### **Abstract**

20 There is an urgent need to identify therapies to prevent and treat SARS-CoV-2 infection. We performed a statistical evaluation of in vitro gene expression profiles reflecting exposure to 1,835 drugs, and found topoisomerase inhibitors and PI3K/mTOR pathway inhibitors among the strongest candidates for reduced expression of ACE2, a host gene associated with SARS-CoV-2 infection. Retrospective clinical data suggest that patients on these agents may be less likely to test positive for SARS-CoV-2.

25

## Introduction

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) continues to spread globally with over 13.1 million diagnosed cases and 574,000 deaths (as of 14 July, 2020). SARS-CoV-2 is a single-stranded  
30 RNA virus that utilizes spike (S) glycoproteins to infect individuals by attaching to angiotensin-converting enzyme 2 (encoded by the ACE2 gene) expressed on airway epithelia<sup>1-3</sup>. After attachment, hemagglutinin cleavage of ACE2 initiates viral internalization and subsequent viral S protein cleavage by the transmembrane protease serine 2 TMPRSS2 to enable viral entry<sup>3</sup>. Other transmembrane proteases, such as ADAM17 and TMPRSS11D, may also influence cleavage of ACE2<sup>4,5</sup>.

35 ACE2 gene expression may provide a unique therapeutic target to help prevent SARS-CoV-2 infection. Hofman et al. found that ACE2 expression on a panel of cell lines correlated with *in vitro* susceptibility to SARS-CoV S-driven infection<sup>4</sup>. Many ACE2-associated factors, including TMPRSS2, have no recognized indispensable somatic functions; drugs targeting this pathway may show a promising therapeutic ratio<sup>6</sup>.

40 The Library of Integrated Network-Based Cellular Signatures (LINCS) program is an open resource for the scientific community that includes expression profiles of cells exposed to a variety of perturbing agents<sup>7</sup> including small molecules over a range of concentrations. Here, we report on a comprehensive statistical evaluation of cell line gene expression signatures associated with various drug exposures in LINCS. We  
45 analyzed 1,835 drugs for which distinct cells lines and variable dosages were available, and sought to identify those with statistically significant reductions in expression of genes associated with SARS-CoV-2 infection. We then utilized retrospective clinical data to evaluate whether cancer patients receiving drugs associated with reduced expression of ACE2 demonstrated a decreased odds ratio for a positive SARS-CoV-2 test compared to patients receiving other antineoplastic therapies.

50

## Results and Discussion

For each drug, we fitted a generalized linear model to moderated Z-score values<sup>8</sup> reflecting relative ACE2 gene expression across seven cell lines and drug dosages from 0.01 uM to 10 uM (Table S1). Among those  
55 drugs with the strongest associated reductions in ACE2 expression, we identified two major categories: (i) topoisomerase inhibitors, and (ii) PI3K/mTOR pathway inhibitors (Table 1). Topoisomerase inhibitors including camptothecin, SN-38, and Genz-644282 demonstrated significant reductions in ACE2 expression, often with a dose dependent relationship (Fig. 1). PI3K/mTOR inhibitors including PF-04691502, GDC-0980(RG7422), and Taselisib also displayed dose dependent reductions in ACE2  
60 expression (Fig. 2). Moreover, two AKT inhibitors related to the PI3K/mTOR pathway, Afuresertib and MK-2206, were associated with reduced ACE2 (Table 1).

We next performed a retrospective review of clinical records to evaluate the frequency of SARS-CoV-2 infection in patients on these ACE2-associated antineoplastics. Retrospective data was obtained from an  
65 IRB-approved study of adult cancer patients tested for SARS-CoV-2 receiving active antineoplastic therapy at Memorial Sloan Kettering Cancer Center (MSKCC) during the COVID-19 epidemic period (n=4,040 patients; Table S2). The overall study population had mainly solid tumors (n=3771; 93.3%). Thirteen percent (n=535) of the study population was actively treated with an ACE2-associated drug (Table S2, Table S5). Patients treated with ACE2-associated drugs showed similar clinical demographics to those  
70 treated with different antineoplastics (Table S2).

Patients receiving ACE2-associated therapies demonstrated a lower univariate odds ratio (0.65, 95% CI 0.00-0.98, P=0.04) for a positive SARS-CoV-2 test during active antineoplastic therapy compared to patients on other agents (Table S3). Additional study covariates shown to be significant in cancer patients  
75 were also evaluated. Patients with non-white race (OR 2.00), hematologic malignancy (OR 2.89) and metastatic disease (OR 1.49) also demonstrated statistically significant increase in the odds of a positive SARS-CoV-2 test (Table S3). Significant covariates were placed into a multivariate logistic regression

model (Table S4). Active therapy trended towards independent significance for a SARS-CoV-2 positive test (OR 0.68, 95% CI 0.40-1.07, BH-corrected  $q=0.13$ ).

80

Our results reveal several antineoplastic agents that may demonstrate reductions in ACE2 expression, a potential target proposed in preventing and treating SARS-CoV-2 infection. Cancer patients taking these potential ACE2-associated agents showed lower rates of a positive SARS-CoV-2 test compared to patients taking other forms of active antineoplastic therapy. These medications were universally held when patients tested positive for SARS-CoV-2, and our study was underpowered to detect possible differences in COVID-19 associated endpoints, such as admission, hypoxic events and death.

85

These findings are consistent with recent studies that propose topoisomerase inhibitors or PI3K/mTOR inhibitors for treatment of COVID-19. One recent study proposed Irinotecan and Etoposide combination therapy for critically ill COVID-19 patients<sup>9</sup> based on the immunomodulatory and viral suppressive profiles of these drugs. Additionally, a recent loss-of-function experiment revealed that certain topoisomerases were required for efficient replication of positive-sense RNA viruses including SARS-CoV-2<sup>10</sup>. Immunoregulatory and anti-viral properties have also been cited as rationales for PI3K/mTOR pathway inhibitors to treat COVID-19<sup>11-17</sup>.

95

This study has several limitations. ACE2-associated antineoplastic therapies were discovered by *in-vitro* computer modeling and need to be validated experimentally. Although *in vitro* data implicates ACE2 in the SARS-CoV-2 infection route, ACE2 is not yet a clinically validated target. Furthermore, clinical data obtained were retrospective and may be underpowered to estimate the true impact of ACE2-associated therapy on SARS-CoV-2 positivity and COVID-19 adverse outcomes. Finally, study patient characteristics are skewed towards non-metastatic (63.2%), solid tumor (93.3%) patients. Despite these limitations, our results suggest that further investigation of PI3K/mTOR pathway inhibitors and topoisomerase inhibitors as a COVID-19 preventative strategy are warranted.

100

## Methods

105 ***In Vitro* Modeling and Analysis.** LINCS gene expression signatures and associated drug exposure  
metadata were collected using the LINCS Data Portal API (<http://lincsportal.ccs.miami.edu/apis>).  
Compounds considered were limited to those tested on the seven specific cell lines of interest with 24 hours  
of exposure time at concentrations ranging from 0.01uM to 10uM. For each candidate drug, a generalized  
linear model was fit to ACE2 moderated Z-scores values adjusted for  $\log_{10}$ (drug concentration). Calculated  
110 by LINCS, moderated Z-scores reflect a weighted average of replicate samples in an experiment of a  
specific cell line and drug concentration. Model coefficients and P-values associated with baseline  
expression and drug concentration (two-sided test; null hypothesis  $\beta=0$ ) were used to prioritize drugs with  
significant reductions in ACE2 expression and dose dependent relationships. P-values were adjusted for  
multiple hypothesis testing using the false discovery rate (FDR).

115  
**Data Availability.** LINCS Phase I data are publicly available through NCBI (GEO accession GSE92742)  
and the LINCS Data Portal 2.0 (<http://lincsportal.ccs.miami.edu/>). Procedures on LINCS signature  
generation and moderated Z-score calculation can be found in the GEO LINCS user guide (v2.1;  
<https://docs.google.com/document/d/1q2gciWRhVCAAnlvF2iRLuJ7whrGP6QjpsCMq1yWz7dU/edit#>).  
120 Aggregated patient data used in this study is available upon request from the corresponding author (L.A.D.).  
Requests will be first reviewed for compliance with the ethical and patient privacy regulations of the  
Memorial Sloan Kettering Cancer Center.

**Code Availability.** The R code used for this study is available upon request from the corresponding author.

125  
**Clinical Data Acquisition and Definitions.** Electronic medical record (EMR) auto-populated flowsheet  
data was obtained for adult cancer patients at Memorial Sloan Kettering Cancer Center (MSKCC)  
undergoing active antineoplastic treatment during the time of the first positive SARS-CoV-2 tests  
(03/01/2020) with a study data freeze on 5/28/20 for analysis. Patients with antineoplastic therapies that

130 were discontinued before this study period were not included in the study. Auto-populated flowsheet data  
was obtained from a standardized-input curated database that assessed the time and date of antineoplastic  
administration, as well as patient demographics, disease characteristics and study endpoints. SARS-CoV-2  
testing was performed at MSKCC using a nasopharyngeal swab to determine the presence of virus specific  
RNA (MSKCC FDA-EUA-approved assay, and commercial assay Cephied®). Patients who had a positive  
135 test were classified as SARS-CoV-2 positive. Patients who tested negative or were not tested for SARS-  
CoV-2 were classified as “Not SARS-CoV-2 positive”.

Study subgroups were classified as in Table S2. Notably, malignancy status as solid or hematologic was  
not mutually exclusive; several study patients had both an active solid and liquid malignancy, and were  
140 thereby coded as having each separate subtype. Although most patients were coded for the study variables,  
several patients did not have coded demographics and these patients were not associated with their  
respective missing demographic. For example, 89.1% of patients were coded for tobacco status with 10.9%  
of patients with an unknown tobacco status; these patients were not associated with a tobacco status in the  
statistical analysis.

145 Antineoplastic therapies were grouped using standardized antineoplastic drug categories (Table S5).  
Antineoplastic agents with significant activity from *in vitro* assessment (Table 1) were cross-referenced  
against the study population to determine ACE2-associated therapy status. If a patient received an ACE2-  
expression reducing therapy during the study period (03/01/20-05/28/20), they were classified in the  
150 “ACE2-associated antineoplastic” subgroup. Patients who did not receive a potential ACE2 expression  
reducing agent were classified in the “No ACE2-associated antineoplastic” subgroup.

**Clinical Data Statistical Analysis.** Univariate, one-sided Fisher’s exact statistical testing was used to test  
the specific hypothesis that active ACE2-associated antineoplastic use is associated with a lower odds ratio  
155 of a positive SARS-CoV-2 test. Additional study covariates (female gender, age greater than or equal to

65, non-white race, smoking, hematologic malignancy, metastatic disease) were similarly evaluated. Odds ratios, 95% confidence intervals, and one-sided p-values were reported for each covariate. Covariates with a p-value of less than or equal to 0.10 were placed into a multivariate model, and logistic regression was performed. To account for multiplicity, p-values for each covariate in the multivariate model were subject  
160 to Benjamini-Hochberg correction and q-values were reported.

The odds ratios of achieving specific clinical endpoints, including admission, hypoxic event (defined as requiring greater than 4 L of oxygen), and death, were assessed comparing patients with ACE2-associated antineoplastics and patients who did not received ACE2-associated antineoplastics using similar Fisher's  
165 exact statistical testing. No significant difference in adverse COVID-19 outcomes (admission, hypoxia requiring greater than 4 liters of supplementary oxygen, death, or composite of these three outcomes) was observed in the overall study population, or a subset population of only SARS-CoV-2 positive patients.

All statistical computation was done with use of R Studio (version 1.2.5033) and R (v4.0.0) statistical  
170 software.

**Study Approval.** This study was approved by the Institutional Review Board at Memorial Sloan  
Kettering Cancer Center.

175

### **Author contributions**

180 J.R.W. and L.A.D. conceived and designed the study. J.R.W. and M.B.F. analyzed and interpreted data. J.J. and M.B.F. collected retrospective patient data. J.C.M.W. and A.G. provided guidance and scientific input. J.C.M.W. and A.G. interpreted results. J.R.W., J.C.M.W., and M.B.F. drafted the manuscript. All authors read and approved the final manuscript.

CDK 4/6 inhibitors	291 (6.0%)	291 (8.3%)	N/A
EGFR inhibitors	195 (4.0%)	195 (5.6%)	N/A
Hedgehog pathway inhibitors	2 (0.1%)	2 (0.1%)	N/A
HER2 inhibitors	223 (4.6%)	223 (6.4%)	N/A
Histone deacetylase inhibitors	2 (0.1%)	2 (0.1%)	N/A
Mitotic inhibitors	523 (10.7%)	523 (14.9%)	N/A
Multikinase inhibitors	388 (8.0%)	388 (11.1%)	N/A
Other antineoplastic	559 (13.8%)	559 (16.0%)	N/A
Oral immunomodulatory	107 (2.2%)	107 (3.0%)	N/A
PARP inhibitors	133 (2.7%)	133 (3.8%)	N/A
Proteasome inhibitors	47 (1.0%)	47 (1.3%)	N/A
Topical chemotherapy	17 (0.3%)	17 (0.5%)	N/A
VEGF/VEGFR inhibitors	330 (6.8%)	330 (9.4%)	N/A

270 **Supp Tab. S3 | Univariate analysis of patients receiving active antineoplastic therapy establishes odds ratios for a SARS-CoV-2 positive test for study covariates.** Univariate analysis of study covariates demonstrates a significant decreased odds ratio for a SARS-CoV-2 positive test in patients with receiving ACE2-associated antineoplastic therapy (OR 0.65, 95% CI 0.00-0.98, p-value 0.04).

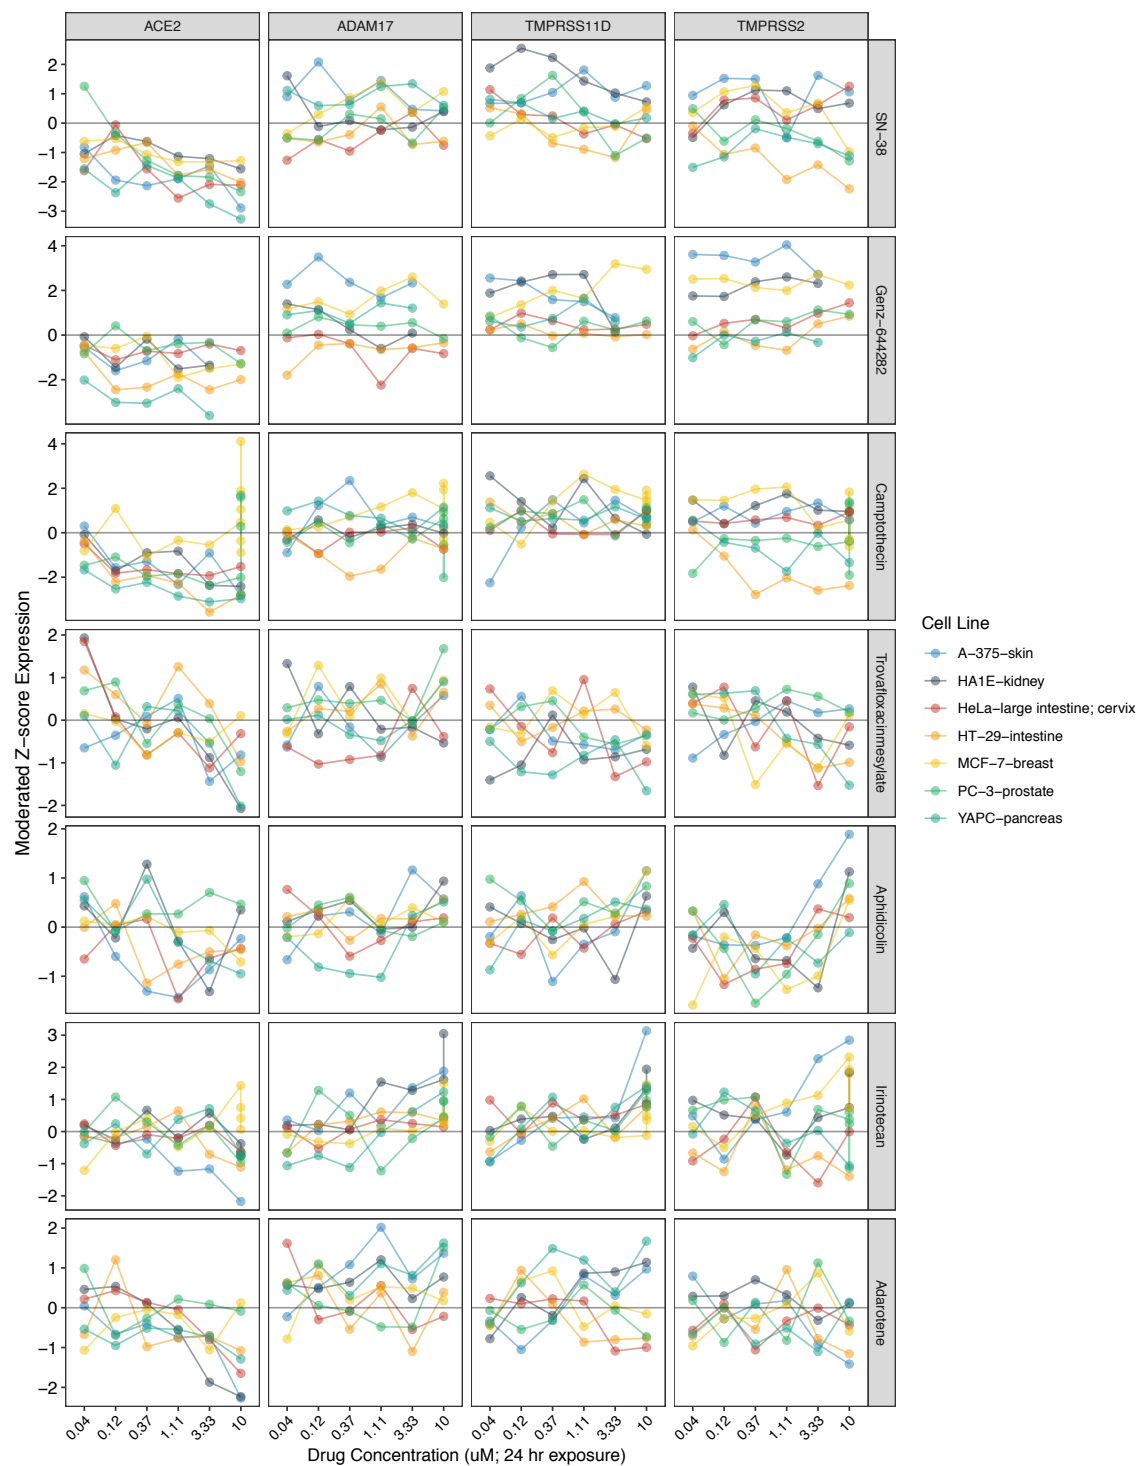

Covariate	OR	95% CI Min	95% CI Max	p-value
ACE2-associated antineoplastic therapy	0.65	0.00	0.98	0.04
Female gender	0.79	0.00	1.01	0.06
Age greater than or equal to 65	1.04	0.81	Inf	0.43
Non-white race	2.00	1.51	Inf	0.00
Smoking	0.91	0.69	Inf	0.76
Hematologic malignancy	2.89	2.02	Inf	0.00
Metastatic disease	1.49	1.16	Inf	0.00

275 **Supp Tab. S4 | Multivariate logistic regression of study covariates in patients receiving active antineoplastic therapy.** Multivariate logistic regression analysis of covariates demonstrating statistical significance ( $p \leq 0.10$ ) in univariate analysis were included in a multivariate logistic regression. ACE2-associated antineoplastic therapy shows a trend towards significance (OR 0.68, 95% CI 0.41-1.07, BH-corrected q-value of 0.13).

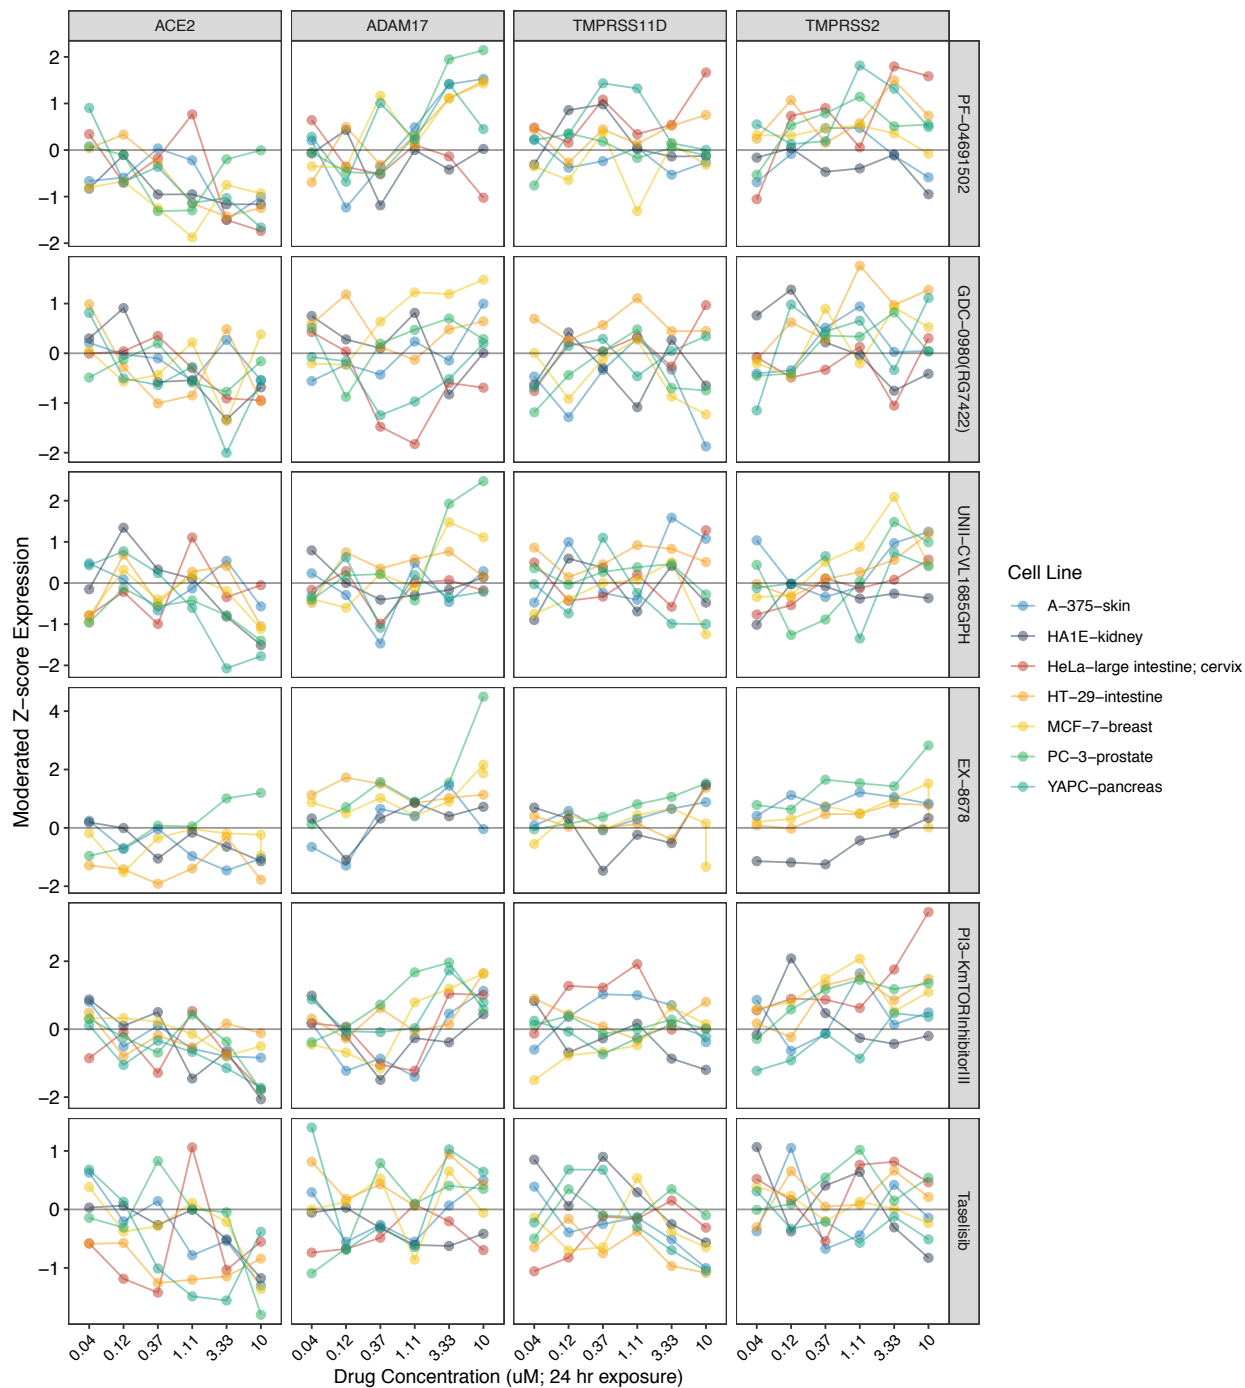

Covariate	OR	95% CI Min	95% CI Max	p-value	BH- corrected q-values
ACE2-associated antineoplastic therapy	0.68	0.40	1.07	0.11	0.13
Non-white race	2.02	1.46	2.77	0.00	0.00
Hematologic malignancy	2.62	1.70	3.93	0.00	0.00
Female gender	0.76	0.57	1.03	0.07	0.12
Metastatic disease	1.26	0.93	1.69	0.13	0.13

280 **Supp Tab. S5 | Major antineoplastic subcategorization key.** Patient classification mapping shown for specific antineoplastic drugs used by patients in the “No ACE2-associated antineoplastic cohort” and their respective antineoplastic subcategory used in Supplementary Table S2.
