day 2. At 6 months, we assessed the patients and families' perspectives on goal-concordant care through a survey and semi-structured interviews.
Results: We enrolled 110 patients, 71 relatives and 205 clinicians. At enrollment, 65% of families reported discussion on prognosis with clinicians and 48% on patient's presumed wishes. Regarding goal-concordance care, 66% of families and clinicians were aligned in their estimates. They felt that prognostic scores and their personal estimates would have a major influence on their decisions in 46% and 55% respectively. The use of hypothetical prognostic scoring (patient's risk of dependency of 50% vs 90%) significantly increases presumed decisions to withdraw LST (29 vs 44%). In addition, 52% said they would strongly regret prolonging LST if they knew the patient could survive with severe and irreversible deficits, while 40% feared withdraw LST even if the chances of recovery were extremely low.
Conclusion: A substantial proportion of families consider that prognostic scores and their own assessment of the patient's chances of recovery significantly influence their decisions. Early discussion on prognostic estimates and goals-of-care may improve decisions concordant with the patients' wishes.

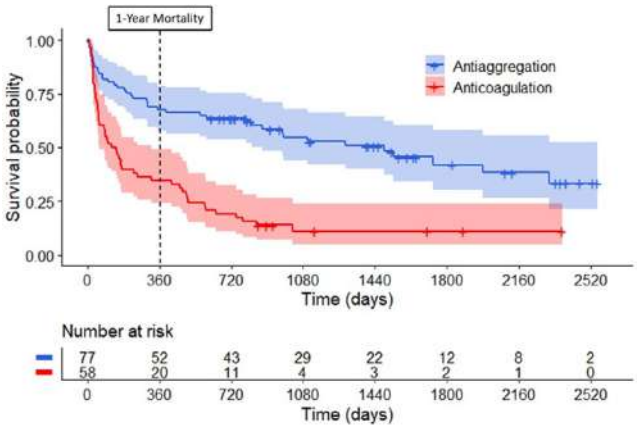
Background and Aims: Acute ischemic stroke (AIS) patients with active cancer are common (≈10% of all AIS) and are at high risk of AIS recurrence and death. Although anticoagulation is often preferred because of the presumed paraneoplastic coagulopathy, the optimal antithrombotic strategy in this population remains undefined. This study aimed to assess the association between anticoagulation versus antiaggregation as secondary prevention in AIS patients with active cancer.
Methods: AIS patients with active cancer were identified in the consecutives AIS patients treated at our comprehensive stroke center between January 2015 and December 2020. The association between anticoagulation versus antiaggregation and mortality in follow-up was assessed and cerebrovascular events in the follow-up were reported.
Results: Of 5012 AIS patients, 135 patients with active cancer were included. The mortality rate at one year was higher in the anticoagulation group ($n = 58$, 66%) than in the antiaggregation group ($n = 77$, 33%). In the adjusted analysis the use of anticoagulation compared to antiaggregation was not associated with lower mortality neither at one year (adjusted hazard ratio [aHR] 0.76; 95% CI 0.36–1.63) nor in the long-term (aHR 1.29; 95%-CI 0.63–2.47). The number of recurrent AIS cases in the long-term follow-up was similar in the anticoagulation group (8.6%) and the antiaggregation group (7.8%; $p = 1.00$).



Long-term survival curves for AIS patients with cancer treated with antiaggregation and anticoagulation as secondary prevention Compared to patients treated with antiaggregation (in blue), patients with anticoagulation (in red) demonstrated higher mortal.

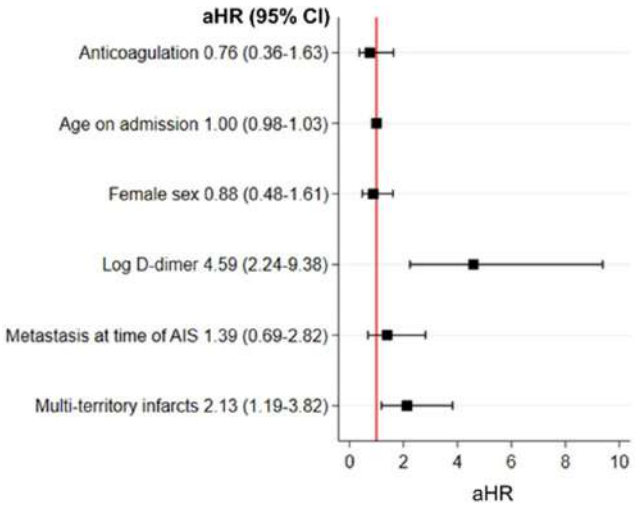


FIGURE 2 Association between one year mortality after AIS and antithrombotic drug prescribed as secondary prevention at discharge and other co-variables. In the adjusted analysis, the primary outcome (mortality at one year after AIS) was not associated.

Conclusion: AIS patients with active cancer treated with anticoagulation showed more signs of paraneoplastic coagulopathy and metastatic cancer. This indication bias resulted in a higher mortality rate in patients with anticoagulation in the unadjusted model. After adjustment, however, there was no difference in outcomes between the two groups.

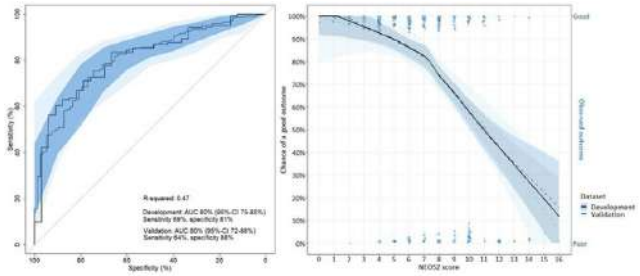
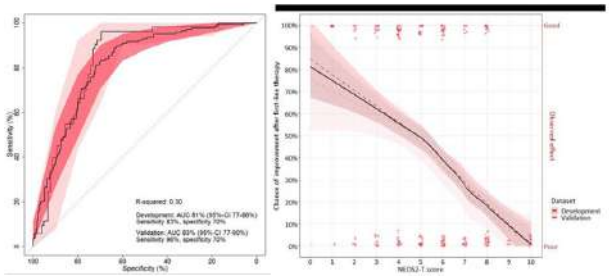
Background and Aims: Anti-NMDAR encephalitis (anti-NMDARE) is a treatable condition, although often resulting in long-term disability. The available 'anti-NMDAR Encephalitis One-Year Functional Status' (NEOS) score predicts independence after one year, considering the effect of first-line treatment only after four weeks. We developed a model predicting outcome already before treatment initiation (NEOS2), and who is likely to improve after first-line treatment.

Methods: International cohorts (France, Germany, the Netherlands, Spain and Japan) were combined to develop (70%) and validate (30%) multivariable models to predict (1) improvement after first-line treatment (NEOS2-T), (2) one-year functional status (NEOS2) and (3) return-to-school/work (NEOS2-W), incorporating variables available at diagnosis. We performed logistic-regression analyses and simplified the models for applicability in clinical practice.

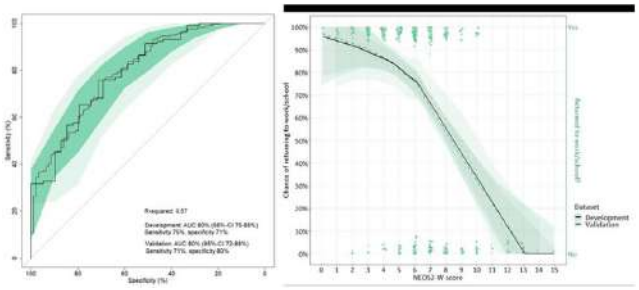
Results: We have included 712 patients (79% female, average age 23 years; 80% independent after one year, 74% resumed school/work). We could predict outcome already at diagnosis, with similar accuracy (AUC 80%) as the original NEOS score. We could predict improvement following first-line immunotherapy with the same variables (AUC 81–83%), identifying patients that could benefit from early intensified treatment, potentially improving outcomes. The NEOS2-T and NEOS2-score accurately identify patients with a high (~80%) likelihood of improving after first-line treatment and a good outcome (~100%), versus patients with high risk of first-line failure (~100%) and a poor outcome (80–90%; Figures 1B and 2B). Resuming school/work was a very long-term outcome-measure (3 years), and could be predicted with the same variables and accuracy.



A: ROC of the model for one-year functional outcome, showing very good accuracy and specificity, and good sensitivity. B: The NEOS2 score classifies (at diagnosis) patients with an almost 100% chance of a good outcome vs high risk (~90%) of a poor outcome.



A: ROC of the model for improvement after first-line treatment, showing very good accuracy, specificity and sensitivity. B: The NEOS2-T score classifies patients with ~80% chance of improvement with first-line therapy vs those with almost definite failure.



A: ROC of the model for resuming school/work, showing very good accuracy, specificity and sensitivity. B: The NEOS2-W score classifies patient almost definitely resuming school/work vs those who are very unlikely.

Conclusion: The easily applicable NEOS2 score accurately predicts (long-term) outcome and identifies anti-NMDARE patients who may benefit from early intensified treatment.
