Chapter V

Structure Evolution of B2B Enterprise Networks

Abstract

This chapter analyzes the structural dynamics of multilateral business-tobusiness (B2B) relationships based on game theoretical approach. It focuses on the evolution of network structures initiated by three major forces: a neutral intermediary, a dominant supply chain partner, and an industry consortium. We show the typical enterprise network structures, identify the conditions that cause structure reconfiguration, and demonstrate the change of social welfare in the evolution process. Webbased technologies have changed the landscape of enterprise networks, and the proposed framework will provide an analytical understanding of the endogenous formation and dynamics of enterprise networks in the information era.

This chapter appears in the book, Advances in the Economic of Information Systems, edited by Kerem Tomak. Copyright © 2005, Idea Group Inc. Copying or distributing in print or electronic forms without written permission of Idea Group Inc. is prohibited.

Introduction

Due to the vast benefits of web-enabled networks, they have become increasingly popular in information-intensive industries. Firms realize that business-tobusiness relationships often have impacts beyond the bilateral exchanges between the firm and its business partner. For example, the well-known bullwhip effect (Lee, Padmanabhan & Whang, 1997) refers to the distortion of demand when the number of intermediaries increases in a supply chain. Thus when the manufacturer evaluates its relationship with a wholesaler, it has to take into account the retailers that the wholesaler serves. Even competing firms are forming horizontal marketplaces, such as the consortia (for example, Covisint, Transora), composed of multiple buyers and sellers to improve purchasing efficiency and facilitate collaboration. Evidently, thanks to information technology, the cost of integrating another firm in the value web continues to decrease. As a result, the formation and evolution of value webs have become highly dynamic.

The benefits of such web-enabled networks are well understood in the industry. They encourage information sharing, thus leading to better coordination among partners in activities such as demand forecasting and new product development. And the formation and evolution of such enterprise networks (EN) have yet to attract attention from researchers. Existing literature in related fields such as economics and management have mostly focused on characteristics of specific network structures that are exogenously given. However little research studies how EN form endogenously and evolve (Tomak & Xia, 2002).

In this chapter we study the formation and evolution of EN. In our setting, each firm is regarded as a rational entity and will create and sever its relationships with others in order to maximize its own payoff. The structure will evolve as firms respond to market changes that will affect their payoff. We analyze three types of EN, which are prevalent in the e-business area. They are: e-Market, EN enabled by a neutral intermediary; e-Hub, EN enabled by information sharing across a dominant supply chain partner; and industry consortia, EN enabled by a buyer-based consortium.

The remainder of the chapter is organized as follows. The next section gives an overview of EN and reviews related literature on network economics; the section on model settings presents the general model of EN; the next sections separately discuss the evolution of the three types of EN; and the final section concludes with a summary of our findings and some future research directions.
